**Results:** Steatosis (grade 1–3) was found in 166 patients (61.0%), 106 patients (39.0%) did not develop any steatosis (grade 0). The distribution of donor TM6SF2 rs58542926 genotypes differed significantly (p = 0.036) between patients with steatosis (CC/CT/TT 80.1/19.3/0.6%) and without steatosis (CC/CT/TT 91.5/8.5/0.0%). The distribution of recipient TM6SF2 rs58542926 genotypes was similar (p = 0.91) in patients with steatosis (CC/CT/TT 77.7/19.9/2.4%) and without steatosis (CC/CT/TT 76.4/21.7/1.9%). On multivariate analysis, donor non-CC TM6SF2 genotype (OR 3.22; 95%CI 1.42–7.99), donor non-CC PNPLA3 genotype (OR 1.87; 95%CI 1.08–3.27) and BMI 1 year after LT (OR 1.14; 95%CI 1.06–1.24) were independent risk factors of development of post-transplant steatosis. The effect of donor PNPLA G allele and donor TM6SF2 T allele was synergic, with OR 7.61 (95%CI 2.04–49.45) for presence of both donor risk alleles and OR 1.84 (95%CI 1.11–3.06) for presence of only one risk allele (PNPLA3 G allele or TM6SF2 T allele).
**Conclusion:** Donor non-CC TM6SF2 rs58542926 genotype is an independent risk factor of steatosis in liver transplant recipients. The effect of donor TM6SF2 genotype is synergic to the effect of donor PNPLA3 genotype.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1102 LEAN NON-ALCOHOLIC FATTY LIVER DISEASE (LEAN-NAFLD): CHARACTERISTICS AND RISK FACTORS FROM A COMMUNITY COHORT FOLLOW-UP STUDY

**M.A. Niriella**[1], S. T. De Silva[1], A. Kasturiratne[1], K. R. Perera[2], C. E. Subasinghe[3], S. K. Kodisinghe[2], C. Piyarathna[2], K. Vithiya[2], A.S. Dassanayake[1], A. P. De Silva[1], A. Pathmeswaran[4], R. Wickramasinghe[1], N. Kato[5], H. J. De Silva[1]

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is usually associated with obesity. However, some NAFLD patients are lean. We assessed the characteristics and risk factors for lean-NAFLD.
**Aims & Methods:** In a community cohort follow-up study (initial screening-2007, re-evaluation-2014), NAFLD was established on USS criteria and exclusion of alcohol overuse and secondary causes. Lean (BMI $<23\,kg/m^2$) and non-lean (BMI $\geq 23\,kg/m^2$) NAFLD were compared. The two groups were compared for differences in gender, diabetes, hypertension, hypertriglyceridemia, low-HDL, weight and waist circumference (WC) at baseline. They were also compared for differences in development of incident diabetes, hypertension, hypertriglyceridemia, low-HDL, and change in weight and WC.
**Results:** 678 (69.6%) individuals with NAFLD detected in 2007 presented for follow up in 2014. 78(11.5%) [males-32(41%); mean-age 53.7(SD-7.1) years] were lean and 600(88.5%) [males-191(31.8%); mean-age 52.3(SD-7.5) years] were non-lean. Hypertension (p = 0.007) and a smaller WC (<90 cm for males, <80 cm for females) (p < 0.001) were associated with lean-NAFLD. After 7 years, change in BMI was less (p = 0.022) among lean-NAFLD. There were no differences in change in WC or incident metabolic co-morbidities. Of those who did not have NAFLD in 2007, 746 developed incident NAFLD in 2014; lean-NAFLD 193/746 (25.9%) [males-100(51.8%); mean age 59.6(SD-7.5) ], non-lean-NAFLD 553/746 (74.1%) [males-201(36.3%); mean age 58.2(SD-7.7) ]. On logistic regression analysis, presence of diabetes (p = 0.002, OR 2.1) and raised WC (p = 0.003, OR 1.7) were associated with incident lean-NAFLD.
**Conclusion:** Among individuals with NAFLD, lean-NAFLD is associated with hypertension and smaller WC. In the community, diabetes and bigger WC predict incident lean-NAFLD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1103 NON-ALCOHOLIC FATTY LIVER DISEASE WITH AND WITHOUT METABOLIC SYNDROME: DIFFERENT PHENOTYPES WITH DIFFERENT LONG-TERM OUTCOMES

**A. J. Käräjämäki**[1], R. Bloigu[2], H. Kauma[1], Y..A. Kesäniemi[1], O. Koivurova[1], J. Perkiömäki[1], H. Huikuri[1], O. Ukkola[1]

**Introduction:** Non-alcoholic fatty liver disease and metabolic syndrome are shown to increase the risk of cardiovascular diseases and type 2 diabetes (1). There is a great overlap between these two diseases (2).
**Aims & Methods:** The present study was aimed to examine the cardiometabolic prognosis of non-alcoholic fatty liver disease with and without metabolic syndrome. Middle-aged subjects (n = 958) were divided into four subgroups, those with non-alcoholic fatty liver disease and metabolic syndrome, those with either non-alcoholic fatty liver disease or metabolic syndrome, and to healthy controls. The follow-up time for cardiovascular events was about 16 years. After approximately 21 years the cardiac ultrasound and laboratory parameters were re-analyzed and new type 2 diabetes cases were recorded.
**Results:** Those with both diseases were at the greatest risk for cardiovascular events (p < 0.001). Compared to healthy controls, only those with metabolic syndrome, with or without non-alcoholic fatty liver disease, were at increased risk for the development of type 2 diabetes (p < 0.001) and for an increase in left ventricular mass index (p = 0.001 and p = 0.005, respectively). The cardiometabolic risk in subjects with non-alcoholic fatty liver disease only was quite similar to that in healthy controls.
**Conclusion:** Non-alcoholic fatty liver disease with metabolic syndrome implies considerable risk for cardiovascular diseases, type 2 diabetes and the increase of left ventricular mass index whereas non-alcoholic fatty liver disease without metabolic syndrome does not.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Familial hypobetalipoproteinemia (FHBL) is monogenic, co-dominant disorder, characterized by reduced serum levels of total cholesterol, low density lipoproteins and apolipoprotein B. Clinical phenotypes of FHBL are related to number of defective apoliporotein B (APOB) alleles, and in some patients, except of liver disease, a range of extrahepatic symptoms can appear.
**Aim:** Genetic analysis of the APOB gene and ophtalmological diagnostics in family members with FHBL and neurological disorders were performed.
**Method:** Five relatives with FHBL were examined: proband with long-lasting asymptomatic steatohepatitis who developed dysarthria and finally severe extrapyramidal syndrome with dysphagia and ataxia, his two children with liver steatosis/steatohepatitisa and mild head/hand tremor and two grandchildren. A sequencing analysis of the whole coding region of the APOB gene, including flanking intronic regions, was performed using the next generation sequencing (NGS) method. An ophthalmological examination contained electrophysiological tests: pattern and flash full-field electroretinography (PERG, FERG), and pattern visual evoked potentials (PVEP).
**Results:** NGS identified the presence of not yet reported, pathogenic according to the American College of Medical Genetics and Genomics (ACMG) recommendations, heterozygous splicing variant c.3696+1 G > T. Two known heterozygous missense variants c.2188G > A, p.(Val730Ile), and c.8353A > C, p.(Asn2785His) in the APOB gene were also detected. The same pathogenic splicing variant was identified in affected proband's relatives. In the PERG examination, in all patients, a delay in implicit time, abnormally low amplitudes of a and b waves in both the scotopic and the photopic conditions were found and and reduced amplitudes of P50 and N95 were noted. In the proband and his children prolonged P100 latency was occurred in PVEP examination.

**Conclusion:** The newly identified splicing variant c.3696+1 G>T can be associated with observed autosomal, dominant FHBL with coexisting neurological symptoms. According to the literature and mutation databases, both identified missense variants could be excluded as the main cause of observed clinical signs. Electroretinography examination is a sensitive method for detection of early neuropathy, therefore should be recommended in care of patients with FHBL.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1105 LOW SERUM MAGNESIUM CONCENTRATION IS INDEPENDENTLY ASSOCIATED WITH NON ALCOHOLIC FATTY LIVER DISEASE AND NON ALCOHOLIC STEATOHEPATITIS

**A. Eshraghian**, S. Nikeghbalian, B. Geramizadeh, S.A. Malek-Hosseini
*Transplant Research Center, Namazi Hospital, Shiraz University of Medical Sciences, Shiraz/Iran*

**Contact E-mail Address:** eshraghiana@yahoo.com
**Introduction:** The pathogenesis of non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) has not been well recognized. Low serum magnesium has been previously shown to be associated with oxidative stress and insulin resistance. Magnesium is also involved in metabolism of lipids.
**Aims & Methods:** This study aimed to investigate the association between serum magnesium concentration and hepatic steatosis in the forms of NAFLD and NASH. A cross-sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy for evaluation of liver histology as a routine pre-transplant check up before living related liver transplantation. Liver function tests, age, gender, weight, height, fasting plasma glucose, magnesium, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist for hepatic steatosis and steatohepatitis. Individuals with a history of chronic liver disease, hepatitis B or C infection, hepato-billiary cancers, those with >20 grams/day alcohol consumption, and individuals receiving medications known to cause hepatic steatosis were excluded from the study.
**Results:** Totally 226 individuals (143 female and 83 male) were included. Eighty two individuals (36.2%) had hepatic steatosis and 22 (9.7%) individuals had steatohepatitis in liver histology. Mean age of individuals with and without hepatic steatosis were $33.28 \pm 7.55$ and $31.72 \pm 6.56$ years respectively ($P = 0.11$). In univariate analysis higher weight ($70.80 \pm 10.79$ versus (vs.) $63.44 \pm 9.57$ kilograms, $P = 0.0001$), increased cholesterol ($179.50 \pm 35.35$ vs. $166.04 \pm 36.50$ mg/dL, $P = 0.009$), triglyceride ($132.90 \pm 79.68$ vs. $93.10 \pm 46.78$ mg/dL, $P = 0.0001$), fasting plasma glucose (FPG) ($92.12 \pm 11.21$ vs. $87.02 \pm 10.21$ mg/dL, $P = 0.001$), alanine aminotransferase (ALT) ($22.59 \pm 12.01$ vs. $17.69 \pm 11.16$ IU/L, $P = 0.002$), alkaline phosphatase ($213.19 \pm 73.31$ vs. $183.22 \pm 62.65$ IU/L, $P = 0.001$) and lower serum magnesium ($2.01 \pm 0.35$ vs. $2.23 \pm 0.31$ mg/dL, $P = 0.0001$) were associated with hepatic steatosis ($P > 0.05$). In multivariate logistic regression analysis, higher FPG, higher alkaline phosphatase and lower serum magnesium concentration were independently associated with hepatic steatosis (Table). In regression analysis, lower serum magnesium concentration was also independently associated with steatohepatitis compared to those without steatohepatitis ($1.80 \pm 0.48$ mg/dL and $2.18 \pm 0.31$ mg/dL) (OR: 0.11; 95% CI: 0.02–0.41, P-Value = 0.001).

| | Odds ratio (OR) | **95% Confidence interval** (CI) | **P-Value** |
|---|---|---|---|
| Weight | 1.03 | 0.99–1.07 | 0.122 |
| Triglyceride | 1.006 | 0.99–1.01 | 0.089 |
| Cholesterol | 0.99 | 0.98–1.01 | 0.768 |
| Alanine aminotransferase | 1.009 | 0.97–1.04 | 0.608 |
| Alkaline phosphatase | 1.01 | 1.003–1.018 | 0.004 |
| Fasting plasma glucose | 1.05 | 1.01–1.10 | 0.012 |
| Magnesium | 0.05 | 0.01–0.32 | 0.001 |

**Conclusion:** Lower serum magnesium concentration was associated with non-alcoholic fatty liver disease and non-alcoholic steatohepatitis and can be targeted for future treatments.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1106 GENES AND ENVIRONMENTAL FACTORS INVOLVEMENT IN DEVELOPMENT OF NAFLD

**Contact E-mail Address:** dananeagoe2014@gmail.com
**Introduction:** Non-alcoholic fatty liver disease is considered a major public health and the natural course of the disease is possible influenced by the interaction of genetic and environmental factors. Aim of our study was to identify the involvement of genetic factor in the development of NAFLD.
**Aims & Methods:** We included 138 subjects with NAFLD and 125 age and sex-matched healthy controls. In both groups we evaluated anthropometric measures, aminotransferases level, presence of diabetes mellitus or metabolic syndrome, insulin resistance and the PNPLA3 gene polymorphism. Metabolic syndrome was defined according to IDF criteria and for insulin resistance we used HOMA-IR index. The genotyping assays were performed using predesigned TaqMan SNP Genotyping Assays.
**Results:** All 138 patients with hepatic steatosis (39 men and 99 women, mean age 49 +/- 13 years) 107 (77.53%) were obese, 120 patients (86.95%) had metabolic syndrome, 53 (38.4%) were diabetics and 81% (58.69%) had elevated liver enzymes.The genotype frequencies for PNPLA3 rs738409 polymorphism in the study group was [CC] (59.42%)> [CG] (32.41%)> [GG] (7.97%).The [CG] genotype carriers had a 1.7 times higher risk of developing hepatic steatosis, compared with the [CC] genotype OR 1.768 (95% CI; 1.006–3.110) ($p = 0.046$). The PNPLA3 polymorphism was associated with an increased risk of hepatic steatosis in patients with BMI $< 30\,kg/m^2$, compared with the control population, when the risk allele [G] carriers were compared with the [C] allele carriers ($p = 0.038$). By comparing the subgroup with steatosis without obesity with the subgroup with steatosis and BMI $\geq 30\,kg/m^2$, we have noticed that the [G] allele carriers compared to the [CC] homozigotes in the dominant model, have a 2.5 times higher risk of developing hepatic steatosis ($p = 0.025$) OR); 2.514 (1.112–5.685). [G] risk allele was significantly associated with the risk of hepatic steatosis in patients without metabolic syndrome ($p = 0.005$) and without insulino-resistance ($p = 0.033$). Also, we found no difference in cholesterol, triglycerides, aminotransferases and gamma-GT levels in [G] allele carrier vs [CC]
**Conclusion:** The [G] allele carriers have a 3 times higher risk of developing hepatic steatosis in the absence of obesity, insulin resistance, or metabolic syndrome. Patients with similar metabolic risk factors (diet, obesity, insulin resistance) differ largely in terms of disease phenotype and progression of disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1107 ELEVATED AMINOTRANSFERASE LEVEL IS ASSOCIATED WITH LOW BONE MINERAL DENSITY IN KOREA USING DATA FROM NATIONWIDE SURVEY

**M. Oh**[1], M.A. Han[2]
[1]*Internal Medicine, Jeongeup Asan Hospital, Jeongeup/Korea, Republic of*
[2]*Preventive Medicine, Chosun University, Gwangju/Korea, Republic of*

**Contact E-mail Address:** medi2006@naver.com
**Introduction:** Elevated liver aminotransferase level was useful indicators for liver disease burden. The aim of the present study was to investigate whether serum aminotransferse level was associated with bone mineral density (BMD) among general adults in Korea.
**Aims & Methods:** The study subjects were 17481 adult who participated in the Korea National Health and Nutrition Examination Survey (2008–2011). Elevated alanine aminotransferase (ALT) and aspartate aminotransferase (AST) concentration were defined as >30 IU/L for men and >19 IU/L for women. Low BMD was defined as a T-score of –1.0 or less. Descriptive analysis and multiple logistic regression analysis were used to investigate the association between aminotransferease level and BMD.
**Results:** The proportions of elevated ALT and AST were 25.6% and 31.0%, respectively. Mean BMD at total hip, lumbar spine and femoral neck were $0.03 \pm 1.06$, $-0.73 \pm 1.31$ and $-0.70 \pm 1.19\,g/cm^2$, respectively. The proportions of low BMD at total hip, lumbar spine and femur neck were 15.8%, 40.4% and 40.2%, respectively. After adjusting for covariates, elevated ALT was significantly associated with low BMD at lumbar spine (aOR = 1.22, 95% CI = 1.12–1.33) and femur neck (aOR = 1.21, 955 CI = 1.10–1.33), respectively. And elevated AST was significantly associated with low BMD at total hip (aOR = 2.70, 95% CI = 2.25–3.23), lumbar spine (aOR = 1.40, 95% CI = 1.28–1.52), and femur neck (aOR = 1.25, 95% CI = 1.15–1.37), respectively.
**Conclusion:** Elevated serum aminotransferase level was independently associated with low bone mineral density among general adults in Korea.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1108 CONTRIBUTION OF B-LYMPHOCYTE ACTIVATING FACTOR TO INSULIN RESISTANCE IN PATIENTS WITH NONALCOHOLIC STEATOHEPATITIS

**T. Himoto**[1], K. Fujita[2], T. Nomura[2], J. Tani[2], A. Morishita[2], H. Yoneyama[2], T. Masaki[2]

[2]*Kagawa University School of Medicine, Kagawa/Japan*

**Contact E-mail Address:** himoto@chs.pref.kagawa.jp
**Introduction:** Approximately 20–40% of patients with nonalcoholic steatohepatitis (NASH) have antinuclear antibodies (ANAs) in their sera. However, the relationship between ANA status and insulin resistance remains uncertain in those patients.
**Aims & Methods:** Twenty-five patients with NASH were enrolled in this study. Degrees of hepatic fibrosis and steatosis were evaluated by the classification proposed by Brunt and colleagues. Obesity and insulin resistance were estimated by calculating body mass index (BMI) and the value of HOMA-IR, respectively. Simplified scoring system was used for the diagnosis of autoimmune hepatitis (AIH).
**Results:** Ten of 25 (40%) patients with NASH had ANAs. However, only one patient was diagnosed as AIH among the patients with NASH seropositive for ANAs. Serum IgG ($1833 \pm 471$ vs $1292 \pm 269$ mg/dl, $p = 0.0055$) and B-

lymphocyte activating factor (BAFF) levels were significantly higher in NASH patients with ANAs than in NASH patients without ANAs. NASH patients seropositive for ANAs had significantly higher value of HOMA-IR than NASH patients seronegative for ANAs ($6.81 \pm 3.46$ vs $4.01 \pm 2.57$, $p = 0.0305$). Interestingly, a close correlation between serum BAFF level and the value of HOMA-IR was observed in those patients ($r = 0.729$, $p = 0.0168$). However, no significant differences in obesity, serum ALT level, and the degrees of hepatic fibrosis and steatosis were found between the groups of NASH patients seropositive and seronegative for ANAs.
**Conclusion:** These data suggest that NASH patients with ANAs may have more severe insulin resistance by way of elevation of serum BAFF levels.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1109 HIP FRACTURE RISK IN PEOPLE WITH ALCOHOLIC CIRRHOSIS COMPARED WITH THE GENERAL POPULATION: A POPULATION-BASED COHORT STUDY

**Introduction:** While numerous studies have shown an association between chronic liver disease and osteoporosis few have documented accurately the risks of osteoporotic fracture in patients with alcoholic liver disease and none have compared incidence rates to the general population. We performed a cohort study using linked primary and secondary care data collected in England to quantify the excess fracture risk in people with alcohol-related cirrhosis.
**Aims & Methods:** We selected 3,416 patients with a diagnostic code for alcohol related cirrhosis within the linked Clinical Practice Research Datalink and Hospital Episodes Statistics database (April 1997 and June 2014) and 34,160 age-, sex- and practice-matched controls. We estimated absolute hip fracture rates and examined hazard ratios for patients with cirrhosis versus general population controls using Cox proportional hazards, adjusted for age, sex and drug use. Analyses were stratified by severity of disease.
**Results:** There was a 5-fold increased risk of hip fracture for the cirrhosis cohort compared with the general population (absolute rate 11.0 per 1000 person years; adjusted HR = 5.4 (95%CI[4.3, 6.8]). The absolute excess rates of fracture were 8.5 hip fractures per 1000 person years. Fracture risk was associated with disease severity such that the hazard ratio of hip fractures was almost twice as high in patients with decompensated cirrhosis than in those with compensated cirrhosis (HR decompensated cirrhosis 7.8 (95% CI [5.9, 10.3]); compensated cirrhosis3.8 (95% CI [2.8, 5.3]).

| | Absolute fracture rates (95% CI) per 1000 person years | Adjusted hazard ratio for hip fracture (95% CI) |
|---|---|---|
| Alcoholic cirrhosis cohort | 11.0 [9.0, 13.5] | 5.4[4.3, 6.8] |
| Compensated | 8.2 [6.0, 11.2] | 3.8 [2.8, 5.3] |
| Decompensated | 14.5 [11.2, 18.8] | 7.8 [5.9, 10.3] |
| Control population | 2.5 [2.2, 2.7] | 1.0 |

**Conclusion:** People with alcohol-related cirrhosis are at increased risk of hip fracture compared with the general population and those with more severe disease have an even greater risk. These findings imply that consideration should be given to interventions in this group to reduce fracture risk.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1110 HEPATIC ENCEPHALOPATHY IS ASSOCIATED WITH PERSISTENT LEARNING IMPAIRMENTS DESPITE ADEQUATE MEDICAL TREATMENT: A MULTI-CENTER, INTERNATIONAL STUDY

**S. Nardelli**[1], S. Allampati[2], O. Riggio[1], K. Mullen[3], S. Gioia[1], J. Bajaj[2]

[2]*Gastroenterology, Hepatology And Nutrition, VCU and McGuire VAMC, Richmond/United States of America*
[3]*Gastroenterology, Metrohealth Medical Center, Case Western Reserve University, Cleveland/United States of America*

**Contact E-mail Address:** nardelli.silvia@gmail.com
**Introduction:** Hepatic encephalopathy (HE) is considered reversible regarding mental status but may not be cognitively in single-center studies
**Aims & Methods:** Aim: To evaluate persistence of learning impairment in prior HE compared to those who never experienced HE (no-HE) in a multi-center study. **Methods**: 174 outpatient cirrhotics from 3 centers (94 Virginia, 30 Ohio, 50 Rome, 36 prior HE) underwent Psychometric hepatic encephalopathy score (PHES) and Inhibitory control (ICT) testing at baseline and then at least 7 days apart. ICT learning (change in 2nd half lures compared to 1st half) was compared between patient groups at both visits. Change in the PHES individual sub-tests and total score between visits were compared in both groups. US vs. Italian trends were also analyzed.
**Results:** HE patients had worse PHES and ICT results compared to no-HE patients at baseline. Significant improvement (1st 7.1 vs. 6.2, 2nd half, $p < 0.0001$) was observed in no-HE, but not in HE (1st 7.9 vs. 7.8, $p = 0.1$) at baseline. At retesting (median 20 days later), no-HE patients continued with significant learning (1st6.0 vs. 2nd half 5.4, $p < 0.0001$), while HE patients again did not improve (1st 7.8 vs. 2nd half 6.9, $p = 0.37$). Between visits, no-HE patients improved significantly on 4 PHES sub-tests and overall score, while HE patients only improved on 2 sub-tests with similar overall PHES score. Trends were similar between US and Italian subjects.
**Conclusion:** In this multi-center study, prior HE patients showed persistent significant learning impairment compared to those without prior HE, despite adequate medical therapy. This persistent change should increase efforts to reduce the first HE episode.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1111 THE EFFECT OF SYNBIOTIC AND PROKINETIC ON INTESTINAL PERMEABILITY, ENDOTOXEMIA AND CHILD-PUGH SCORE IN PATIENTS WITH LIVER CIRRHOSIS: A PROSPECTIVE COHORT STUDY

**Introduction:** Increased intestinal permeability and small intestinal bacterial overgrowth are important pathophysiological factors of bacterial translocation in liver cirrhosis. Several clinical trials have shown an association among increased intestinal permeability, severity of liver cirrhosis and increased endotoxemia levels. Therapeutic modulations of intestinal microbiota with probiotics have demonstrated efficacy in reduction of endotoxemia in cirrhotics and decrease of bacterial infections after liver transplantation. Prokinetics were proved to accelerate gastrointestinal motility and reduce small intestinal bacterial overgrowth in patients with liver cirrhosis.
**Aims & Methods:** The aim of the study was to investigate the effect of synbiotic and prokinetic on intestinal permeability, endotoxemia levels and the severity of liver cirrhosis in patients with liver cirrhosis. 78 patients with liver cirrhosis were randomized to receive synbiotic composition of two fibers and probiotic bacteria *Lactobacillus plantarum*, *L. Rhamnosus*, *L. Bulgaricus*, *L. Acidofilus*, *Bifidobacterium* (n = 31), synbiotic and prokinetic domperidon (n = 27) or none of them (n = 20) for 30 days. The patients underwent standard clinical examination, had blood tests performed and the level of endotoxin was determined. Their intestinal permeability was measured by lactulose/manitol excretion ratio (LMR) from the urine samples that were collected before and after the treatment. During the follow-up period the occurrences of bacterial infections were recorded. 32 healthy controls (HC) were included in the study to assess intestinal permeability and a level of serum endotoxin.
**Results:** 48 (61.5%) patients had Child A, 19 (24.4%) Child B and 11 (14.1%) Child C with the mean age of 54 (SD = 11.6) years in the study. The Child-Pugh functional class overall improved in 29% of patients, and this improvement reached statistical significance in two patients groups treated both with synbiotic alone and in combination with domperidon. Intestinal permeability was increased in 7 (10.1%) patients. LMR was higher in patients than in healthy controls (patients vs HC = 0.0123 [0.0023–0.0508; 0.0103] vs 0.0069 [0.0003–0.0242;0.0103]; $p = 0.027$). However, the LMR of the patients did not significantly varied among different Child classes neither among different liver cirrhosis etiologies nor among patients groups. The endotoxin levels were comparable in three patients groups and did not significantly differ before and after the treatment (endotoxin before vs after the treatment = 0.5524 [SD = 0.299] vs 0.5555 [SD = 0.299], $p = 0.914$). During the follow-up period the occurrences of infections did not vary significantly in the patients groups nor in the patients with normal and increased intestinal permeability.
**Conclusion:** We proved that short-term treatment with synbiotics alone or in combination with domperidon was significantly effective and improved liver cirrhosis severity in 29% of cases. However, the treatment did not affect intestinal permeability neither endotoxemia levels nor occurrences of infections.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** sergiogiao@hotmail.com

**Introduction:** Recently the EASL-CLIF Consortium has developed and validated the CLIF-C acute decompensation (AD) score, with the aim of predicting mortality in cirrhotic patients with acute decompensation (AD) without evidence of acute-on chronic liver failure (ACLF) .[1]

**Aims & Methods:** To compare the accuracy of CLIF-C ADs with some of the previously validated models: Child-Pugh, MELD, iMELD, Refit-MELD, MELD-Na, MESO and Refit-MELD-Na; for predicting the 30 and 90-day mortality in hospitalized cirrhotic patients without ACLF. Retrospective cohort study that evaluated all admissions due to decompensated cirrhosis in 2 centers between 2011 and 2014. The presence of ACLF was defined according to the CLIF Consortium Organ Failure Score. Demographic, analytical and medical records were reviewed. At admission (<24 h) each score was assessed, and the discrimination ability was compared by using Areas Under the Roc Curves (AUROCs) for the 30 and 90-day mortality.

**Results:** We identified 565 cirrhotic patients with acute decompensation without ACLF; the most common etiology was alcohol (64.2%), followed by hepatitis C (21.3%); 37.7% met criteria for infection at admission; 27.3% presented gastrointestinal bleeding (esophageal variceal bleeding=86%); 30 and 90-day mortality were respectively, 10.3% and 31.1%. When evaluated the 30-day mortality CLIF-C ADs (AUC = 0.689; 95% CI = 0.647–0.728) presented the highest discrimination ability, although when compared AUROCs with the other scores, for the exception of MELD (AUC = 0.605; p = 0.0296), it was not significantly better. When analyzed the 90-day mortality, CLIF-C ADs (AUC = 0.672; 95% CI = 0.630–0.712) was not significantly different from the other tested models.

**Conclusion:** Although the new CLIF-C ADs reveled a good discrimination ability in predicting 30 and 90 day-mortality in hospitalized cirrhotic patients without ACLF, it was not significantly better than the other tested prognostic models with the exception of MELD in predicting 30-day mortality.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ascitic fluid cell analysis is considered to be the gold standard method for diagnosing spontaneous bacterial peritonitis (SBP). Recent studies have reported mean platelet volume (MPV) as a marker for systemic inflammation that does not suffer the influence of the different stages of cirrhosis, with a good accuracy for predicting SBP. Nonetheless, most studies excluded factors that could influence its value, and that literature reports as having an high prevalence in patients with cirrhosis (previously antibiotic therapy, comorbidities as heart failure, diabetes, hyperlipidemia and neoplasia), and so, the real value of MPV as a screening test for SBP still needs to be tested. [1–3]

**Aims & Methods:** To assess the value of MPV as (1) an inflammation marker in decompensated chronic liver disease secondary to bacterial infection (2) its ability to predict SBP. Retrospective multicentric study that analyzed all admissions secondarily to decompensated chronic liver disease, between 2011 and 2014. By using areas under the ROC curves, we compared the variables white blood count (WBC), c-reactive protein (CRP) and MPV for predicting SBP, and compared them. We defined infections according to standard criteria.

| | CLIF-C ADs(95% CI) | Child-Pugh(95% CI) | MELD(95% CI) | MELD-Na(95% CI) | iMELD(95% CI) | MESO(95% CI) | REFIT MELD(95% CI) | REFIT MELD-Na(95% CI) |
|---|---|---|---|---|---|---|---|---|
| 30-day mortality | 0.689 (0.647–0.728) | 0.665 (0.622–0.705) | 0.605 (0.561–0.647) | 0.658 (0.616–0.699) | 0.666 (0.624–0.706) | 0.626 (0.583–0.668) | 0.637 (0.594–0.678) | 0.673 (0.631–0.713) |
| p value vs. CLIF-C ADs | | 0.5905 | 0.0296 | 0.3442 | 0.4391 | 0.0830 | 0.1519 | 0.6135 |
| 90-day mortality | 0.672 (0.630–0.712) | 0.649 (0.606–0.690) | 0.644 (0.601–0.685) | 0.689 (0.647–0.729) | 0.707 (0.666–0.746) | 0.662 (0.619–0.702) | 0.670 (0.627–0.710) | 0.700 (0.659–0.739) |
| p value vs. CLIF-C ADs | | 0.4422 | 0.2966 | 0.4238 | 0.0500 | 0.6830 | 0.9233 | 0.1565 |

**Results:** We identified 605 patients, 326 with active infection and 118 with SBP. WBC (10.638 vs 7.560 x109/L; p = 0.000) and CRP (42.48 vs 17.66 mg/L p = 0.000) were statistically higher in the group of patients with active infection compared to uninfected. Although MPV was higher in the infected group of patients, it was not a statistically significant difference (10.08 vs 9.77 fL; p = 0.072). When matched patients with SBP versus uninfected and patients with other infections, WBC (10.792 vs 8.837 x109/L; p = 0.001), CRP (55.94 vs 25.10 mg/L; p = 0.000) and MPV (10.71 vs 9.74 fL; p = 0.000), were statistically higher. Within the group of patients with active infection, those with SBP, presented statistically higher values of MPV (10.71 vs 9.70 fL; p = 0.000) compared to the other infections. Although MPV was not correlated to 30-day mortality, it was correlated to 90-day mortality (Rs = 0.137; p = 0.001). In order to predict SBP, the areas under the ROC curves were: WBC = 0.574; CRP = 0.729 and MPV = 0.684. When compared the discriminating ability, no statistically significant difference was found between CRP and MPV (p = 0.071), but they were both superior to WBC (respectively, p = 0.000 and p = 0.033).
**Conclusion:** 1) MPV seems to be a good marker for the presence of systemic inflammation; 2) although patients with SBP presented higher values of MPV, our data does not support the general use of MPV as a screening method for SBP. Nevertheless, MPV presented an average discriminating power for SBP prediction, similar to CRP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** sergiogiao@hotmail.com

**Introduction:** Excessive alcohol consumption is associated with a vast spectrum of hepatic manifestations, including alcoholic fatty liver disease, alcoholic hepatitis (AH), and cirrhosis. AH in its severe form, presents a high morbidity and mortality and there are several prognostic models validated for predicting prognosis and for guiding treatment decisions.
**Aims & Methods:** To compare in patients with AH, the accuracy of Chronic Liver Failure Consortium organ failure (CLIF-C OF) score with the traditional models: Model for End-Stage Liver Disease (MELD), Maddrey Discriminant Function (MDF) and Age-Bilirubin-INR-Creatinine (ABIC) index, for predicting in the first 24 h of hospitalization, the 30 and 90 day-mortality. We performed a retrospective analysis of 58 patients with the diagnosis of AH admitted in our department between 2010 and 2015. AH was defined according to clinical and analytical criteria: Bilirubin > 1.5 mg /dL; ratio AST / ALT > 1.5 with AST > 75UI/L; history of chronic alcohol abuse; absence of other causes of chronic liver disease, including viral infection. We excluded hospitalizations for bleeding and patients with known neoplasia. Receiver operating characteristic (ROC) curves were generated to assess the prognostic utility of each model.
**Results:** At admission, the mean CLIF-C OFs, MELD, MDF and ABIC were respectively, 8 ± 2, 20 ± 6, 45 ± 30 and 8 ± 1. The Thirty-day and 90-day mortality was 25.9% and 43.1%, correspondingly. In the prediction of 30-day mortality, CLIF-C OFs presented an area under the curve (AUC) of 0.796 (95% CI: 0.670 to 0.891). Although it was significant better than ABIC (AUC = 0.625; p = 0.0433), its discrimination ability was not superior to MELD (AUC = 0.695; p = 0.0814) and MDF (AUC = 0.676; p = 0.1158). In assessing the 90-day mortality, the CLIF-C OFs also presented the highest discrimination ability (AUC = 0.73; 95% CI: 0.604–0.843). When compared, it was significant better than MDF (AUC = 0.633;p = 0.0077) and similar to MELD (AUC = 0.656; p = 0.2078) and ABIC (AUC = 0.645; p = 0.2436).
**Conclusion:** In our sample the CLIF-C OFs was the best model to predict 30 and 90-day mortality. If our results are validated in other cohorts, we should eventually aim to delevop prospective studies that could designate cut-off points like in MDF, for guiding treatment decisions.

### P1115 PORTAL VEIN THROMBOSIS AND CIRRHOSIS PROGRESSION: WHAT IS THE RELATION?

**R. Barosa**[1], M. Patita[1], G. Nunes[2], C. Fonseca[1], J. Freitas[3]
[1]*Dept. Of Gastroenterology, Hospital Garcia de Orta, Almada/Portugal*
[2]*Hospital Garcia de Orta, Almada/Portugal*
[3]*Hospital Garcia Da Orta - Almada, Hospital Garcia de Orta, Almada/Portugal*

**Contact E-mail Address:** a.rita.b@gmail.com

**Introduction:** The incidence of portal vein thrombosis (PVT) in cirrhotic patients reported in the literature varies (0.6 to 30%). The role of PVT in cirrhosis progression is controversial and recently it has been suggested that PVT does not depend on previous progression of liver disease nor is responsible for its future progression.[1]
**Aims & Methods:** We aimed to evaluate the relation between PVT and progression of liver disease. Retrospective observational study including Child Turcutte Pugh (CTP) A and B cirrhotic patients followed in outpatient clinic between March 2008 and August 2015. Progression of cirrhosis was defined as: "de novo" ascites or hepatic encephalopathy, variceal bleeding, bilirubin > 2.6 mg/dL, prothrombin rate < 45%, serum albumin < 2.8 mg/dL and/or creatinine > 1.3 mg/dL.
**Results:** 107 patients were included (male sex 54.2%, mean age 55.5 ± 14.4), with a median follow-up of 62.5 months (IQR 39.0–82.3). Alcohol was the etiology of cirrhosis in 52.3%, 76.6% were CTP A. 8.4% had PVT and 44.4% of those patients were anticoagulated. The overall mortality was 20.0% and was not significantly superior in PVT patients (p = 0.776). PVT was associated with liver disease progression (p = 0.034) and this association remained significant in multivariate analysis (OR 4.423 95%IC 1.014–18.424), however only 44.4% of the patients with PVT had cirrhosis progression during or after the event. PVT was not associated with liver disease progression before the thrombotic event (p = 0.559). The progression of the disease was associated with age (p = 0.037), hepatic encephalopathy at the inclusion (p = 0.05), but not the development of previous or concomitant PVT (p = 0.194).
**Conclusion:** PVT and cirrhosis progression might be two common events of the disease course but do not seem to have a cause-effect relation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Esophageal varices (EV) screening is recommended in cirrhotic patients. In a non-invasive era of hephatology clinical practice, we aimed to assess the performance of non-invasive test in predicting EV on cirrhotic patients with Chronic hepatitis C.
**Aims & Methods:** Retrospective study evaluated cirrhotics for their liver stiffness (FibroScan®), platelet count (PC), Fib-4, APRI and AST/ALT ratio. Upper endoscopy was preformed for detection of EV. Performance was measured by: sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), area under the ROC curve (AUROC) and accuracy.
**Results:** The study included 144 HCV-related cirrhotic patients, 73% male with mean age of 59[28–88] years. FibroScan was performed for staging of chronic hepatitis C. All tests were preformed within 3 months of upper endoscopy. AST/ALT ratio did nor correlate with presence of EV. FS, CP, Fib-4 and APRI showed statistical significance in predicting EV ($p < 0.05$).Platelets count and Fib-4 obtained higher NPV, 91.3% and 89.7% respectively. The combination of FS > 20 and PC < 150x10 ^ 3 / uL obtained VPN of 87% and increased the accuracy to 78.3% for predicting EV. The presence of FS > 20 and PC < 150 x10 ^ 3 / uL is associated with an increased risk of EV OR: 11.36 (95% CI: 4.56 to 28.02).
**Conclusion:** FibroScan, Platelet Count and FIB-4 had a satisfactory performance in predicting LV. The combination of FibroScan and Platelet Count increased accuracy for predicting EV. PC was the best predictor for absence of EV. Their use in clinical practice may allow a better selection of patients for endoscopic screening portal hypertension. These results are consistent with the recent tendency to use non-invasive methods in hepatology clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1117 SPONTANEOUS BACTERIAL PERITONITIS IN CIRRHOTIC PATIENTS UNDER SECONDARY ANTIBIOTIC PROPHYLAXIS

**C. Atalaia Martins**, P. Marcos, S. Barbeiro, F. Silva, M. Canhoto, L. Eliseu, A. Santos, C. Gonçalves, I. Cotrim, H. Vasconcelos
*Gastroenterology Department, Centro Hospitalar de Leiria, Leiria/Portugal*

**Contact E-mail Address:** catarinatalaiamartins@gmail.com
**Introduction:** Spontaneous bacterial peritonitis (SBP) was historically caused by Gram-negative bacteria (GNB) by enteral translocation. However, we are assisting to the emergency of SBP to Gram-positive bacteria (GPB) and Gram-negative resistant to quinolones, which could be related with prolonged antibiotic prophylaxis. Secondary antibiotic prophylaxis is recommended in high risk patients such as the ones with prior SBP episode.
**Aims & Methods: Aim –** Characterization of SBP in cirrhotic patients under secondary antibiotic prophylaxis and identification of predictor factors of SBP to multidrug resistant microorganisms **Methods** – Unicentric retrospective study of a cohort of patients admitted in a Gastroenterology ward with SBP under secondary antibiotic prophylaxis by a previous SBP episode between January/2009 and January/2015. Statistic analysis with SPSS v.23.
**Results:** 37 episodes of SBP were included corresponding to 24 patients. 83.3% were men with mean age of 64,5 years old (49–86). 78.4% had a recent previous hospitalar admission (≤ 30 days before). The average length of stay was 9,92 days. 83.8% had alcoholic cirrhosis etiology. 67.7% were Child-Pug C. 97.3% were receiving norfloxacin as antibiotic prophylaxis and 2.7% sulfamethoxazole/trimethoprim. Ascitic fluid culture was positive in 27% of patients: 80% by GNB being E. coli the most frequent isolated agent. 70% of the isolated bacteria were quinolone-resistant and 60% were third generation cephalosporin-resistant. 86.5% started antibiotic treatment with ceftriaxone but in 21.6% it was necessary an antibiotic adjustment. Quinolones resistant agents happened in patients with a more prolonged time of antibiotic prophylaxis (mean time of 9.7 months versus 2.4 months in non-resistant) and all of them had a previous recent hospitalar admissions. Mortality in SBP episode was 16.2% and 1 year-mortality was 77.4%.
**Conclusion:** SBP in patients under secondary antibiotic prophylaxis was associated with GNB quinolones-resistant. This microbiologic resistance seems to be associated with a more prolonged time of antibiotic prophylaxis. Mortality and 1 year-mortality were high.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1118 STUDY OF PRURITUS IN CHRONIC LIVER DISEASES

**K. Michitaka**, H. Yamago, M. Kanetoh, H. Tomida, Y. Miyamoto, A. Hiraoka, R. Iwasaki, T. Ninomiya
*Gastroenterology Center, Ehime Prefectural Central Hospital, Matsuyama/Japan*

**Contact E-mail Address:** c-kmichitaka@eph.pref.ehime.jp
**Introduction:** Pruritus is a common symptom in patients with liver diseases, however, there is a paucity of information regarding its frequencies among patients with various liver diseases and with various etiologies.
**Aims & Methods:** The aim of this study is to clarify the frequency and severity of pruritus, and effect of therapies including nalfurafine hydrochloride in various chronic liver diseases. A total of 288 patients with chronic liver diseases (157 males, 131 females, 64.8 ± 11.9 years' old) were included in the study. The study was performed using a questionnaire with itch scale sheet for asking the degree, time of itch, and the effect of therapies. Diagnoses of the subjects were as follows: chronic hepatitis (CH), 176; liver cirrhosis (LC), 21; hepatocellular carcinoma (HCC), 74; primary biliary cirrhosis, 6; others, 11. Etiologies of diseases were as follows: hepatitis B virus (HBV), 34; hepatitis C virus (HCV), 210; non-B, non-C, 44.
**Results:** The frequencies and severities of pruritus were as follows: none, 180 (62.5%); mild, 89 (30.9%); moderate, 15 (5.2%); severe, 4 (1.4%). Frequencies of pruritus were 31.8% in patients with CH, 46.3% with LC, and 50.0% with PBC. The rate was significantly higher in patients with LC than that with CH ($p < 0.05$). Frequencies did not differ between HBV and HCV in the present subjects (36.7% and 31.6%). Itch was felt mainly in nighttime in 65.7%, daytime in 9.8%, and both in 24.5%. Among patients with pruritus, 38.0% were treated by crèmes or lotions and 12.0% were with oral medicaments (antihistamine). Effect of therapies was limited in 56.3% of them. Four patients with moderate or severe pruritus were treated by nalfurafine hydrochloride, and the severity of pruritus was improved in all of them ($3.25 \pm 0.25$ to $1.50 \pm 0.29$, $p < 0.01$) by 6 grade-itch face score). Among 19 patients with moderate or severe pruritus, only 5 of them told the doctors the complaint of itch, and the doctors knew the patients' symptom of pruritus for the first time by the itch scale sheet of the present study in the rest 14 patients.
**Conclusion:** Pruritus was found in 37.5% of patients with chronic liver diseases, and the rate was high in LC and PBC, however, no difference was found between HBV and HCV. Many patients did not tell the doctors the complaint of pruritus. Nalfurafine hydrochloride is one of a therapeutic option in patients with limited effect by other therapies.

### P1119 EVALUATION OF SERUM ZINC LEVEL IN PATIENTS WITH LIVER CIRRHOSIS IN DUHOK GOVERNORATE

B. A. Qasim[1], A. Salih[1], M. Habibe[1], **L. S. Aldohuky**[2], R. F. Abduljaqbbar[1]
[1]*Internal Medicine, University of Duhok/College of Medicine, Duhok/Iraq*
[2]*Internal Medicine, Azadi Teaching Hospital, Duhok/Iraq*

**Contact E-mail Address:** lawinshihab@gmail.com
**Introduction:** Cirrhosis is a consequence of chronic liver disease characterized by replacement of liver tissue by fibrous scar leading to progressive loss of liver function. It is most commonly caused by alcoholism and hepatitis B or C. Low serum zinc level is common in patients with liver cirrhosis and appears to be due to anorexia and reduced intake of animal proteins, increase in cytokines or hormones involved in zinc metabolism, increases in renal loss and poor absorption of nutrients due to portal hypertension.
**Aims & Methods:** To determine the serum zinc level in patients with liver cirrhosis in Duhok Governorate. This case control study was conducted on a population of 70 randomly selected sample of patients with liver cirrhosis from 1st of January 2015 to 30th of December 2015, who came for follow up in the Center of Gastrointestinal and Hepatic Disease, Duhok governorate, Iraq and those who admitted in the medical ward at Azadi General Teaching Hospital and 70 of matched healthy individuals as control group. The patients were interviewed and examined, and their blood samples taken for zinc level and assessment of Child–Pugh score was done for them.
**Results:** The mean zinc level in cases group was 73.11μg/dl versus 81.24 in control group ($P = 0.006$). The number of participants, who were low for zinc level was 29 (41.4%) versus 14 (20%) in cases and control groups respectively ($P = 0.006$). As severity of liver cirrhosis increased, the zinc level decreased, it was 2 (14.3%) in class A, versus 19 (43.2%) in class B, versus 8 (66.7%) in class C of Child Pugh score, the P value was significant at 0.024.
**Conclusion:** Hypozincemia is very common in patients with liver cirrhosis in Duhok. A routine biochemical assessment of serum zinc level in patients with

liver cirrhosis is an important step in the management of such patients which will potentially lead to reduction of the progression of their disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Acute-on-chronic liver failure (ACLF) represents a major challenge for clinicians due to the fact that no single universally accepted diagnostic criteria exist. The illness is characterized by a rapid progression to multiple organ failure and a very high short-term mortality of 50–90%. Liver transplantation is the only therapeutic option to improve survival, but a large proportion of patients succumb while waiting on the transplant list. As a result, other therapeutic options are being investigated such as the use of erythropoietin (EPO). EPO is a pleiotropic cytokine known chiefly for its role in the stimulation of erythropoiesis, however, it also has a number of other functions including: cytoprotective, anti-apoptotic, anti-inflammatory and antioxidant activity. In addition it raises the level of calcium in the vascular endothelium, and stimulates the actions of angiotensin II, leading to enhanced perfusion and tissue healing.
**Aims & Methods:** The aim of this study was to predict the 28-day mortality outcome of patients with ACLF based on levels of EPO at admission and at 48 hours. This prospective cohort study, performed from January 1st 2014 to July 1st 2015, included 104 patients diagnosed with ACLF according to the EASL-CLIF criteria, at the Emergency Centre of the Clinical Centre of Serbia, Department for Gastroenterology and Hepatology, Belgrade, Serbia. The patients were divided into two groups based on the type of insult: Group A = gastrointestinal bleeding, and Group B = insult other than gastrointestinal bleeding. The control group consisted of patients with chronic stable liver failure. All patients underwent a complete biochemical workup, including measurement of EPO values on admission, along with calculation of relevant scores for assessing liver function and outcome in ACLF (Child-Pugh, MELD, MELD-Na, SOFA, APACHE II, CLIF C, and AoCLIF). Values of EPO in correlation to the type of acute insult and final outcome (28 day mortality rate) were analyzed.
**Results:** Group A (n = 31) had a mean age of 60.32 ± 9.29 years, and in Group B (n = 73), the mean age was 59.9 ± 10.19 years. The control group (n = 20) mean age was 61.1 ± 8.3 years. The underlining etiology of disease was alcohol abuse in majority of the patients (Group A = 80.6%, Group B = 76.7%, Control group- = 75%). The collected parameters for the test groups are presented in Table 1. The control group had expectedly lower values for all parameters assessed particularly EPO at admission 14.27 ± 13.45mIU/mL and EPO at 48 h 13.78 ± 9.96mIU/mL. Lethal outcome was observed in 15 (48.4%) patients from Group A, and in 37 (50.7%) patients from Group B. In Group A, patients with a lethal outcome had statistically significant higher values of EPO at admission (319.26 ± 326.58mIU/ml) and at 48 hours (136.83 ± 99.06mIU/mL), $p < 0.005$. In Group B, the EPO values were lower ($p = 0.002$) in patients with a lethal outcome (29.88 ± 34.6mIU/mL and 37.77 ± 49.2mIU/mL, respectively). For a cut-off EPO value of 30.65mIU/mL the sensitivity and specificity to predict lethal outcome was 87.5% and 57.4%, respectively.

**Table 1:** Levels of EPO and prognostic scores in test groups (n = 104)

| | Group A (n = 31) | Group B (n = 73) | p values |
|---|---|---|---|
| EPO (mIU/mL) | 293.62 ± 282.76 | 41.59 ± 50.91 | < 0.001 |
| EPO 48 h (mIU/mL) | 161.94 ± 170.36 | 41.39 ± 44.60 | < 0.001 |
| Child-Pugh | 10.74 ± 2.02 | 11.16 ± 1.72 | 0.279 |
| MELD | 20.29 ± 5.83 | 22.37 ± 6.68 | 0.135 |
| MELD-Na | 22.19 ± 5.97 | 24.58 ± 6.58 | 0.086 |
| SOFA | 9.10 ± 2.59 | 9.62 ± 2.59 | 0.351 |
| APACHE II | 14.03 ± 4.02 | 14.47 ± 4.31 | 0.634 |
| CLIF C | 55.87 ± 6.26 | 55.74 ± 8.21 | 0.943 |
| AoCLIF gr I | 6 | 13 | |
| AoCLIF gr II | 15 | 30 | 0.692 |
| AoCLIF gr III | 10 | 30 | |

EPO: Erythropoeitin, MELD: Model of End Stage Liver Disease, MELD-Na: Model of End Stage Liver Disease with Sodium, SOFA: Sequential Organ Failure Assessment, APACHE II: Acute Physiology and Chronic Health Evaluation II, CLIF C: Chronic Liver Failure - Consorcium ACLF score, AoCLIF: Acute-on-Chronic Liver Failure grade.

**Conclusion:** Patients suffering from ACLF without bleeding as an insult had significantly lower values of EPO, and based on our results, we can recommend that these patients would benefit most from EPO therapy. Taking into account the positive effects of EPO treatment in stimulating hepatic regeneration and improving hepatic function, further studies are necessary to solidify our data.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1121 SUBCLINICAL HYPOTHYROIDISM MAY BE AN INDEPENDENT RISK FACTOR FOR LIVER DECOMPENSATION IN CIRRHOTIC PATIENTS

**F. D'Errico**[1], G. Losurdo[1], N.M. Castellaneta[1], A. Mongelli[1], A. Iannone[1], M. Barone[1], M. Principi[2], E.G. Ierardi[1], A. Di Leo[1]

[2]*Energency And Organ Transplantation, University of Bari, Bari/Italy*

**Contact E-mail Address:** francescaderrico@hotmail.it

**Introduction:** Patients with end-stage liver cirrhosis are at risk for major events of decompensation (ascites, bleeding or encephalopathy). We aimed to investigate whether cirrhotic patients with hypothyroidism may show higher rate and earlier events of decompensation than those with normal thyroid function.
**Aims & Methods:** We enrolled cirrhotic patients with (n = 20 with 30 episodes of decompensation) and without hypothyroidism (n = 23), with a median follow up time of 292.5 days. For each patients, decompensation was considered as hospital re-admission for ascites, bleeding or encephalopathy, and we collected data about etiology of cirrhosis, age, sex, MELD score, presence of hepatocarcinoma and blood levels of T3, T4 and TSH hormones. Hypothyroidism was considered as compensated when TSH and thyroid hormones were in their normal range, while subclinical hypothyroidism was defined by high TSH in the presence of normal T3 and T4 levels. A Kaplan-Meier curve was plotted and, at univariate analysis, log-rank test for survival was applied. For multivariate analysis, Cox regression model was applied.
**Results:** Patients with hypothyroidism (both compensated and subclinical) had higher overall TSH levels ($p = 0.04$), but comparable values of T3 and T4 hormones ($p = 0.9$ and 0.16 respectively) compared to cirrhotic without hypothyroidism. The risk of hepatic decompensation was higher when hypothyroidism occurred (HR = 1.725, p log-rank = 0.035), and hospital readmission for cirrhotic with hypothyroidism was earlier (median time = 77.5 days) than those without (median time = 300 days). Subjects with subclinical hypothyroidism had shorter survival time than for compensated hypothyroidism (median 55 vs 210 days respectively, despite not significant $p = 0.14$). Cox multivariate analysis showed that none of considered variables affected survival time, except the presence/absence of hypothyroidism.
**Conclusion:** Hypothyroidisms (both compensated and subclinical) are an independent risk factor for hepatic decompensation. This factor could influence the course of liver disease independently from other well-known variables.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1122 IN SEARCH OF THE BEST PROGNOSTIC MODEL IN DECOMPENSATED CIRRHOSIS: WHAT IS THE VALUE OF C-REACTIVE PROTEIN?

**P. Sousa**[1], J. Pinho[1], D. Martins[1], J. Fernandes[2], R. Araújo[1], E. Cancela[1], A. Castanheira[1], P. Ministro[1], A. Silva[1]

[2]*Gastroenterology, Cova da Beira Hospital, Covilhã/Portugal*

**Contact E-mail Address:** paulacrfsousa@gmail.com

**Introduction:** Inflammation is an essential factor in the pathogenesis of decompensated cirrhosis and of acute-on-chronic liver failure (ACLF). As such, C-reactive protein (CRP) may have a key role on the evaluation of prognosis of this group of patients.

**Aims & Methods:** Retrospective study with inclusion of all patients admitted in a gastroenterology and hepatology unit between January 2013 and December 2015 due to decompensated cirrhosis (including but not limited to patients with ACLF criteria). Patients with overt infection at admission or hepatocellular carcinoma were excluded. Demographic, clinical and analytical (including CRP) data, prognostic scores [Model for end-stage liver disease (MELD) and MELD-Na), in-patient mortality (IPM) and mortality within 3 months of admission (M3) were collected. Statistical analysis was performed with SPSS 20.0.

**Results:** One hundred and 30 patients (80% males) with a median of age of 60.1 years were included; 16.5% of these patients had ACLF criteria. IPM was 13.1% and M3 22.2%. On exploratory analysis there were statistically significant differences between the median value of CRP in patients with and without IPM (1.85 versus 0.99 mg/dL; $p = 0.026$) and with and without M3 (1.89 vs 0.90 mg/dL; $p = 0.006$). In the logistic regression model, CRP only remained as an independent predictor for M3, with an increase of 15.7% on the odds of M3 for each increase of 1 mg/dL of CRP. On analysis of the receiver operating characteristic (ROC) curves, the best predictive model for both IPM and M3 was Meld-Na, with a strong discrimination power of 0.81 [confidence interval (CI) 95% 0.67–0.95;$p < 0.001$] and 0.78 (CI 95% 0.67–0.89; $p < 0.001$), respectively. CRP had a moderate discrimination power of 0.69 (CI95% 0.54–0.83;$p = 0.02$) and 0.68 (CI95% 0.57–0.80; $p = 0.004$) for IPM and M3, respectively. In a model incorporating Meld-Na and CRP, the discrimination power for IPM didn't improve in comparison to Meld-Na alone (0.79, CI95% 0.68–0.90; $p < 0.001$); there was a slight improvement in the discrimination power for M3 (0.79; CI95% 0.68–0.89; $p < 0.001$). The isolated discrimination powers of MELD-Na and CRP were better when applied to the subpopulation of patients with ACLF [MELD-Na with a discrimination power of 0.95 (CI95% 0.01–1.00; $p = 0.001$) and 0.94 (CI95% 0.01–1.00; $p = 0.001$) for IPM and M3, respectively and CRP with a discrimination power of 0.82 (CI95% 0.01–1.00; $p = 0.02$) and 0.79 (CI95% 0.57–1; $p = 0.33$) for IPM and M3, respectively]. However, there were no advantages in their association in a single model [discrimination power of 0.93 (CI95% 0.01–1.00; $p = 0.002$) for IPM and 0.94 (CI95% 0.01–1.00; $p = 0.001$) for M3].

**Conclusion:** CRP has a prognostic value in patients with decompensated cirrhosis, and it's an easily accessible tool. However, it doesn't appear to add any value to the predictive model MELD-Na.

**Disclosure of Interest:** P. Ministro: Medical advisor for Abbvie, Ferring, MSD and Hospira

## P1123 ACUTE-ON-CHRONIC LIVER FAILURE - A DYNAMIC SYNDROME

**M. F. Cardoso**, G. Alexandrino, J. Branco, V. Anapaz, R. Carvalho, D. Horta, A. Martins, J. Reis
*Gastroenterology, Hospital Prof. Doutor Fernando Fonseca, Amadora/Portugal*

**Contact E-mail Address:** marianafc@sapo.pt

**Introduction:** Acute-on-chronic liver failure (ACLF) is a recently defined syndrome characterized by an acute decompensation of cirrhosis with organic failure (s) and high mortality.[1] It is a dynamic syndrome that changes over time and should be assessed repeatedly. It is not clear whether there is a time point that correlates best with prognosis.[2]

**Aims & Methods:** Retrospective unicentric study including patients admitted for acute decompensation of cirrhosis between January/14 and December/15 that fulfilled ACLF criteria, at admission or during hospitalization. Patients were characterized at ACLF onset, at 48 h, 3 to 7 days and at the last available assessment in the first 28 days. 28-day (M28) and 90-day mortality (M90) were calculated.

**Results:** 38 patients (age $62.0 \pm 10.0$ years; 89.5% male) fulfilled ACLF criteria, at admission (50.0%) or during hospitalization. ACLF grades were: ACLF1 63.2%, ACLF2 23.7%, ACLF3 13.2%. 18 patients (47.4%) were admitted in an intensive care unit. ACLF resolved or improved in 62.2%, had a steady or fluctuating course in 13.5% and worsened in 24.3%. Resolution was observed in 58.3% ACLF1, 55.6% ALCF 2 and 25.0% ACLF3. Patients with ACLF resolution had lower M28 (10.0% vs 82.4%, $p < 0.0001$) and M90 (45.0% vs 88.2%, $p = 0.006$). Patients who developed ACLF during hospitalization had higher M28 (63.2% vs 26.3%, $p = 0.022$) and M90 (84.2% vs 47.4%, $p = 0.017$) than patients with ACLF at admission. Despite not reaching statistical significance, final ACLF grade was superior to the initial grade predicting M28 (AUROC $0.882 \pm 0.070$ vs $0.655 \pm 0.090$, $p = 0.09$) and M90 ($0.742 \pm 0.687$ vs $0.645 \pm 0.0745$, $p = 0.45$); the final CLIF-OF (CLIF Organ Failure) score was also superior to the initial score predicting M28 (AUROC $0.968 \pm 0.0267$ vs $0.800 \pm 0.0802$, $p = 0.05$) and M90 ($0.927 \pm 0.0418$ vs $0.765 \pm 0.0760$, $p = 0.06$).

**Conclusion:** In our population, prognosis was better defined by the early course of ACLF than by the initial evaluation, illustrating the dynamic nature of this syndrome.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1124 CLINICAL PROFILE OF PATIENTS WITH HEPATITIS E

**V.V.S. Vijayanand Kumar**[1], V. L[1], J. Krishnaveni[2], N. Mohandas[1], M. S[1], K. Murthy[1], A. Kulkarni[2], S. R. Dharamsi[1]
[1]*Department Of Gastroenterology, PSG Hospital, Coimbatore/India*
[2]*Gastroenterology And Hepatology, PSG Hospital, Coimbatore/India*

**Contact E-mail Address:** vijaie2000@yahoo.com

**Introduction:** Hepatitis E is an important cause of acute viral hepatitis in India.[1] The disease is usually self limited and has a case fatality rate of $<0.1\%$ in general population. However it is more severe, amongst pregnant women and often lead to fulminant hepatic failure and death in a significant proportion of patients.[2]HEV is a positive sense single stranded RNA icosahedral virus with a 7.5 kilobase genome classified under the genus Hepevirus.[3] Transmission is fecoral. Epidemic occurance is common. According to the South-East Asia Regional Office of the World Health Organization (WHO), hepatitis E is widespread in developing countries, accounting for upto 60–70% of all sporadic cases of acute viral hepatitis.[1,4] HEV causes high mortality in pregnant women, 20–30% as compared to 0.2–1% in general population.[5,6]

**Aims & Methods:** This study was conducted over a period of 5 years from Jan 2010 till Dec 2015. This was a retrospective observational study. All the patients tested positive for anti HEV IgM antibodies were included in the study including pregnant women, children and patients with preexisting Chronic Liver Disease. Details of clinical history at presentation to the hospital, history of pre existing Chronic Liver Disease, clinical examination, Investigation reports, Progression of the disease, response to treatment, complications encountered and outcome of the disease were noted.

**Results:** Males were more affected than females in all the age groups. The highest incidence was found in the age group of $>51$ yrs. Three out of the fifteen females were pregnant on admission. Twenty three (31.5%) patients amongst the seventy three had preexistent chronic liver disease. A majority of the patients presented with jaundice (91.78%). Other associated symptoms in the decreasing order of frequency were – anorexia (78.08%), nausea/vomiting (68.49%), abdominal pain (58.90%), sleep disturbances (49.31%) and hepatomegaly (50.68%). Pruritis, bleeding manifestations and altered consciousness were present in 23.28%, 20.54% and 16.43% of patients, respectively Serum Bilirubin values were elevated in all the patients with the lowest value noted at 1.5 mg/dl and the highest value noted was 41.2 mg/dl. ALT raise was seen in 84.12% patients. The highest value noted was 7355 U/L. Hepatic coagulopathy was the commonest complication (34.24%). Renal failure was noted in 16.43%, hepatic encephalopathy in 13.69% and fulminant hepatic failure in 7.93% respectively. There were no deaths among the general population. Overall mortality was 5 patients (6.84%) and all of them had background history of CLD. There were no deaths among pregnant women in the study nor were any cases of Intra Uterine Deaths. Among 23 patients with CLD, 21 patients (91.30%) had ACLF with mortality of 5 amongst them.

**Conclusion:** We concluded that acute viral hepatitis E is generally a self limiting disease among the general population, but can cause significant morbidity and mortality among special groups (pregnant women and people with preexisting Chronic Liver Disease). Progression of HEV related illness depends on multiple factors like age, comorbid illnesses, nutritional status, initial severity at presentation, early diagnosis, timely intervention and effective treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** 1044050245@qq.com

**Introduction:** Hepatitis B Virus infection is a common chronic liver disease characterised by familial aggregation in Chinese population in which host genetic factors may be involved. Keratin serves as a cytoskeleton that protects the liver from injuries and its mutations lead or predispose to the development of multiple liver diseases.

**Aims & Methods:** This study is to explore the characteristic of keratin variants in Chinese patient with liver disease caused by HBV. Our research has sequenced the entire coding regions and exonic-intronic boundaries of Keratin 8 and 18 with Sanger method that were amplified by polymerase chain reaction from blood DNA of HBV group and matched control group in the First Affiliated Hospital of Sun Yat-sen University from January 2009 to December 2015. HBV serologic indicators, HBV DNA levels, liver function, blood cells count and imaging examination were assessed.The relation among HBV infection, disease severity and keratin mutation was assessed by chi-square test. Conservation analysis of Keratin mutation firstly discovered in our study was performed with Clustal X software.

**Results:** Of the 713 examined subjects, 174 cases were diagnosed with chronic hepatitis B (CHB), while 192 cases with hepatitis B associated liver decompensated cirrhosis (HBDLC) and 174 cases with primary liver carcinoma (PLC). The frequency of mutations including missense mutation and intron mutation at keratin in study group was significantly higher than that of control group (8.15% vs 0.58%, respectively, $p = 3.66*10\,E\text{-}6$). Additionally, there was a trend toward an increase in both missense mutation and intron mutation in the study group as compared with control group (3.89% vs 0.58%, $p = 0.03$, 4.26% vs 0%, $p = 0.045$). Significant statistics difference was found between CHB group and control in multiple comparison (6.32% vs 0.58%, $p = 0.006$), except HBDLC and PLC. 21 missense mutations (3.89%) were found in study group, and K8 R341H constituted the most frequent amino acid-altering variant found. We also detected four novel and hitherto undescribed amino acid-altering variants (K8R469C, K8R469H, K8 A447V, K8K483T). Multiple sequence comparison analysis revealed that all novel K8 variants were at conserved site except for K8 A447V. In CHB subgroup, both of the HBV DNA levels and median model for end-stage liver disease (MELD) score were higher in those with missense mutation than that of without. But we did not find differences in positive HBV family history rates between the mutation patients and those without. Both HBV aggregation family and control group exhibited similar rates of mutations.

**Conclusion:** Keratin serves as a predisposing factor in exacerbation of CHB, but may not be linked to HBV familial aggregation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1126 ASSOCIATION OF INTERLEUKIN 28B SINGLE NUCLEOTIDE POLYMORPHISMS WITH THE SUSCPTIBILITY OF HEPATITIS C VIRUS INFECTION IN EGYPTIAN POPULATION. A MULTICENTRE FAMILY BASED ASSOCIATION STUDY

**Introduction:** Approximately 25% of infected individuals with acute HCV will spontaneously resolve HCV infection, developing robust protective immunity against reinfection while the remaining 70% of those individuals will develop chronic infection. Recently, genome-wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) near the IL28B gene (encoding IFN-λ3) to be strongly associated with the spontaneous and treatment-induced viral clearance.

**Aims & Methods:** The aim of this work to show the possible association of IL-28B with HCV infection outcome. Five SNPS spanned on 14 kb in promoter region of IL28B gene were genotyped by real time PCR using TaqMan allelic discrimination kit (Applied Biosystems, Foster City, CA, USA) according to the manufacturer's protocol. A total 230 families (985 subjects) from upper & lower Egypt (east & west delta), we compared the risk of allele carriage of selected markers in different groups. These groups included spontaneous clearance (n108), chronic HCV patients (n397), and negative control (n480) individuals. Genotyping of five SNPs (rs12980275, rs8105790, rs12979860, rs8099917 and rs10853728) near the IL28B region was performed.

**Results:** Across the different markers the allele carriage of wild alleles was significantly higher in in spontaneous clearance compared to that in chronic. The peak of significant results obtained with T allele of SNP rs 8099917 (OR = 0.3307, 95% CI 0.1917 to 0.5703, P = 0.0001) and extended across the C allele of rs 1297860 (OR = 0.6004.95% CI 0.4328 to 0.8329 P = 0.0022), T allele of rs 8105790 (OR = 0.7336, 95% CI 0.3692 to 0.7837, P = 0.0012) and A allele of rs 12980275 (OR = 0.7458.95% CI 0.5803 to 0.9275, P = 0.0035) then the significant result disappear at rs 10853728 (G/C).This indicates that T allele of rs 8099917 SNP of IL28B gene polymorphism may have crucial role in spontaneous viral clearance of HCV infection. However, the allele carriages of mutant alleles of different SNPs were significantly higher in chronic HCV group compared to that of negative control group. The peak of results was observed with allele T of SNPrs 1297860 (OR = 1.758, 95% CI 1.4812 to 1.991, P < 0.0001) and extended along the C allele of rs 8105790 (OR = 1.5369, 95% CI 1.1812 to 1.7991, P = 0.0096), G allele of rs 12980275 (OR = 1.5069, 95% CI 1.4812 to 1.7991, P = 0.0009) and C allele of rs 10853728 (OR = 1.3569, 95% CI 1.0912 to 1.6689, P = 0.0052). This indicates that T allele of rs 1297860 SNP of IL28B gene polymorphism may have crucial role in persistence of HCV infection. Furthermore it was found that spontaneous clearance of HCV was associated with the carriage of protective haplotype ATCTG, While the chronic HCV was associated with carriage of the haplotype GCTGC.

**Conclusion:** Spontaneous clearance of HCV was associated with the wild allele carriage with the peak at T allele of rs 8099917 SNP of IL28B gene and with the carriage of protective haplotype ATCTG, While the chronic HCV was associated with T allele of rs 1297860 SNP & with the carriage of the haplotype GCTGC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Serum autotaxin (ATX) is originally isolated from the conditioned medium of human melanoma cells as a stimulator of cell migration, but it is reported to be a highly reliable, non-invasive marker of liver fibrosis in patients with hepatitis C virus infection[1] or cirrhosis[2].

**Aims & Methods:** We assessed the ability of serum ATX to diagnose liver fibrosis in patients with chronic hepatitis B virus (HBV) infection. Serum ATX levels were retrospectively evaluated in 101 treatment-naïve patients with HBV-related chronic hepatitis and cirrhosis who had undergone liver biopsy at our hospital.

**Results:** Consistent with a previous report[3], serum ATX exhibited gender differences. The correlations between ATX and other non-invasive markers (hyaluronic acid type IV collagen 7 S, WFA+-M2BP, APRI, FIB-4, serum albumin, and platelet count) and those markers indicating hepatitis activity (AST/ALT and histological activity) were stronger in men than in women. Serum ATX levels significantly correlated with liver fibrosis stages ($r = 0.524$ and $p = 0.0006$ in women; $r = 0.552$ and $p = 0.00001$ in men), and serum ATX proved to be the most reliable factor for accurately predicting significant fibrosis with an area under the receiver operating characteristic curve (AUROC) of 0.792 in men and 0.786 in women, when compared with all other non-invasive markers.

**Conclusion:** These results suggest that serum ATX can predict liver fibrosis with chronic HBV infection, although gender differences should be taken into consideration. This is the first study clarifying the clinical importance of serum ATX in HBV-infected patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** To date, there are few reports on therapeutic effects of sequential therapy (ST) with chronic hepatitis B responding to nucleoside analogues (NAs).

**Aims & Methods:** Patients who had achieved favorable therapeutic outcomes with long-term administration of NAs are prospectively being followed up by dividing them into those switching to ST and those continuing NA therapy, and we assessed therapeutic effects for up to 96 weeks from the start of follow-up. Thirty patients with chronic hepatitis B who achieved a HBsAg level below 2000 IU/mL and a hepatitis B virus (HBV) DNA level below 2.1 log copies (LC)/mL with long-term administration of NAs (median: 50 months) were divided into two groups: the ST group of 15 patients who consented to switching to ST and the NA group of 15 who continued NA therapy without consenting to ST. The therapeutic effects from the start of follow-up to 96 weeks were prospectively assessed. In the ST group, pegylated interferon (Peg-IFN) a-2 a was administered for 48 weeks, including 4 weeks of concomitant administration with NAs, after obtaining consent. Drug-free remission was defined as an alanine aminotransferase (ALT) level below 31 IU/L and an HBV-DNA level below 4.0 LC/mL.

**Results:** There were no differences in pretreatment patient characteristics between the ST and NA groups. At 96 week from the start of follow-up, all NA group patients maintained an ALT level below 31 IU/L and a HBV-DNA level below 2.1 LC/mL. On the other hand, in the ST group, 60% of patients achieved drug-free remission at 96 week (including those with complete remission defined as ALT < 31 IU/L and HBV-DNA < 2.1 LC/mL, accounting for 20%), whereas approximately 15%, with an ALT level of 31 IU/L or more and an HBV-DNA level of 4.0 LC/mL or more, required NA therapy resumption. Moreover, the patients who required NA therapy resumption had been unable to maintain hepatitis B core-related antigen (HBcrAg) levels below 3.0 log U/mL during Peg-IFN administration, and the levels rose to 4.0 log U/mL or more after ST completion. Regarding fluctuations in HBsAg levels, the median in the NA group was 689 IU/ml before treatment, 630 IU/mL at 48 week, 558 IU/mL at 72 week, and 554 IU/mL at 96 week, remaining essentially unchanged, whereas the respective median values in the ST group were 691, 458, 326, and 264 IU/mL, showing a significant decrease ($P < 0.05$). However, no patients showed HBsAg loss during follow-up. Interestingly, as HBV-DNA elevation and severe hepatic dysfunction were observed in one patient of ST group at 72 week, administration of NA was resumed. As a result, HBsAg levels markedly decreased (72w: 188 IU/mL, 96w: 0.13 IU/mL).

**Conclusion:** In patients who had achieved favorable therapeutic outcomes with long-term NA administration, administering ST decreased HBsAg levels, and the 96 weeks follow-up results showed that drug-free remission was achieved in 60% of these patients. In addition, based on the marked decrease in HBsAg levels in one case following acute exacerbation after ST completion, the adoption of ST is considered to be useful for lowering HBsAg levels.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1129 MAY "GILBERT'S-LIKE" SYNDROM BE PART OF SPECTRUM OF PERSISTENT UNCONJUGATED HYPERBILIRUBINEMIA IN POST-HEPATITIS PATIENT?

**R. Lin**, J. Ye, O. Banafa
*Gastroenterology, Wuhan Union Hospital, wuhan/China*

**Contact E-mail Address:** selianlin35@hotmail.com

**Introduction:** Following the effective treatment of acute and chronic liver diseases, the majority of patients in recovery of liver diseases present liver enzyme index declining to normal. However, it is not uncommon that persistent or intermittent mild unconjugated hyperbilirubinemia could be detected and hardly be eliminated. The UGT1A1 mutation has been claimed to lead to Gilbert syndrome (GS) and appears to be considerably different among ethnic groups.

**Aims & Methods:** To investigate the correlation between gene polymorphisms of bilirubin uridine diphosphate-glucuronosyltransferase (UGT1A1) and the development of unconjugated hyperbilirubinemia in clinical Gilbert's syndrome and posthepatitis hyperbilirubinemia. The blood samples of 294 patients, including 85 patients who were clinically diagnosed as Gilbert syndrome (GS), 70 patients who had indirect hyperbilirubinemia during the recovery period of chronic liver diseases, 109 patients with normal hepatic function and 21 active chronic hepatitis B patients as the hepatitis control group patients were collected. All samples were tested for the identification of UGT1A1 *28 and UGT1A1 *6 genotype by pyrosequencing technique. The total bilirubin and indirect bilirubin levels were measured. The frequency and the diverse UGT1A1 diplotypes formation were analyzed to evaluate the correlation between development of indirect hyperbilirubinemia and gene polymorphisms of UGT1A1. The data were presented as mean ± standard error of the means (SEM). Statistical analysis was performed by SPSS statistical software version 19.0 using either Chi-square, contingency table or Fisher's exact probability method depending on the dataset. A $p < 0.05$ indicated statistical significance.

**Results:** The gene variation of UGT1A1 *28 and UGT1A1 *6 were positively correlated to the level of serum bilirubin. Homozygous TA insertion in the TATA box of the promoter region (UGT1A1*28) (22%) and homozygous UGT1A1*6 (14%) were frequent in GS. There is no homozygous genotype for both UGT1A1*6 and UGT1A1*28 were detected in healthy control patient (UGT1A1*28: 0.465 vs 0.101; UGT1A1*6: 0.288 vs 0.142; $p < 0.05$). The allele gene frequency for UGT1A1*28 was significant elevated in GS comparing with healthy-control patients. Homozygous TA insertion in the TATA box of the promoter region (UGT1A1*28) (14%) and homozygous UGT1A1*6 (11%) were frequent in GS. There is no homozygous genotype for both UGT1A1*6 were detected in hepatitis control patient. And homozygous genotype for UGT1A1*28 was only found in one hepatitis control patient. The allele gene frequency for UGT1A1*28 was significant elevated in post-hepatitis comparing with hepatitis-control patients (UGT1A1*28: 0.350 vs 0.143; UGT1A1*6: 0.286 vs 0.119; $p < 0.05$). The polymorphosim of UGT1A1 present similar patten in GS and post hepatitis hyperbilirubinemia patients.

**Conclusion:** Gene polymorphisms of UGT1A1*28/*6 in patients who had indirect hyperbilirubinemia during the recovery period of chronic liver diseases present similar pattern as GS patient. The "Gilbert's-like" syndrom might be part of spectrum of persistent unconjugated hyperbilirubinemia in post-chronic hepatitis patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic Hepatitis B (CHB) remains an important disease in many parts of the world and with the rising prevalence of metabolic syndrome worldwide, patients with concomitant CHB and hepatic steatosis are increasingly encountered. However the characteristics, interaction and long-term follow-up in these patients remain to be elucidated.

**Aims & Methods:** Aim. To assess the liver histology, clinical characteristics and progression to cirrhosis and hepatocellular carcinoma (HCC) in CHB patients with or without concomitant hepatic steatosis. Methods. 182 CHB patients with liver biopsy performed between 2000–2006 were identified from hospital records. Liver biopsy histology was reviewed for presence of >5% steatosis and non-alcoholic steatohepatitis (NASH). The clinical characteristics were analysed and stratified by presence (Group 1) or absence (Group 2) of hepatic steatosis. Patients were prospectively followed-up for development of Hepatocellular carcinoma (HCC) or new cirrhosis in patients with low fibrosis score till 1/04/2016. HCC was confirmed based on contrast enhanced imaging. Cirrhosis was defined based on fibroscan or liver histology or at least two of the three ultrasound findings i.e nodular liver, irregular margins or caudate lobe hypertrophy.

**Results:**

Baseline characteristics

| | Group 1 (Hepatic steatosis) N = 100 | Group 2 (no steatosis) N = 82 | p value |
|---|---|---|---|
| Age in years | 44.5 ± 11.1 | 41.4 ± 14.1 | 0.09 |
| Gender (% males) | 77.0 | 65.8 | 0.07 |
| HBV DNA in log copies/ml | 7.15 ± 1.64 | 7.46 ± 1.40 | 0.18 |
| ALT in IU/L | 155 ± 216 | 183 ± 252 | 0.35 |
| Bilirubin in μmol/l | 17.65 ± 12.9 | 20.83 ± 33.8 | 0.39 |
| Albumin | 39.5 ± 4.8 | 40.62 ± 22.6 | 0.628 |
| Diabetes Mellitus in % | 16.5% | 6.1% | 0.025 |

Hepatic steatosis was seen in 54.9% (100/182) of patients with hepatitis B on biopsy. At the time of biopsy the mean age was 43.1 ± 12.5 years with 72.0% males, predominantly of Chinese ethnicity (94.5%). Baseline characteristics are shown in table 1. Cirrhosis was seen in 19/100 in Gp1 and 21/82 in Gp 2 at baseline. On mean follow-up of 10.6 ± 3.8 years, hepatocellular carcinoma was seen in 12/100 subjects in Gp1 and 7/82 in Gp 2 ($p = 0.28$). HCC was seen in 12/99 in Gp1 and 7/83 in Gp 2 ($p = 0.29$). However on cox-regression analysis for HCC risk factors, Diabetes Mellitus (HR 4.4, CI 1.97–13.7 $P = 0.002$), Age

($p < 0.001$) were significant risk factors for development of HCC. Hepatic steatosis was not a significant risk factor for HCC on cox-regression analysis ($p = 0.18$) New cirrhosis was seen in 20/81 in Gp1 and 18/62 in Gp 2 ($p = 0.56$). Age was significantly different in the patients who progressed to cirrhosis ($p = 0.02$), while Diabetes Mellitus (DM), Fatty liver, ALT were not significant. In the subgroup of patients with low HBV DNA (< 6 log copies/ml) and low Ishak fibrosis score (< 4) 31 patients were identified. Progression to cirrhosis was seen in 3 of 22 patients in Gp 1 and none of the patients in group 2. Diabetes mellitus and advanced age being significant risk factors (with $p = 0.045$ and 0.04 respectively) with HR of 19.6, CI 1.18–333.0 for DM on cox-regression analysis

**Conclusion:** In patients with Hepatitis B presence of concomitant steatosis does not increase the risk of hepatocellular cancer development but Diabetes mellitus remains a risk factor. However in patients with low viral load and early fibrosis, presence of diabetes mellitus remains independent risk factor for progression to cirrhosis and not hepatic steatosis alone.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1131 EARLY DECREASE OF LIVER STIFFNESS AFTER INITIATION OF ANTIVIRAL THERAPY IN PATIENTS WITH CHRONIC HEPATITIS C INDICATES THAT LOWER CUT-OFF VALUES FOR LIVER STIFFNESS ARE APPROPRIATE FOR MONITORING LIVER FIBROSIS AFTER INITIATION OF ANTIVIRAL TREATMENT

**S. Moser**[1], E. Gutic[1], M. Gschwantler[2]

**Contact E-mail Address:** dr.stephan.moser@gmail.com

**Introduction:** Liver elastography is widely used to assess liver fibrosis in patients with chronic hepatitis C and has also been recommended to monitor liver fibrosis after successful antiviral therapy. We studied early changes of liver stiffness after initiation of antiviral treatment.

**Aims & Methods:** The study population comprised 53 patients with chronic hepatitis C (mean age: $49.4 \pm 10.7$; METAVIR fibrosis stage F2, n = 23; F3, n = 12; F4, n = 18; genotype (GT), n = 32; GT3, n = 17; GT4, n = 4; mean BMI: $25.1 \pm 3.8$). All patients were treated with interferon-free regimens. Prior to therapy and 1–6 weeks after initiation of antiviral treatment fibrosis stage was assessed by transient elastography using the Fibroscan® 502 Touch device. Cut-off values for liver stiffness were defined as 7.1 kPa for $F \geq 2$, 9.5 kPa for $F \geq 3$ and 12.5 kPa for F = 4. Only procedures with 10 successful measurements of liver stiffness with an interquartile range < 30% were considered reliable.

**Results:** Mean liver stiffness at baseline was $14.69 \pm 11.15$ kPa and decreased to $12.41 \pm 9.83$ kPa at week 1–6 ($p = 0.006$). When the same Fibroscan® cut-off values applied at baseline were applied after initiation of antiviral therapy the following results were obtained: Within 6 weeks after initiation of treatment fibrosis stage improved by at least one stage in 23/53 (43%) patients, remained stable in 28/53 (53%) and worsened in 2/53 (4%). Decrease of liver stiffness did not correlate with baseline AST ($r = 0.28$) or ALT ($r = 0.04$) levels.

**Conclusion:** After initiation of antiviral therapy a significant decrease of liver stiffness can be observed within 6 weeks, probably caused by resolution of inflammation. Our data clearly indicate that lower cut-off values for liver stiffness are appropriate for monitoring liver fibrosis after initiation of antiviral therapy.

### P1132 REAL LIFE EXPERIENCE WITH DIRECT ACTING ANTIVIRALS IN THE MANAGEMENT OF HCV PATIENTS WITH REDUCED FUNCTIONAL HEPATIC RESERVE

**A. S. Hanafy**
*Internal Medicine, Zagazig University, Zagazig/Egypt*

**Contact E-mail Address:** amrhanafy@zu.edu.eg

**Introduction:** Treatment of HCV showed a remarkable change recently. Many direct acting antiviral (DAA) drugs are introduced as Sofosbuvir which is a pangenotypic HCV NS5B nucleotide polymerase inhibitor. It has been tried both as dual therapy with ribavirin or simeprevir and also as a part of triple therapy which included pegylated interferon alfa and ribavirin. High rates of SVR have been theoretically shown with a postulated safety profile both in cirrhotic and noncirrhotic patients. Patients with decompensated cirrhosis mostly will not benefit from HCV antiviral therapy even if HCV-RNA became negative, as they reached a point of no return. Many patients with apparently adequate liver function tests and Child Pugh score may not sustain combined antiviral therapy due to development of complications and this may need the development of a practical index.

**Aims & Methods:** Assessing the efficacy, safety of direct acting anti virals in a cohort of Egyptian patients presented with occult reduction in functional hepatic reserve. Patients were included if they had chronic active HCV proved by positivity of HCV RNA and elevated transaminases. the functional hepatic reserve was predicted by a model composed of defined cutoff values: AST to platelet count ratio (APRI) + Caudate/right lobe ratio + prothrombin concentration (PC) in points. APRI score with the selected cut-off value of 1.The cutoff value of Caudate/right lobe ratio (C/RL) was 0.66, Prothrombin concentration (PC) is a sensitive prognostic indicator. According to PC, the patient is given a score as follows; PC > 80% → 0, PC: 70–79% → 1, PC: 60–69 → 2, PC: 50–59 → 3, PC < 50→ 4. 300 patients with chronic active HCV (275 M, 125 F) were evaluated and enrolled if their functional hepatic reserve score (FRS) was more than 3.66; in the period from January 2015 till October 2015. they were subclassified into: **(Dual therapy):** (n = 200), 30 patients received simeprevir and sofosbuvir for 3 months and 170 patients received ribavirin and sofosbuvir for 6 months. **(Triple therapy):** (n = 100) who received Sofosbuvir plus peginterferon and ribavirin for 12 weeks.

**Results: (Dual therapy):** Complications occurred in 120 patients (60%, functional hepatic reserve score (FRS) $4.06 \pm 0.5$) mainly anaemia (80 patients, 66.7%), ascites (34 patients, 28.3%), GIII hyperbilirubinemia mainly direct (89 patients, 74.2%), photosensitivity in 14 patients (11.7%), hepatic encephalopathy (HE) (20 patients, 16.7%), accidental diagnosis of HCC near the end of treatment in 10 patients (8.3%); 130 patients showed SVR (65%, FRS mean value $3.55 \pm 0.4$), 70 patients developed virological relapse (35%, FRS: $3.88 \pm 0.5$) **(Triple therapy):** Complications occurred in 61 patients (61%, FRS: $3.78 \pm 0.3$) mainly anaemia (51 patients,83.6%), jaundice GII-III mainly indirect bilirubin (43 patients, 70.5%), ascites in 12 (19.7%), HE in 8 (13.1%). 86 patients (86%) achieved end of treatment response, 75 patients achieved SVR (75%, FRS mean value $2.9 \pm 0.7$), 25 patients showed relapse of viremia (25%, FRS: $3.79 \pm 0.3$).

**Conclusion:** In real life, SVR with DAAs in dual therapy is 65% and 75% in triple therapy in patients with reduced functional hepatic reserve with FRS more than 3.66.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The aim of this study was to compare the feasibility of four ultrasound based elastographic methods used for assessing spleen stiffness.

**Aims & Methods:** The study included 42 subjects diagnosed with HCV compensated liver cirrhosis in whom spleen stiffness (SS) was evaluated in the same session by means of 4 elastographic methods: Point shear wave elastography techniques: Virtual Touch Tissue Quantification (VTQ)-Acuson S2000, Siemens and ElastPQ technique-Affinity, Philips; 2D Shear Waves Elastography-Aixplorer, Supersonic Imagine (2D SWE) and the LogiqE9, General Electric (2D-SWE GE). All examinated patients (n = 42) presented splenomegaly defined by values higher than 12.5 cm. Reliable SS measurements were defined as follows: for ElastPQ, VTQ and 2D-SWE.GE- the median value of 10 SS measurements with a success rate ≥60% and an interquartile range < 30% and for 2D-SWE the mean value of 3 measurements acquired in a homogenous area. SS was expressed in kPa for 2D-SWE, ElastPQ and in m/s for VTQ and 2D-SWE GE.

**Results:** Reliable SS measurements were obtained in: 85.7% with 2D-SWE.GE, 85.7% with VTQ, 47.61% with 2D-SWE and 30.95% with ElastPQ. 2D-SWE

GE and VTQ had similar rates of reliable SS measurements. The mean value for 2D-SWE GE was 2.46 ± 0.74 m/s and for VTQ was 3.14 ± 0.58 m/s.
**Conclusion:** 2D-SWE GE and VTQ were the most feasible shear-waves elastographic methods in assessing spleen stiffness in patients with HCV compensated liver cirrhosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1134 DIRECT ACTING ANTIVIRALS FOR CHRONIC HEPATITIS C GENOTYPE 3: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

**F. A. c. Berden**[1], B.R. Aaldering[1], H. Groenewoud[2], J. Inthout[2], W. Kievit[2], J. Drenth[1]

**Introduction:** Although the introduction of direct acting antivirals (DAAs) improved efficacy of chronic hepatitis C virus (CHC) treatment significantly, results in CHC genotype 3 remain suboptimal. There are several treatment options available, but head-to-head studies are the exception.
**Aims & Methods:** We aimed to (1) perform a systematic review and network meta-analysis to indirectly compare efficacy (sustained virological response, SVR) of DAAs in CHC genotype 3; (2) assess the role of ribavirin, length of therapy and presence of cirrhosis on treatment efficacy. We conducted a systematic search in the Pubmed, EMBASE and Web of Science databases (Jan 2004–Mar 2016). We performed a Bayesian network meta-analysis using a random effects model to indirectly compare identified regimes (R and Winbugs). Data per regime is presented as mean chance on SVR and 95% credibility interval (95%CrI). Effect of ribavirin, extension of treatment and cirrhosis are presented as odds ratio (OR) with 95%CrI.
**Results:** Our search identified 3261 articles. A total of 19 studies (2998 patients in 29 different treatment regimes) met inclusion criteria. Some 1673 (56%) patients were treatment naïve and 497 (17%) were cirrhotics. The numerically highest chance on SVR were estimated for the regimes sofosbuvir/velpatasvir with ribavirin for 12 weeks (98.4%, 95%CrI 96.1–99.5) or without ribavirin for 24 weeks (98.7%, 95%CrI 96.5–99.7). For other regimes the chances of SVR were numerically lower, but 95%CrIs overlapped: sofosbuvir/daclatasvir with ribavirin for 12 (84.1%, 95%CrI 59.9–96.3), 16 (92.4%, 95%CrI 78.1–98.5) or 24 (95.5%, 95%CrI 86.5–99.2) weeks or without ribavirin for 24 weeks (86.6%, 95%CrI 63.9–97.4), sofosbuvir with peginterferon and ribavirin for 12 weeks (92.9%, 95%CrI 84.5–97.5), and sofosbuvir/velpatasvir for 12 weeks (94.8%, 95%CrI 89.0–98.2). For the added value of RBV, we found an OR of 3.53 (95%CrI 2.00–5.89), and an OR of 4.57 (95%CrI 2.52–7.76) for extension of therapy from 12 to 24 weeks, and an OR of 0.76 (95%CrI 0.39–1.35) for the effect of cirrhosis on SVR.
**Conclusion:** This indirect comparison of treatments using Bayesian network meta-analysis reveals that sofosbuvir /velpatasvir with ribavirin for 12 or without ribavirin for 24 weeks in CHC genotype 3 patients is the best option. However, this was not significantly higher than the currently available regimes for genotype 3. Our analyses suggest that both ribavirin and extension for treatment have an additional value in obtaining SVR, while cirrhosis did not significantly affect SVR. Choice of treatment may depend on factors such as patient characteristics, risk of adverse events and price of therapy.

## P1135 EFFECT OF HEPATITIS C TREATMENT WITH DIRECT-ACTING ANTIVIRALS ON VITAMIN D IS DEPENDENT ON SEASONALITY

**M.J. Silva**, P. Russo, C. Bernardes, V. Borges, R. Vasconcelos Loureiro, T. Capela, F. Calinas
*Gastroenterology, Centro Hospitalar de Lisboa Central, Lisboa/Portugal*

**Contact E-mail Address:** mariojorgesilva01@gmail.com
**Introduction:** Hypovitaminosis D is very common in chronic infection with hepatitis C virus (HCV), and is possibly due to viral effects on 25-hydroxylation and/or lipid metabolism. On the other hand, vitamin D levels vary according to sun exposure, which is necessary to its endogenous synthesis. Vitamin D has antifibrotic effects and modulates immune responses, and therefore its deficiency may be implicated in the pathogenesis of liver disease.
**Aims & Methods:** We aim to characterize the impact of treatment of hepatitis C with direct-acting antivirals without interferon (DAA) on vitamin D levels.
Analysis of all patients with chronic hepatitis C treated with DAA at one center, with serum 25-hydroxycholecalciferol levels prospectively performed on first day of therapy (baseline), end-of-treatment (EOT) and/or 12 weeks after end-of-treatment (PT12). Patients with detectable viral load on PT12 were excluded. Vitamin D deficiency was defined as $<20$ ng/mL (according to Endocrine Society). Year months were classified as "sunny" vs "non-sunny", if sun hours were $\geq 8$ (April-September) vs $<8$ (October-March) respectively, according to data on http://www.weatheronline.pt for Lisbon. Patients were treated according to national and/or EASL recommendations. Statistical analysis performed with STATA®v12.1 and Excel®2010.
**Results:** Fifty-five patients were analyzed, 72.7% (40/55) males, median age 57 (41;78) years. All patients were treated with sofosbuvir/ledipasvir, with or without ribavirin, during 12 or 24 weeks, and had viral load $<15$UI/mL on EOT. Treatments were initiated between April and October 2015. Thirty-two patients had HCV genotype 1, 19 had HCV genotype 3 and 4 had HCV genotype 4. On baseline, 63.6% (35/55) of patients had vitamin D deficiency. Globally, mean vitamin D levels decreased from baseline to EOT (18.8 ng/mL to 14.5 ng/mL; $p < 0.01$; $n = 55$) and then further declined from EOT to PT12 (16.1 ng/mL to 13.1 ng/mL; $p < 0.01$; $n = 27$). Among patients who completed therapy on "sunny" months ($n = 6$), mean vitamin D levels increased from baseline to EOT (17.0 to 19.6 ng/mL; $p = 0.35$; $n = 6$), and then decreased from EOT to PT12 (21.0 ng/mL to 15.3 ng/mL; $p = 0.13$; $n = 4$). Among patients who completed therapy on "non-sunny" months ($n = 49$), mean vitamin D levels decreased from baseline to EOT (19.0 ng/mL to 13.9 ng/mL; $p < 0.01$; $n = 49$), followed by a further decrease from EOT to PT12 (15.3 ng/mL to 12.8 ng/mL; $p < 0.01$; $n = 23$).
**Conclusion:** The impact of seasonality seems to override a possible effect of elimination of hepatitis C virus on vitamin D levels.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1136 FERROKINETICS, CALCIUM, VITAMIN D2 AND RED BLOOD CELL INDICES, DO THEY PREDICT CIRRHOSIS ON LIVER BIOPSY AND NON-RESPONSE TO ANTIVIRAL TREATMENT IN CHRONIC HEPATITIS C?

**R.B. Thandassery**[1], H. Wani[1], M. E. Soofi[2], S. R. Al-Kaabi[1]

**Contact E-mail Address:** doc.ragesh@gmail.com
**Introduction:** There is limited literature on the role of iron indices, calcium, vitamin D2 levels and red blood cell (RBC) indices in predicating fibrosis stages and anti viral treatment (AVT) response in chronic hepatitis C (CHC).
**Aims & Methods:** Aim: To correlate pre-treatment serum iron indices, RBC indices [mean platelet volume (MPV), red cell distribution width (RDW) and RDW/platelet count index (RPI) ], calcium and vitamin D2 levels with cirrhosis on liver biopsy (LB) and AVT response in CHC. Methods: We analyzed data of 1602 patients (January 2002 -July 2014) with CHC who underwent LB (Scheuer staging) and received AVT (pegylated interferon and ribavirin). Pre-treatment baseline parameters including serum iron indices, calcium, vitamin D2 levels and RBC indices were correlated with LB fibrosis stages and response to AVT.
**Results:** The mean age of the patients was 41.8 ± 9.6 years (1,365 males), the most common genotype was genotype-4 (65.6%). LB results showed stage-0 fibrosis in 1.9%, stage-1 in 32.9%, stage-2 in 39.5%, stage-3 in 19%, and stage-4 (cirrhosis) in 6.6% of the patients. On univariate analysis (UVA) high iron ($p < 0.001$), high ferritin ($p < 0.001$), high transferrin saturation ($p = 0.001$), high MPV ($p = 0.01$), high RPI ($p < 0.001$) correlated with cirrhosis on LB. On UVA, high serum iron levels ($p < 0.001$), high serum ferritin ($p < 0.001$), low vitamin D ($p = 0.036$) and high RPI (0.02) correlated with non-response to AVT. However none of these were independent predictors on multivariate analysis (MVA). On MVA, albumin (adjusted odds ratio, AOR = 0.84, CI = 0.74–0.91, $p = 0.001$), AST (AOR = 1.015, CI = 1.008–1.022, $p = 0.001$) and platelet count (AOR = 0.98, CI = 0.974–0.989) correlated with cirrhosis on LB. We derived a study score [8.5 -0.2(albumin, g/dL) + 0.01(AST, IU/L) - 0.02(platelet count, $10^9$/dL) ], which at a cut-off of > 4.7 had a predictive accuracy of 0.86 (95% CI- 0.83–0.90) for cirrhosis. Similarly on MVA; age (AOR = 1.036, CI = 1.007–1.065, $p = 0.01$), ALT (AOR = 0.990, CI = 0.984–0.996, $p = 0.002$), gamma-glutamyl transpeptidase (AOR = 1.012, CI = 1.007–1.017, $p < 0.001$) and platelet count (AOR = 0.989, CI = 0.984–0.995, $p < 0.001$) predicted non-response to AVT. We derived a study score [ (0.072 + 0.035(age, years) - 0.01(AST, IU/ml) + 0.01(GGT, IU/ml) - 0.01(platelet count, $10^9$/dL) ], which at a cut-off of 0.32 had a predictive accuracy of 0.748 (95% CI = 0.708–0.789) for non-response to AVT.
**Conclusion:** Iron indices and RDW/platelet index correlated with cirrhosis on liver biopsy and non-response to antiviral treatment on univariate analysis. However, only AST, albumin and platelet count were independent predictors of cirrhosis. Age, GGT, AST and platelet count were independent predictors of non-response to antiviral therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1137 REAL-LIFE SIDE EFFECTS OF INTERFERON-FREE THERAPY (OMBITASVIR / PARITAPREVIR / RITONAVIR + DASABUVIR +RIBAVIRIN) AND END OF TREATMENT RESULTS IN PATIENTS WITH COMPENSATED HCV CIRRHOSIS

only regimen is the Ombitasvir / Paritaprevir / Ritonavir + Dasabuvir + Ribavirin association.

**Aims & Methods:** The aim of this study was to evaluate the real-life side effects occurring during Ombitasvir / Paritaprevir / Ritonavir + Dasabuvir +Ribavirin therapy in a group of such patients who started treatment in December 2015 - January 2016, as well as their response to therapy. Methods: We conducted a prospective study including 50 patients with compensated HCV cirrhosis, diagnosed by clinical, elastographic, biologic or pathologic criteria treated for 12 weeks with Ombitasvir / Paritaprevir / Ritonavir + Dasabuvir +Ribavirin regimen. Each patient had follow-up visits at two, four, eight and twelve weeks after treatment initiation. Biologic tests included total bilirubin, ALT, AST and hemoglobin. Subjective complaints of the patients were also recorded. Anemia secondary to the treatment was defined as a decrease in hemoglobin <12 g/dL in women and <13 g/dL in men, or with more than 1 g/dl as compared to baseline; jaundice was defined as an increase in total bilirubin >3 mg/dl, and cytolysis was defined as an increase in AST or ALT of at least 2 times as compared to baseline. End of treatment (EOT) response was evaluated by viral-load assessment by PCR. EOT response was defined as a viral load < 15 IU/ml.

**Results:** The group included 50 patients - mean age 60 ± 8 years, 58% (29) women, all of them genotype 1 b. At two, four and more than four weeks of treatment 4(7%), 2(4%) and one patient (2%) showed jaundice. One patient presented cytolysis during therapy. Regarding anemia, 12(24%) patients had anemia at 2 weeks, 14(28%) at 4 weeks and 10(20%) at more than 4 weeks after baseline. Subjective complaints included: headache 10(20%) cases, nausea 7(14%) cases, fatigue 7(14%) cases, pruritus 2(4%) cases and 1(2%) case each of: gingival bleeding, depression, insomnia, dry mouth, edema and weight loss. Ribavirin dose reduction was needed in 4(8%) patients. None of the patients stopped the treatment due to side effects. All 50 patients had EOT response.

**Conclusion:** The most common side effect among patients in the study group was anemia (24%), while the most frequent subjective complain was headache (20%). None of the patients had to stop the treatment due to side effects. All 50 patients had EOT response.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1138 DISTURBANCES OF VITAMIN D–PARATHYROID HORMONE AXIS IN HEPATITIS C VIRUS INFECTED PATIENTS

**Introduction:** 25-hydroxyvitamin D (25[OH]D) is produced in the liver from vitamin D. Studies correlating 25(OH) D-PTH status and severity of the various chronic liver injuries reported conflicting results.

**Aims & Methods:** Our aim was to determine the prevalence and type of vitamin D–parathyroid hormone (PTH) disturbance in a homogeneous cohort of ambulatory patients with non-cirrhotic chronic hepatitis C (CHC) and its relationship with disease severity and liver function in northern Taiwan (latitude, 25° 2' 21'' N). We studied 66 consecutive outpatients (28 men, 38 women; mean age, 52.7 ± 13.7 [SD] y) with non-cirrhotic CHC. Serum concentrations of 25(OH) D, PTH, calcium, phosphate, magnesium, creatinine, and liver function tests were determined.

**Results:** Serum 25(OH) D levels were inadequate in 25 patients: vitamin D deficiency (10 ng/mL) was found in 3 patients and vitamin D insufficiency (11–20 ng/mL) was found in 22 patients. Fifteen (22.7%) patients had PTH levels lower than the lower level of reference interval (10 pg/ml). The severity of chronic hepatitis C according to HALT-C formula showed insignificant correlation with the serum 25(OH) D concentration (Table 1). The mean serum concentration of 25(OH) D was similar in 3 groups (P = 0.466). Nine of group 3 patients had a desirable level of serum 25(OH) D. The percentages of subjects with hypovitaminosis D ( 20 ng/mL) were as follows: group 1, 58.8%; group 2, 30.6%; and in group 3, 30.8%. There was no significant correlation between vitamin D and serum level of PTH, calcium, phosphate, ALT, AST,

ALP, urea, creatinine, platelet count, hemoglobin, serum albumin, INR or serum bilirubin.
**Conclusion:** Vitamin D inadequacy exists in CHC patients without cirrhosis but does not correlate with the severity of the disease. In addition, low PTH levels occur in CHC but the explanation is still ill-defined. Therefore, we recommend that future trial should evaluate the economic efficacy of vitamin D supplementation in CHC and the impact of low PTH levels on virologic response rates during and after treatment.

**Introduction:** Autoimmune hepatitis (AIH) is a chronic liver disease which may lead to advanced fibrosis and cirrhosis. Unlike in viral etiology, data on elastographic assessment of liver fibrosis in AIH is scant and virtually do not exists in terms of spleen elastography.
**Aims & Methods:** The aim of this study is to evaluate the potential association between shear wave elastography (SWE) of the liver and spleen with various parameters including serum fibrosis markers in patients with autoimmune hepatitis (AIH) and AIH variants. Fifty consecutive in and out-patients (M/F (16/34, mean age: 37 yrs.) with AIH and its PSC and PBC variants defined according to recent EASL Clinical Practice Guidelines (J Hepatol 2015) were included. They underwent liver and spleen SWE (SuperSonic Imagine Aixplorer®). Different biochemical tests were performed including fibrosis markers and non-invasive tests: Fibrosis-4, aspartate aminotransferase (AST)-to-platelet ratio index (APRI), AST-to-alanine aminotransferase (ALT) ratio (AAR), APRI, FibroQ and Model For End-Stage Liver Disease (MELD) score. Pearson correlation coefficients analysis with was performed and p values $<0.05$ were considered significant.
**Results:** 13 patients (26%) fulfilled elastographic criteria for diagnosing liver cirrhosis. Liver SWE showed a significant correlation with spleen SWE ($p < .05$), AST ($p < .001$), ALT ($p < .01$), alkaline phosphatase (ALP)($p < .001$), INR ($p < .001$) and MELD ($p < .001$), Fibrosis-4 ($p < .001$), APRI ($p < .001$) and Fibro-Q ($p < .05$). There was also a significant, negative correlation between Liver SWE and platelet count ($p < .01$) and serum albumin ($p < .001$). Of interest, spleen SWE correlated with Fibrosis-4 ($p < .05$) and showed a negative correlation with platelet and serum albumin ($p < .05$).
**Conclusion:** Liver SWE could be of use in a non-invasive assessment of liver fibrosis in patients with AIH and its variants. The possible role of spleen SWE in the assessment of portal hypertension in AIH has to be established in larger cohorts of patients however, present results may suggest that it can potentially serve as an additional modality in evaluation of patients suffering from liver autoimmune diseases.

### P1140 IS THERE ANY PROGNOSTIC IMPACT OF EXTRA-HEPATIC SYSTEMIC CONDITIONS IN PRIMARY BILIARY CHOLANGITIS?

**M. Gravito-Soares**[1], V. Silva[2], E. Gravito-Soares[1], S. Lopes[1], D. Gomes[1], C. Agostinho[1], P. Figueiredo[1], L. Tomé[1], C. Sofia[1]
[1]*Gastroenterology, Coimbra Hospital, Coimbra/Portugal*
[2]*Gastroenterology, Medicine Faculty of Coimbra University, Coimbra/Portugal*

**Contact E-mail Address:** ms18498@gmail.com

**Introduction:** Primary Biliary Cholangitis (PBC) can be associated with extrahepatic conditions (EHC). These conditions can negatively influence the clinical course of disease. The prognostic implication of EHC is not well established.
**Aims & Methods:** Aims: To determine the prevalence, predictors and prognosis of EHC in PBC. Methods: Case-control retrospective study of PBC patients between 2000–2014. Patients with PBC and EHC (cases) were compared with patients with PBC without EHC (controls). Variables evaluated included age, gender, clinic, biochemical profile, histology, autoimmune profile, Child-Turcotte-Pugh, MELD and Mayo-Risk scores, and prognostic variables, including extrahepatic tumors development, necessity of liver transplantation and overall mortality or PBC-related mortality.
**Results:** Of a total of 82 patients with PBC, 53.7% ($n = 44$) had more than one extrahepatic manifestations, mostly with combination of different conditions (56.8%;25/44). Systemic manifestations preceded the PBC diagnosis in 34.1% (15/44), with an average pre-diagnostic time of $7.6 \pm 7.5$years. The most frequent EHC were rheumatologic (93.2%;41/44), mainly osteoporosis (50.0%;11/53), Sjögren Syndrome (26.8%;11/41) and Scleroderma (17.1%;7/41). After multivariable analysis, the risk factors associated with EHC occurrence were > 7years of PBC, (cut-off 7: AUROC 68.7%; OR 2.700;$p = 0.040$), hypertensive gastropathy (OR 7.299;$p = 0.020$), serum LDH at diagnosis > 203U/L (cut-off 103: AUROC 72.9%; OR 5.313;$p = 0.006$) and serum rheumatoid factor positivity (OR 7.425;$p = 0.020$). Patients with EHC had worse prognosis: cirrhosis complications, need of liver transplantation with overall mortality (63.6%vs36.8%;$p = 0.015$) or with PBC-related mortality (61.4%vs36.8%;$p = 0.027$). However, no differences in survival curves for overall mortality (Kaplan-Meier curve:log-rank-test 0.371;$p = 0.542$) and PBC-related mortality (Kaplan-Meier curve:log-rank-test 0.557;$p = 0.455$) or extrahepatic tumors frequency (20.5%vs7.9%;$p = 0.109$).
**Conclusion:** EHC are frequent and multiple, preceding PBC diagnosis in 1/3 of cases. They are associated with poor prognosis, including cirrhosis complications, need of liver transplantation, overall mortality and PBC-related mortality, despite of no impact in patients' survival curves.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1141 EFFECT OF FIBRATE-ADD-ON TREATMENT IN PRIMARY BILIARY CHOLANGITIS PATIENTS WITH AN INSUFFICIENT RESPONSE TO URSODEOXYCHOLIC ACID (UDCA)

**C. Weber-Freissmuth**[1], K. Kozbial[2], A. F. Staettermayer[1], S. Beinhardt[1], R. Stern[1], P. Ferenci[1], M. Trauner[1], H. Hofer[1]
[1]*Intneral Medicine Iii, Department For Gastroenterology And Hepatology, Medical University Vienna, Vienna/Austria*
[2]*Internal Medicine Iii, Medical University of Vienna, Vienna/Austria*

**Contact E-mail Address:** clfreissmuth@gmail.com

**Introduction:** Ursodeoxycholic acid (UDCA) is the treatment of choice for patients with primary biliary cholangitis (PBC), although a substantial proportion of patients do not respond fully to UDCA treatment. In this respect, fibrates – acting via peroxisome proliferator-activated receptors (PPARs) - have been shown to exert additional beneficial effects on cholestatic liver enzymes and ameliorate pruritus.
**Aims & Methods:** Aim of this study was to investigate the effect of fibrate add-on treatment in patients with an insufficient biochemical response to UDCA.
**Patients:** 22 PBC patients (female: 17[xx%], age: $57 \pm 11$years [mean $\pm$ SD], BMI $25 \pm 3.4\,kg/m^2$, duration of treatment with UDCA $9 \pm 6$years) treated with bezafibrate 400 mg/d for at least 6 months in addition to UDCA after an incomplete biochemical response (Alkaline phosphatase (AP) > ULN) to UDCA (13–15 mg/kg/d) were included. AP, Gamma-glutamyl transpeptidase (GGT), serum creatinine, triglycerides (TG) and serum cholesterol were analyzed at baseline and during treatment every 3 months.
**Results:** AP and GGT decreased during bezafibrate add-on treatment (APbaseline $190.6 \pm 84$, AP3months $119.4 \pm 66.7$, AP9months $112 \pm 69.5$ U/L, mean $\pm$ SD, $p \leq 0.01$ when compared to baseline). 15/68% of patients reached AP levels within the normal range. We did not observe any effect on serum creatinine in our patients treated with UDCA and bezafibrate (Creabaseline $0.77 + 0.24$, Crea3months $0.78 + 0.36$, Crea9months $0.75 + 0.41$ mg/dl). Serum cholesterol and TG did not change (table 1).
**Conclusion:** Fibrate treatment is an effective adjunct therapy for patients with PBC and an insufficient response to UDCA. Within our treatment period we did not observe worsening of renal function. No adverse events were reported.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Table 1.**

| | Baseline | 3 Months | 9 Months |
|---|---|---|---|
| AP (U/L) | $190.6 \pm 84$ | $119 \pm 66.7$* | $112.3 \pm 69.5$* |
| GGT (U/L) | $166.3 \pm 145$ | $116.4 \pm 129.5$* | $136.6 \pm 109$* |
| Serum Creatinine (mg/dl) | $0.77 \pm 0.24$ | $0.78 \pm 0.36$ | $0.75 \pm 0.41$ |
| Triglycerides (mg/dl) | $119 \pm 56$ | $89 \pm 46$ | $100 \pm 56$ |
| Serum Cholesterol (mg/dl) | $202.2 \pm 56.3$ | $198.2 \pm 78.3$ | $199 \pm 104$ |

AP, GGT, Serum Creatinine, TG and Serum Cholesterol during treatment with bezafibrate (mean$\pm$SD, *$p < 0.01$ [when compared to baseline in a paired T-Test])

### P1142 SERONEGATIVE PRIMARY BILIARY CHOLANGITIS: A DISTINCT ENTITY?

| **2D-SWE.GE** | 5.24 ± 0.23 | 5.47 ± 0.16 | 5.2 ± 0.23 | 5.20 ± 0.24 | p^** = 0.42 p^*** = 0.90 p^**** = 0.91 |

with PBC are seronegative. The characterization and clinical significance of this subgroup of patients remain unclear.
**Aims & Methods:** Aims: Determine at the diagnosis, the clinical, biochemical, serological and histological profiles and the prognosis of patients with seronegative PBC. Methods: Case-control retrospective study of inpatients in gastroenterology unit, between 2000–2013, with seronegative PBC diagnosis (cases) and positive AMA (controls). Variables evaluated included clinical, biochemical, autoimmune profile and pathology, as well as prognosis, including portal hypertension complications, mortality or liver transplantation necessity.
**Results:** Of the total of 93 patients with PBC, 13(14.0%) were seronegative. In cases group, there was a significantly lower proportion of women (69.2%vs78.8%;p = 0.001), but similar age of diagnosis (54±18vs54±14yo;p = 0.071) and follow-up of the disease (9±5vs8±5yo;p = 0.818). Relatively to the clinic, the most cases were symptomatic (92.3%vs72.5%;p = 0.049), mainly jaundice (53.8%vs7.9%;p = 0.001), fatigue (69.2%vs42.5%;p = 0.256), pruritus (53.8%vs36.2%;p = 0.577) and portal hypertension complications (15.4%vs8.8%;p = 0.508). Dyslipidemia was more frequent in cases (61.5% vs48 .8%;p = 0.026), but there were no significant statistically differences in the biochemical and immunological profiles. In respect to serological/autoimmunity characterization, cases presented more positivity to ANA (76.9%vs55.4%;p < 0.001), SML (15.4%vs1.2%;p < 0.001), anti-SSA (7.7%vs0.0%;p < 0.001) and anti-parietal cells (46.2%vs38.0%;p < 0.001), and more frequency of other autoimmune diseases (69.2%vs23.8%;p = 0.001): Raynaud's phenomenon (23.1%vs5.0%;p = 0.049), diabetes mellitus type 1 (23.1%vs2.5%;p = 0.008), autoimmune hepatitis (23.1%vs1.25%;p = 0.001) and idiopathic thrombocytopenic purpura (7.7%vs0.0%;p = 0.043). At histological level, there were a cases predominance of stage I (44.4%vs30.8%;p = 0.451), stage IV (33.3%vs21.5%;p = 0.462), severe hepatocellular and piecemeal lymphocytic necrosis (25.0%vs1.7%;p = 0.007) and lobular necrosis (25.4%vs1.7%;p = 0.013). There were no significant statistically differences in the Mayo risk score, mortality, death causes and need/time of disease to liver transplantation.
**Conclusion:** At the diagnosis, patients with seronegative PBC have more symptoms, dyslipidemia, other autoimmune diseases and hepatocellular necrosis in the histology. However, there was no prognostic implications relatively to portal hypertension complications, mortality or liver transplantation necessity.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1143 CARDIOVASCULAR RISK ASSESSMENT IN PRIMARY BILIARY CHOLANGITIS: A SYSTEMIC DISEASE?

**E. Soares**, M. Gravito-Soares, S. Lopes, C. Agostinho, P. Figueiredo, D. Gomes, L. Tomé, C. Sofia
*Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** es18497@gmail.com
**Introduction:** Like other cholestatic liver diseases, there is hypercholesterolemia in primary biliary cholangitis (PBC), due to the supression of bile acids secretion, mainly in advanced stage. Despite frequent, the dyslipidemia impact at cardiovascular level remains unclear.
**Aims & Methods:** Aims: Determine the frequency of dyslipidemia before ursodesoxycholic acid tretment in PBC and its impact on cardiovascular risk (nonfatal/fatal heart and cerebrovascular events, clinically relevant). Methods: Case-control retrospective study of inpatients in gastroenterology unit, between 2000–2013, with PBC diagnosis (G1-cases:93 patients) and diverticular colic disease (DCD) without autoimmune diseases (G2-controls:101 patients), and between PBC without cardiovascular risk factors (G3-cases:22 patients) and DCD without cardiovascular risk factors (G4-controls:23 patients).
**Results:** PBC patients were mostly middle-aged women (women:75vs56, p < 0.001; age: 54 ± 15vs73 ± 14yo, p < 0.001). Dyslipidemia was more frequent in cases (51.6%vs19.8%, p < 0.001), with total-cholesterol 223 ± 76, LDL-cholesterol 115.8 ± 83.8, HDL-cholesterol 50 ± 18 and triglycerides 141 ± 102; however hypertension (38.7%vs60.4%;p = 0.003) and mellitus diabetes (16.1%vs28.7%;p = 0.027) were more frequent in the controls. Vascular events occurred in 22.6% of patients (vs24.8%;p = 0.722), 11.8% of witch was cardiovascular events (vs20.8%;p = 0.093): 5-acute myocardial infarction; 6-ischaemic heart disease; and 15.0% cerebrovascular events (vs5.9%;p = 0.037): 7-transient ischemic accident; 6-ischemic stroke; 1-hemorrhagic stroke. Of cases, 11.8% died due to no cardiovascular cause. Relatively to Mayo risk score at the diagnosis, the majority of cases presented low risk (54.8%), with more dyslipidemia (60.8%vs40.5%;p = 0.043) and cardio/cerebrovascular events (27.4%vs16.7%;p = 0.174), compared to intermediate/high risk. In relation to the histological stage at the diagnosis, there were more cases in stage I (31.1%) and stage II (31.1%), with more dyslipidemia (stageI:52.2%;stageII:56.5%) and cardio/cerebrovascular events (stageI:39.1%;stageII:17.4%). After cardiovascular risk factors exclusion (G3vsG4), there was no significant statistically difference in the frequency of cardiovascular (4.5%vs21.7%;p = 0.090) and cerebrovascular events (4.5%vs4.3%;p = 0.974).
**Conclusion:** PBC patients have more dyslipidemia, however without more nonfatal/fatal cardiovascular risk compared to the patients without PBC. Therefore, preventive strategies of vascular events should be the same of those for the general population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1144 THE INFLUENCE OF FOOD INTAKE ON LIVER STIFFNESS MEASUREMENTS OBTAINED BY TWO 2D-SWE METHODS

**A. Popescu**[1], R. Lupusoru[2], F. Bende[3], R. G. Mare[3], R.L.D. Sirli[3], M. Danila[3], T. Moga[3], C. Pienar[2], I. Sporea[2]

**Contact E-mail Address:** alinamircea.popescu@gmail.com
**Introduction:** The liver stiffness measurements obtained by ultrasound based elastographic methods may be influenced by different factors.
**Aim**: The aim of the study was to assess the influence of food intake on liver stiffness values obtained by two 2D-SWE techniques 2D-SWE and 2D-SWE.GE.
**Material and Methods:** 2 groups of healthy volunteers in whom liver stiffness measurements were performed first in fasting condition, followed by measurements made at 30 minutes, 1 h, 2 h after food intake, were included in this study. All subjects received the same standard solid meal. **Group 1** included 50 subjects (39 female, 11 male) in whom the liver stiffness was assess by 2D Shear Waves Elastography-[Aixplorer, Supersonic Imagining (SSI) ], valid measurements being defined as the median value of 3 measurements acquired in a homogenous area. **Group 2** included 33 subjects (20 female, 13 male) in whom the liver stiffness was assess by 2D-SWE.GE-(LOGIC E9, General Electric), valid measurements being defined as the median value of 10 measurements. For both groups the mean values of liver stiffness on fasting, at 30 minutes, 1 h, 2 h after food intake were calculated and compared.
**Results:** The liver stiffness values did not increase after food intake neither for 2D-SWE, nor for 2D-SWE.GE (table). Table. Liver stiffness values on fasting and after food intake.
**Conclusion:** Our preliminary results show the food intake did not significantly increased the LS values obtained by 2D share wave elastography techniques.

## P1145 CORRELATION OF LIVER STIFFNESS MEASUREMENT ON TRANSIENT ELASTOGRAPHY WITH INCIDENCE OF HYPOVASCULAR HYPOINTENSE NODULE ON GADOXETIC ACID-ENHANCED MRI IN PATIENTS WITH HEPATITIS B VIRUS

**J.A. Hwang**, T.W. Kang
*Radiology, Samsung Medical Center, Seoul/Korea, Republic of*

**Contact E-mail Address:** mu-equita@hanmail.net
**Introduction:** There have been some reports which evaluated the imaging features of hypovascular hypointense nodules on gadoxetic acid-enhanced MR images in patients with chronic liver disease that may be related with progression to hypervascular HCC. However, to the best of our knowledge, there has been no report which evaluated relationship between hypovascular hypointense nodule and many baseline characteristics including liver cirrhosis. The purpose of this study was to evaluate the correlation of liver stiffness measurement based on transient elastography with hypovascular hypointense nodule on gadoxetic acid-enhanced magnetic resonance imaging (MRI) in patients with hepatitis B virus (HBV).
**Aims & Methods:** This retrospective study was approved by the institutional review board, and the requirement for informed consent was waived. Between August 2012 and March 2016, consecutive 430 patients with HBV who had received transient elastography for liver stiffness measurement and gadoxetic acid-enhanced MRI were retrospectively analyzed. The patients were divided into two groups according to the presence or absence of hypovascular hypointense nodule. Baseline characterisctis including presence of liver cirrhosis, hepatocellular carcinoma, viral hepatitis, alcoholic liver disease and level of biologic markers were compared between the two groups. The correlations between incidence of hypovascular hypointense nodule on gadoxetic acid-enhanced MRI and the degree of fibrosis stage F0 from F4 on the METAVIR scale were assessed using linear-by-linear association.
**Results:** Except presence of liver cirrhosis, there was no significant difference in baseline characteristics including coexisting with hepatocellular carcinoma in both groups. Median liver stiffness values measured using transient elastography was 11.8 (range, 3–75). The degrees of fibrosis stage in patients included were 46 in F0, 60 in F1, 65 in F2, 35 in F3, and 224 in F4, respectively. The

incidence of hypovascular hypointense nodule on gadoxetic acid-enhanced MRI tended to be increase with the degree of fibrosis stage ($p = 0.047$).
**Conclusion:** The incidence of hypovascular hypointense nodule on gadoxetic acid-enhanced MRI Liver in patients with HBV was associated with the degree of liver fibrosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic liver diseases encountered in daily practice are due to chronic viral infections or to other conditions, such as alcoholic steato-hepatitis (ASH) or non-alcoholic fatty liver disease (NAFLD). The evaluation of chronic liver disease's severity is mandatory, for a decision regarding therapy or to establish prognosis. For many years, liver biopsy (LB) was the only method to evaluate such patients and it is still considered the "gold-standard" method. In the last years non-invasive modalities for liver diseases' assessment are being used more and more in daily practice, especially in Europe.
**Aims & Methods:** The current study's aim is to evaluate the performance of 2D-SWE.GE in noninvasive fibrosis assessment as compared to a validated method-Transient Elastography (TE) and to identify liver stiffness (LS) cut-off values for predicting different stages of liver fibrosis, considering Transient Elastography (TE) as the reference method, since it is a validated method for liver fibrosis assessment (EASL Guidelines). Our prospective study included 307 consecutive subjects with or without chronic hepatophaties (only compensated liver disease evaluated for decision regarding treatment), in which liver stiffness (LS) was evaluated in the same session by means of 2 elastographic methods: TE (M or XL probes) and 2D-SWE.GE (LOGIQ E9, GE Healthcare, Chalfont St Giles – UK). Reliable LS measurements were defined as follows: for TE – the median value of 10 measurements with a success rate of $\geq$60% and an interquartile range $<$ 30% and for 2D-SWE.GE - the median value of 10 measurements acquired in a homogenous area and an interquartile range (IQR) $<$ 30%. To discriminate between various stages of liver fibrosis by TE we used the following cut-offs (kPa): F1–6; F2- 7.2; F3- 9.6; F4- 14.5.[1]
**Results:** Reliable LS measurements were obtained in 292/307 (95.1%) subjects by 2D-SWE.GE, and in 291/255 (94.7%) by TE ($p = 0.975$). The final analysis was performed on 278 subjects with valid measurements by both methods. Based on TE cut-off values we divided our cohort into the following groups: F $<$ 2: 79/278 (28.4%); F = 2: 13/278 (4.7%); F = 3: 44/278 (15.9%) F = 4: 142/229 (51%). We found a strong correlation between the LS values obtained by the 2 methods: $r = 0.825$, $p < 0.0001$. The mean values obtained by 2D-SWE.GE considering TE cut-off values as reference were: F $<$ 2: **5.76** $\pm$ 1.51 kPa; F = 2**: 7.24** $\pm$ 1.7 kPa; F = 3: **10.47** $\pm$ 1.89 kPa; F = 4: **13.55** $\pm$ 2.76 kPa ($p < 0.001$). The best cut-off value for F $>$ 2 was **6.7** kPa (AUROC = 0.967, Sensitivity = 95.96%, Specificity = 85%), for F $>$ 3 was **8.6** kPa (AUROC = 0.977, Sensitivity = 94.05%, Specificity = 90.32%) and for F $>$ 4 was **10.7** kPa (AUROC = 0.934, Sensitivity = 87.32%, Specificity = 86.03%).
**Conclusion:** 2D-SWE.GE and TE had good feasibility (95.1% and 94.7%) with no statistical differences between them ($p = 0.975$). There was a strong correlation between the two methods, with LS values significantly increasing with the severity of fibrosis. The best 2D-SWE.GE cut-off values for predicting F $>$ 2, F $>$ 3 and F $>$ 4 were 6.7 kPa, 8.6 kPa and 10.7 kPa.

**Contact E-mail Address:** 1044050245@qq.com

**Introduction:** Real-time shear-wave elastography, as a novel stiffness measurement method of hepatic fibrosis, allows quantitative detection of larger liver specimens in real time with two-dimensional shear wave generating from tissue directly, which overcome the shortcomings of Transient elastography and Point shear wave elastography to some extent. However, whether the advantages of SWE can decrease interruption of factors identified in other elastography remains unclear.
**Aims:** To identify factors influencing the performance of SWE and investigate their effect.
**Methods:** Patients with chronic hepatitis B (CHB) were included from July 2013 to February 2016 at the First Affiliated Hospital of Sun Yat-sen University were included. Fibrosis stage were acquired according to liver biopsy or clinically diagnosed decompensated cirrhosis Liver stiffness were assessed with SWE (Supersonic Imagine, France) and parameters of anthropometry, liver inflammation score, hepatic enzymes levels, virology (HBV DNA levels, HBsAg titre) and metabolism (lipid profile, glucose, insulin, and uric acid concentrations) markers were measureed. Logistic regression model was performed to identify factors that correlated with discordance between historic results and SWE. Effect of factors was assessed by comparing the Receiver operating characteristic curve (ROC) between patients with or without these factors.
**Results:** The analysis was included in 261 CHB patients (133 undergone liver biopsy and 128 decompensated cirrhosis). 192 (73.6%) patients were males and the average age was 38.6(16~54) years. ①The Area Under ROC (AUC) for liver stiffness measurement with SWE were 0.861, 0.932 and 0.910 for the diagnosis of significant fibrosis (7.8kpa, $\geq$ F2), advanced fibrosis (8.9 kpa, $\geq$F3) and cirrhosis (9.4kpa, F4), respectively. ② When predicting the liver fibrosis stage with cut-off values of SWE, overall misdiagnostic rate was 6.51%, omission diagnostic rate was 11.9%. ③The risk of discordance between SWE and historical results with multivariate analysis was associated with ultrasonic sign of fatty liver ($P = 0.048$, OR = 2.23.95%CI:1.01–4.94), liver inflammation activity score over 1 ($P = 0.01$, OR = 2.12.95%CI:1.20–3.73) and fibrosis stage ($P = 0.046$, OR = 0.74.95%CI:0.54–0.96).Liver inflammation activity score over 1 also ($P = 0.037$, OR = 2.10.95%CI:1.05–4.22) predicted overestimation of SWE while no variables were considered to predict of underestimation for the assessment of fibrosis. ④AUC of CHB patienrs with liver inflammation activity score over 1 was inferior to those without when SWE was applied to distinguish significant fibrosis (0.756 vs 0.891, $p = 0.021$) instead of other stage, as well as the AUC of patients with ultrasonic sign of fatty liver to those without (0.703 vs 0.938, $p = 0.000$)
**Conclusion:** SWE can differentiate liver fibrosis accurately. The presence of inflammation of pathology and ultrasonic sign of fatty liver is the main factor that decrease the accuracy of SWE.

**Introduction:** The purpose of transjugular intrahepatic portosystemic shunt (TIPS) is to decompress portal venous system and prevent rebleeding from varices in patients who fail pharmacologic and endoscopic treatment, or reduce the formation of diuretic refractory ascitis, among other less common indications. Recent data suggest that achieving a portal pressure gradient below 12 mmHg for variceal bleeding and below 8 mmHg for refractory ascitis is the optimal technical end-point.

**Aims & Methods:** We present the results of TIPS procedures of a Portuguese referral center from October 2007 to December 2015. Data were collected retrospectively from hospital records. Since January 2015, the procedure protocol includes record of the pressure gradient after TIPS. A secondary objective of this study is to compare the outcome of the group of patients that were submitted to TIPS without hemodinamic measurements and the group submitted to TIPS with portal pressure measurements.
**Results:** During the study period, 143 patients were proposed for TIPS. 79% of patients were males and the average age was 54.6 years. Primary liver disease was alcoholic in 67.1%, mixed alcoholic/viral in 14%, viral in 10.5% and other in 9.1%. Indications for TIPS were: refractory ascitis (62.2%), variceal bleeding (34.2%) and hydrothorax (3.5%), MELD and Child-Pugh scores before TIPS were 13.88+-4.95 and 8.62 + -1.6. Pre-existing encephalopathy was recorded in 15.4%. Technical success rate was 92.3% (n = 132). Hemodynamic success rate (since january 2015) was 81.3% for refractory ascitis and 100% for variceal bleeding indications. MELD and Child-Pugh scores 1 and 6 months after TIPS were 17+-7.2, 9.5+-1.6, 16+-5.7 and 8.8+-1.8, respectively. Outcome analysis by indication showed that 40.5% (n = 34) patients with refractory ascitis experienced improvement. Rebleeding rate was 16.3%. One patient presented with de novo variceal GI bleeding. In 3 patients with hydrothorax, records showed improvement in fluid retention, though data was not available for the other two patients. When considering the results before and after routine hemodinamic-guided TIPS dillation, there was no statistical difference in ascitis improvement, rebleeding rate or encephalopathy development. 37.9% with TIPS were transplanted during follow up (284.1+- 243.5 days). Mortality in patients not submitted to liver transplantation was 41.5 (226.1+-257.7 days) 4.2% had immediate, procedure-related complications: haemoperitoneum 1.4%, porto-billiary fistula 0.7%, haemorrhagic shock 0.7%, cervical haematoma 0.7%, anestesia complication 0.7%. Most common clinical complications after TIPS placement were: encephalopathy (newly installed or worsened)–27.3%, TIPS thrombosis in 8.3%, hiperdynamic circulation or cardiac failure–5.3%, TIPS infection 0.8%, haemolytic anaemia 0.8%, worsening of acute liver failure 0.8%, pulmonary thromboembolism 0.8%, other not specified-3.8%.
**Conclusion:** This is an evolving experience in a Portuguese referral center. When analysing this results, it is important to bear in mind that techinical practices have changed over the last decade, with introduction of covered stents that are less prone to thrombosis or other complications. Outcomes on ascitis should be assesed with caution, since data on diuretic therapy adjustment were lacking. It is possible that some partial responders were not included due to lack of records. Rebleeding rate was higher than expected. However, data on timing of rebleeding was lacking, as was the endoscopic site. Hence, we can not exclude bleeding from previous elastic band scarring, a complication of endoscopic treatment, not a failure of TIPS. In recent years, our protocol of TIPS for variceal bleeding also includes endovenous cyanoacrylate obliteration of upper GI varices, therefore we expect the rate of recurrence of GI bleeding to drop in the following years. Our data did not show improvement in outcome with hemodinamic-guided TIPS dillation at placement, although the number of patients in the second group is small (n = 22) which could bias the results. Although not exsempt of complications, TIPS remains an important salvage technique in difficult to treat patients with portal hypertension.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1149 SERPINB3 MAY AFFECT LIVER CANCER PROGRESSION BY DIFFERENTLY REGULATING HYPOXIA INDUCIBLE FACTORS - 1A AND -2A

**B. Foglia**[1], S. Cannito[1], G. Villano[2], C. Turato[2], E. Morello[1], E. Novo[1], S. M. Quarta[2], S. Colombatto[3], F. Lopitz Otsoa[4], M.L. Martinez-Chantar[4], T. Cardoso[4], P. Pontisso[2], M. Parola[5]

**Contact E-mail Address:** beatrice.foglia@unito.it
**Introduction:** SerpinB3 is a hypoxia and hypoxia-inducible factor (HIF)-2$\alpha$ up-regulated cysteine-proteases inhibitor overexpressed in hepatocellular carcinoma (HCC). SerpinB3 has been reported to act as a paracrine mediator able to up-regulate, in normoxic conditions, HIF1$\alpha$ and HIF2$\alpha$ as well as their related target genes in liver cancer cells, with differential regulation of their expression and stabilization. The ubiquitin-like molecule NEDD8 is a key regulator of cell growth, viability and malignant transformation and neddylation promotes stabilization of proteins with essential regulatory roles. Overexpression of global neddylation has been detected in HCC and suggested to be associated with its poorest prognosis.
**Aims & Methods:** The present study has been designed to investigate the mechanisms by which SerpinB3 can induce up-regulation of HIF1$\alpha$ and HIF2$\alpha$ in liver cancer cells. The cross-talk between S-B3 and HIF1$\alpha$/HIF2$\alpha$ has been investigated by taking advantage of morphological, molecular, biochemical and cell biology techniques in the following experimental models: i) control HepG2 stably transfected with empty vector; ii) HepG2 stably transfected to overexpress SerpinB3 (HepG2/SB3); iii) transgenic mice overexpressing SerpinB3 in the liver.
**Results:** Immunohistochemistry performed on liver sections from SerpinB3 transgenic mice shows immune-positivity for HIF1$\alpha$ and HIF2$\alpha$ not only around centrilobular vein, but also in hepatocytes of the entire parenchyma, with a more impressive level of nuclear staining for HIF2$\alpha$ vs HIF1$\alpha$. Different experimental approaches revealed that SerpinB3, in normoxic conditions, differentially regulate HIF1$\alpha$ and HIF2$\alpha$ up-regulation: i) SerpinB3 increases transcription of HIF1$\alpha$, but not HIF2$\alpha$; ii) the up-regulation of HIF1$\alpha$ protein levels is rapid and transient and results in up-regulation of target genes involved in anaerobic glycolysis; iii) Seahorse metabolic analysis revealed an increase of ECAR (ExtraCellular Acidification Rate) and a reduction of OCR (Oxygen Consumption Rate) parameters; iv) increased HIF2$\alpha$ protein levels and related target genes are dependent on its selective neddylation/stabilization but not on an inhibition of overall proteasome activity by SerpinB3; v) the use of a specific siRNA of NAE-1 (NEDD8 Activating Enzyme-1) selectively reduces HIF2$\alpha$, but not HIF1$\alpha$, protein levels.
**Conclusion:** SerpinB3 can affect the behaviour of target cells by increasing protein levels of HIF1$\alpha$ and HIF2$\alpha$, with HIF1$\alpha$ that facilitates cell survival in harsh microenvironment by inducing early cellular metabolic switch to glycolytic phenotype. On the other hand neddylation/stabilization and nuclear translocation of HIF2$\alpha$ promotes proliferation and tumor progression.

**Introduction:** Hepatocellular carcinoma (HCC) represents a complication of liver cirrhosis limiting the curing option by liver transplantation. Depending on their splice variants – with transactivation (TA) domain or dominant negative (DN) - p53-family transcription factors (p53, p63, p73) exert tumorsuppressive or oncogenic functions in cell cycle by transcriptional regulation of a specific set of genes. In previous studies we identified the MCL1 gene (Myeloid cell leukemia sequence 1, Mcl-1) as potential target gene of the p53 family and confirmed its prognostic relevance in HCC. Mcl-1 is a member of the Bcl-2 protein family being involved in the control of mitochondrial integrity. Mcl-1 represents an anti-apoptotic member of the Bcl-2 family, supporting cell survival by binding and inhibition of pro-apoptotic Bcl-2 proteins.
**Aims & Methods:** Aim of this study was to elucidate the impact of p53 family members on MCL1 gene regulation. Hep3B cells were transfected with rAd-GFP, -p53, -TAp63$\alpha$, -TAp73$\beta$, -DNp63$\alpha$, and DNp73$\beta$. MCL1 expression was measured by real time qPCR. Western Blot analyses determined intracellular levels of Mcl-1 after specific siRNA interference. Potential binding sites of p53 family members in the MCL1 locus were identified by database analyses (pDraw32, Husar, MatchTM) and verified by luciferase reporter assays. Direct protein interactions of Mcl-1 and p53 proteins were evaluated by LUminescence-based Mammalian IntERactome mapping (LUMIER) technology.
**Results:** p53 and the isoforms TAp63 and TAp73 inhibited MCL1 expression, whereas $\Delta$Np63$\alpha$ and $\Delta$Np73$\beta$ induced transcription of the MCL1 gene. These effects were confirmed for Mcl-1 protein levels. Reduction of Mcl-1 protein levels was abrogated after silencing of p53, TAp63 and TAp73. Database analyses identified two potential p53 binding sites and one potential p63 binding site each in promoter, intron 1 and 2 of the MCL1 gene. Luciferase reporter assays of these cloned putative binding sites confirmed a regulation of the MCL1 gene by p53 family members. Furthermore, a direct protein-protein interaction of Mcl-1 with p53 and TAp63, respectively, was detected.
**Conclusion:** p53 family members directly regulate the expression of the MCL1 gene. p53, TAp63 and TAp73 are potent repressors, whereas DNp63 and DNp73 act as inducers of MCL1. On posttranslational level, Mcl-1 interacts with p53 and TAp63. Since Mcl-1 has anti-apoptotic functions, a downregulation of Mcl-1 by TA-isoforms of p53 proteins results in an increase of apoptosis susceptibility. HCC is often associated with chemotherapeutic resistance, which could be overcome by reconstitution with p53, TAp63 and TAp73 or a direct inhibition of Mcl1.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1151 BRG1 PROMOTES HEPATOCARCINOGENESIS BY MODULATING CYCLINB1, D1, E1 AND MATRIX METALLOPROTEINASE 7

**Contact E-mail Address:** benedikt_kaufmann@hotmail.com
**Introduction:** The chromatin remodeler complex SWI/SNF plays an important role in physiological and pathological processes. The role of BRG1, a catalytic subunit of the SWI/SNF complex, that is known to be mutated in hepatocellular carcinoma (HCC) remains unclear.
**Aims & Methods:** The aim of this work is to investigate the role of BRG1 on cell growth and its effect on the expression of target genes. We examined the expression of BRG1 in human tissue samples and in HCC cell lines by qRT-PCR and Western Blot. In addition, we used siRNA to down-regulate BRG1 in

human HCC cell lines and analysed its effect. Cell growth of siRNA-treated cells was analyzed and the expression of target genes after BRG1 downregulation was investigated in detail.
**Results:** BRG1 was found to be significantly increased in HCC samples compared to non-HCC samples. After BRG1 downregulation by siRNA, cell growth decreased in HuH7 and HepG2 cell lines. A modulating effect of BRG1 could be shown for the expression of CyclinB1, D1, E1, p21, Cdkn2a, Cdkn1b and MMP7 in either HepG2 or HuH7 cell lines. These target genes showed a positive correlation with BRG1 expression.
**Conclusion:** Our results support the hypothesis that overexpression of BRG1 increases cell growth in HCC. Furthermore, the data obtained by qRT-PCR highlight particular genes that are being regulated by BRG1 during hepatocarcinogenesis. In particular, CyclinB1, D1, E1 and MMP7 appear to play a major role in this context and might be an important link between BRG1 expression and HCC development.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1152 PROTEIN KINASE CK2 REGULATES ONCOGENIC PROPERTIES OF CHOLANGIOCARCINOMA CELLS

**Contact E-mail Address:** giovanni.dimaira@unifi.it
**Introduction:** Cholangiocarcinoma (CCA) is a malignant tumour arising from cholangiocytes in the biliary tree, characterized by a poor prognosis and alterations in various signaling cascades and genetic mutations (1,2). The mechanisms underlying the CCA occurence and progression are largely unknown. CK2 is a ubiquitous serine-threonine protein kinase (3) which contributes to the malignant phenotype in various types of cancer, and its overexpression is associated with unfavorable prognosis (4,5). CK2 may be targeted by different inhibitors, including CX-4945, that is currently being evaluated in clinical trials (6,7).
**Aims & Methods:** This project aims to understand the role of CK2 in CCA cells, using the selective inhibitor CX-4945 to block its catalytic activity. Human cholangiocarcinoma cells (HuCCT-1 and CCLP1) were cultured by standard methods. CX4945 was used as a specific CK2 inhibitor. CK2 activity was measured using a CK2-specific peptide substrate. Cell cycle progression was analyzed using flow cytometry. Cell migration and cell invasion assays were performed using Boyden chambers.
**Results:** CK2 was found to be highly expressed in the CCA cell lines. Treatment with CX4945 induced a significant reduction of its catalityc activity as measured by kinase assay and phosphorylation levels of a CK2 substrate by western blotting. Pharmacological inhibition of CK2 decreased cell viability, and activated the apoptotic process. Moreover CK2 activity was also found to be necessary for cell cycle progression, as exposure of CCA cells to CX4945 altered cell cycle progression, in particular blocking the G1/S transition. Finally, CK2 inhibition affected the protumorigenic effects of Tgf-$\beta$ in CCA cells, blocking the promotion of epithelial-mesenchymal transition (EMT), cell motility and invasiveness, relevant actions in the progression and metastasis of cholangiocarcinoma.
**Conclusion:** The results obtained in this study indicated that CK2 contributes to the malignant phenotype of CCA cells modulating proliferation, cell cycle regulation and metastatic processes. These data strengthen the need for further investigations in order to characterize the action of CK2 on CCA biology and could contribute in the design and execution of more effective trials with the clinical-grade CK2-inhibitor CX4945 in patients with CCA.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Oncostatin M (OSM), a pleiotropic cytokine that belongs to the interleukin-6 (IL-6) family, has been reported to orchestrate hypoxia-influenced processes such as liver development, liver regeneration and angiogenesis, being then potentially involved in the progression of chronic liver diseases towards cirrhosis and the genesis of hepatocellular carcinoma (HCC). Accordingly, both OSM and its related LIFR$\beta$ (leukemia inhibitory factor receptor $\beta$) receptor subunit were found to be overexpressed in cirrhotic liver. Recently, hypoxia, as an independent signal operating through hypoxia-inducible factors (HIFs), has been shown to induce epithelial-to-mesenchymal transition (EMT) in cancer cells, including HepG2 cells. In this connection, OSM-related signaling pathway has been reported to up-regulate HIF1$\alpha$ and switch on EMT program.
**Aims & Methods:** This study has been designed in order to investigate, in vivo and in vitro, the relationships between OSM, expression of vascular endothelial growth factor A (VEGF-A) and increased invasiveness. EMT, invasiveness, angiogenesis and signal transduction pathways were analyzed by integrating morphological, molecular and cell biology techniques in the following experimental models: i) Liver specimens from HCV cirrhotic patients carrying G1 and G2 HCC; ii) HepG2 and Huh7 cells exposed to human recombinant OSM; iii) HepG2 stably transfected to overexpress OSM or transfected with empty vector.
**Results:** OSM was expressed in HCC in areas also positive for HIFs and VEGF-A, with OSM expression correlating with early recurrence and poor prognosis in HCV cirrhotic patients carrying HCC. Recombinant human OSM induced EMT-related changes within 48–72 hrs and stimulated invasiveness in hepatic cancer cells. Different experimental approaches revealed that OSM-dependent invasiveness is due to release of VEGF and involve activation of PI-3 K, ERK1/2, and p38MAPK: 1) HepG2 cells exposed to human recombinant OSM (hrOSM) lead to an increase of HIF1$\alpha$ and VEGF-A mRNA levels as well as release of VEGF-A protein in culture medium; 2 a) specific pharmacological inhibitors against PI-3 K, ERK1/2, p38MAPK signaling pathways results in decrease of invasiveness induced by conditioned medium collected by HepG2 cells treated with OSM for 48 hrs; 2 b) the same result was obtained using neutralizing antibody raised against Flk-1 (VEGF receptor type 2) or specific inhibitor of Flk-1; 3) HepG2 cells stably transfected in order to overexpress OSM show increased invasiveness and metalloproteinase-2 activity, VEGF-A mRNA levels as well as VEGF-A release in culture medium.
**Conclusion:** OSM, expressed in human HCC, switches on EMT and induces increased invasiveness in human hepatic cancer cells through a mechanism involving HIF1$\alpha$-dependent release of VEGF-A.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1154 METFORMIN AND SORAFENIB SYNERGISTICALLY INDUCE CELL SENESCENCE IN HEPATOCELLULAR CARCINOMA CELLS

**C. Wu**[1], H. Chen[1], J. Lin[2]
[1]*Division Of Gastroenterology, Taichung Veterans General Hospital, Taichung/Taiwan*

**Introduction:** Sorafenib improves overall survival for patients with advanced hepatocellular carcinoma (HCC); however, the effect is limited. Metformin has been reported to be beneficial in HCC patients' outcome. Whether metformin synergistically interacts with sorafenib to inhibit HCC cells remains unknown.
**Aims & Methods:** The in vitro effect of metformin and sorafenib combination on cell senescence was evaluated on hepG2 and Huh7 hepatoma cell lines. Western blotting was used to detect cyclin-dependent kinase inhibitor p27/Kip1 and cyclin E. Flow cytometry and activation of senescence-associated $\beta$-gal (SA-$\beta$-gal) was used to determine senescence.
**Results:** We found both metformin alone and sorafenib alone therapy led to cell cycle arrest at G0/G1 phase. Combined metformin and sorafenib therapy further increased the effect to inhibit cell cycle arrest. SA-$\beta$-gal activation was found in both metformin alone and sorafenib alone therapy. This senescence effect in HCC cells was significantly higher in combination therapy. In signaling pathway, we found combination therapy synergistically induced Skp2 degradation, which resulted in p27/Kip1 accumulation and cyclin E inactivation.
**Conclusion:** Metformin and sorafenib combination therapy causes HCC cell senescence via the Skp2–p27/Kip1-cyclin E pathway. The clinical significance of our observation needs more studies to confirm.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Aldehyde dehydrogenase 2 (ALDH 2) metabolizes acetaldehyde, the major cause of alcohol hangover symptoms. It also detoxifies lipid peroxidation-induced reactive aldehydes, such as 4-hydroxynonenal (4-HNE). Nonalcoholic steatohepatitis (NASH)- induced oxidative stress promotes lipid

peroxidation of cellular membrane, leading to the generation and accumulation of 4-HNE. This byproduct reacts with DNA to form highly carcinogenic exocyclic etheno-DNA adducts, potentially developing hepatocellular carcinoma. Recently, a variety of anti-hangover products are commercially available, however, almost none of them has been proven to show enhanced acetaldehyde-metabolizing capacity in a live subject.

**Aims & Methods:** We aimed to investigate a specific product of interest. The enzyme activities of the anti-hangover substance were examined by in-vitro & in-vivo experiments to measure the amount of NADH formation which is generated through catalytic conversion of alcohol and acetaldehyde, by using a spectrophotometer at 340 nm. Powder sample of a commercial anti-hangover product (South Korea) was used as the experimental substance. In-vivo examination tested the ethanol and acetaldehyde concentration in blood of rats with oral infusion of experimental substance before or after ethanol intake. In first test, twenty-four SD male rats were randomly assigned into one of four groups: group1 received only saline, group2 was subjected to ethanol only, group 3 received ethanol with substance (73 mg/kg), and group 4 ethanol with substance (220 mg/kg). Oral dosing of 50% ethanol (3 g/kg body weight) was given 30 minutes after substance gavages, followed by time-dependent collection of rat's blood when zero, 1, 3, 5, and 8 hours after dosing of ethanol. In second test, similar examination was repeated with two groups including ethanol only ($n = 6$) and ethanol with substance (220 mg/kg) ($n = 6$). The differentiator of second in-vivo test was that experimental substance be given 1 hr after ethanol gavage, approximately near maximum level of blood acetaldehyde.

**Results:** In vitro measurements of the activities of alcohol dehydrogenase & aldehyde dehydrogenase within the anti-hangover substance were 1.84 unit/g and 0.28 unit/g, respectively. The enzyme activities in rats' blood under the substance that was given 30 minutes before ethanol intake are as follows: after 1 hour of ingestion of ethanol, the concentration of ethanol in blood showed maximum values for all testing group, but decreases by 15.5% ($p < 0.246$) and 28.3% ($p < 0.011$) were observed for testing groups of dosing substance 73 and 220 mg/kg, respectively. In the case of a group with dosing 220 mg/kg, meaningful decrease in the concentration of ethanol through all measurement times was observed compared to a group of ingestion of ethanol only. With acetaldehyde level in blood, the maximum values for all testing groups were measured 1 hr after ethanol ingestion, demonstrating no significant differences among testing groups. However, the concentration of acetaldehyde in blood for ethanol only group started to decease after 3 hours, in contrast, those of groups with anti-hangover substance have shown concentration-dependent reduction after one hour. As for a group of dosing substance 220 mg/kg, meaningful level of decreases were observed after 3 hours ($p < 0.01$) and 5 hours ($p < 0.05$). Finally, the cases with oral intake of substance 220 mg/kg after 1 hr of ethanol intake have shown more significant and obvious decreases in blood acetaldehyde concentration through the period of all measurement times.

**Conclusion:** Oral intake of a specific anti-hangover substance has significantly enhanced alcohol and acetaldehyde-metabolizing capacity in rat model, potentially suggesting increased ALDH 2 capacity within circulation. Using this substance, further research on animal model of disease and detoxifying ability of other reactive aldehydes is recommended to conduct.

### P1156 PROGNOSTIC ROLE OF 25-HYDROXYVITAMIN D IN PATIENTS WITH LIVER METASTASES FROM COLORECTAL CANCER TREATED WITH RADIOFREQUENCY ABLATION

**A. Facciorusso**, N. Crucinio, M. Di Maso, N. Muscatiello
*Gastroenterology, University of Foggia, Foggia/Italy*

**Contact E-mail Address:** antonio.facciorusso@virgilio.it

**Introduction:** Vitamin D is implicated in the etiology of several neoplastic diseases but its relationship with colorectal cancer survival is still unclear. Aim of this study was to determine whether vitamin D levels influence survival outcomes in colorectal cancer liver metastases patients treated with percutaneous radiofrequency ablation.

**Aims & Methods:** We measured 25-hydroxyvitamin D levels in 143 patients with 215 colorectal liver metastases who underwent radiofrequency ablation between 1999 and 2011 at our Institution. The influence of 25-hydroxyvitamin D levels on overall survival and time to recurrence was evaluated in univariate and multivariate Cox analyses.

**Results:** Median age was 68 years (range 41–85) and median number of nodules was 2 (1–3) with a median maximum diameter of 26 mm (10–48). Median survival was 44 months (36–62) and survival rate was 91.4%, 46.5% and 42.2% at 1, 4 and 5 years in the whole cohort. Median survival was 65 months (52–74) if 25-hydroxyvitamin D $>$ 20 ng/mL and 34 months (24–41) if $\leq$ 20 ng/mL ($p < 0.001$). In the whole cohort median time to recurrence was 34 months (26–47), 50 months (36–62) in the case of 25-hydroxyvitamin D $>$ 20 ng/mL and 24 months (20–32) if $\leq$ 20 ng/mL ($p < 0.001$). Nodule size and 25-hydroxyvitamin D resulted as significant predictors of both overall survival and time to recurrence in multivariate analysis.

**Conclusion:** Our study provides support for the use of 25-hydroxyvitamin D as a new predictor of outcome for colorectal liver metastases patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1157 ROLE OF MIR-122 EXPRESSION IN EVALUATION OF PROGNOSIS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

M. Franck, K. Schuette, P. Malfertheiner, **A. Link**
*Department Of Gastroenterology, Hepatology And Infectious Diseases, Otto-von-Guericke University Magdeburg, Magdeburg/Germany*

**Contact E-mail Address:** alinkmail@gmail.com

**Introduction:** New non-invasive diagnostic and prognostic biomarkers are needed to improve the clinical management of patients with hepatocellular carcinoma (HCC). Several studies, predominantly from Asian region, demonstrated differential expression of liver-specific microRNA miR-122 in tissue as well as in sera of patients with mostly HBV/HCV-induced HCCs. Therefore, miR-122 has been suggested as a biomarker for HCC.

**Aims & Methods:** In this study, we aimed to evaluate the prognostic value of miR-122 in patients with HCC in the European population and to determine potential factors related to miR-122 expression in serum. During the period of two years, we included 91 patients with confirmed HCC. Tumor staging was performed based on the BCLC-Classification. Clinical status and laboratory parameters (including AFP, ALAT, ASAT etc.) were assessed. Total RNA was extracted using miRNeasy kit. MiRNA expression analyses were performed using TaqMan qPCR for miR-122 normalized to a spiked-in cel-miR-39. Overall survival data were used to evaluate the prognostic value of miR-122.

**Results:** miR-122 showed a high interindividual expression variability in patients with HCC. Patients with different BCLC stages showed similar miR-122 expression in serum. In similar fashion, no significant differences were found neither for the Child-Pugh-Stage nor for the etiologically underlying liver disease. Overall, we observed positive correlation between the miR-122 in serum and parameters such as ALAT ($p < 0.0001$), ASAT ($p = 0.0001$), AFP ($p = 0.0034$) and hemoglobin concentration ($p = 0.0076$). A negative correlation was observed for creatinine concentration ($p = 0.0028$). Subsequently, miR-122 expression was higher in patients with pathological ALAT-, ASAT- or AFP-values; while significantly lower in patients with impaired renal function measured by creatinine concentration. Despite the correlation to liver-/tumor-related laboratory parameters, miR-122 level variation in serum was not associated with the survival of patients with HCC.

**Conclusion:** miR-122 expression in sera from patients with HCC strongly correlated with AFP and liver enzymes. Furthermore, miR-122 concentration seems to be influenced by renal function and hemoglobin concentration. However, we could not observe a significant prognostic value of miR-122 in sera of HCC patients with predominantly alcohol-induced liver damage.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Sorafenib is the recommended standard of care in HCC patients with preserved liver function who are ineligible or have failed surgical or loco-regional treatments.

**Aims & Methods:** Characterize efficacy and safety of sorafenib in routine clinical practice in Italian centers. Data from the Italian subgroup of GIDEON (international study) and from STELLA (Italian study), two prospective observational studies were pooled. Efficacy and safety of sorafenib were primary objectives in the two studies. Eligible patients were those for whom the decision to treat with sorafenib has been made prior to enrollment.

**Results:** Between June 2009 and January 2014, 512 patients were enrolled in both studies of which 498 were valid for efficacy and 485 for safety analysis. Demographic characteristics: male 81%, median age 70y (range 28–90) and $>$26% 75y or above. Etiology: hepatitis C in 55% and hepatitis B in 20% of patients. The majority (62%) had ECOG PS 0 and Child-Pugh A/B/C was present in 79/13/1% respectively. More than half of patients were BCLC stage C (58%) whereas BCLC B and BCLC A accounted for 31% and 9% respectively. Overall incidence of adverse events-(AE) (all grades) was 82%. The most frequent were fatigue (29%), diarrhea (24%) and hand-foot skin

reaction (16%). Incidence of AEs resulting in permanent discontinuation (drug-related or not) was 32%. Median overall survival was 10.7 [95%CI:9.3–12.7] months and median time to progression was 6 [95%CI:5.2–7.0] months.
**Conclusion:** This pooled analysis represents the largest prospective database of patients treated with sorafenib in routine clinical practice in Italian centers and confirms the efficacy and safety data of the phase III registrational studies. The use of sorafenib in the advanced as well as in the intermediate and early stage HCC confirms its role in the continuum of care of HCC patients and the treatment stage migration approach in clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1159 IMPROVING SURVIVAL OF PATIENTS WITH HEPATOCELLULAR CARCINOMA BETWEEN 2005 AND 2012 IN THE FINISTERE AREA

M. Calament[1], M. Cariou[2], A. Billot-Grasset[2], F. Tanne[3], **M. Robaszkiewicz**[4], J. Nousbaum[4]

**Introduction:** Relevant diagnostic procedures and advanced treatments have been introduced in the management of hepatocellular carcinoma (HCC)
**Aims & Methods:** The aim of the study was to assess the effect of treatment procedures evolution on survival between 2005 and 2012 in the Finistere area. All cases of HCC (n = 971) diagnosed from January 1st, 2005, throughout December 31st, 2012, were registered in the database of the Finistere registry of digestive cancers. Diagnostic circumstances, medical background, type of diagnosis confirmation, Child-Pugh score and BCLC staging classification, treatment and AFP levels have been tested for their effect on survival. Patients were divided into two groups according to the diagnosis date. The 5-year cancer specific survival (CSS) was calculated by Kaplan-Meier method and a multivariate analyse by cox model.
**Results:** Overall, the 5-year CSS significantly increased during this 8-year period, from 12.9% for cases diagnosed between 2005 and 2008 to 21% for cases diagnosed from 2009 onward ($p < 0.05$). Patients diagnosed during screening procedures had a 5-year survival rate of 25.5% vs 7.6% in case of symptomatic diagnosis ($p < 0.001$). They underwent more curative or interventional treatment in 67.0% of cases whereas it dropped to 22.2% in case of symptomatic diagnosis. We observed a strong association between the AFP level and prognosis, CSS being 25.9 months (IC95 20.5–30.8) for AFP level below 14 ng/mL, as compared with 9.7 months (IC95 7.3–11.5) and 3.1 months (IC95 2.6–3.8) for levels between 14 and 199 ng/mL or above 200 ng/ml respectively. In the multivariate analysis, clinical presentation, tumor size, AFP level, Child-Pugh score, BCLC stage and treatment were independent prognostic factors for the 5-year CSS.
**Conclusion:** Cancer specific survival rate significantly increased during this 8-year period in HCC patients, mostly in patients diagnosed during screening. A low level of AFP is a significant prognostic factor.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1160 SURVEILLANCE FOR HEPATOCELLULAR CARCINOMA (HCC): A CLINICAL AUDIT

**A. Abdul-Sattar**[1], C. Ch'Ng[2]
[1]*Gastroenterology, Singleton Hospital, Swansea/United Kingdom*
[2]*Department Of Gastroenterology, Singleton Hospital, Swansea/United Kingdom*

**Contact E-mail Address:** asmaabdulsattar@gmail.com
**Introduction:** AASLD and EORT guidelines recommend 6-monthly ultra-sound surveillance for the detection of hepatocellular carcinoma in patients with cirrhosis[1,2]. Our previous audits showed that compliance with ultrasound surveillance remains unsatisfactory despite patients' involvement and consent, using our previous paper based recall system[3]. We aim to check our compliance rate of six monthly surveillance ultrasound scans (USS) following implementation of our recall system using Excel.
**Aims & Methods:** All patients known to CLC until end Dec 2015 were audited. Cirrhosis was confirmed by liver biopsy, Fibroscan, ELF test or a shrunken liver in the clinical setting. Comparison was made with audit data from 2012 and 2014. A database of all patients with cirrhosis was constructed and their details entered into an Excel spreadsheet. USS surveillance was requested upon receipt of a non-significant report and the patient informed. For patients with a significant report, further investigation was organised and an early outpatient review was made. Using the Excel spreadsheet date function, the patient was sent a reminder letter if s/he did not attend USS when due.
**Results:** Compliance rate for previous audit years 2012 and 2014 were 26% and 56% respectively. There were 423 patients in total. 256 were male and 167 were female. 92 patients were excluded: 63 patients died, 25 patients moved to another hospital or consultant and 4 declined surveillance. Of the 331 remaining patients (205 male, 126 female; ratio 1.6:1) we found that: 236 (71.3%) had a surveillance USS within the last 6 months 95 (28.7%) did not attend the appointment
Females complied better with surveillance; 138 (67.3%) of males attended versus 98 (77.8%) of females who attended.
**Conclusion:** Our results show that our rate of compliance has improved over the years and following the introduction of a departmentally designed recall and reminder system using a standard off the shelf Excel program. To further improve our compliance, we are planning a telephone appointment reminder aimed especially at patients who are recurrent non-attenders with a subsequent re-audit of results in a further 1 to 2 years.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1161 VIRTUAL PALPATION MODEL BASED ON SPIRAL CT AND ELASTOGRAPHY DATA - PROOF OF CONCEPT

**C.T. Streba**[1], I. A. Gheonea[2], L. Sandulescu[1], A. Săftoiu[1], D. Gheonea[1]
[1]*Gastroenterology, University of Medicine and Pharmacy of Craiova Dept. of Gastroenterology, Craiova/Romania*
[2]*Imagistics, University of Medicine and Pharmacy of Craiova, Craiova/Romania*

**Contact E-mail Address:** costinstreba@gmail.com
**Introduction:** Palpation is a skill that has been increasingly neglected over recent years due to the advent of numerous new technologies that facilitate diagnosis. However, it remains one of the four pillars of proper clinical investigation and is a prequisite in all medical schools worldwide. It traditionally involves direct contact with the outer layers of the body, therefore being restricted to organs in close contact to adjacent structures.
**Aims & Methods:** Our aim was to implement modern imaging data combined from computed tomography (CT) and real-time elastography (RT-E) and Fibroscan in a haptic simulator capable of reproducing a virtual deformable model of a liver tumor. We have obtained ethical clearance from the local committee and obtained informed consent from 25 patients scheduled for surgery with hepatocellular carcinomas. All patients underwent CT scans as part of their medical work-up, as well as liver elastography and Fibroscan for obtaining elastographic data of the tumor. By using previously described methods [1] we created a three-dimensional model of the liver and the tumor using the CT data and integrated elasticity information by superimposing the RT-E and Fibroscan data on the stiffness of each tumor, obtaining virtual models containing segmented color-map data superimposed on high-fidelity representations of the tumors. This three-dimentional rendering was integrated in a virtual reality system and we used a haptic device to simulate direct contact. A test group of 120 medical students that already completed the Gastroenterology course was presented with the model and asked to complete a survey after using the device for 1

**P1161**

| | Strongly disagree | Disagree | Partially agree | Agree | Strongly Agree |
|---|---|---|---|---|---|
| The model is accurate in size | 0 | 0 | 5 | 18 | 97 |
| The model is accurate in shape | 0 | 0 | 6 | 27 | 87 |
| The model is accurate in location | 0 | 0 | 8 | 31 | 81 |
| The model is easily maneuverable | 0 | 0 | 1 | 24 | 25 |
| The haptic device provides accurate interaction with the virtual model | 0 | 5 | 31 | 12 | 72 |
| The virtual reality glasses provided an adequate experience | 0 | 3 | 21 | 12 | 84 |
| The system is easy to use | 0 | 1 | 3 | 46 | 70 |
| The interface is user-friendly and intuitive | 0 | 0 | 6 | 55 | 59 |
| The system provided useful insight on the characteristics of liver tumors | 0 | 0 | 0 | 14 | 106 |
| The system effectively increased knowledge on the studied pathology | 0 | 0 | 0 | 0 | 120 |

hour each. They also had access to data on the real tumor (size, shape and location).
**Results:** The results to the survey are presented in the table below. According to the survey answers, all students considered the model to be accurately depicted by the three dimensional rendering. They found the system to be useful and to increase knowledge on liver malignancy, providing insight otherwise unobtainable through standard teaching methods. The system, however, was not easy to operate and did not provide an accurate interaction for all students.
**Conclusion:** We have continued our previous work by expanding the capabilities of a haptic device used to facilitate virtual palpation of a liver tumor. Medical training should include modern techniques in an approachable manner, facilitating direct contact between the student and the studied pathology. The results of our survey proved that such systems increase knowledge on liver tumors.
**Disclosure of Interest:** C.T. Streba: Supported by Partnership Project No. 2011–3.2–0503, VIPsystem

**Contact E-mail Address:** ivica.grgurevic@zg.htnet.hr
**Introduction:** Biomarkers have the potential for early detection of disease translating to better management. Concerning the great burden of chronic liver disease (CLD) and hepatocellular carcinoma (HCC), biomarkers for the detection of HCC have great potential to change the management and prognosis of patients with CLD and HCC.
**Aims & Methods:** The aim of the study was to investigate diagnostic performance of Protein induced by vitamin K absence or antagonist-II (PIVKAII) and new candidates Glypican-3 (GP3), Cystatin B (CSTB), Squamous cell carcinoma antigen 1 (SCCA1) and Hepatocyte growth factor (HGF) as potential biomarkers for hepatocellular carcinoma (HCC) in patients with alcoholic liver cirrhosis (ALC). Eighty two participants were included: 19 healthy volunteers, 31 patients with ALC and 32 patients with HCC. Peripheral blood sampling was performed for each participant and serum levels of PIVKAII, GP3, CSTB, SCCA1 and HGF were analyzed using commercial ELISA kits. Patients were excluded if they were younger than 18, had prior treatment of HCC, history of other solid tumour, or elevated serum creatinine level.
**Results:** Only serum levels of PIVKAII were significantly higher in HCC patients as compared to ALC and healthy controls (cut-off 2.06 ug/L; AUC 0.903), whereas diagnostic performance of other individual compounds and their combinations was suboptimal. All tested compounds had significantly higher serum levels in cirrhotic patients as compared to healthy controls. Moreover, significant increase in serum concentration of GP3, CSTB and SCCA1 (all $p < 0.01$) was observed along progressive Child-Pugh stages of cirrhosis, whereas CSTB and SCCA1 expressed moderately strong correlation ($r2 = 0.6$ and 0.65 respectively, both $p < 0.001$) with liver functional stage expressed by MELD score.
**Conclusion:** With the exception of PIVKAII, examined biological compounds had suboptimal diagnostic performance for HCC in ALC. Obtained results might indicate CSTB and SCCA1 as potential non-invasive biomarkers of liver function and cirrhosis development which should be further investigated.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1163 MIRIZZI SYNDROME: HOW TO MANAGE

**E. El Hanafy**
*Surgical Departement, Mansoura University, gastroenterology center, Mansoura/Egypt*

**Contact E-mail Address:** dr_ehab_elhanafy@yahoo.com
**Introduction:** Mirizzi syndrome (MS) is a rare complication of cholelithiasis. The Mirizzi Syndrome (MS) is characterized by impaction of gallstone in either the cystic duct or the Hartmann pouch of the gallbladder, resulting in compression of the adjacent common hepatic duct **(1).** It has been extending to patients in whom there is an erosion of the gallbladder wall or cystic duct so that it communicates with the bile duct, forming a cholecystocholedochal fistula **(2,3)**. This entity should be considered in the differential diagnosis of all patients with obstructive jaundice. Failure to recognize this condition preoperatively can result in a major bile duct injury. In this study, our aim is to describe the clinical presentations, investigations, operative details, endoscopic management and the complications of both procedures.
**Aims & Methods:** We performed a retrospective analysis on the records of 85 patients with MS. All patients had a cholangiogram either; magnetic resonance cholangiopancreatography (MRCP) or endoscopic retrograde cholangiopancreatography (ERCP). We used a McSherry classification to divide patients with MS into type I MS and type II MS.
**Results:** The incidence of MS was 0.98% from a total of 4620 patients who had undergone cholecystectomy. From 85 patients with MS 30 patients underwent ERCP where it was the sole treatment (28 of which had stent while 2 had the stone extracted). The overall surgically treated patients were 55 (28 patients with preliminary ERCP with stent and 27 patients with primary surgical treatment), 28 patients had MS type I while 27 patients had MS type II. Patients with different types of MS underwent different types of surgical procedure.
**Conclusion:** Surgery is the mainstay of therapy of Mirizzi syndrome, and requires the safe completion of cholecystectomy and the appropriate management of the cholecystocholedochal fistula. Endoscopic treatment may be effective as a temporary measure before surgery and can be definitive treatment for unsuitable surgical candidates.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1164 ENDOSCOPIC ULTRASOUND-GUIDED GALLBLADDER DRAINAGE VERSUS ENDOSCOPIC TRANSPAPILLARY GALLBLADDER DRAINAGE FOR ACUTE CHOLECYSTITIS IN HIGH RISK SURGICAL PATIENTS: WHICH IS BETTER?

**D. Oh**, S.S. Lee, D.H. Cho, T.J. Song, D.H. Park, D. Seo, S.K. Lee, M. Kim
*Dept. Of Internal Medicine, Asan Medical Center, Seoul, Korea, Seoul/Korea, Republic of*

**Contact E-mail Address:** dongwook.oh1@gmail.com
**Introduction:** Although endoscopic transpapillary gallbladder drainage (ETGBD) has been reported to be an effective treatment for acute cholecystitis, it may not be technically feasible in difficult cases. As an alternative, endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) has been introduced as a safe and effective method for drainage of the gallbladder.
**Aims & Methods:** The aim of this study was to compare the outcomes of EUS-GBD and ETGBD. Retrospective review of a prospectively collected endoscopic gallbladder drainage database at the Asan Medical Center (From January 2010 to December 2014) was performed to identify consecutive patients with acute cholecystitis who underwent attempted endoscopic gallbladder drainage for decompression of the gallbladder. A total of 179 patients (83 in EUS-GBD group and 96 in ETGBD group) who had undergone either EUS-GBD or ETGBD for acute cholecystitis were included. The inclusion criteria were: 1) acute cholecystitis, 2) advanced malignancy and/or poor surgical performance (class III or IV on the American Society of Anesthesiologists Physical Status classification system).
**Results:** Technical success rate (EUS-GBD vs. ETGBD group; 98.8% (82/83) vs. 83% (80/96), $P < 0.05$) and clinical success rate (EUS-GBD vs. ETGBD group; 95.2% (79/83) vs. 83% (80/96), $P < 0.05$) were significantly higher in EUS-GBD group than ETGBD group. There was no significant differences in the mean procedure time (EUS-GBD vs. ETGBD group; $21 \pm 6.2$ minutes vs. $19.5 \pm 9.6$ minutes, $P = 0.22$) and procedure-related adverse event rate (EUS-GBD vs. ETGBD group; 8.4% (7/83) vs. 8.3% (8/96), $P = 0.74$). In the EUS-GBD group, procedural adverse events included self-limitied pneumoperitoneum (3/83, 3.6%), self-limited abdominal pain (3/83, 3.6%), and duodenal perforation (1/83, 1.2%). In the ETGBD group, post-procedural pancreatitis occurred in 8 patients (8.3%). All procedure-related adverse events resolved with conservative treatment. During the follow-up periods, acute cholecystitis recurred more frequently in ETGBD group (EUS-GBD vs. ETGBD group; 7.2% (6/83) vs. 17.7% (17/96), $P = 0.02$) As a result, re-intervention was more frequently needed in ETGBD group (EUS-GBD vs. ETGBD group; 7.2% (6/83) vs. 17.7% (17/96), $P = 0.02$).
**Conclusion:** In patients with acute cholecystitis and unfit for surgery, EUS-GBD might be more useful treatment method than ETGBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1165 BILE DUCT STONES RECURRENCE AFTER ESWL IN THE ELDERLY: PREDICTIVE FACTORS

**D. Mandolesi**[1], R. Muratori[1], C. Pierantoni[1], D. Festi[2], G. Mazzella[1], F. Bazzoli[2], F. Azzaroli[1]

**Contact E-mail Address:** dani.mandolesi@gmail.com

**Introduction:** Extraction of ductal stones via endoscopic biliary sphincterotomy may be complex, the most frequent reason is stone size greater than 15 mm[1]. Extra-corporeal shock wave lithotripsy (ESWL) can be considered in difficult bile duct stones (DBDS) with a success rate greater than 90%[2] but data about the recurrence rate of common bile duct stones after ESWL are limited.
**Aims & Methods:** From May 1992 to October 2012, patients who underwent ESWL treatment for DBDS, not amenable to endoscopic extraction, were included. Patients who had undergone liver transplantation or choledochotomy were excluded. Clinical information was retrospectively reviewed, and data about long-term outcome were collected through phone interviews and medical records. Chi square test and Mann-Whitney test were used to study significant differences between patients with or without bile duct recurrence. Subsequent multivariate analysis on significantly different variables was performed by means of logistic regression. The accuracy of the identified predictors of recurrence was evaluated with ROC curve analysis.
**Results:** A total of 202 patients (median age 77 years, range 41–95) with a successful clearance of DBDS after ESWL were included. 85 had gallbladder stones, while 112 underwent cholecystectomy before the DBSD diagnosis or within a month from the last ESWL session. During a median follow-up period of 4.64 years, 40 patients (20%) developed a recurrence of bile duct stones with biliary colic in 18 patients, cholangitis in 15, acute pancreatitis in 2 and asymptomatic in 5. As expected, there was a significantly higher number of patients with gallbladder stones (60% vs 38%, $p = 0.0185$) and not cholecystectomized (60% vs 40%, $p = 0.0395$) in the recurrence group. Mean diameter of stones ($2.458 \pm 0.96$ vs $2.089 \pm 0.710$, $p = 0.0315$) and of the common bile duct were significantly higher in the recurrence group. Logistic regression analysis confirmed that the common bile duct diameter (OR 1.42; 1.19–1.71, $p = 0.0001$) and the maximum stone diameter (OR 1.90, 1.19–3.03, $p = 0.0065$) were significantly associated with recurrence. Interestingly, ROC curve analysis identified a main bile duct diameter of $> 10$ mm to be associated with recurrence (sensitivity 92.5%, $p < 0.0001$).
**Conclusion:** In our elderly population we observed a recurrence of 20% over a median follow-up of 4 years. This study confirms that the presence of stones in the gallbladder is a risk factor for bile duct stone recurrence as well as stone size. However, the common bile duct diameter associated with a higher risk of recurrence is lower than what has been previously published[3], a data that may impact on clinical decisions in elderly fit subjects.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1166 PROCHOLESTATIC GENE VARIANTS AND MUTATIONS IN SECONDARY SCLEROSING CHOLANGITIS IN CRITICALLY ILL PATIENTS (SC-CIP)

**C. Jüngst**, M. Reichert, V. Zimmer, F. Grünhage, F. Lammert, M. Krawczyk
*Department Of Internal Medicine 2, Saarland University Medical Center, Homburg/Germany*

**Contact E-mail Address:** christoph.juengst@uks.eu

**Introduction:** Secondary sclerosing cholangitis in critically ill patients (SC-CIP) has been recently defined as new disease entity. The pathogenesis of SC-CIP is unclear, however ischemia and "toxic bile" might be involved.
**Aims & Methods:** It was our aim to study selected procholestatic gene variants and mutations in patients who developed secondary sclerosing cholangitis (SSC) after an intensive care unit (ICU) stay. In total, we screened data of 4,641 cholangiography procedures performed between January 2008 and April 2015 at Saarland University Medical Center. In total, we identified 17 patients (age 33–80 years, 14 males) with a history of ICU treatment and signs of SSC. In these patients, we retrospectively analyzed the data concerning ICU therapy. In all patients we genotyped the following procholestatic mutations (marked with an asterisk) and polymorphisms: ATP8B1 (p.N45T*, p.E429A*, p.I661T*, p.R952Q), ABCB4 (p.R590Q*, c.787 A > T, c.504 T > C), ABCB11 (p.E297G*, p.A444V, p.D482G*, c.3084A > G), and FXR (c.-1 G > T). The genotype frequencies were compared with data from reference populations.
**Results:** Among the SC-CIP patients, myocardial infarction ($n = 5$, 29%) was the most common reason for the ICU stay, followed by cardiac surgery, pneumonia, and polytrauma ($n = 3$, respectively). The first endoscopic retrograde cholangiography procedure was performed on an average of 105 days (range 24–1155 days) after the ICU treatment. All patients presented with increased cholestatic markers (median bilirubin 3.5 mg/dl, gamma-GT 731 U/l, alkaline phosphatase 428 U/l). All SC-CIP patients had infectious complications during their ICU stay. In 6 of 8 patients with cholangitis, microbiological analysis of bile revealed *Entercoccus faecium* (66.7%) and *Enterococcus faecalis* (50.0%) species; a single patient tested positive for Candida species. The disease progressed to liver cirrhosis in 8 (47%) patients, two received liver transplantation, and three patients died (17.6%).One patient was a heterozygous carrier of the FXR c.-1 > t mutation. Otherwise, we did not detect any differences in ABCB4, ABCB11 and ATP8B1 genotype distributions as compared to the general population.
**Conclusion:** To our knowledge this is the first study investigating hepatobiliary transporter variants in patients with SC-CIP. Although our preliminary results do not indicate an association between the gene variants and SC-CIP development, a more comprehensive approach (next-generation sequencing) is required to fully explore the impact of rare gene variants on SC-CIP risk.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1167 PREDICTORS FOR DETECTION OF DIFFICULT-TO-TREAT BACTERIA IN BILIARY TRACT INFECTION

**Introduction:** Empiric antimicrobial therapy for severe bacterial infection should sufficiently cover the possible causative pathogens. For this purpose, it is important to accurately predict the causative microbes. However, few studies have revealed the relation between host factors and causative bacteria in biliary tract infection.
**Aims & Methods:** We aimed to determine the patient factors which predict detection of difficult-to-treat bacteria (DTTB) as pathogens of biliary tract infection. A hundred and twenty-three cases of bacteraemia derived from biliary tract infection treated in our hospital between January 2010 and September 2015 were included. We examined the relation between the detection of DTTB and the patient factors, such as age, sex, biliary tract malignancy, complication, timing of bacteraemia, severity, device in the biliary tract, immunosuppressive therapy, loss of the sphincter function of the papilla, history of hospitalization within 30 days, use of antibiotics within 3 months and history of DTTB detection. We defined DTTB as extended-spectrum beta-lactamase (ESBL)-producing organisms, metallo-beta-lactamase (MBL)-producing organisms, a group of "SPACE" (which stands for *Serratia*, *Pseudomonas*, *Acinetobacter*, *Citrobacter*, and *Enterobacter*), and ampicillin-resistant enterococci.
**Results:** DTTB were detected in 28 cases (22.8%). Univariate analysis revealed that the factors significantly correlated to DTTB detection were the following: biliary tract malignancy (32.6% vs 16.9%, $p = 0.04$), loss of the sphincter function (37.9% vs 18.1%, $p = 0.03$), history of hospitalization (35.3% vs 18.0%,

Table 1

| Animal | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|---|---|---|---|---|---|---|---|---|---|---|
| Technical success | Yes | Yes | Yes | Yes | Yes | Yes | Yes | Yes | Yes | Yes |
| Procedure duration (minutes) | 35 | 37 | 28 | 17 | 19 | 15 | 14 | 16 | 20 | 19 |
| Time of acrifice (hours/days) | 6 h | 24 d | 10 d | 21 d | 42 d | 42 d | 42 d | 42 d | 1 h | 1 h |
| Complications | None | None | None | None | None | None | None | None | None | None |
| Migration of the stent | No | No | No | No | Yes | No | Sham procedure | Sham procedure | No | No |
| Gallbladder status on ERCP | Normal | Normal | Normal | Normal | Normal | Normal | Normal | Sludge in the gallbladder | Normal | Normal |
| Device conditions at autopsy | Normal | Normal | Normal | Normal | Normal | Normal | Not implanted | Not implanted | Normal | Normal |

p = 0.04), resent use of antibiotics (37.8% vs 16.3%, p < 0.01), and history of DTTB detection (42.1% vs 19.2%, p = 0.04). In multivariate analysis, only resent use of antibiotics was significantly correlated to DTTB detection (P < 0.01).
**Conclusion:** Resent use of antibiotics increases the possibility of DTTB detection in biliary tract infection.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1168 A NOVEL NITINOL GALLBLADDER STENT FOR PREVENTION OF STONE MIGRATION AND IMPACTION

**Introduction:** Up to 20% of western populations have gallstones. Cholecystectomy is the standard treatment with 2 million procedures annually worldwide. Although safe and routinely performed, cholecystectomy can lead to complications and even death 1. Gallstones become a problem requiring intervention only when they block bile flow from the galblladder or migrate into the bile ducts. The LithoBlocker™ is a patented nitinol umbrella-like stent, designed to prevent gallstones from blocking the orifice of the gallbladder and from migration into bile ducts, while maintaining gallbladder function, as well as free bi-directional bile flow. The stent accomodates itself within the gallbladder facing its orifice upon release from the delivery system.
**Aims & Methods:** The LithoBlocker™ is inserted into the gallbladder during a standard ERCP procedure using a conventional metalstent delivery system. The aim of the present study was to investigate the feasibility and safety of insertion and deployment of the stent into the gallbladder of pigs. In addition, short-term safety of the stent was evaluated.
**Results:** The study protocol was approved by the hospital ethical committee. ERCP was done in 10 animals at the facility of the Catholic University of Rome, Italy. The mean weight of the animals was 35 kg. Before ERCP the animals were held on an overnight fast and abdominal ultrasound was done to determine the size of the gallbladder (to choose the stent size) and to exclude any unexpected anatomical abnormalities. After ERCP, the animals were held at the facility, allowing water and food ad libitum. The animals were sacrificed at the end of the follow-up period. The procedures were performed with a standard Olympus duodenoscope (TJF 140) under fluoroscopic control and general anesthesia. After biliary cannulation, cholangiography and sphincterotomy, the gallbladder was cannulated with a hydrophilic guidewire through the cystic duct. The LithoBlocker™ device was introduced over the same guidewire into the gallbladder with an 8Fr or 8.5 Fr introducer catheter. The stent (available between 4–8 cm in length) was deployed in the gallbladder under fluoroscopy. A total of ten procedures, 8 device placements and 2 sham procedures (complete procedure with contrast injection, sphincterotomy, insertion of guide wire and delivery system into the gallbladder without stent deployment) were performed. Data are shown in Table 1. No procedure or device related complications were observed. The mean procedure time was 20.5 minutes (14–37). The maximum follow-up until sacrifice was 42 days. On autopsy, the stent was correctly in place in 7 pigs, while it migrated completely in 1.
**Conclusion:** The LithoBlocker™ can be easily introduced into the gallbladder by a standard ERCP procedure, without any immediate or short term complications. It is a promising tool that could prevent gallstone migration and impaction. Clinical trials are warranted to confirm these results.
**Disclosure of Interest:** F. Konikoff: Prof. Konikoff is a medical director at Lithiblock
S. Ben Muvhar: Founder and CEO at Lithiblock. Financial support for the study done at the animal facility of the Catholic University of Rome, Italy
J. Tsehori: Dr. Tsehori is a cofounder of Lithiblock

## P1169 RELATIONSHIP BETWEEN GALLBLADDER STONE AND CARDIOVASCULAR DISEASE RISK

**E. Borekci**[1], M. Celikbilek[2]
[1]*Internal Medicine, Bozok University Hospital, Yozgat/Turkey*
[2]*Gastroenterology, Bozok University, Yozgat/Turkey*

**Contact E-mail Address:** elifborekci@mynet.com
**Introduction:** Cardiovascular disease (CVD) and gallstones are among the most common diseases in the society and share common risk factors. Our aim is to determine whether there is an increase in 10-year CVD risk in the patients with gallstones and whether gallstone is a risk factor for cardiovascular disease.
**Aims & Methods:** We analyzed 90 patients diagnosed with gallstones disease and 72 healthy subjects without gallstones. Demographic and laboratory data were collected, Framingham risc scores were calculated and both groups were compared for the 10-year CVD risk. Then, demographic and laboratory data of individuals who had moderate-severe risk and low risk for CVD were compared. Moreover, multivariate logistic regression analyses were performed and ORs with 95%CI were calculated in order to indentify the risk factors of CVD.
**Results:** 10-year CVD risk is significantly higher in cases with gallstone disease than without gallstones (p:0.005). In the cases having moderate- severe risk for CVD, total cholesterol, systolic blood pressure, hematocrit etc. were significantly higher acording to the cases with low risk (Table-2). In the results of multivariate logistic regression analyses, 7,8-fold increase in the risk of CVD was found in the patients with gallbladder stone. Odds ratio of other possible risk factors in the increased risk of CVD risk are given in Table 2.
**Conclusion:** At the end of the study; it was found that gallstones were associated with a high risk of cardiovascular disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1170 LAPAROENDOSCOPIC RENDEZVOUS FOR TREATING CHOLELITHIASIS WITH CONCOMITANT CHOLEDOCHOLITHIASIS UNSUITABLE FOR LCBDE

C. Dai, X. Wang, L. Liu, M. Wang, **Z. Fan**
*Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China*

**Contact E-mail Address:** fanzhining@njmu.edu.cn

**Introduction:** Choledocholithiasis is reported to accompany with cholelithiasis in 10–15% patients. The two-stage approach is widely applied: endoscopic etrograde cholangiopancreatography (ERCP) and common bile duct (CBD) clearance by laparoscopic cholecystectomy. Recent studies demonstrated laparoscopic management of CBD stones with choledochoscope-assistanted laparoscopic CBD exploration (LCBDE), as a single stage procedure, might be efficient and cost effective. For some ERCP-failed cases, intraoperative ERCP (IO-ERCP) using the laparoendoscopic rendezvous technique followed by laparoscopic cholecystectomy (LC) was effective and safe. It's still controversial for defining the ideal treatment of CBD stones. Rare reports showed the recommended strategy for patients not suitable for LCBDE with the choledochoscope assistance. Our aim was to evaluate the advantage of IO-ERCP combined with laparoendoscopic rendezvous in these cases.
**Aims & Methods:** For the patients suspected cholelithiasis with concomitant choledocholithiasis, Magnetic Resonance Cholangiopancreatography (MRCP) was performed to assess the CBD diameter and stone number. Acquired the written informed consent, patients were cured by cholecystectomy and LCBDE with the choledochoscope assistance if no contraindications. IO-ERCP and laparoendoscopic rendezvous would be applicable for exploring CBD and cleaning stones while the CBD diameter was $<1$ cm and the stone number was $<3$. The cannulation was performed, and the stones was cleared by Dormia basket or balloon. Endoscopic nasobiliary drainage (ENBD) was carried out routinely, and removed due to no infection, no pancreatitis and no discomfort, which should be confirmed by clinical manifestation and blood tests after oral diet. For all patient, baseline characteristics, operation procedure, complication, hospitalization period and costs were recorded and compared.
**Results:** From Dec 20, 2014 to Sep 15, 2015, a total of 10 patients received the management of combining IO-ERCP and LC. Male/Female was 4/6. The mean diameter of CBD was 0.85 cm (0.7–1.0). The average number of stones was 2.1 (1–3). The average operation time was 120.8 min (98–154 min). No PEP or sever complications occurred. Patients were discharged after 4.8-day (3–7) hospitalization and the average costs were 35.000 RMB (33.000–38.000 RMB).
**Conclusion:** Combining IO-ERCP and LC for patients with these indications was efficient, safe and cost effective. Cooperating management ensured the successful cannulation, even without radiography. This innovative strategy could reduce the sphincter damnification, avoid post-operative stricture of CBD and prevent the PEP occurrence. For future clinical application, randomized controllable trials should be designed to demonstrate the superiority of this method.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1171 CLINICAL IMPACT OF PER-ORAL DIGITAL CHOLANGIOSCOPY (SPYGLASS) – A SINGLE CENTER EXPERIENCE

**R. Hustak**, J. Usak, F. Zavada, J. Martinek
*Gastroenterology Department, Internal Clinic Universitary hospital of Trnava, Trnava/Slovak Republic*

**Contact E-mail Address:** rhustak@gmail.com

**Introduction:** A new single-operator digital cholangioscopy (d-SOC) has recently been introduced in the clinical practice. In contrast to the 1st fiberoptic generation, it provides better imaging quality and superior maneuvaribility. Initial reports with 1st generation demonstrated low/intermediate diagnostic accuracy for visual diagnosis as well as for targeted biopsies under visual control in patients with indeterminate biliary strictures*.
**Aims & Methods:** The aim of our retrospective analysis was to assess the diagnostic accuracy and clinical impact of SOC, and of a digital version in particular, in patients with undetermined biliary strictures and in patients with difficult choledocholithiasis. Procedural success was defined as an ability to (1) visualize target lesions and collect biopsy specimens for histological evaluation, if indicated, and (2) achievement of a complete duct clearance.
**Results:** A total of 44 procedures (22 digital) were performed in 42 patients, 36 (86%) patients underwent cholangioscopy for diagnostic purposes and 6 (14%) for laser litothripsy. Overall, sensitivity, specificity and diagnostic accuracy in patients with undetermined biliary stricture was 90.0%, 88.2% and 88.9% respectively. First generation of SOC achieved sensitivity, specificity and diagnostic accuracy of visual impression 87.5%, 92.3% and 68.8%, while digital SOC achieved sensitivity and specificity 100%. Overall diagnostic yield of targeted biopsies for both generations was 78.6% (95% CI. 60.5–89.8%). The sensitivity of Spybit histology for the first generation SOC was 20% (95% CI 2.52-55.61%), the sensitivity of second generation Spybit histology was 100% (95%CI 15.8 – 100%) with no statistical difference ($p=0.5$ – chi square with Yates correction – low counts). All laser lithotrypsies ($n=6$) were performed by using a new d-SOC system and we achieved a complete duct clearance with stone removal in one session was accomplished in 5/6 patients (83%). Non-fatal adverse events occurred in a total of 8 patients (cholangitis, mild post-procedural pancreatitis, liver hematoma, bleeding) and occurred during diagnostic cholangioscopies with a similar frequency in d-SOC and the first generation SOC.
**Conclusion:** We observed a trend for improved both diagnostic accuracy and diagnostic yield of targeted biopsies with a new generation of digital single operator per oral cholangioscopy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1172 A PROSPECTIVE STUDY OF THE CLINICAL EFFICACY AND EFFECT OF PHOTODYNAMIC THERAPY FOR THE TREATMENT OF UNRESECTABLE EXTRAHEPATIC CHOLANGIOCARCINOMA

**J. Yang**, X. Zhang, H. Jin, H. Shen, Q. Lou
*Gastroenterology, Hangzhou First People's Hospital, Hangzhou/China*

**Contact E-mail Address:** yjf-1976@163.com

**Introduction:** Photodynamic therapy (PDT) combined with stent placement is considered an effective palliative treatment for unresectable extrahepatic cholangiocarcinoma (EHCC). However, the available evidence is still insufficient and not yet strong enough for prospective, controlled study results reported infrequently [1–2]. The time interval between PDT procedures was no standardized recommendation. It remains unclear whether PDT plays a role in promoting a systemic inflammatory response in patients with EHCC.
**Aims & Methods:** This study aimed to explore the clinical efficacy and effect of this treatment on tumor tissues and the systemic inflammatory response in patients with EHCC. Patients with unresectable EHCC underwent either a combined treatment of PDT and stent placement (PDT+stent group, 12 patients) or stent-only treatment (stent group, 27 patients). Thickness of the tumor mass was measured using intraductal ultrasonography (IDUS) in every 3 months. TNF-$\alpha$ and IL-6 levels were determined 1 week pre- and postoperatively. Quality of life was assessed using Karnofsky performance scale (KPS) scores every 3 months.
**Results:** Average jaundice alleviation time was significantly lower in the PDT+stent group (19.7 (7–28) vs. 28.9 (13–45) d, $p=0.03$). Average survival time [13.8 (6.2–16.5) vs. 9.6 (4.5–12.7) months, $p<0.001$], 6-month (91.7% vs. 74.1%, $p<0.001$), and 1-year (58.3% vs. 3.7%, $p<.001$) survival rates were significantly increased compared with the stent group. KPS scores in the PDT+stent group were higher after 1, 3, and 6 postoperative months compared with the stent group ($p<0.05$). Incidence of postoperative adverse events was not significantly different (16.7% vs. 22.2%). Mean thickness of the tumor mass was significantly decreased after 1 and 3 postoperative months ($6.8\pm1.1$ vs. $13.8\pm4.1$ mm, $p=0.02$; $10.5\pm2.4$ vs. $15.4\pm3.9$ mm, $p=0.04$) and TNF-$\alpha$ and IL-6 levels were significantly increased 1 week postoperatively in the PDT+stent group compared with the stent group ($p<0.05$). TNF-$\alpha$ and IL-6 levels were significantly higher in the PDT+stent group compared with the stent group.
**Conclusion:** PDT combined with stent placement is an effective, safe treatment for EHCC can significantly improve alleviation of jaundice, prolong survival time, and improve quality of life, while not increasing the incidence of adverse events. The optimal time interval between PDT is 4 to 6 months. PDT could cause systemic inflammation in patients with EHCC in addition to direct destructive effect on cancer tissue.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The best available potential curative therapy for cholangiocarcinoma is complete surgical resection. Peroperative biliary decompression is frequently performed in clinical setting.
**Aims & Methods:** To determine the impact of preoperative endosopic nasal biliary drainage (ENBD) and/or endoscopic retrograde biliary drainage (ERBD) procedures on intrahepatic recurrence rate in patients with cholangiocarcinoma after surgical resection, we performed this study. Between January 2005 and January 2015, 126 patients diagnosed cholangiocarcinoma and received surgical resection were included. Among 126 patients, 85 patients were treated with preoperative ENBD and/or ERBD. We retrospectively analysed prognostic factors (age, gender, preoperative ENBD and/or ERBD, tumor differentiation, pT factor, lymph node metastasis, surgical margin, lymphovascular invasion, preoperative maximal total bilitubin, postoperative chemoradiation/chemotherapy/radiation therapy, CA19–9) for recurrence after surgical resection.
**Results:** Intrahepatic recurrence after surgical resection was detected in 23/85 (27%) patients with preoperative ENBD and/or ERBD, and 4/41(9.7%) patients without preoperative ENBD and/or ERBD for median period of 12.5 months (range 0–115). The overall 1-, 3-, and 5-year cumulative recurrence rates were 24.6%, 36.9% and 36.9%, with preoperative ENBD and/or ERBD, and were 6.2%, 11.4% and 20.3%, without preoperative ENBD and/or ERBD, respectively ($P = 0.032$). On univariate analysis, intrahepatic recurrence rate of patients who underwent ENBD and/or ERBD ($n = 85$) was higher than that of patients who did not ($n = 41$) ($P = 0.042$) and that of patients who had elevated CA19–9 ($> 200$) ($n = 43$) was higher than that of patients who had not ($n = 83$) ($P = 0.001$). In multivariate analyses, preoperatively ENBD and/or ERBD and elevated serum CA19–9 level ($> 200$ ng/mL) were prognostic factors for intrahepatic recurrence, with hazard ratios (HR) of 3.203, (95% confidence interval (CI) 1.098–9.347, $P = 0.033$) and 3.930 (95% CI 1.803–8.569, $P = 0.001$), respectively.
**Conclusion:** Preoperative ENBD and/or ERBD procedures may affect intrahepatic recurrence of tumor in patients with cholangiocarcinoma after surgical resection.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1174 CONTRAST-ENHANCED ULTRASONOGRAPHY OF GALLBLADDER POLYPOID LESIONS

**Introduction:** To determine whether contrast-enhanced ultrasonography with perflubutane (Sonazoid®; Daiichi-Sankyo, Tokyo, Japan) can differentially diagnose gallbladder polypoid lesions.
**Aims & Methods:** We treated 179 patients with polypoid lesions of the gallbladder including adenocarcinoma ($n = 10$), adenoma ($n = 3$), benign polyps ($n = 138$), and fundal adenomyomatosis ($n = 28$). Lesions were assessed by ultrasonography using an Aplio 500 TUS-A500 (Toshiba Medical Systems, Tokyo, Japan) and a Prosound alpha10 (Hitachi Aloka Medica Ltd., Tokyo, Japan). The largest cross-section of lesions was initially visualized using B-mode ultrasonography with an infusion of Sonazoid®. The characteristics and behavior of blood flow in lesions during the early vascular phase were assessed over a period of about 30 sec and then observed for approximately the next 3 min. Thereafter, lesions were assessed using contrast harmonic and real-time perfusion imaging with infused Sonazoid®. Microflow imaging and capture mode proceeded after replenishing the Sonazoid®. The regions of interest were configured for all lesions and time intensity curves (TIC) of brightness were analyzed.
**Results:** Gallbladder cancer was characterized by hypervascular staining and the "eruption sign" that resembles vigorously boiling water splashing from the entire lesion in 11 (78.5%) of 14 patients. Blood flow images revealed irregularly sized, buckled and tortuous vessels as well as erratic blood flow in 8 (57.1%) of these patients. Gallbladder adenoma was also characterized by the eruption sign in 2 (66.7%) of 3 patients. Staining was scattered among gallbladder benign polyps and the "flicker sign" resembling bubbling already boiled hot water was evident in 130 (94.2%) of 138 patients. Staining was hypervascular in a few patients. Contrast enhancement was less persistent in gallbladder benign polyps than in cancer. Blood flow images revealed normal vessels. Staining of gallbladder fundal adenomyomatosis was scattered and mild flicker signs were evident in 26 (92.9%) of 28 patients. Blood flow was obvious at the surface of the prominence and at the internal Rokitansky-Aschoff sinus.Regions of interest were configured for all lesions and analysis of TIC for gallbladder cancer revealed a tendency towards sustained, intense brightness.
**Conclusion:** Contrast-enhanced ultrasonography using Sonazoid® can detect hemodynamics and differentially diagnose gallbladder polypoid lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1175 FACTORS ASSOCIATED WITH TECHNICAL SUCCESS OF BILATERAL ENDOSCOPIC METALLIC STENTING WITH PARTIAL STENT-IN-STENT PLACEMENT IN PATIENTS WITH MALIGNANT HILAR BILIARY OBSTRUCTION

**T. Fujita**, S. Hashimoto, T. Sakae, H. Hamamoto, H. Yano, H. Maeda, M. Hokonohara, K. Kawabata, S. Arima, Y. Nasu, F. Sasaki, H. Taguchi, S. Kanmura, H. Setoyama, A. Ido

**Contact E-mail Address:** ffjjtt@m3.kufm.kagoshima-u.ac.jp
**Introduction:** It is controversial whether unilateral or bilateral self-expandable metallic stent (SEMS) placement is preferable in patients with malignant hilar biliary obstruction. Bilateral biliary drainage decreases the risk of cholangitis, but bilateral endoscopic metallic stenting is technically challenging.
**Aims & Methods:** We retrospectively evaluated factors associated with successful bilateral SEMS placement with the partial stent-in-stent (PSIS) method for malignant hilar biliary obstruction and the safety and efficacy of this technique. From April 2010 to February 2016, 47 consecutive patients (mean age, $73.0 \pm 8.8$ years; 32 males and 15 females) were treated with PSIS placement for malignant hilar biliary obstruction in our hospital. Patients were excluded from this study if they were previously treated with SEMS placement, underwent side-by-side placement, or had prior gastric surgery with gastrointestinal reconstruction. The technical success rate for PSIS, clinical response, and complications were investigated. Factors associated with technical success of PSIS were assessed. In patients treated with bilateral SEMS placement, procedure time, clinical response, and complications were compared based on whether the size of the SEMS delivery system was less than 6.0 Fr. Clinical response was defined as a serum total bilirubin decline to a normal level ($< 1.2$ mg/dL) or less than half of the pre-SEMS placement level.
**Results:** The technical success rate was 77%. Successful biliary decompression was achieved in 92% of patients. The clinical response rate was 91% and the complication rate was 26%. Regarding complications, pancreatitis occurred in five patients (11%), cholangitis occurred in six patients (13%), and cholecystitis occurred in one patient (2%). Multiple logistic regression analysis identified the use of a SEMS with a delivery system less than 6.0 Fr as a factor associated with technical success ($P = 0.046$; odds ratio, 0.112; 95% confidence interval, 0.013–0.966). In patients who underwent bilateral endoscopic metallic stenting, procedure time (ERCP time plus stenting time) was significantly shorter in patients with delivery system size $< 6.0$ Fr ($P < 0.01$). There were no significant differences in the clinical response or complication rate between the two groups.
**Conclusion:** Use of a delivery system with size less than 6.0 Fr contributes to an improved technical success rate and shortens the procedure time.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Many studies have reported the effectiveness of endoscopic ultrasound-guided biliary drainage (EUS-BD) for palliative treatment of biliary strictures caused by unresectable malignancies. We often experience biliary strictures which are unable to achieve transpapillary biliary drainage, also with benign diseases or preoperative malignancies. However, the utility of EUS-BD for such cases was controversial.
**Aims & Methods:** The aim of this study was to clarify the acceptability of EUS-BD against benign diseases and preoperative malignancies. We reviewed 54 consecutive patients (35 males; mean age, 70.7 years) treated with EUS-BD from October 2008 to December 2015. A total of 57 EUS-BDs, 30 EUS-guided choledochoduodenostomies (EUS-CDS), 23 EUS-guided hepaticogastrostomy (EUS-HGS) and 4 EUS-guided randez-vous were performed, and we devided them into 3 groups as described; group A: benign biliary strictures (7 cases), group B: preoperative biliary drainages (11 cases), and group C: unresectable malignancies (39 cases). We evaluated the clinical outcomes of group A and B, compared to group C.
**Results:** Technical successes were achieved in 6 cases (85.7%) in group A, 10 cases (90.9%) in group B, and 32 cases (78.0%) in group C. Among them, 5 cases (83.3%), 9 cases (90.0%), and 29 cases (90.6%) were clinically effective, respectively. Early complications occurred in 1 case each in group A and B (1 peritonitis each), while there were 17 cases in group C (6 peritonitis, 3 double puncture, 3 cholangitis, 2 bleeding, 2 pancreatitis, and 1 dislocation). Late

complications occurred in 1 case in group B (dislocation), and 2 cases in group C (1 dislocation and 1 relapse cholangitis). Although clinical efficacy was not obtained in a case of severe pancreatitis with cholangitis in group A, other cases achieved long-term patency, and only 1 case required re-intervention to date. In group B, 2 cases underwent unscheduled surgical resection due to stent dislocation, among the 9 cases which ended up operable. Six cases successfully maintained their drainage route, but 3 cases of them required re-intervention before surgery. There were no dissemination and surgical failure due to EUS-BD procedure.
**Conclusion:** In this study, EUS-BD was effective for benign biliary stricture and preoperative biliary drainage in large, except for severe infection. For a reliable evidence of the utility of EUS-BD against benign biliary strictures, further reviews with long-term outcomes would be required.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic ultrasonography guided biliary drainage (EUS-BD) is an effective alternative to failed endoscopic retrograde cholangiopancreatography (ERCP). EUS-BD is performed either by transmural (EUS-choledocoduodenostomy or EUS-hepatogastrostomy; EUS-BD-TM) or transpapillary (antegrade or rendezvous; EUS-BD-TP) techniques. Data regarding efficacy of these modalities is limited.
**Aims & Methods:** Aim: To compare stent patency after EUS-BD when performed via TM or TP approach using metal stents in inoperable malignant biliary obstruction (MBO). Methods: Retrospective data of patients undergoing EUS-BD using metal stents for palliation of unresectable MBO after failed ERCP from 2011 to 2015 was collected. Data included etiology and stage of disease, relevant clinical, laboratory and imaging findings, reason for failed ERCP, EUS-BD technique (TM or TP). Follow up (physical or telephonic) was obtained untill reappearance of jaundice, re-intervention or death. Statistical analysis included Kaplan-Meier graph and Log-rank test. $P < 0.05$ was considered significant.
**Results:** Total ERCPs during the study period at our centre = 4064; total EUS-BD = 108(2.6%); EUS-BD with metal stents for MBO = 71; follow up data was available for 56. EUS-BD-TP = 23 & EUS-BD-TM = 33. Both groups were comparable for demographic and clinical characteristics. Overall median stent patency for both groups was 77 days (IQR 48–228 days); & was similar in both groups, median 69 days (IQR 51 – 240) for TM and 87 days (IQR 42 – 213) for TP ($P = 0.35$). Stent related AE occured more in the TP group than in TM group (8– TP vs 4 – TM), although the difference was statistically not significant ($P = 0.08$). AE included stent migration (0 – TP vs 2 – TM) and cholangitis or stent occlusion (8 – TP vs 2 – TM).
**Conclusion:** Outcomes of EUS-BD by TM or TP approach are comparable in terms of stent patency.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1178 CLINICOPATHOLOGIC STUDY OF BILIARY INTRAEPITHELIAL NEOPLASIA IN CHOLANGIOCARCINOMA

**Introduction:** Biliary intraepithelial neoplasia (BilIN), is well known as a precursor to cholangiocarcinoma (CC). However, how often BilIN occurs and what its clinical implications is largely unknown.
**Aims & Methods:** We aimed to study about the prevalence and characteristics of BilIN. We performed a retrospective study of patients with histologically confirmed CC in Korea University Guro hospital between Jan 2012 and December 2014. Gallbladder cancer, ampullary cancer and combined hepatocellular-cholangiocarcinoma were excluded. In this study, we analyzed the surgically resected specimens of 48 patients who underwent curative resection. Immunohistochemical analysis of MUC2, MUC5AC Ki-67, P53 and SMAD were also examined.
**Results:** Of enrolled 48 patients, 34 patients were extrahepatic CC and 14 were intrahepatic CC. Six patients had invasive carcinoma arising from intraductal papillary neoplasm (IPN). BilIN was found in 58% (28/48) and more frequently in extrahepatic CC, 74% than intrahepatic CC, 21%. In extrahepatic CC, size and gross type of tumor was not different according to BilIN status, but poorly differentiation was less in BilIN positive CC. BilIN1 was 1 case, BilIN2 was 7 cases, and BilIN3 was 20 cases. BilIN was found in 88% of patients with Ki-67 labeling index over 10%, in 65% of patients with p53 overexpression over 5%, and in 71% of patients with loss of SMAD expression. Expression of MUC5AC was observed in 65%, while MUC2 was negative in all patients.
**Conclusion:** BilIN is frequently found in extrahepatic CC. Tumor differentiation and progression was more favorable in BilIN-positive CC than BilIN-negative. Ki-67 is suggested to be related with the malignant transformation of BilIN in carcinogenesis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1179 CLINICAL OUTCOME OF STENT-IN-STENT METHOD IN BILATERAL SELF-EXPANDABLE METALLIC STENT DEPLOYMENT FOR MALIGNANT HILAR BILIARY OBSTRUCTION: TWO-CENTER RETROSPECTIVE STUDY

**H.S. Lee**, J.Y. Heo, S. Bang
*Department Of Internal Medicine, Institute of Gastroenterology, Yonsei University College of Medicine, seoul/Korea, Republic of*

**Contact E-mail Address:** lhs6865@gmail.com

**Introduction:** Endoscopists deploy bilateral self-expandable metallic stent (SEMS) in patients with malignant hilar biliary obstruction by stent-in-stent (SIS) or side-by-side (SBS) method. Especially, recent technical improvements have allowed common use of SIS despite difficulty in deployment. However, previous studies of SIS method showed the diverse duration of stent patency. We investigated that recent data of patency using SIS in bilateral SEMS deployment in patients with malignant hilar biliary obstruction.
**Aims & Methods:** We retrospectively reviewed the patient data in two tertiary hospital, South Korea. We analyzed the clinical outcomes including patent duration and overall survival in patients with malignant hilar biliary obstruction. Multivariate anaysis was performed to find the prognostic factor related with stent patency and overall survival.
**Results:** In total, 70 patients with malignant hilar biliary obstruction underwent SIS deployment in this study between 2011 and 2015. Median age was 67 years old and median follow-up duration was 126 days. The Bismuth classification was as follows: type II, 13 (18.6%); type III, 17 (24.3%); type IV, 40 (57.1%). There were 35 (50.0%) stent occlusion events during follow-up period. Complications related with biliary stent insertion occurred in 17 (22.4%) patients. The median stent patency and survival were 108 and 189 days, respectively. On multivariate analysis, early complication and baseline bilirubin level were independent prognostic factors related to stent patency (HR 3.105, 95% CI 1.125–8.571, $P = 0.029$; HR 2.431, 95% CI 1.123–5.186, $P = 0.024$). High-grade hilar biliary obstruction was a significant risk factor for stent patency.

| Variables | Values |
|---|---|
| Gender (male/female) | 38/32 |
| Age, years | 68.0 ± 12.3 |
| Diagnosis | |
| Cholangiocarcinoma | 37 (52.9%) |
| Gallbladder cancer | 22 (31.4%) |
| Others | 11 (15.7%) |
| Bismuth classification | |
| II | 13 (18.6%) |
| III | 17 (24.3%) |
| IV | 40 (57.1%) |
| Previous stenting | |
| Plastic | 25 (35.7%) |
| Metal | 2 (2.9%) |
| Baseline total bilirubin | 6.1 ± 11.1 |
| Baseline ALP | 450.0 ± 354.8 |
| Treatment | |
| Yes | 38 (56.4%) |
| No | 32 (43.6%) |

**Conclusion:** The stent patency of SIS method in bilateral SEMS insertion was low compared to previous results. We need further study and alternative option for patients with high-grade malignant hilar biliary obstruction.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Various studies indicate potential involvement of various populations of bone marrow derived stem cells (BMSCs) in the process of tissue regneration. Phenomen of BMSCs mobilization to the peripherial blood was recently described, inter alia, in patients with stroke, heart infarction, Crohn's disease and pancreatic cancer [1].Moreover, studies on animal models show involvment of BMSCs in the process of pancreatic regeneration [2,3].However, the precise mechanisms of BMSCs mobilisation to peripherial blood and tissues and their role in pathogenesis of pancreatic disorders in humans is still a subject of reasearch.
**Aims & Methods:** Comprehensive analysis of circulating populations of BMSCs: mesenchymal, hematopoietic, endothelial progenitor cells (MSCs, HSCs, EPCs, respectively) as well as population of very small embryonic like stem cells (VSELs) in patients with acute and chronic pancreatitis in relation to controls, clinical setting and selected chemoattractants for stem cells. 35 patients; 18 with acute (AP), 17 with chronic pancreatitis (CP), and 31 healthy controls were included to the study. The absolute numbers and the percentage of 10 populations of BMSCs: HSCs (CD45+/Lin-/CD133+, CD45+/Lin-/CD34+), MSCs (CD45-/Stro-1+/CD105+, CD45-/Stro-1 -/CD105+, CD45-/Stro-1+/CD105-, CD45-/CD90+/CD29+), EPCs (CD45-/CD31+/ CD133+, CD45-/CD31+/CD34+/KDR+,) and small CD45-/CD31-/CD133+, CD45-/Lin-/CD34+ cells that correspond to VSELs, were enumerated and counted in peripheral blood with flow cytometry (FACS). The serum concentrations of chemoattractive factors (stromal derived factor 1-$\alpha$, sphingosine-1-phosphate, complement proteins, hepatocyte growth factor) were measured by ELISA.
**Results:** A significant mobilization of circulating VSELs (Lin-CD45-CD34+) in patients with AP comparing to controls was observed ($p = 0.012$). This phenomenon strongly correlates with high concentrations of HGF ($p = 0.008$). The decrease of circulating other stem cells as HSCs,(Lin-CD45+CD133+) subpopulation and MSCs, both CD45-STRO-1+CD105- and CD45-CD90+CD29+ subpopulations in AP patients was noted ($p = 0.022$, $p = 0.040$, $p = 0.026$). In contract, in patients with CP only decrease of HSCs (Lin-CD45+CD133+)($p = 0.011$) and EPCs (CD45-CD31+CD34+)($p = 0.004$) was observed.
**Conclusion:** The results suggest that VSELs could play a role in the regeneration of pancreatic tissue in acute pancreatitis with HGF as a chemoattractive factor. The mobilization of BMSCs to the peripheral blood, in pancreatic inflammatory disorders seems to be associated only with acute pancreatitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chemerin is an immunomodulatory protein secreted mainly by adipocytes and skin cells. This adipokine stimulates chemotaxis of macrophages and NK cells toward the site of inflammation, but on the other hand, chemerin has been shown to reduce synthesis of pro-inflammatory cytokines. Chemerin signal was detected in the pancreas and this adipokine is involved in the insulin secretion, but the role of chemerin in the pancreatic inflammation is unknown.
**Aims & Methods:** To determine the effects of chemerin on caerulein-induced pancreatitis (AP) in the rats and on the nuclear factor kB (NF-kB) and tumor necrosis factor alpha (TNFalpha) protein signals in AR42J pancreatic acinar cell line. AP was induced by subcutaneous caerulein infusion (25 microgr/kg). Chemerin (1, 5, or 10microgr/kg was given intraperitoneally to the rats 30 min prior to the induction of AP. Blood samples were taken for evaluation of amylase and TNFalpha concentrations. Protein signals of NF-kB and TNFalpha were determined by Western blotting in AR42J pancreatic cells subjected to chemerin ($10^{-12}$, $10^{-10}$, $10^{-8}$ M) without or with addition of caerulein ($10^{-8}$ M).
**Results:** AP was confirmed by histological examination and by the increases of amylase and TNF alpha blood levels (by 600% and 300%, respectively). Chemerin markedly diminished histological manifestations of AP and decreased amylase and TNFalpha blood levels. In AR42J cells chemerin decreased protein signals for NF-kB p65 and TNFalpha induced by caerulein ($10^{-8}$ M).
**Conclusion:** Chemerin attenuated acute pancreatitis and this effect could be related, at least in part, to the reduction of proinflammatory pathway in pancreatic acinar cells.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1182 DEVELOPMENT OF ACUTE PANCREATITIS PORCINE MODEL BY USING ENDOSCOPIC RETROGRADE NOXIOUS AGENT INFUSION

**Introduction:** Acute pancreatitis is an inflammatory disorder that affects the pancreas and surrounding organ. About 85% to 80% of acute pancreatitis patients show a benign clinical course, which is relatively easy to cure and responds well to conservative treatment. Meanwhile, the other 15% to 20% of patients develop a severe hemorrhagic necrotizing pancreatitis, follows a grave clinical course that is more often accompanied by multi-organ failure despite intensive careful treatment or surgery. However, effective specific treatment strategies are limited due to a poor understanding of its exact pathogenesis. A better understanding of the pathogenesis of acute pancreatitis may lead to more effective therapeutic options, potentially leading to improved survival. However, access to the pancreas during the different stages of acute pancreatitis is very limited because of the anatomical location of pancreas.
**Aims & Methods:** The aim of this study was to develop an animal model of acute pancreatitis using endoscopic methods. This experimental study was conducted on 6 mini pigs. Pancreatitis models were induced by pressure-controlled (1.000 or 100 mmHg) infusion of contrast media or sodium taurocholate (TCA) into the main pancreatic duct using endoscopic retrograde pancreatography. The animals were randomly allocated into three groups: (1) contrast-induced pancreatitis (2) 10% TCA-induced pancreatitis, (3) 20% TCA-induced pancreatitis. Injury of the pancreas was evaluated histologically. Serum amylase and lipase level were measured.
**Results:** Endoscopic procedures were performed successfully in all animals. No technical difficulty or adverse events occurred during the procedures. Acute pancreatitis in all animals was observed on hematologic and histologic examination. There was a significant increases in serum amylase and lipase levels (>10 times of baseline level) and they observed increases in pancreatic edema formation, vacuolization of acinar cell, and hemorrhagic necrosis. Degree of pancreatitis in the TCA (the mean histologic acute pancreatitis score, 10) groups tended to be greater than contrast-induced group (6.5). An analysis of degrees of pancreatitis according to concentration of TCA showed that the

higher concentration of TCA, the more severe pancreatitis was occurred (necrosis score in 20% TCA vs. 10% TCA, 4 vs. 2.5)
**Conclusion:** The two endoscopic procedures described are effective and safe for creating a swine model of acute pancreatitis. We estimated that these endoscopic methods could be helpful for developing the treatment strategy of acute pancreatitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1183 ACENOCOUMAROL ACCELERATES RECOVERY IN ISCHEMIA/REPERFUSION-INDUCED ACUTE PANCREATITIS

**Introduction:** Coagulation is one of the mechanisms of hemostasis. Its activation causes the clot formation to prevent blood loss from a damaged vessel. Coagulation disorders may take the form of insufficient or excessive clotting. Insufficient clotting can result in bleeding or hemorrhage; whereas excessive activation of clotting can lead to thrombosis and/or disseminated intravascular coagulation (DIC). Moreover, there is close bidirectional relationship between coagulation and inflammation. Activation of the coagulation induces inflammation, but at the same time the development of the inflammatory process activates the clotting cascade. Previous studies have also shown that coagulative disorders occur in acute pancreatitis and are related to the severity of this disease.
**Aims & Methods:** Aim of the present study was to examine whether administration of acenocoumarol affects the course of ischemia/reperfusion-induced acute pancreatitis. Materials & Methods: Acute pancreatitis was induced in anesthetized rats by pancreatic ischemia followed by reperfusion. Saline or acenocoumarol at the dose of 50, 100 or 150 $\mu$g/kg/dose were administered intragastrically once a day, starting the first dose 24 h after the initiation of pancreatic reperfusion.
**Results:** Morphological features of pancreases showed that treatment with acenocoumarol reduces pancreatic edema, necrosis, and hemorrhages. Also, a decrease in pancreatic inflammatory infiltration and vacuolization of pancreatic acinar cells was observed in rats treated with acenocoumarol. These findings were accompanied with a reduction in serum activity of lipase and amylase, serum concentration of interleukin-1$\beta$ and plasma D-dimer concentration. Moreover administration of acenocoumarol improved pancreatic blood flow and pancreatic DNA synthesis. Acenocoumarol given at the dose of 150 $\mu$g/kg/dose was the most effective in the treatment of early phase of acute pancreatitis; however later, acenocoumarol given at the highest dose failed to exhibit any therapeutic effect; whereas lower doses of acenocoumarol were still effective in the treatment of acute pancreatitis.
**Conclusion:** Administration of low doses of acenocoumarol after the development of acute pancreatitis accelerates recovery in this disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1184 PROTECTIVE MECHANISMS OF N-ACETYL-CYSTEINE AND SIMVASTATIN AGAINST CHRONIC PANCREATITIS: AN EXPERIMENTAL STUDY IN MICE

**Introduction:** Although anti-oxidants and anti-fibrotic agents could act as therapeutics in chronic inflammation, its effect is still unclear in chronic pancreatitis (CP). In our previous study, we investigated that simvastatin as anti-fibrotic agent was effective to modurate of cell proliferation in pancreatic stellate cells.[1] However, its effect and mechanism in CP was not proven in vivo. And developing an appropriate animal model of CP is also challenging.
**Aims & Methods:** In this study, we compared animal models of CP and investigated the therapeutic effect of N-acetyl-cysteine (NAC), an antioxidant, and simvastatin, an anti-fibrotic agent, on CP. Animal models of CP were generated by repeated intraperitoneal injection of cerulein (50 ug/kg) in BALB/c and C57BL/6 mice, hourly for 6 hours, thrice a week, for 4 or 8 weeks. Pancreatic weights, pancreas/body weight ratios, and histopathologic findings were compared. Using the best animal model, we evaluated the therapeutic effect of NAC and simvastatin alone or in combination on CP by assessing pancreas/body weight ratios, histopathologic findings (H&E and Sirius red staining), and western blot analysis [$\alpha$-SMA, collagen type I, and extracellular signal related kinase (ERK) 1/2].
**Results:** The pancreatic weight was significantly lower in C57BL/6 than in BALB/c mice with CP. Atrophic changes appeared earlier in C57BL/6 mice, their pancreas/body weight ratio was significantly different after 4 weeks of treatment. The pancreas/body weight ratio was about 1% in the control C57BL/6 mice and about 0.6% in mice with CP. In this experimental CP model using C57BL/6 mice, NAC and NAC + simvastatin combination therapy effectively prevented pancreatic atrophy (NAC group, 0.78%; NAC + simvastatin group, 0.82%). Acinar cell atrophy was alleviated by administration of NAC and/or simvastatin. Additionally, the fibrosis area was significantly reduced by NAC and/or simvastatin treatment. While cerulein administered mice showed a 5.6 fold increase in the pancreatic fibrosis area when compared to that of control mice, NAC and/or simvastatin treatment significantly decreased fibrotic changes against cerulein-induced pancreatic damage. ERK 1/2 and $\alpha$-SMA expressions were significantly decreased by NAC + simvastatin treatment, but not significant in collagen type I.
**Conclusion:** The C57BL/6 mouse is a better model of CP generated by intraperitoneal injection of cerulein (50 ug/kg), hourly for 6 hours, thrice a week, for 4 weeks. NAC and simvastatin alone or in combination have therapeutic effects against CP. And, the inhibition of ERK pathway would be one of the targets for treatment of CP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** About 20% of acute pancreatitis (AP) cases are severe with considerable mortality rate of 10–25%. Despite several scoring systems and markers used, none are offering high sensitivity and specificity in identifying patients with a high risk of severe acute pancreatitis.
**Aims & Methods:** This study aimed to evaluate intestinal fatty acid binding protein (i-FABP) as potential marker for severity assessment and prediction of AP. The study was designed as part of the Pancreas 2000 educational program. Patients with AP were prospectively included at 5 clinical centers the years 2010–2012. Local complications were confirmed by performing abdominal CT. Severity of AP was determined based on 1992 Atlanta criteria[1] as data was collected before the revision of Atlanta classification. Serum i-FABP levels at day 1 and 3 of AP were determined using ELISA. Mann-Whitney U-test, Chi-square, Multivariate logistic regression analysis and ROC curve tests were used for statistical analysis.
**Results:** In the cohort of 402 patients (253 men, 149 women), 65 patients had severe AP. Serum i-FABP levels at day 1 were significantly higher in patients with pancreatic necrosis (median – 698 pg/mL vs 342 pg/mL), in patients having systemic complications (median – 501.5 pg/mL vs 382.5 pg/mL), in patients treated invasively (median – 549.5 pg/mL vs 379.5 pg/mL) in patients treated in ICU (median – 578 pg/mL vs 372 pg/mL) in patients with severe AP (median – 638.5 pg/mL vs 353 pg/mL) and in deceased patients (1073 pg/mL vs 382.5 pg/mL). i-FABP levels at day 1 yielded an AUC of 0.732 with an optimal cut-off value of 537 pg/mL in discriminating patients with pancreatic necrosis (sensitivity - 73.3%, specificity of 70.2%, negative predictive value (NPV) – 96.6%, positive predictive value (PPV) – 18.6%). Furthermore, i-FABP levels at day 1 of AP provided AUC of 0.669 with an optimal cut-off value of 465.5 pg/mL in predicting severe AP (sensitivity - 62.7%, specificity - 64.2%, NPV – 89.21%, PPV – 26.66%). Multivariate logistic regression analysis revealed that a model including i-FABP levels at day 1, lactate levels, CRP at day 2 was superior to either of these markers used alone in predicting severe AP – AUC of 0.874 (sensitivity - 41.6%, specificity - 96.64%, NPV – 85.1%, PPV – 78.26%).
**Conclusion:** Higher i-FABP levels on day 1 of AP were associated with pancreatic necrosis, systemic complications and severe AP. i-FABP levels on day 1 had a high negative predictive value for pancreatic necrosis and severe AP. Combination of several markers, including i-FABP, in predicting severe AP was superior to either of markers used alone.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1186 COMPARING HAPS AND BISAP SCORES IN PREDICTING SEVERITY AND OUTCOME IN ACUTE PANCREATITIS

**A. Yelsangikar**, P. Kakkadasam Ramaswamy, A. Nagar Krishnamurthy, N. Bhat
*Gastroenterology And Liver Diseases, Aster CMI Hospital, Bangalore/India*

**Contact E-mail Address:** amitgy@gmail.com

**Introduction:** The Bedside Index for Severity in Acute Pancreatitis (BISAP) and Harmless Acute Pancreatitis Score (HAPS) have been shown to be useful for predicting the severity of acute pancreatitis. BISAP score comprises Blood urea nitrogen >25 mg / dl, Impaired mental status, Systemic inflammatory response syndrome (SIRS), Age > 60 years, and Pleural effusion. HAPS is considered positive when there is no rebound tenderness, normal hematocrit and a normal creatinine.

**Aim**: The aim of this study was to compare the performance of BISAP with HAPS in predicting severity, mortality, length of hospital stay, ICU stay, organ failure, infections and need for interventions in patients with acute pancreatitis (AP).

**Methods**: Clinical and laboratory data from consecutive patients with AP admitted to our institution between June 2013 and July 2015 was retrospectively analyzed. The BISAP score and HAPS were calculated at admission. Patients were classified into mild, moderately severe or severe acute pancreatitis as per the Revised Atlanta classification.

**Results:** Seventy-five patients with AP were included in the study, with a mean age of 40.3 years (of which 81.3% were male). Forty-three patients (57.3%) had mild AP and 32 patients (42.7%) developed moderately severe or severe acute pancreatitis. Overall, 3 (4%) patients died, 11 patients (14.67%) developed infections and 16 patients (21.3%) developed organ failure. BISAP ≤ 1 and HAPS positive at admission accurately predicted a mild course of acute pancreatitis in 83.7% (AUROC 0.92, Accuracy 85.33%) and 88.3% (AUROC 0.95, accuracy 90.67%) of patients, respectively. The sensitivity, specificity, PPV and NPV of BISAP ≤ 1 for predicting a mild course was 83.7% (95% CI 69.3 to 93.1%), 87.5% (95% CI 71–96.5%), 90% (CI 76.3 to 97.2) and 80% (CI 63 to 91.5%) respectively. In comparison, HAPS had a PPV of 95% (95% CI 83 to 99.3%), NPV of 85.7% (95% CI 69.7 to 95.1%), sensitivity of 88.3% (95% CI 74.9 to 96.1%) and specificity of 93.7% (95% CI 79.1 to 99.2%). Patients with BISAP ≤ 1 or HAPS positive had a significantly shorter hospital and ICU stay, lower risk of infection and organ failure when compared to BISAP ≥ 2 or HAPS negative (Table 1). However they did not predict mortality. HAPS positive at admission had significantly fewer interventions.

**Conclusion:** HAPS and a BISAP are accurate for risk stratification in patients with acute pancreatitis and can be used for patient triage and predicting outcomes. HAPS positive and BISAP ≤ 1 at admission accurately predict a mild course of acute pancreatitis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1187 INFLUENCE OF FATTY LIVER ON THE CLINICAL OUTCOME IN ACUTE PANCREATITIS

**I. Mikolasevic**, L. Orlic, D. Stimac, I. Jakopcic, A. Klanac, S. Milic
*UHC Rijeka, Rijeka/Croatia*

**Contact E-mail Address:** ivana.mikolasevic@gmail.com

**Introduction:** Acute pancreatitis (AP) is a common disease in the departments of gastroenterology with the variable severity, from being mild and self-limited to severe and fatal. During the last decades, the rate of death has not significantly declined, in spite of development of modern medicine. Therefore, the early recognition of high-risk patients is of a great interest. The aim of our study was to investigate the relationship between the presence of fatty liver disease and the course of AP determined by disease severity, the presence of local and systemic complications and survival rate.

**Aims & Methods:** A total of 1028 patients with the diagnosis of AP were initially evaluated in the period from January 1, 2008 up to June 31, 2015. Of the 1028 included patients, 138 patients were excluded due to alcoholic etiology of AP. Of the remaining 890 patients with AP, 68 were excluded due to uncertain etiology of AP. A total of 822 patients with AP were included in the final analysis. The most common etiology of AP was biliary (83.7% of patients). The diagnosis and the severity of AP were made according to the revised Atlanta classification criteria from 2012. Fatty liver disease was assessed by multislice computed tomography (MSCT) and/or magnetic resonance cholangiopancreatography (MRCP). Therefore, nonalcoholic fatty liver disease (NAFLD) was diagnosed by the presence of following findings: steatosis was detected by imaging (MSCT and/or MRCP); alcoholic etiology of AP was excluded; patients with specific disease or therapy than can lead to steatosis were not a part of this analysis.

**Results:** Of 822 patients with AP, 198 fulfilled the criteria for NAFLD. There was no significant difference due to age, gender, presence of coronary heart disease, chronic kidney disease as well as due to etiology of AP (biliary, hypertrygliceridemia and other etiologies of AP) between the patients with NAFLD and those without fatty liver (FL). Patients with NAFLD had statistically significantly higher incidence of arterial hypertension (54.5% vs. 43.3%; p = 0.007), diabetes mellitus type 2 (22.7% vs. 9.6%; p < 0.001), dyslipidemia (22.2% vs.8.2%; p < 0.001), as well as higher values of body mass index (29.1 ± 4.6vs. 27.3 ± 4.6; p < 0.001) and waist circumference (105.4 ± 13.6vs. 100.1 ± 13.1; p = 0.0003). Patients with NAFLD had a higher values of APACHE II score at admission, as well as higher levels of C-reactive protein (CRP) at the admission, as well as higher levels of CRP at day three in comparison to the AP patients without FL. Additionally, NAFLD patients had higher incidence of local (0.9 ± 0.9 vs. 0.3 ± 0.7; p < 0.0001) and systemic (0.4 ± 0.8 vs. 0.2 ± 0.6; p = 0.002) complications, as well as higher values of CT severity index (2.9 ± 2.9 vs. 1.1 ± 2; p < 0.0001) in comparison to those without NAFLD. Patients with NAFLD had a statistically longer total hospital stay (15.4 ± 10.6 vs. 12.9 ± 8.2; p = 0.0006), higher dependency unit stay (4.5 ± 3.6 vs. 3 ± 3.2; p < 0.0001) and had a statistically longer stay in intensive care unit (1.0 ± 5.1 vs. 0.3 ± 1.9; p = 0.004) in comparison to the patients without FL. Comparing survival rates, AP patients suffering from NAFLD had a higher death rate compared to patients without NAFLD (5.6%vs. 4.3%; p = NS), although that difference was not statistically significant.

**Conclusion:** The presence of NAFLD at admission portends a higher risk of moderately severe and severe AP. Patients with NAFLD developed more local and systemic complications in AP. NAFLD patients also had higher mortality rate (although that was not statistically significant) and longer duration of hospital stay, as well as longer stay in intensive care unit. Therefore, the presence of fatty liver in patients admitted because of acute pancreatitis may play a prognostic role in these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1189 FAT GLOBULES WITHIN ORGANIZED PANCREATIC FLUID COLLECTIONS ON CT SCAN IMPACT THE OUTCOMES OF NONSURGICAL DRAINAGE

**Introduction:** T2-weighted MRI is the most accurate means of quantifying debris in organized pancreatic fluid collections (PFC) but is rarely obtainable over computed tomography (CT) prior to drainage. Debris within PFC represents necrosis of pancreatic fat and its presence can affect the approach to drainage.

**Aims & Methods:** To assess whether the presence of fat globules in PFCs on CT scan impacts the outcomes of non-surgical drainage. Patients with an organized PFC as well as CT scan obtained at least 4 weeks after their episode of acute pancreatitis between 1/1993 and 1/2015 were identified using an administrative database. CT scans were interpreted by single radiologist for the presence of fat globules defined as foci of fat attenuation. For those patients undergoing non-surgical drainage (endoscopic and/or percutaneous), differences in technical and clinical success in terms of completion of procedure, resolution in PFC size (<50% reduction) and need for reintervention (the need for a repeat procedure for the same PFCs) were assessed between the PFCs with or without fat globules. Analysis was conducted using Pearsons Chi Square test or Fisher's exact tests for categorical variables and student's t test for continuous data.

**Results:** There were 58 patients identified with a mean age of 53.76 ± 15.08 years and 35 (60.3%) males. There were 77 PFCs evaluated as 13 patients had more than one PFC. There were 22 (29%) PFCs that spontaneously resolved whereas 55 (61%) PFCs required drainage after a mean of 24.5 ± 44.7 days from the time of PFC diagnosis. Fat globules were seen in 35 (45%) PFCs on CT with 21 PFCs drained endoscopically, 5 drained using

both endoscopic and percutaneous approach and 2 drained percutaneously as compared to 42 (55%) PFCs with no fat on CT of which 12 were drained endoscopically, 14 were drained percutaneously and 1 was drained using both endoscopic and percutaneous drainage ($p = 0.03$). Technical success was achieved in all PFCs. Among the PFCs with fat globules, 12 were endoscopically drained using lumen-apposing metal stents (LAMS) and 8 using double pigtail plastic stents versus 6 and 4 in PFCs without fat globules, respectively ($p = 0.001$). There were 9 PFCs with fat globules that required reintervention as compared to 3 PFCs without fat ($p = 0.024$). PFCs containing fat globules resolved after a mean time of $57.30 \pm 46.81$ days as compared to PFCs without fat globules which resolved after $29 \pm 25.1$ days ($p = 0.003$)

**Conclusion:** PFCs containing fat globules on CT scan more commonly required LAMS, combined drainage modalities, multiple interventions, and had a significantly longer duration to resolution as compared to PFCs without fat globules. Fat globules seen within PFCs on CT scan helps endoscopists with pre-procedure planning, thereby avoiding requirement of MRI to differentiate PFCs into walled-off necrosis or pseudocyst.

## P1190 THE ROLE OF SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR AS AN EARLY BIOMARKER OF SEVERITY AND ORGAN FAILURE IN PATIENTS WITH ACUTE PANCREATITIS

**A. Soleimani**[1], L.T. Sørensen[1], M.B. Hansen[2], S. Ladelund[3], J. Eugen-Olsen[3], L. N. Jorgensen[1], S. Novovic[4]

**Contact E-mail Address:** 18amisol@gmail.com

**Introduction:** Acute pancreatitis (AP) is an inflammatory condition with a high mortality rate in the severe cases. Conventional biomarkers like C-reactive protein (CRP) fall short in their ability to predict severity in early-phase AP. We assessed suPAR, a soluble urokinase plasminogen activator receptor (suPAR), as an early prognostic biomarker in AP with respect to disease severity, organ failure and mortality.

**Aims & Methods:** During a 15-month period, 75 patients with their first episode of AP were prospectively enrolled in the study. Blood samples were drawn on day of admission, day 1, 2 and 14 and debut of symptoms were recorded. Data was collected from the medical records for age, gender, alcohol intake, smoking, medications, organ function and need for intensive care unit (ICU).

**Results: Results:** suPAR levels were significantly related to ICU ($p = 0.013$) and renal failure ($p = 0.021$) but we found no association to multi organ failure (MOF). There was a significant association between suPAR levels at admission and mortality ($p = 0.004$). A subgroup analysis of AP demonstrated a significant increase in suPAR over time in patients with other causes of AP than alcohol and gallstone (p=0.015). However, for all comers with AP, suPAR levels didn't change significantly over time.

**Conclusion:** Our results suggest, that although suPAR is associated with disease severity and organ failure, it has poor predictive potential in AP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Mutations in the human cationic trypsinogen gene (PRSS1) are associated with hereditary chronic pancreatitis. The most frequent mutations (p.R122H, p.N29I and p.A16V) cause early activation of trypsinogen inside the pancreas. Family members carrying these mutations develop chronic pancreatitis usually in childhood. Inheritance of chronic pancreatitis in these families follows an autosomal dominant pattern with incomplete penetrance. A subset of rare mutations such as p.L104P seem to exert their effect by causing trypsinogen misfolding and endoplasmatic reticulum stress. However, whether misfolding-causing mutations casue hereditray pancreatitis or sporadic disease only has remained unclear.

**Aims & Methods:** Our aim was to establish the association between the PRSS1 p.L104P mutation and the development of hereditary chronic pancreatitis in a Hungarian family. Genetic testing was performed in all family members who signed informed consent. Peripheral blood or buccal swabs were collected and genomic DNA was isolated. Sanger sequencing was carried out in all exons of PRSS1, CTRC, SPINK1 and CPA1 genes and in exon 4,10 and 11 of the CFTR gene of the index patient. Sanger sequencing of exon 3 of the PRSS1 gene was carried out in all other family members. Diagnosis of chronic pancreatitis was based on abdominal CT scan, abdominal ultrasound, clinical signs and indirect functional tests.

**Results:** Three members of a Hungarian family with clinically documented idiopathic recurrent acute and chronic pancreatitis carried the rare p.L104P mutation in the PRSS1 gene. First episode of acute pancreatitis was documented over 18 years of age in all cases. The rarely diagnosed pancreatolithiasis was also found in all affected individuals. Four members of the family also carried the same mutation without acute or chronic pancreatitis, however 3 of them are under 18 years of age. Family members without the investigated mutation did not develop pancreatitis.

**Conclusion:** This is the first study showing clear association between the PRSS1 p.L104P mutation and clinically documented hereditary chronic pancreatitis with unusual features of later age of onset and pancreatolithiasis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic ultrasound-guided pancreatic core biopsy (EUS-PCB) has been performed to establish histologic diagnosis of pancreatic disease. Recently Procore® needle with reverse bevel design has become available for EUS-PCB.

**Aims & Methods:** The aim of this study was to evaluate the usefulness of EUS-PCB using Procore® needles for the diagnosis of AIP. From June 2012 and November 2015, a total of 62 patients (18 in a 19-gauge needle group and 44 in a 22-gauge needle group) who were suspected with AIP included.

**Results:** A sample adequate for diagnosis was obtained more in 54 of 62 patients (87.1%). 54 patients (type 1 $n = 46$, type 2 $n = 8$) were diagnosed with AIP. Pancreatic malignancies were excluded in 8 patients (12.9%) by EUS-PCB. Lymphoplamacytic infiltration, storiform fibrosis, and abundant IgG4-positve cells were shown in 53.7% ($n = 29$), 40.7% ($n = 22$), and 48.1% ($n = 26$). Obliterative phlebitis was shown only in 19-gauge group ($n = 4$, 7.4%). Granulocytic epithelial lesions were shown in 3 (37.5%) patients. The 19 gauge group showed significantly more histologic findings than 22-gauge group ($n = 14$, 82.4% vs. $n = 17$, 45.9%, $p = 0.01$). Overall sensitivity, specificity of histologic diagnosis of AIP were 57.4%, 100%. The sensitivity was significantly higher in

**P1194**

| | Type of Needle | Macroscopic Evaluation | Microscopic score |
|---|---|---|---|
| 1 | ECHOTIP PROCORE (20 G) | Fragmented. Presence of core | 9 |
| 2 | SPIROTOME TM | Non-fragmented core | 6 |
| 3 | FRANSEEN LUNG Biopsy Needle (18 G) | Fragmented. Presence of core | 10 |
| 4 | TROCAR NEEDLE (18 G) | Micro fragments | 1 |

**Introduction:** Morphological changes of chronic pancreatitis (CP) are significantly associated with functional alterations of the gland at advanced stages of the disease. This morphological-functional correlation has been shown not to be so evident in patients with early CP. It is well known that pancreatic secretion of enzymes and bicarbonate decreases as the fibrosis degree of the glans increases in CP. We have previously shown that the degree of pancreatic fibrosis in CP can be quantified by endoscopic ultrasound elastography (EUS-E). Pancreatic secretion can be accurately evaluated by the endoscopic pancreatic function test (ePFT), which can be used for the early diagnosis of CP.
**Aims & Methods:** Aim of the present study was to evaluate the correlation between the degree of pancreatic fibrosis and pancreatic bicarbonate secretion in patients with early morphological changes of CP. Methods: A prospective, cross-sectional study was designed. Patients with clinical suspicion of CP and 3–4 EUS criteria of the disease were included. EUS-E was performed with the slim Pentax Echoendoscope (EG-3270UK) and the HITACHI-Ascendus ultrasound equipment. Elastographic strain ratio (SR) was evaluated as the mean SR at the head, body and tail of the pancreas (normal < 2.25). After that, 0.2$\mu$g/kg secretin was intravenously administered and bicarbonate concentration was measured in samples of duodenal juice collected after 15, 30 and 45 minutes (normal peak > 80 mEq/L). Data are shown as mean ± SD and percentages. Correlation between SR and bicarbonate peak was analysed by linear regression.
**Results:** 43 patients were included (mean age 39.9 years, range 18–66, 22 female). 30 patients (69.8%) had 3 EUS criteria of CP, and 13 (30.2%) 4 criteria. Peak bicarbonate concentration was 66.1 ± 27.7 mEq/L. 33 (76.7%) patients had an abnormally low bicarbonate secretion. Mean SR was 3.55 ± 1.01 and it was abnormally high in all patients. Correlation between SR and bicarbonate secretion was highly significant ($r = 0.768$; $p < 0.0001$).
**Conclusion:** There is a strong correlation between the degree of pancreatic fibrosis as evaluated by EUS-elastography and stimulated pancreatic secretion of bicarbonate. These results support the use of EUS-E for the early diagnosis of CP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1194 ACCURACY OF DIFFERENT NEEDLES TO OBTAIN HISTOLOGICAL SAMPLES FROM HEALTHY PANCREATIC TISSUE. A COMPARATIVE EXPERIMENTAL STUDY ON HEALTHY PIGS

**Introduction:** The diagnosis of early chronic pancreatitis remains a clinical challenge, especially in the absence of methods for histologic confirmation. Histological diagnosis could be possible by endoscopic ultrasound (EUS)-guided fine needle biopsy (FNB), but appropriate needles to obtain core tissue samples from a slightly fibrotic pancreas are lacking
**Aims & Methods:** Aim of this study was to evaluate the accuracy of different biopsy needles to obtain core tissue samples from healthy pancreas. Our goal, based on the results of this study, is to design a new EUS needle in collaboration with specialized biomedical engineers.
**Methods:** Pilot, single-blind, comparative, animal study of histological evaluation of FNB samples from healthy pig pancreas. The pancreas of a 2-months aged pig, 22Kg weight, was manually exposed after laparotomy under general anesthesia. Pancreatic samples obtained with nine different needles (Cook-Medical, Limerik, Ireland) were evaluated. Three biopsies were taken from the pancreas with each needle (total of 27 biopsies). A macroscopic descriptive evaluation of the samples was performed. All samples were coded and placed in formalin for blind histological evaluation. Histological quality of samples was scored from 0 to 10 by an expert pathologist on pancreatic cyto-histology, being 0 the absence of sample and 10 a sample suitable for histological and immunohistochemical study. This study was approved by the Ethics Committee of the Veterinary Hospital Rof Codina of Lugo.
**Results:** The table shows the macroscopic and microscopic evaluation of each of the needles evaluated.
**Conclusion:** The echotip-Procore 20 G and the Franseen lung 18 G needles provide very good tissue samples from the healthy pig pancreas. Whether EUS-guided FNB with the echotip-Procore 20 G needle is appropriate for the histological diagnosis of early chronic pancreatitis deserves further clinical research studies.
**Disclosure of Interest:** J. Iglesias-García: International advisor Cook Medical
J.E. Domínguez-Muñoz: International advisor Cook International

### P1195 TREATMENT OF PANCREATIC STONES BY ESWL AND ENDOSCOPY-OUR EXPERIENCE OF 618 CASES IN 26 YEARS

**T. Tsuji**
*Gastroenterology, Saitama Kyoudou Hospital, Kawaguchishi|Japan*

**Contact E-mail Address:** t-tsuji@mcp-saitama.or.jp

**Introduction:** We have experienced 618 cases of pancreatic stone in our hospital over a period of 26 years; 482 alcoholic (male 442, female 40), 77 idiopathic (male 32, female 45),16 hyperparathyroidism,12 hereditary pancreatitis,11

divisum, 7 autoimmune pancreatitis, 6 anomalous pancreatobiliary union, 4 juvenile pancreatitis, 2 post surgical operation and 1 post papilla EMR.
**Aims & Methods:** Usefulness and safety of the medical treatment and their long prognosis were evaluated. 577 cases were treated medically (symptomatic 535, asymptomatic 42). 90 were treated by endoscopy alone, 50 by ESWL alone, and 437 by ESWL and endoscopy. 36 without symptoms had no therapy, and 3 were primarilly treated surgically. 88 cases were treated via minor papilla. 125 cases were complicated with pseudocyts.
**Results:** Stone-free-rate was 75% (462/613), pain-free-rate was 98% (519/535), stone-relapse rate was 6.2% (27/460) and the operation rate after medical treatment was 2.5% (16/577). Endocrine and exocrine function improved in 29%, 30% respectively. Cancer occurred in 21 cases (3.5%) - pancreas 6, lung 6, larynx and pharynx 4, esophagus 1, colon 1, liver 1, kidney 1 and choledochus 1.
**Conclusion:** The medical treatment (ESWL + endoscopy) of pancreas stones is a usuful and safety method with stone-free-rate 75%, pain-free-rate 98%, stone-relapse rate 6.2% without major complications. Patient with pancreatic stone have high risks for pancreatic, lung, laryngo-pharyngeal and esophageal cancer. So careful examination after stone removal is necessary.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Department Of Surgical Oncology, Medical and Rehabilitation Center under the Ministry of Health of Russian Federation, Moscow/Russian Federation*

**Contact E-mail Address:** ozola.zalite@gmail.com
**Introduction:** Over the time in the chronic pancreatitis (CP) patients both endocrine and exocrine insufficiency may develop and lead to different metabolic alterations, malnutrition. Little is known about muscle depletion or sarcopenia and its impact on CP disease course. Sarcopenia might be as a hint to early pancreatic exocrine insufficiency in patients with no specific complaints or negative results of functional tests.
**Aims & Methods:** Aim of the study was to evaluate the prevalence of sarcopenia, analyzed by additional measures of computed tomography (CT) imaging scans, in CP patients, as well it influence on the course of disease. The study was multicenter retrospective cohort study with data inclusion for one year time period, year 2015. Body constitution were analyzed by additional measurements of CT examinations. ImageJ v1.49q standard program (National Institutes of Health) for CT image analysis was used. The third lumbar vertebra (L3) was selected as the standard landmark measurements, chosen these image-level axial cuts. Muscular, visceral, subcutaneous and intramuscular adipose tissue areas were measured. Values were normalized for height to get the lumbar skeletal muscle index in $cm^2/m^2$. Sarcopenia cut-off values were used: 52.4 $cm^2/m^2$ for men, 38.5 $cm^2/m^2$ for women. Data about pancreas morphological changes by CT imaging, BMI, endocrine and exocrine insufficiency status were collected, sarcopenia influence was evaluated.
**Results:** The study included 140 patients with mean age 48 years (range 30–82 years); 98 males, 42 females. Assessing by CT images (according to the Cambridge classification) patient's morphological changes of the pancreas - 41 patients were marked, 76 patients – moderate, 23 – mild. Mean skeletal muscle indexes were 44.08 $cm/m^2$ for men, 38.55 for women $cm/m^2$. Sarcopenia was found in patients with chronic pancreatitis in 69% (96 patients). In patients with normal BMI sarcopenia was in 81% (57 patients, $n = 70$), with underweight 70% (7 patients, $n = 10$), with overweight and adiposity 53% (24 patients, $n = 45$; 8 patients, $n = 15$) ($p = 0.02$). Sarcopenia was not found significantly more often in patients with marked changes in the CT exam according to Cambridge classification ($p = 0.06$). No significant differences of sarcopenia in patients with diabetes mellitus ($n = 28$), proven exocrine insufficiency with enzyme supplementing therapy ($n = 16$) were found.
**Conclusion:** Sarcopenia was found quite often (69%) in patients with CP. Even in patients with normal or higher BMI, muscles depletion still was observed (53 – 70%). Proven sarcopenia might be an additional indication for more intense approach with enzyme replacement therapy and nutritional support, also physical activity and exercises could give improvement for CP therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1197 COMPARISON BETWEEN ENDOSCOPIC AND SURGICAL DRAINAGE OF THE PANCREATIC DUCT IN CHRONIC PANCREATITIS

**Y. Kawaguchi**, T. Mine
*Gastroenterology, Tokai University School of Medicine Dept. of Gastroenterology, Isehara/Japan*

**Contact E-mail Address:** y711kawa@is.icc.u-tokai.ac.jp
**Introduction:** Treatment of recurrent chronic obstructive pancreatitis is pancreatic duct decompression with endoscopic drainage (endoscopic pancreatic stenting [EPS] with extracorporeal shockwave lithotripsy [ESWL]) or surgical drainage. Despite the recent popularization of endoscopic treatment, treatment or stent removal is difficult in many patients. We compared the efficacy, safety, and medical cost of endoscopic and surgical treatments.
**Aims & Methods:** We retrospectively compared the treatment course and medical cost of hospitalization between 41 patients who had undergone pancreatic stenting between 2006 and 2010 and could be followed up for 1 year or longer (EPS group) and 10 patients who had undergone surgery for poor control of pancreatitis between 2001 and 2005 and could be followed up for 1 year or longer (surgery group). The EPS group included 35 men and 6 women with a mean-± standard deviation age of 59 ± 14 years who had a stenosis at the pancreatic head. The causes of recurrent chronic pancreatitis (CP) were alcohol consumption in 35 patients, pancreas divisum in 3 patients, postoperative anastomotic stenosis in 1 patient, and idiopathic in 2 patients. The surgery group included 5 men and 5 women with a mean ± standard deviation age of 49 ± 16 years. The causes of recurrent CP were alcohol consumption in 8 patients, postoperative anastomotic stenosis in 1 patient, and idiopathic in 1 patient. The types of surgery were pylorus-preserving pancreaticoduodenectomy (PpPD) in 6 patients, distal pancreatectomy (DP) in 2, and the Beger procedure in 2.
**Results:** In the surgery group, the patients were younger ($P = 0.07$) and the ratio of women to men was higher ($P = 0.03$) compared to the EPS group. No intergroup differences were observed in causes, symptoms, disease duration, smoking history, or endocrine and exocrine functions. The technical success rate was 100% in both groups, and pain was improved in all of the patients in the two groups. The incidences of complications did not differ significantly, and the mortality rate was 0% in both groups. The stents could be removed in 25 (61%) and maintained in 16 (39%) of 41 patients with stent placement. The mean stent placement period in the patients in whom stent removal was possible was 516 days (93–1438 days), the mean frequency of stent replacement was 2.7 (0–9 times), and the frequency of concurrent ESWL was 1.6 times. The mean medical cost of hospitalization was 1,350,130 yen. The mean stent placement period in the patients with continuous stenting was 1396 days (436–2534 days), the mean frequency of stent replacement was 8.2 times (2–17 times), the mean frequency of concurrent ESWL was 3.2 times, and the mean medical cost of hospitalization was 3,357,080 yen. Significant differences were noted for all four items ($P = 0.02$, $P < 0.01$, $P = 0.04$, and $P < 0.01$, respectively). In the surgery group, none of the patients underwent reoperation. However, 2 patients were rehospitalized (1 for stomal ulcer and 1 for sub-ileus). The rehospitalization rate was significantly higher in the EPS group (78%) than in the surgery group (20%; $P < 0.01$). This was considered attributable to rehospitalization for stent replacement. The effect to improve endocrine and exocrine functions was not different between the two groups before and after treatment, and the current condition was maintained in 80% or more of the patients. For the entire EPS group, the mean hospitalization period was 18 days and the mean medical cost of hospitalization was 2,133,330 yen. For the entire surgery group, the mean hospitalization period was 23 days and the mean medical cost of hospitalization was 2,246,548 yen, with no significant differences between the two groups.
**Conclusion:** Although both endoscopic and surgical treatments achieved high symptom control and safety rates, hospitalization is required for stent replacement, which leads to poor cost-effectiveness, particularly in patients in whom stent removal is difficult. Hence, surgery should also be considered.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Aberrant activation of the Ras pathway exists in many human tumors, such as pancreatic (PC) (90%) and colorectalcancers (CRC) (40%). Ras mutations have been associated with increased tumorigenicity. However, development ofdirect and in direct inhibitors has not proved to be effective. We propose to exploits the hyperactive Ras pathway. Wepreviously reported that recombinant adenoviruses, carrying a pro-apoptotic gene (PUMA) under the regulation of Ras-responsive elements suppressed the growth of cancer cells harboring hyperactive Ras. Moreover, we had shown thatby replacing PUMA with more potent toxins, such as the bacterial MazF-MazE toxin-antitoxin regulated system, thepotency of this killing strategy was significantly improved (Shapira et al,2015). P53 is a classical tumor suppressor, it'smutated in many malignancies (PC 75%, and CRC 60%)
**Aims & Methods:** To establish a tight control dual system based on the Ras and p53 responsive elements. Adenoviral vectors carrying the toxin (PY4-MazF-mcherry) and the antitoxin (RGC-MazE-IRES-GFP) were designedunder the regulation of Ras responsive elements and p53 responsive elements, respectively. Those two constructswere cloned into a "first generation" ΔE1/ΔE3 human type-5 adenoviral-vector. Virus particles were produced, theirtiter was calculated by the End-Point Dilution Assay and their potency was tested in vitro. Cell death was measuredqualitatively by using the fluorescent microscopy and was quantified by the enzymatic MTT assay. SHP77;Rasmut/p53mut, H2030;Rasmut/p53wt, H1650;Raswt/p53wt and H1975;Raswt/p53mut-lung cancer cell lines were used as amodel system for testing the potency of the

adenoviruses-based system. Mia Paca2, Colo357, Panc1;Rasmut/p53mut, and BxPC3; Raswt/p53mut-PC cell lines were tested as well. Co-infection assays were performed on our modelsystem in different toxin-antitoxin ratios (2:1, 1:1 and 1:0.5)
**Results:** Massive cell death was induced in a dose-dependent manner; 70% with a titer of 7.5 MOI in cells with hyper-activatedRas, compared to 21% in cells with WT Ras. The cytotoxic effect of the toxin was qualitatively confirmed byfluorescence microscopy. Similar therapy in PC lines expressing mutated Ras showed 50% cell death in a dosedependentmanner with a titer of 15 MOI, compared to 18% in cells with WT Ras. Co-infection with MazF andMazE encoded viruses, using the optimal 1:0.5 ratio, showed decrease in the mortality of the mutated Ras cellsexpressing WT p53; 36% with a titer of 7.5 MOI. These results indicate that cells that expressed the toxin wereprotected by the anti-toxin expressed under the p53 responsive element
**Conclusion:** Outside the box cancer gene therapy by exploiting activate Ras and P53 pathways are effective in vitro.The low toxicity in WT Ras as well as WT p53 expressing cells allows selective and safe therapy of cancer cells

## P1199 GSK3B INHIBITOR DOWN-REGULATES PD-L1 IN KRAS-MUTANT PDAC THROUGH INHIBITING NF-KB

**W. Shibata**, S. Nagayama, T. Sato, Y. Ishii, M. Sugimori, E. Kameta, S. Sue, S. Maeda
*Gastroenterology, Yokohama City University, Yokohama/Japan*

**Contact E-mail Address:** wshibata-tky@live.jp
**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) is the sixth leading cause of cancer death in the world, with a 5-year survival rate of less than 5%. Recent reports suggested that overexpression of programmed cell death ligand 1 (PD-L1), known as a ligand for PD-1, showed poor prognosis in patients with pancreatic cancer due to the deterioration of anti-tumor immune responses. Although the use of anti-PD-1 antibody, nivolumab, showed promising effect on variable cancers, the effect of anti-PD-1 on PDAC has not been fully confirmed yet. Since the regulation of PD-L1 expression has not been clarified yet, we sort to elucidate the signaling pathways to express PD-L1, and hypothesized that downregulation of PD-L1 expression could be one of the therapeutic option for PDAC treated with anti-PD-1 therapy.
**Aims & Methods:** The aim of this study was to elucidate the upstream signaling pathway to express PD-L1 in PDAC. We used pancreatic cancer tissue array to evaluate PD-L1 protein expression in pancreatic cancer by immunohistochemistry (PA1001a, US Biomax, Rockville, MD, USA). To clarify the upstream signaling pathways regulating PD-L1 expression, we tested 96 inhibitors on Panc1 pancreatic cancer cells in regulation of PD-L1 expression (inhibitors were provided by Screening Committee of Anticancer Drugs supported by Grant-in-Aid for Scientific Research, Japan). 24 hrs after adding 10 microM of each inhibitor, we selected candidate inhibitors that were able to downregulate PD-L1 mRNA/protein expression as assessed by real-time qPCR analysis or western blotting. We also performed cell proliferation assay (Cell Counting Kit-8, Dojindo, Kumamoto, Japan) by using these candidate inhibitors on the proliferation of pancreatic cancer cells.
**Results:** Fourteen out of forty-five pancreatic cancer cases (31%) were positive for PD-L1 protein expression as assessed by immunohistochemistry. There were no differences in positive rate of PD-L1 over gender, age, or clinical stages. Six out of 96 protein kinase inhibitors showed decreased PD-L1 protein expression in Panc1 cells compared with non-treated control cells, which consisted of five signaling pathways (Table 1). GSK-3 inhibitor IX was confirmed to inhibit PD-L1 mRNA/protein expression. Cell proliferation was also assessed and GSK-3 inhibitor IX was significantly inhibited cell proliferation time dependent manner. We also detected decreased activation of NF-$\kappa$B by inhibiting GSK3 pathway, and TNF-induced PD-L1 mRNA expression was downregulated by using NF-$\kappa$B inhibitor, MG132 (20microM) (relative PD-L1 mRNA expression; TNF with DMSO vs. TNF with MG132, 4.9 fold vs. 2.0 fold).

| Name of Inhibitor | Signaling pathway | Inhibitory Rate (%) |
|---|---|---|
| Kenpaullone | CDK | 60.4 |
| AG1024 | IGF-IR | 60.8 |
| purvalanol A | CDK | 60.8 |
| NU6102 | CDK | 61.8 |
| GSK-3 inhibitor IX | GSK | 65.3 |
| Lavendustin C | CAMKII | 70.6 |
| SU4984 | FGFR | 71.5 |

**Conclusion:** We identified GSK3 pathway as one of the novel target to PDAC. Downregulation of PD-L1 may sensitize the effect of anti-PD-1 therapy as well as restoring anti-tumor immunity in PDAC. These data suggested that inhibition of PD-L1 by using certain protein kinase inhibitors could be a potential therapeutic option as a combined therapy with the current anti-PD-1 antibody against pancreatic cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The transcription factor CUX1, a regulator of cell differentiation and cell cycle progression, supports cell migration and resistance to apoptosis in vitro and in a xenograft model in vivo. The impact of CUX1 on tumor progression in a genetic mouse model of pancreatic cancer has not been elucidated.
**Aims & Methods:** Aim: Analysis the effect of CUX1 on tumor progression in vivo and molecular characterization of effector signaling cascades. Methods: A transgenic mouse model expressing CUX1 under the control of the CMV-promotor was crossbred with a pancreatic PanIN mouse model expressing constitutively active K-Ras under the control of the pancreas-specific p48 promotor (p48-Cre;LSL-KRASG12D). Subsequently, PanIN burden and tumor incidence was examined, as well as the regulation of CUX1 dependent signaling cascades in the context of K-Ras activation.
**Results:** The transgenic CUX1 expression in cooperation with pancreas-specific K-Ras activation caused a significant increase of PanIN lesions and invasive carcinomas. This correlates with a significantly enhanced proliferation rate in vivo and increased colony formation of CUX1 expressing cells in the presence of activated K-Ras in vitro. Interestingly, CUX1 significantly synergizes with K-Ras by inducing activation of MEK/ERK signaling, which occurred exclusively in the presence of activated K-Ras.
**Conclusion:** The in vitro und in vivo data show cooperation of CUX1 and K-Ras dependent pathways, resulting in an enhanced MEK/ERK signaling pathway leading to acceleration of pancreatic carcinogenesis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1201 THE FEATURES OF HOST IMMUNE RESPONSE IN PATIENTS WITH PANCREATIC DUCTAL ADENOCARCINOMA

**T. Komura**[1], Y. Sakai[1], K. Harada[2], S. Kaneko[1]

**Introduction:** Despite the development of diagnostic imaging and treatment, pancreatic ductal adenocarcinoma (PDAC) remains the lethal malignancy with extremely poor prognosis. Surgical resection is the only treatment achieving radical curation; however, only 15–20% of patients are diagnosed in the operable early stage. For unresectable PDAC patients, chemotherapy is efficacious; however, improvements in survival are extremely limited.
**Aims & Methods:** It is extremely important to understand the host inflammatory immune response of PDAC for development of novel diagnostic tool as well as therapy. In the current study, we examined the local immune response of 20 PDAC tissues resected by surgery assessed with immunohistochemistry (IHC). Next, we analysed gene expression profile for CD4+cells, CD8+ cells, CD14+ cells and CD15+ cells in peripheral bloods by DNA microarray, which are obtained from five PDAC patients (Age; $76.6 \pm 11.2$, Gender; Male/Female=5/0, Stage I/II/III/IV = 0/3/1/1) and seven healthy volunteers (Age; $61.7 \pm 3.9$, Gender; Male/Female = 3/4). Furthermore, we examined surface antigens expressed on CD4+ cells and CD14+ cells to characterize the subpopuplation of these cells in PDAC patients by flow cytometry.
**Results:** We observed that CD4+ cells were abundantly infiltrated in PDAC focal site, compared to CD8+ cells in T cells. In infiltrated CD4+ cells, PD-1, immune checkpoint molecule, as well as FoxP3, master molecule of regulatory T cell, were prominently expressed, compared to T-bet, master molecule of helper T cell. Furthermore, we observed CD33+ cells, phenotypic of myeloid cells, were significantly infiltrated in focal tumor site, and most CD33+ cells also expressed CD163+ cells, suggesting M2 like macrophages. The gene expression profile of peripheral blood CD4+ T cells and CD14+ monocytes was discernible between PDAC patients and healthy volunteers, although CD8+ cells and CD15+ cells were not. 496 genes whose expression was significantly different in CD4+ T cells of PDAC patients were related to the cell cycle and inflammation as well as DNA damage and apoptosis, and 261 genes those of CD14+ monocytes in PDAC patients were related to the cell cycle, inflammation, blood coagulation, cell adhesion and development. Flow cytometric analysis showed that the frequency of molecules related to immune

suppression, which were CD4+PD-1+ cells, CD4+CD25+CD127+ cells and CD11b+CD33+ cells was significantly increased in both CD4+ cells and CD14+ cells of PDAC patients.
**Conclusion:** Immune reaction including immune-suppression-related molecules and cells were indicated in systemically circulating peripheral blood cells as well as local cancer tissues in PDAC patients. These findings are useful for understanding immune condition of PDAC for exploration of novel diagnostic tool as well as novel immunotherapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1202 EXHAUSTIVE ANALYSIS OF MICRORNAS IN THE PANCREATIC CANCER TISSUE OBTAINED BY ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION (EUS-FNA)

**Introduction:** MicroRNAs (miRNAs) which is small molecule RNA conducts translation suppression of the target molecule and is associated with the molecular mechanism of cancerogenesis and the extension process deeply. The pancreatic cancer, is one of the refractory gastrointestinal carcinoma, has difficulty in early detection, and the metastasis of tumor cells, an invasion tendency are strong, and the treatment resistance. Recently, there are some reports that the microRNAs have been associated with these refractory characteristics in the pancreatic cancer. Therefore, we examined likelihood of the clinical application by the analysis of miRNAs in the tissue of the pancreatic cancer obtained by EUS-FNA.
**Aims & Methods:** A total of 51 consecutive patients (21 men and 30 women, mean age 67.9) underwent EUS-FNA for pancreatic tumor from April, 2013 to February, 2016. They were all diagnosed pancreatic ductal adenocarcinoma by the cytopathologist. Firstly, the pancreatic cancer tissue obtained by EUS-FNA was cryopreserved using RNA stabilization reagnet (RNA later, Qiagen). After total RNA extraction, we exhaustively analyzed expression of microRNAs using microRNA array tip (TORAY company) which approximately 2,500 molecules were put on.The statistical analysis assumed a significant difference ($p$ value $< 0.05$) using Wilcoxon signed-rank test.
**Results:** In the comparison of the microRNAs between resection group (13 cases) and non-resection group (38 cases), 92 genes showed a significant difference. In comparison of the microRNAs between the locally advanced group and the each metastatic group (liver metastases 17 cases, lung metastases 4 cases, lymph node metastases 9 cases), 326, 32 and 164 genes showed a significant difference, respectively. Oncogenic microRNAs indicating the overexpression, tumor suppressor microRNAs indicating the expression decrease were identified in each. Furthermore, microRNAs at the time of pancreatic cancer diagnosis were also observed that seems to be related with the site of recurrence in the post-operative patients.
**Conclusion:** Analyzing miRNAs exhaustively extracted by EUS-FNA at the diagnosis, we identified miRNAs which prescribed the clinical features of the pancreatic cancer. In the future, we want to examine clinical application of these microRNAs as the biomarker of the pancreatic cancer used for a diagnosis, a prognostic value and an effect of treatment judgment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1203 EFFECTS OF ARGININE–GLYCINE–ASPARTIC ACID PEPTIDE CONJUGATED QUANTUM DOTS INDUCED PHOTODYNAMIC THERAPY ON PANCREATIC CARCINOMA IN VIVO

M. Li, J. Cao, **L. Xu**
*Department Of Gastroenterology, Xinhua Hospital, Shanghai Jiaotong University School of Medicine, Shanghai/China*

**Contact E-mail Address:** leiming.xu@aliyun.com
**Introduction:** Pancreatic cancer is currently one of the deadliest of the solid malignancies. Overall prognosis is poor with palliative chemotherapy and/or radiotherapy. Photodynamic therapy (PDT), a minimally invasive treatment capable of local destruction of tumor tissue may have a place in the treatment. Quantum dots (QDs) are colloidal semiconductors. Arginine-glycine-aspartic acid (RGD), sequence of small peptide, is an integrin antagonist which can link to integrin of cancer cells. We successfully combined the construction of RGD conjugated quantum dots (QDs-RGD). Our previous studies have showed the potential applications of QDs-RGD for PDT as photosensitizers in pancreatic cancer cells in vitro. In this study we investigated its applications for PDT in pancreatic carcinoma bearing mice.investigated its applications for PDT in pancreatic carcinoma bearing mice.
**Aims & Methods:** Nude mice were subcutaneously injected with SW1990 pancreatic cancer cells on the back. The mice were maintained with regular food and water, until the tumor volumes approached 500–1000mm$^3$. Different dosages of QDs-RGD, such as 0.1 pmol, 0.2 pmol, 0.5 pmol, 1 pmol, 2 pmol, 5 pmol, 10 pmol, 20 pmol, 50 pmol, were dissolved in 100 $\mu$L of sodium borate. Then they were injected into the tumor-bearing mice intratumorally or intravenously. In vivo optical imaging was performed with the IVIS Imaging System. Images were acquired at different time points after injection, including 0 h, 1 h, 3 h, 5 h, or 24 h. PDT was performed with an optical fiber directly injected into the tumor connecting the laser light asset. For the PDT group (group 1), mice were intratumorally injected with 5 pmol of QDs-RGD and then irradiated for 20 min with laser light (630 nm) at a power density of 100mW/cm$^2$. The control groups included mice that received a QDs-RGD injection at the same dose but were not irradiated (group 2) and mice that did not received a QD-RGD injection but were irradiated (group 3). The tumor sizes were measured using a caliper every other day. All the procedure above was performed once again on the 14$^{th}$ day. Mice were sacrificed at the 28$^{th}$ day and histology analyses of tumor tissues were performed. Tumor tissues were separated and embedded in paraffin. The sliced tumor tissues were stained with hematoxylin–eosin (H&E).
**Results:** When the dosages of QDs-RGD were lower than 1 pmol, neither the intratumorally injected group nor the intravenously group could maintain in the tumor with a high level of Fluorescence Radiant Efficiency. When the dosages of QDs-RGD reached 5 pmol or above, the intratumorally injected QDs-RGD group could maintain in the tumor with a high level of Fluorescence Radiant Efficiency for at least 3 hours, while the efficiency of the tumor in the intravenously group still retained low. After the PDT treatment, tumors on the back of the mice in group 1 grew slowly, whose average $V/V_0$ ratio is 3.36, while in the control group (group 2 and 3), tumors grew fast with their average $V/V_0$ ratios could reach 13.46 and 16.66, which means tumors could grew to 16 times of its previous size within 4 weeks. The H&E results of tumor tissues showed that there are more necrotic tissues, more inflammatory cells, and less vascular tissue in tumor tissue of intratumorally PDT groups (group 1) as compared to control without treatment (group 2 and 3).
**Conclusion:** These results indicated that intratumorally injected QDs-RGD could achieve high Fluorescence Radiant Efficiency in the tumor of nude mice. QDs-RGD-mediated PDT, with the illumination of an optical fiber directly inserting into the tumor, is able to destroy the growth of SW1990 tumors with high efficiency in nude mice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1204 A GLYCOPROTEIN AS A NOVEL SEROLOGICAL MARKER FOR PANCREATIC CANCER

**K. Taniuchi**[1], T. Okabayashi[2], Y. Shima[2], T. Saibara[1]
[1]*Kochi Medical School, Nankoku/Japan*
[2]*Kochi Health Sciences Center, Kochi/Japan*

**Contact E-mail Address:** ktaniuchi@kochi-u.ac.jp
**Introduction:** Accurate peripheral markers for the diagnosis of pancreatic ductal adenocarcinoma (PDAC) are lacking. Biomarkers for the diagnosis of patients with PDAC are needed to improve prognosis.
**Aims & Methods:** The aim of the present study is to assess if a glycoprotein which we found in condition media of cultured human PDAC cells is useful as a serum diagnostic marker for differentiating PDAC from individuals without pancreatic disorders compared with cancer antigen 19–9 (CA19–9). A case-control study included two subcohorts: the discovery cohort that included 23 PDAC patients (stage 0: n = 1, IIA: n = 2, IIB: n = 4, III: n = 6 and IV: n = 10 according to the classification of International Union against Cancer) and 51 control individuals, and the validation cohort that included 29 PDAC patients (stage IA: n = 1, IIA: n = 7, IIB: n = 16, III: n = 3 and IV: n = 2) and 14 control individuals. PDAC patients and control individuals who were treated in Kochi Medical School Hospital and Kochi Health Sciences Center were included from April 2014 to March 2015 in the discovery cohort and from April 2015 to January 2016 in the validation cohort. The serum glycoprotein was measured by a commercial sandwich ELISA kit.
**Results:** The discovery cohort demonstrated that the area under the receiver-operating characteristic curve (AUC) were 0.973 (95%CI 0.943–1) for this glycoprotein and 0.802 (95%CI 0.693–0.912) for CA19–9. The AUC for the glycoprotein was significantly higher than that for serum CA19–9 (P = 0.004). The validation cohort showed the similar results of the discovery cohort.
**Conclusion:** Our data suggest that measuring the level of this glycoprotein has the potential to improve detection of PDAC. Further research is necessary to confirm its value for early detection of PDAC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1205 THE ACTUAL INCIDENCE OF PANCREATIC CYSTIC NEOPLASM RELATED SYMPTOMS: WE ARE OVERESTIMATING A MAJOR INDICATION FOR SURGERY

**S. Andrianello**, G. Marchegiani, C. Miatello, A. Pulvirenti, A. Borin, G. Perri, C. Dal Borgo, G. Malleo, C. Bassi, R. Salvia
*General And Pancreatic Surgery - The Pancreas Institute, University of Verona, Verona/Italy*

**Contact E-mail Address:** stefano.andrianello@gmail.com
**Introduction:** The treatment of pancreatic cystic neoplasms (PCNs) relies on several International guidelines that identify key features able to predict the

risk of malignancy. The most important of these factors is represented by the presence of symptoms. The incidence of symptomatic PCNs is based on retrospective series that might overestimate the actual incidence and consequently lead to inappropriate indication for surgery.
**Aims & Methods:** To evaluate the actual PCN related symptoms incidence and profile. Patients affected by PCNs (n = 108) observed between September 2015 and February 2016 were prospectively enrolled. All patients underwent physical examination, MRI with cholangiopancreatography and a specific interview on gastrointestinal (GI) symptoms. An identical survey was carried out on a matched control population (n = 98) in which the presence of PCNs or other pancreatic focal lesion were excluded by MRI with cholangiopancreatography.
**Results:** The study group showed an increased prevalence of female subjects (66.7 vs. 43.9%, $p < 0.01$) and a higher median age (64 vs. 56 years, $p < 0.01$), while matched with the control group regarding comorbidities. There was no difference in terms of incidence of GI symptoms. Of note, abdominal pain was reported in 61% of subjects with and in 51% of subjects without PCNs ($p = 0.1$). Patients with PCNs were more aware of their symptoms being able to better characterize them in relation with food intake and sleep. Same results were obtained comparing patients with BD-IPMN (53.7%) and the control group. Seven patients with PCN (6.4%) have been proposed for surgery due to the presence of worrisome features or high risk stigmata, however, none of this patients experienced symptoms.
**Conclusion:** Subjects affected by PCNs have similar GI symptoms incidence and profile if compared with individuals without pancreatic disease. Care must be taken recommending surgery for PCNs due to the presence of symptoms, as these might not be actually related to the cyst itself.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Precise knowledge of the extent of disease guides the surgical management of IPMN. We hypothesized that preoperative DSOP alters the operative plan in patients with IPMN.
**Aims & Methods:** A multicenter retrospective review of 16 patients who had DSOP attempted for IPMN was performed. A single-use, multi-purpose 10.5 Fr flexible endoscope, all-inclusive design with independent irrigation and a 1.3 mm therapeutic channel (SpyGlass DS$^{tm}$, Boston Scientific, MA, USA) was used in an outpatient setting under monitored anesthesia, without prophylactic antibiotics and without sphincterotomy in 13 cases; The duct was swept with a balloon prior to ductoscopy. Standard imaging findings, endoscopic findings, surgical treatment and pathology were reviewed.
**Results:** DSOP was performed in 16 patients with pancreatic IPMN, 11 men, 5 women, mean age 72 years. The majority (13) had main duct IPMN and 3 had mixed-IPMN (main duct and branched). DSOP was successfully performed in 15/16 patients reaching the tail (One patient had an alpha-loop in the head). The location of the IPMN by imaging studies was in the head (5), body (8), and tail (3). Endoscopic findings included: mucin extruding from the ampulla (14), villiform protrusions with a transparent appearance (15), villiform protrusions with central vessel (13), nodules (13), luminal mucin (14), "fish-egg" appearing side branches (9), and stones (1). In the patients with a tail mass, the remainder of the duct was normal. In patients with a distal mass (head/body/neck), the proximal duct appeared hyperemic, with prominent vascular surface, subepithelial edema, nodules and shallow villi to the tail (10). Compared to standard preoperative imaging, DSOP further extended the location of the tumor in 8/13 (61%). Biopsies (SpyBite$^{tm}$, Boston Scientific, MA, USA) were performed in 14 revealing mucinous lesion (14), low grade and high grade dysplasia (5 and 3, respectively). In one patient with a mass in the tail, biopsies of the distal duct showed dysplasia despite a normal appearance. Ten patients underwent surgery, 4 showing early adenocarcinoma and 5 showing high-grade dysplasia: all these patients had central vessels in the villi. The pre- DSOP surgical approach was modified in 6/10 of the patients (3 pancreatoduodenectomy versus total pancreatectomy; 1 total pancreatectomy instead of pancreatoduodenectomy. Complications included one patient with mild pancreatitis requiring an overnight hospitalization.
**Conclusion:** DSOP with biopsy in IPMN reveals more extensive disease than standard preoperative imaging and frequently alters the surgical plan particularly in patients with lesions in the head of the pancreas where dysplastic changes are noted throughout the duct. Villi with central vessels may be associated with more advanced disease.

### P1207 THE FEASIBILITY OF TISSUE SPECIMEN OBTAINED FROM EUS-FNA FOR PATIENT-DERIVED TUMOR XENOGRAFT IN PANCREATIC CANCER

**C. Cho**[1], A.N. Seo[2], H.I. Bae[2], I.K. Lee[3]

**Introduction:** There has been an increasing interest in the development and characterization of patient-derived tumor xenograft (PDX) models for cancer research. Although most of the published studies have relied on surgical specimens, it is difficult in pancreatic cancer because most patients were initially diagnosed as advanced stage and surgically inoperable. The aim of our study is to evaluate the feasibility of PDX using EUS-FNA specimens in pancreatic cancer.
**Aims & Methods:** Patients were referred for EUS-guided tissue acquisition were prospectively enrolled. Among them, patients with locally advanced or distant metastasis were included. After the acquisition of tissue specimen for pathologic diagnosis, additional EUS-guided tissue sampling was performed for xenograft and storage for further DNA analysis. The acquired FNA specimen was implanted subcutaneously into the dorsal region of athymic nude mouse. We evaluated the success rate of implantation and compared the histologic correlation between human tumor and xenograft mass.
**Results:** Between April 2014 and January 2015, 10 patients (median age, 69 years; range 47–79; male:female ratio, 7:3) were enrolled and all were diagnosed as pancreatic cancer by EUS-tissue sampling. The mean size of tumor was $32.7 \pm 15.3$ mm by $25.6 \pm 9.2$ mm. Tumor formation was observed in two cases (20%) at 3 week and 5 week after implantation. Finally, it took 6 weeks and 21 weeks until the growth of 1 $cm^3$ in volume. In successful xenograft tissues, histologic and immunohistochemical staining revealed identical pathologic findings to those of the human tumor.
**Conclusion:** With the successful PDX using EUS-FNA specimen in pancreatic cancer, we expect that this may contribute to the development of a tailored therapy for pancreatic cancer in the future. However, further studies are required to shorten the growth period to obtain a sufficient volume of xenograft before applying clinical management.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1208 EARLY VERSUS DELAY INITIATION IN ADJUVANT TREATMENT FOR PANCREATIC CANCER

**H.W. Kim**, J. Lee, J. Lee, **J. Kim**, J. Hwang
*Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si/Korea, Republic of*

**Contact E-mail Address:** broad_earth@naver.com

**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive tumor with a tendency for early recurrence, even after curative resection. Although adjuvant treatment improves survival, it is not well described early initiation of adjuvant therapy shows better outcomes in patients with PDAC.
**Aims & Methods:** One hundred thirteen patients who underwent chemotherapy or chemoradiotherapy after curative resection of PDAC were enrolled retrospectively: 56 in early group and 57 in delay group according to the median value of the time to initiation treatment.
**Results:** The median time to start adjuvant treatment was 34 days (range, 20 – 83 days), and 71 patients underwent adjuvant treatment completely. The median overall survival was 39.1 vs. 21.1 months, and disease-free survival was 18.8 vs. 10.0 months in the early and delay groups, respectively ($p = 0.018$ and 0.034), during the median 20.3-month follow-up. Also, the overall and disease-free survival rate of the early group tends to be higher than those of the delay group in whom underwent complete adjuvant treatment ($p = 0.129$ and $= 0.195$, respectively). On multivariate analysis, an incompletion of therapy (hazard ratio [HR]: 4.536, 95% confidence interval [CI]: 2.570 – 8.005), delay initiation of therapy (HR: 2.042, 95% CI: 1.178 – 3.541), and positive angiolymphatic invasion (HR: 2.135, 95% CI: 1.143 – 3.988) were significantly associated with shorter overall survival.
**Conclusion:** Adjuvant treatment would be delivered earlier and completed for better outcomes after curative resection of PDAC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** rosacoelhoabrantes@hotmail.com

**Introduction:** Pancreatic cancer (PC) is the gastrointestinal cancer with the lowest survival rate. Therefore it is essential to provide the best treatment for each disease stage, this is the reason why it is crucial to perform a proper staging [1].
**Aims & Methods:** The aim was to compare the correlation between the pre and post-operative staging through various imaging methods. This is a single-center retrospective study (2010–2015) including all the patients proposed to surgical resection for PC. Agreement analysis was performed through specific proportion. Statistics analysis was performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.
**Results:** We identified 77 patients, 57.1% male, with a mean age of 67.0 years (IQR: 58.5–72.0) at diagnosis. The median survival period was 12.0 months (IQR: 8.0–25.5). The staging of PC was performed in 96.1% patients by computed tomography (CT), 24.7% patients by endoscopic ultrasound (EUS) and in 20.8% patients by both methods. Before surgery, most of the patients belonged to stages IIb (25.3%) and IIa (24.0%); Surgical and post-operative staging revealed that the majority of patients belong to stage IIb (32.9%) and IIa (25.0%). Nineteen percent of the patients enrolled showed non-resectability criteria at the time of surgery, 70.6% due to locally advanced disease. Patients not resected had performed pre-operative staging by EUS and CT in 35.3% and 94.1%, respectively. Considering patients who underwent staging by EUS, 31.6% had no resectability criteria at the time of surgery, and this occurred in 31.2% of patients whose staging was performed by CT. According to TNM Classification, the concordance between the pre and post-operative staging with CT was: T (56.3%) and N (39.7%); EUS: T (52.4%) and N (53.8%). The agreement between the pre and post-surgery staging was not associated with more than one imaging method, location and/or size of the lesion.
**Conclusion:** Pre and post-operative staging showed low agreement using CT and EUS. Performing more than one imaging method has not determined an increase in the accuracy of TNM staging.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1210 VALUE OF CA 19–9 LEVELS FOR PANCREATIC CANCER SCREENING IN NEW-ONSET DIABETIC PATIENTS REGARDLESS OF BILIRUBIN ELEVATION

**J.S. Kim**[1], J.W. Choe[1], H.J. Kim[1], M.K. Joo[2], B.J. Lee[2], J. Park[1], Y. Bak[1]
[1]*Internal Medicine, Korea university Guro hospital, Seoul/Korea, Republic of*
[2]*Korea University Guro Hospital, Seoul/Korea, Republic of*

**Contact E-mail Address:** hjkimmd@korea.ac.kr

**Introduction:** Early check-up of CA 19–9 could be a useful marker for screening for pancreatic cancer (PC) in asymptomatic patients with new-onset diabetes mellitus (DM). However, PC group had significantly higher bilirubin levels, which could be the confounding factor for evaluating screening tool of CA 19–9.
**Aims & Methods:** This study aims to confirm the utility of measuring CA 19–9 in asymptomatic new-onset diabetic patients as a screening test for PC, independent of bilirubin elevation. Patients who newly diagnosed with DM and measured CA 19–9 at Korea University Guro Hospital health promotion center from January 2005 to January 2014 were enrolled. Medical records of patients were reviewed retrospectively, Statistical analyses were performed using $\chi^2$ tests, independent two tailed T-tests and area under ROC curve.
**Results:** In the 5111 patients (male 64.2%, mean 60.3 years) selected for analysis, 87 (1.7%) patients developed PC after the DM diagnosis. There was no statically significant difference in the clinical profiles of patients, including age, sex, smoking history, BMI, glucose, HbA1C, liver function test, and CEA between the PC group (87 patients) and non-PC group (5024 patients). However, CA 19 -9 level and bilirubin were significantly higher in the PC group than non-PC group. In the subgroup of 322 patients with elevated bilirubin (1.7 mg/dL), 42 (73.7%) of 57 patients with elevated CA 19–9 level ($>$ 37 IU/mL) were finally diagnosed with PC. The other 265 patients were checked normal CA 19–9, and 12 cases (4.5%) of them showed PC (OR 16.3, 95% C.I. 8.06 to 32.8; $P < 0.001$). In the other subgroup of 4789 patients with normal bilirubin, 20 (3.8%) PC in 522 patients with elevated CA 19–9 and 13 (0.3%) PC in 4267 patients with normal CA 19.9 were finally detected (OR 12.6, 95% C.I. 6.22 to 25.43; $P < 0.001$).
**Conclusion:** Check-up of CA 19–9 following new-onset DM diagnosis could be a useful marker as a screening test for pancreatic cancer, independant of bilirubin elevation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1211 CONTINUOUS LOW-DOSE-RATE IRRADIATION OF IODINE-125 SEEDS INHIBITS PERINEURAL INVASION IN PANCREATIC CANCER

Z. Lu[1], T. Dong[2], P. Si[3], W. Shen[2], Y. Bi[2], M. Min[2], Y. Xu[2], X. Chen[4], **Y. Liu**[2]

**Contact E-mail Address:** 13911798288@163.com

**Introduction:** Perineural invasion (PNI) extending into the extrapancreatic nerve plexus is a histopathologic characteristic in pancreatic cancer. The proper treatment of neural invasion has not been established. According to the valuable observations in the previous clinical studies, we established the PNI models of pancreatic cancer in vivo and in vitro, observed the treatment effect of continuous low-dose-rate (CLDR) irradiation to PNI and assessed PNI-related pain relief caused by 125I seeds implantation.
**Aims & Methods:** Aims: To observe the treatment effect of continuous low-dose-rate (CLDR) irradiation to perineural invasion with iodine 125 seeds implantation. Methods: The in vitro PNI model established by co-culture the dorsal root ganglion (DRG) with cancer cells was interfered under CLDR irradiation of 2 and 4 Gy. The subcutaneous and orthotopic models of PNI were established and iodine 125 seed was implanted in the tumor. The PNI related molecules were analyzed. In 31 patients, the pain relief was assessed using a visual analogue scale (VAS). Pain intensity was measured before and 1 week, 2 weeks, 1, 3, 6 months after implantation.
**Results:** In co-culture groups, the increased number of DRG neurite and pancreatic cell in radiation group was significantly less. In subcutaneous models, the PNI positive rate in radiation and control group was 33.3% (4/12) and 80% (8/10) ($P < 0.05$). In orthotopic models, the PNI degree between radiation and control group was significantly difference. At week 2, the average pain score in patients decreased by 50%. The pain scores were lower in all patients and the pain-relieving effect was retained about three months.
**Conclusion:** The CLDR irradiation could inhibit PNI of pancreatic cancer with the value of further study. The CLDR irradiation could do great favor in preventing local recurrence and alleviating pain.
**Disclosure of Interest:** All authors have declared that they have no competing interests.

## P1212 MENSTRUAL AND REPRODUCTIVE FACTORS AND RISK OF PANCREATIC CANCER IN WOMEN

**A. Pourshams**, S. Masoudi, R. Malekzadeh
*Ddri, TUMS, Tehran/Iran*

**Contact E-mail Address:** akrampourshams@gmail.com

**Introduction:** Pancreatic cancer (PC) is a deadly disease with a 5-year survival of less than 5%. Worldwide PC incidence rates are lower among women than men. While this suggests a protective role for steroid hormones in PC risk, results from epidemiologic studies are not consistent.
**Aims & Methods:** Odds ratios and 95% confidence intervals for reproductive factors and PC were estimated using Logistic regression methods in a prospective case –control study. A hundred sixty-seven new incident PC cases and 198 controls were both recruited in the study from a referral center for endoscopic ultrasound between 2011 and 2016. A structured valid and reliable questionnaire was used for data collection by trained interviewers.
**Results:** Mean age (SD) of cases and controls were 63.8 (11.8) and 63.5 (12.0) years respectively. Age at menarche, age at menopause, number of parity, gravidity and abortion were not associated with PC risk.
**Conclusion:** This study does not support for the hypothesis that menstrual and reproductive factors are associated to PC risk.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1213 EUS-ELASTOGRAPHY (STRAIN RATIO) IN THE DIAGNOSIS OF SOLID PANCREATIC LESIONS: A PROSPECTIVE COHORT STUDY

**S. Carrara**[1], M. Di Leo[1], A. Anderloni[1], A. Zerbi[2], A. Repici[1]
[1]*1. department Of Gastroenterology, Digestive Endoscopy Unit, Humanitas Research Hospital, Rozzano (MI)/Italy*
[2]*Pancreatic Surgery Unit, Humanitas Research Hospital, Rozzano Milan, Italy, Rozzano/Italy*

**Contact E-mail Address:** silvia.carrara@humanitas.it

**Introduction:** Preoperative diagnosis of solid pancreatic masses (SPL) is a challenging clinical problem. EUS elastography is a non-invasive ultrasound technique that displays the relative stiffness of tissues by taking advantage of the deformation caused by the compression or vibrations of the tissues. The level of hardness of SPL can be evaluated using either a qualitative scores and/or quantitative methods (strain ratio; SR).
**Aims & Methods:** This single-center prospective cohort study aimed to evaluate the feasibility and efficacy of the combination of EUS elastography and SR in the diagnosis of SPL by using the elastography software on the new Olympus compact ultrasound processor EU-ME2 in association with the linear array Olympus GF-UCT-180 series echoendoscopes. Two different areas were selected for SR. Area A was a representative area of the mass and included the biggest possible area of the tumor. Area B was placed in a soft peri-tumoral normal parenchyma to calculate the pSR and in the GI wall to calculate the wSR. The quantitative score of elastography was calculated by the SR method, dividing the non-mass soft tissue area (area B) by the tumoral area (area A). Every time, 3 measures of SR for pSR and wSR were recorded and the mean value for each was calculated and used as final SR result for each lesion. Patients with SPL detected by CT or MRI and confirmed by EUS, with age >18 years, were included. Procedures were performed between February 2016 and April 2016. Informed consent was obtained from all patients. The hospital institutional review board approved the study. Final diagnosis was made on the basis of EUS-FNA, surgical specimens, and follow up.
**Results:** Study population included 28 patients: 15 male and 13 female (mean age 69 years). The mean size of SPL was 26.5 mm (SD 13.7). The localization was the tail in 10 (35.7%), body in 10 patients (37.5%), neck in 3 (10.7%), head in 8 (28.6%), uncinated process in 4 (14.3%). Twenty-three patients underwent EUS-FNA. The adequacy was obtained in all patients (96%) but one with suspected autoimmune pancreatitis. The mean number of passages was 2 (SD 0.8; range 1–3). Final diagnosis was pancreatic ductal adenocarcinoma (PDAC) in 18 patients, NET in 4 patients. Two of 5 SPL without FNA were suspected for NET, and the lesions were stable compared to previous EUS or radiological imaging. The other two lesions showed a solid component of degenerate cystic neoplasm confirmed by surgery. An other LST was an inhomogeneous area in a patient with past acute pancreatitis, stable after 6 months follow up. SR was feasible in all patients with both methods, pSR and pSR. The patient with suspected autoimmune pancreatitis, without a final diagnosis, was excluded from the study. The mean pSR of PDAC, NET and non neoplastic SPL was respectively 26, 11 and 2. The mean wSR of PDAC, NET and non neoplastic SPL was 47.5, 15, and 10. The major limitation of this study is the low n° of benign mass, but these preliminary data showed the feasibility of the SR calculated with the Olympus EU-ME2 echo-processor and the higher SR values in PDAC.
**Conclusion:** EUS-elastography may add information in the EUS assessment of SPL, especially in the identification of lesion suspected for PDAC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Bariatric surgery improves the metabolic state of subjects with type 2 diabetes (T2D) through weight-independent mechanisms. Duodenal mucosal resurfacing (DMR) is an investigational endoscopic procedure involving novel balloon catheter-based thermal ablation of duodenal mucosa. An initial single-site, first-in-human (FIH) study in Chile has reported robust improvements in glycaemic control after DMR among a cohort of subjects with T2D.
**Aims & Methods:** We report the early safety, feasibility, and efficacy of implementing DMR in an European multi-centre study (5 sites) in subjects with T2D. At study sites, endoscopists received a day of both didactic and hands-on DMR training in a porcine model before treating subjects with T2D, sub-optimally controlled (HbA1c 7.5–11.0%) on oral glucose-lowering medication. DMR involved duodenal lumen measurement, mucosal lifting with a submucosal expansion catheter followed by circumferential mucosal ablation (length ~8 cm) with a thermal ablation catheter. Subjects on sulfonylurea (SU) medication had their SU withdrawn 4 weeks prior to procedure to mitigate hypoglycaemia potential. All subjects followed a graduated diet for 2 weeks post-procedure and a proton pump inhibitor was prescribed for 5 weeks.
**Results:** Twenty-eight subjects (age $55 \pm 9$ years, baseline HbA1c $8.7 \pm 1.0$%, BMI $32.3 \pm 4.3$ kg/m$^2$) received DMR treatment with current follow-up of 12 weeks post-procedure for the full cohort and some subjects currently followed for 24 weeks. The procedure was implemented according to protocol and well tolerated by all subjects. There were no procedure-related severe adverse events including no duodenal stenoses. Adverse events have been mostly mild in severity. Metabolic indices improved significantly 12 weeks after DMR (change from baseline lowering of FPG 31 mg/dL, HbA1c 0.7%, ALT 7.7 IU/L) despite protocol-driven withdrawal of SU therapy in the majority of subjects prior to DMR. BMI decreased significantly by 0.9 kg/m$^2$ during 12 weeks after DMR.
**Conclusion:** The DMR procedure is a novel endoscopic catheter-based treatment for the management of T2D and current clinical use suggests that the procedure can be implemented in a multi-centre setting. This study reports a favourable safety and tolerability profile observed to date with further evidence of the improved glycaemic and hepatic measures elicited by DMR. Further

assessment of clinical applicability, and efficacy and safety of the DMR procedure is necessary.

**Introduction:** Acute non-variceal upper gastrointestinal bleeding (NV-UGIB) is a frequent indication for hospital admission and blood transfusions; meta-analysis and randomized controlled trials examining red blood cell (RBC) transfusions for the management of NV-UGIB were inconclusive and the appropriate strategy for transfusions in patients with haemorrhage and haemoglobin (Hb) value between 7 and 9 gr/dl is still unclear.

**Aims & Methods:** We aim to evaluate the impact of different transfusion strategies on death risk in patients admitted for NV-UGIB focusing on haemoglobin (Hb) value between 7 and 9 gr/dl Data on patients admitted for GI bleeding were collected from January 2014 to January 2016. 30-day mortality and type of transfusion strategy adopted were the primary outcomes measured. Transfusion strategy definitions: "restrictive" for Hb levels $\leq$7 g/dL; "not justified" (depending on symptoms) for Hb levels from 7 to 9 gr/dL; "liberal" for Hb levels from 9 to 10 gr/dL; "not indicated" for Hb levels $\geq$ 10 gr/dL. All participating centres were free to follow the transfusion strategies approved in their own hospital. Mortality was defined as any death occurred within 30-day from admission.

**Results:** A total of 3224 patients were included. Of these 2,764 (83.1%) had NV-UGIB (mean age 69.1 $\pm$ 16.2, 67.8% males). Comorbidities were present in 79.8% of the patients, the mean Rockall score was 3.9 $\pm$ 1.9. At admission, mean Hb value was 9.2 $\pm$ 2.6 and 7.6% of the patients had hemodynamic instability. 58.2% of the patients were transfused, receiving a mean of 3.1 RBC units per patient with a 30-day mortality of 5.6%. Overall, a total of 5015 units were transfused, 2629 in the restrictive group, 2053 in the "not justified" or "not indicated" groups, while 333 units were administered without any indication. Transfusions impacted on mortality, being statistically different between those who received any RBC unit vs those who did not (7.7% vs 2.9% $p < 0.000$); the death risk varies considerably within the Hb strata value (tab.1). 43% of the patients had a "restrictive" transfusion strategy, 39% a "not justified" strategy, 4.9% the liberal transfusion and 3% the transfusions were not indicated. Considering only the "not justified" group, after transfusions, 93 out 1084 patients still had an Hb value $\leq$ 8 gr/dl with a mortality rate of 23.6% [vs. 6.8% of the other groups ($p < 0.000$) ]. Both in the group <= 7 g/dl and in that 7–8 g/dl those in which the average value of Hb has exceeded 8 g/dl mortality has decreased substantially and fluctuated between 5.5 and 8.6% ($P = 0.24$).

**Conclusion:** In patients with NV-UGIB the "not justified" strategy must be reconsidered for the substantial death risk. A transfusion strategy to achieve a target Hb value ranging from 8 to 9 gr/dL is advisable.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1216 PERORAL ENDOSCOPIC MYOTOMY FOR TREATING ACHALASIA PERFORMED BY A GASTROENTEROLOGIST: 4 YEARS' EXPERIENCE FROM A SINGLE ENDOSCOPY CENTER

**Introduction:** Esophageal achalasia is most commonly treated with endoscopic dilation or laparoscopic Heller myotomy. Peroral endoscopic myotomy (POEM) has recently been described as a novel treatment for achalasia in humans.

**Aims & Methods:** The aim of this study was to assess the clinical effectiveness and safety of POEM for treating esophageal achalasia performed by a gastroenterologist in a single endoscopic center within 4 years. Between June 2011 to May 2015, POEM was performed in 115 consecutive patients with achalasia. POEM procedure consisted of the following step: firstly, submucosal tunnel was created and extended below the lower esophageal sphincter (LES) onto the gastric cardia after a mucosal incision was made; then endoscopic myotomy of circular muscle bundles was done; finally, the mucosal entry was closed by hemostatic clips. The Eckardt score and manometry were used to evaluate the outcomes. Treatment success was defined as symptom relief, based on an Eckardt score $\leq$ 3.

**Results:** POEM was successfully performed in all cases. Mean procedure time was 48.7 min (range 35–93) and mean myotomy length was 9.2 cm (range 7–15). Mucosal perforations occurred in 7 (6%) patients during submucosal tunnel creation, major bleeding occurred in 8 (7%) patients, and 6 (5.7%) patients suffered pneumothorax immediate after procedure. All the complications were managed conservatively. During a mean follow-up period of 25 months (range 6–59.4 months), treatment success was achieved in 106/115 patients (93.5%). Mean LES pressure was 54.5 mmHg (28.5–81.4) and 16.4 mmHg (4.8–25.3) before and after the procedure ($P < 0.05$), respectively. Mean Eckardt score was 6.2 (3–11, median 6) and 0.5 (0–2, median 1) before and after POEM, respectively ($P < 0.05$). 20 patient (17.3%) developed mild reflux symptoms and required

**Contact E-mail Address:** drgwei@foxmail.com
**Introduction:** Peroral endoscopic myotomy (POEM) has been proved to be effective for treating achalasia, but there are limited data on POEM in the elderly patients.
**Aims & Methods:** This study was aimed to assess the role of POEM for achalasia in patients 60 years of age and older. All consecutive patients underwent POEM between December 2011 and Novermber 2015 at a single center were retrospectively reviewed. Patients with age $\geq$ 60 years old were assigned to group A, while patients younger than 60 years old were assigned to group B. Demographic, clinical, manometric data, treatment outcomes and adverse events were compared between these groups.
**Results:** During the study period, one hundred and seven patients (15 in group A, and 92 in group B) were enrolled. The mean age of the group A was $63 \pm 8$ years (range 60–72; 53% female) and that for the group B was $45 \pm 7.6$ years (range 18–58; 56% female). There were no significant differences in the sex and other baseline characteristics between the two groups. Procedural time in the group A was similar to the group B ($54.8 \pm 24.9$ vs. $52.0 \pm 20.7$ min, $P > 0.01$). There was also no significant difference in the incidence of intraoperative complications ($P > 0.01$) and gastroesophageal reflux rate (21.2% vs. 23.5%, $P > 0.01$) between the two groups. During the mean follow-up period of 23 months, treatment success (Eckardt score $\leq 3$) was achieved in 93.3% (14/15) of patients in group A and 92.3% (85/92) of patients in group B ($P > 0.01$).
**Conclusion:** POEM can safely be performed in elderly patients, providing significant symptom relief. POEM may be recommended as the first therapeutic approach to achalasia in elderly achalasia patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1218 TRANSORAL OUTLET REDUCTION FOR THERAPY OF WEIGHT REGAIN AFTER GASTRIC BYPASS

**I. Boskoski**[1], R. Landi[1], P. Familiari[1], A. Tringali[2], V. Perri[1], G. Costamagna[2]

[2]*Digestive Endoscopy Unit, Catholic University, Gemelli University Hospital, Rome, Italy, Rome/Italy*

**Contact E-mail Address:** ivoboskoski@yahoo.com
**Introduction:** Enlargement of gastrojejunal anastomosis aperture is associated with weight regain in patients with Roux-en-Y gastric bypass (RYGB) 1. Endoscopic transoral outlet reduction (TORe) has proven safe and effective for treatment of weight regain. The objective of this study was to evaluate the results of endoscopic outlet reduction in single Italian center.
**Aims & Methods:** The series included consecutive post-RYGB patients with weight regain and enlarged gastrojejunal anastomosis aperture (>15 mm). Endoscopic reduction was performed with Overstitch (Apollo Endosurgery) which is a full-thickness endoscopic suturing device. All the procedures were done at the Digestive Endoscopy Unit of the Catholic University of Rome.
**Results:** Twenty-two patients who had weight regained after RYGB (BMI > 30) underwent TORe from January to December 2015. Baseline mean BMI was 36.8 (range 33–43.6) and weight was 104.5 kg (range 85–131). The procedure was done with the Overstitch and Olympus double channel operative endoscope. An Overtube was placed before the procedure in all patients. Before suturing the outlet rims were cauterized with pulsed pulsed Argon Plasma on 40 Watts in all patients. Mean procedure time was 35 minutes (range 15–60) and a mean number of 2.3 stitches per patient were placed (range 2–4) on the level of the gastric outlet. After suturing, the patency of the new redone outlet was tested with standard gastroscope. There were three (13.6%) complications of which two were mild (1 intraoperative bleeding that arrested spontaneously and 1 patient with fever due to small retrogastric collection treated with antibiotics), while one patient (5.2%) had gastric perforation that required urgent laparoscopic surgery. Mean hospital stay was 2.8 days (range 2–10). Telephonic follow-up was done at 1, 3 and 6 months. Mean BMI at 1 month follow-up was 33.8, at 3 months was 32.4 while at 6 months was 32.3.
**Conclusion:** In our experience TORe was safe and effective procedure in patients with weight regain after RYGB. Longer follow-up and larger clinical trials are needed to establish the durability of these results and to better understand the role of TORe after RYGB and the methods for proper selection of the patients.

**Contact E-mail Address:** gianeugeniotontini@libero.it
**Introduction:** The Thulium laser system is a novel therapeutic technique for open surgery and endourological treatments [1]. Recent experience on animal models showed that the wavelength of 2$\mu$m allows for ablation and vaporesection of the superficial GI layer providing efective control on penetration depth (0.2–0.4 mm) and tissue damage [2].
**Aims & Methods:** We conducted a pilot study in an established animal model to test both feasibility and safety of the Thulium Laser system (Cyber TM®, Quanta System, Varese, Italy) for gastric endoscopic submucosal dissection (ESD) and endoscopic ablation of esophageal lesions. For gastric ESD, different optical fibers (272 and 365 um thick) were evaluated with various power settings (15, 20, 25, 30, and 35 watts) and laser configurations (continued or pulsed modality). The ESD of large (>3 cm) injection-induced lesions of the stomach was performed following a standard technique. For safety, we evaluated the depth of laser ESD impact on gastric layers after having completed the resection. For ablation of artificial esophageal lesions, we used a dedicated 600um side fiber with a line beam that emerges at 45 degrees with soft power settings (5–10 watts) and continued laser modality. The safety endpoint was the lateral and vertical spread of tissue damage induced by laser ablation after having vaporesected circumpherentially a 3 cm-length esophageal surface. All procedures were performed using standard HD video-gastroscope and digitally recorded. Two expert GI pathologists performed histopathological analysis.
**Results:** Neither transmural perforation, nor any muscular layer damage was observed after gastric ESD procedures. Both fiber diameters and configuration modalities were effective and precise. Complete ESD resection was feasible in all cases in 30–70 minutes, showing a fast learning curve. In esophagus, neither transmural perforation, nor any submucosal layer damage was observed. Each of two endoscopists completed a circumferential ablation of a 3 cm-length esophageal surface in 1 minute. Overall, each laser ablation on target produced mucosal vaporesection with only a diminutive lateral spreading of epithelial injury (1–3 mm), depending on the distance between the fiber's tip and the esophageal target.
**Conclusion:** The Thulium laser system appears to be an effective tool for advanced endoscopic treatments in the upper GI endoscopy. This novel therapeutic technique has proven to be precise and very easy to use for gastric ESD and esophageal ablation in ex vivo animal models, thereby showing promising results concerning its safety. In vivo studies should now confirm these initial results in a prospective, multicenter setting.
**Disclosure of Interest:** F. Fagnani: Filippo Fagnani is currently employed at Quanta System S.p.A.

**Introduction:** The prevalence of obesity is increasing worldwide. Bariatric surgery has increased dramatically in the last few decades. A variety of upper gastrointestinal abnormalities have been noted in obese patients. Pre-operative

multidisciplinary evaluation is recommended. The role of pre-operative upper endoscopy is still controversial.
**Aims & Methods:** To evaluate the role of gastroscopy in the obese population before bariatric surgery and its impact on the per-procedural outcomes. Six hundred and twenty-eight adult patients who underwent bariatric surgery (sleeve gastrectomy or RYGB), from 3/ 2007 to 3/2015, in our hospital were included. Patient's data such as demographics, BMI, comorbidities, medications, gastroscopy findings, barium swallow studies, biopsy, HP status, surgery, peri-procedural complications, resected stomach pathology, imaging reports and laboratory parameters were reviewed retrospectively. The patients were divided in 2 groups, Group A (barium imaging before surgery) and Group B (gastroscopy before surgery). Comparison was made between the 2 groups.
**Results:** Groups A and B consisted of 442 and 188 patients, respectively. Group B (gastroscopy) patients were older than group A (barium swallow) (mean age 45 Vs 39.7), had more previous bariatric surgeries (17.2% vs.7.2%) and received more anti platelet and anticoagulation medications (30.1% vs. 16.7%) ($p < 0.01$). Two patients in group B (gastroscopy) (2/188, 1.06%) had significant findings that precluded surgery. No statistically significant difference was found between the two groups in terms of the findings in the pre- procedural imaging, the type of operation preformed, additional procedures in surgery, macroscopic abdominal findings at the time of surgery, histopathological findings, HP status, surgical complications and the average decrease in BMI. In 99% of patients, pre surgical endoscopic findings were not significant and included mainly mild peptic lesions and gastric polyps (all polyps non-neoplastic, requiring to treatment). In both groups, a significant improvement in BMI and laboratory parameters such as liver enzymes, cholesterol, triglycerides and HBA1C was demonstrated post-surgery.
**Conclusion:** Pre procedural gastroscopy rarely offers advantage before bariatric surgery. It is costly and time consuming but significant pathology can be found and therefore should be considered routinely before bariatric surgery.

**Contact E-mail Address:** drgwei@foxmail.com
**Introduction:** Presently, peroral endoscopic myotomy (POEM) has been developed to treat esophageal achalasia as a less invasive mode. It allows for cutting the esophageal and proximal circular muscle bundle by creation of a submucosal tunnel.
**Aims & Methods:** We aimed to compare clinical efficacy and safety between peroral endoscopic shorter and longer myotomy for treating achalasia. Between July 2011 and September 2015, 38 patients underwent peroral endoscopic shorter myotomy (myotomy length $\leq$ 7 cm) in our department. These patients were matched by age, gender, symptoms duration, Eckardt score, and LES pressure with 59 patients who underwent longer myotomy (myotomy length $>$ 7 cm). Procedure-related parameters, manometry outcomes and complications were compared between the two groups.
**Results:** There was no significant differences in baseline characteristics between the two groups. Mean myotomy length was $6.1 \pm 0.5$ cm in shorter myotomy group, and $11.7 \pm 2.4$ cm in longer myotomy group ($P = 0.000$). The mean operation time was significantly less in shorter myotomy group than longer myotomy group ($44.2 \pm 16.3$ min vs. $68.5 \pm 23.2$ min, $P < 0.01$). During a median follow-up period of 24 months (range 7–38.2 months), treatment success (Eckardt score $\leq$ 3) was achieved in 92.1% (35/38) of patients in shorter myotomy group and 91.5% (54/59) of patients in longer myotomy group ($P > 0.01$). There was also no statistical difference in the incidence of intraoperative complications (7.4% vs. 9.2%, $P > 0.01$) and gastroesophageal reflux diseases (17.2% vs. 18.5%, $P > 0.01$) between the two groups.
**Conclusion:** POEM was effective and safe for treating achalasia, and shorter myotomy is comparable with longer myotomy for treating achalasia with regard to long-term clinical efficacy and safety, and have the advantage of shorter procedure time. Further randomized controlled trials are warranted to evaluate the efficacy and safety of these two myotomy methods.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1222 NOVEL DEVICE FOR FULL THICKNESS ENDOSCOPIC SUTURE, USING BACK AND FORTH NEEDLING: EX VIVO ANIMAL STUDY

**Introduction:** Nonsurgical endoscopic closure of the gastrointestinal wall may be desired in many situations, such as fistulae, perforation. With the emerging and development of natural orifice transluminal endoscopic surgery (NOTES) as a minimally invasive surgical platform, endoscopic suturing is especially important. Here, we studied the feasibility of new developed endoscopic suturing device by demonstrating the strength of closure in ex vivo animal study.
**Aims & Methods:** A total of 30 porcine stomachs were used for the test. Standard gastrotomy was made on each stomach by blade incision. Porcine stomachs were assigned randomly to 3 groups and closed by new endoscopic closer with curved needle (En-closer), endoscopic clips and hand sewn. Each stomach was inflated by an automated pressure gauge. After that, the stomach was dipped in water and air leakage pressure was measured by automated pressure gauge when an air bubble was first observed.
**Results:** The average leakage pressure for the En-closer, Endoclip, and full-thickness hand sutures was 43.25 mmHg, 44.10 mmHg, and 63.19 mmHg. The average closer strength of the En-closer does not significantly differ from that of the Endoclip ($p > 0.05$). The standard deviation for the En-closer, Endoclip, and full-thickness hand sutures was 6.37 mmHg, 14.35 mmHg, and 12.97 mmHg, respectively. The standard deviation of the En-closer is significantly smaller than that of the Endoclip and full-thickness hand sutures ($P < 0.05$). It is determined that the closer strength of the En-closer does not significantly differ, but is more consistent than the closer strength of the Endoclip.
**Conclusion:** The En-closer, which can performs multiple stitches with a single endoscope insertion showed feasible result comparing with Endoclip and hand-sewn suture. This research proposes a novel approach for minimally invasive endoscopic surgery.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1223 NEWLY DESIGNED HIGHLY FLEXIBLE MAGNETIC DEVICE FOR ENDOSCOPY ASSISTED FERROMAGNETIC FOREIGN BODY REMOVAL

**V. Sharma**[1], R. Sharma[2]
[1]*Gastroenterology, Manipal Hospital, Jaipur/India*
[2]*Public Health, Regional Institute of Health, Medicine and Research, Jaipur/India*

**Contact E-mail Address:** vijaysadashiv@yahoo.com
**Introduction:** Metallic foreign bodies have been removed under endoscopic guidance. Removal of sharp objects using an overtube or hood has been reported, It can be hazardous. There are reports of magnetic devices which are less flexible, with plastic sheath and thick metal wire. We have designed a newer device.
**Aims & Methods:** To evaluate our experience with newly designed highly flexible magnetic device for endoscopy guided Ferromagnetic foreign body removal Patients presenting with history of metallic foreign body ingestion included. X ray abdomen done. Informed consent taken. We used nitinol hydrophilic guide wire (200 cm in length, 0.035 inch thick) with two 6-mm-diameter magnetic discs (with a strength of 0.18 tesla) fixed at the base of 10 cm long hydrophilic tip. A ligator cylinder was used during foreign-body retrieval (Figure [1]). The cylinder was fixed at the tip of the endoscope. Guide wire passed in the channel through the tip of the endoscope, So that the magnet was positioned at the tip of the endoscope. As the endoscope reached the foreign body, the magnet was pushed out and the foreign body stuck to the magnet. Part of foreign body and magnet were then drawn into the cylinder and the endoscope was removed. Pentazocine (15 mg) and hyosine butylbromide (20 mg) were used as premedication. The time required, and the complication and failure rates were recorded.
**Results:** Ten patients 9 children (1 to 10 years old), one 18 years old female, who had ingested sharp and rounded foreign bodies were included in the study. 5 cases ingested large coin, 1 had ingested pin, 1 had ingested safety pin, 1 ingested key, 1 child had ingested earring, 1 ingested screw, no foreign body was impacted and none penetrating. 9 foreign bodies were in stomach, while key just beyond DJ flexure. All the foreign bodies were removed using this method without any complications in mean time of 57 seconds (range 40–126 seconds). We first time used our instrument for coins (figure 2), later for sharp metals. We could use our retriever for gastric foreign body even in nonfasting patient. Key reached beyond DJ flexure, we pushed the magnetic retriever beyond DJ flexure, took out the key. In duodenum and proximal jejunam where placing the scope is difficult, using the endoscopic accessories like snare and rat-tooth forceps not possible this

device can be used. This new retriever which is more flexible because of use of nitinol guidewire, and the magnet is small and strong, it can get stuck to foreign body in food material, it can reach up to proximal jejunum to takeout foreign body. The sharp foreign bodies were light and so were attracted by the small magnet, and the pulling back of the magnet led to their disimpaction. We have not used it for penetrating sharp foreign bodies, possible they can also be pulled out because the head portion of the pins and safety pins can be visualized. The portion of the foreign body with a larger surface area had a tendency to stick to the magnet, and tend to aligned themselves along their longitudinal axis. The sharp end of the foreign body followed the head, thus avoiding mucosal injury. This device is safe for use even in small kids, no risk of injury to endoscope and Gastrointestinal wall, no need of sheath to cover the wire. Size of magnet is small so it can easily cross Narrow areas of upper GIT.
**Conclusion:** New magnetic device is highly flexible, easy to use, with no risk of injury to patient and scope, effective even for proximal jejunum ferromagnetic foreign body removal.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1224 CLINICAL OUTCOMES IN VERY ELDERLY PATIENTS WITH GASTRIC CANCER TREATED USING ENDOSCOPIC SUBMUCOSAL DISSECTION: ANALYSIS WITH EMPHASIS ON THE RELATIONSHIP BETWEEN PATIENT CHARACTERISTICS AND PROGNOSIS

**M. Sekiguchi**[1], I. Oda[1], H. Suzuki[1], S. Abe[1], S. Nonaka[1], S. Yoshinaga[1], H. Taniguchi[2], S. Sekine[2], Y. Saito[1]

**Contact E-mail Address:** masekigu@ncc.go.jp

**Introduction:** With an increase in the aging population, there are increasing chances of encountering very elderly patients with early gastric cancers (EGCs). Now endoscopic submucosal dissection (ESD), which has been widely accepted as a less invasive treatment option for EGC compared with surgery, is increasingly performed for the very elderly patients. However, only limited data are available regarding gastric ESD in this population. Furthermore, the prognosis of very elderly patients with EGC treated using ESD and the associated prognostic factors have rarely been examined, although these are essential in determining the significance of treatment with ESD in this population.
**Aims & Methods:** Here, we aimed to examine the clinical outcomes and prognosis in very elderly patients with EGC treated using ESD and to identify the associated prognostic factors. We retrospectively reviewed 108 elderly patients aged≥ 85 years with 149 EGC lesions treated using ESD between January 1999 and December 2014 at our institution. The evaluated outcomes included en bloc/R0/curative resections, complications, procedure time, and overall survival (OS). To identify the prognostic factors, the relationships between OS and the following factors were assessed by univariate analysis using log rank tests and multivariate analysis using a Cox proportional hazard model: ESD curability, sex, performance status (PS), Charlson comorbidity index (CCI),[1] Onodera's prognostic nutritional index [PNI, calculated using the following formula: 10 × serum albumin value (g/dl) + 0.005 × total lymphocyte count (per $mm^3$) ],[2,3] the neutrophil-to-lymphocyte ratio (NLR),[4] and the modified Glasgow prognostic score (mGPS).[5]
**Results:** The patients included 82 males and 26 females, with a median age of 86 years (range: 85–93 years). PS according to the Eastern Cooperative Oncology Group (ECOG) scale was 0–1 for all patients, and PS according to the American Society of Anesthesiologists was 2 in 89 patients and 3 in 19 patients. CCI varied between 0 and 5, and 94 patients (87.0%) showed an index of 1 or higher. In the majority of patients (92.6%), mGPS was 0. The median value of PNI was 48.9 (range: 31.4–59.1), and the median NLR was 2.2 (range: 0.6–7.3). En bloc, R0, and curative resections were achieved in 98.0%, 91.3%, and 72.7% lesions, respectively, with a median procedure time of 60 min. Regarding complications, perforation and delayed bleeding were observed in 0.7% and 5.4% lesions, respectively. There were no severe complications that required surgery and no treatment-related deaths. Following ESD, 23 deaths, including two deaths due to gastric cancer, were observed during the median follow-up period of 40.2 months (range: 1.8–108.7 months); the 3- and 5-year OS rates were 90.3% and 72.0%, respectively. Univariate analysis showed that PNI was the only factor significantly associated with OS; the 3- (54.3% vs. 95.9%) and 5- (54.3% vs. 76.3%) year OS rates were significantly lower in patients with low PNI (< 44.6; the cutoff value was determined using the receiver operating characteristic analysis) than higher PNI ($P < 0.001$). In addition, multivariate analysis showed that low PNI (< 44.6) was the only independent risk factor for poor OS (HR, 5.5; 95% CI, 1.9–15.8; $P = 0.002$).
**Conclusion:** The present study clarified the feasibility and safety of ESD for elderly EGC patients aged≥ 85 years with ECOG-PS between 0 and 1. The finding that a relatively large proportion of the elderly patients treated using ESD were estimated to live longer than 5 years also supports the validity of ESD for this population. However, patients with low PNI were found to be at higher risk of poor prognosis, indicating the need to evaluate PNI in determining whether to perform ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1225 THE EFFECT OF A FLEXIBLE 3D ENDOSCOPE ON THE LEARNING CURVE OF ENDOSCOPIC SUBMUCOSAL DISSECTION: A BENCH TOP EX-VIVO STUDY

**B.P.M. P.M. Yeung**, D. X. Xia, C. C.H. Lam, P.W.Y. Chiu
*Surgery, Prince Of Wales Hospital, Chow Yuk Ho Technology Center for Innovative Medicine, The Chinese University of Hong Kong, Shatin/Hong Kong Prc*

**Contact E-mail Address:** byeung@doctors.net.uk

**Introduction:** Endoscopic submucosal dissection (ESD) is a technically challenging procedure with a steep learning curve. The lack of depth perception from a conventional 2D endoscope may be a contributing factor to its difficulty. This study assesses the effect of a 3D flexible endoscope on the learning curve of gastric ESD.
**Aims & Methods:** This is a prospective preclinical bench study to compare the effect of 3D endoscope on the performance of ESD between an experienced endoscopist and a novice. The participants included an endoscopist with more than 1000 endoscopic procedures but little experience in ESD and a novice with total endoscopic experience of less than 50 cases. The performance of gastric ESD was standardized in an ex-vivo porcine model using a prototype 3D endoscope (Olympus R&D, Tokyo, Japan). Each participant was asked to perform 8 ESD over the greater curvature using Dual knife jet (Olympus Co Ltd). The time to complete ESD, occurrence of perforation and en-bloc resection rate were recorded. Resected specimens were digitalized and surface area was calculated using GIMP 2.8 image analysis software. Descriptive statistics and non-parametric analysis was performed using IBM SPSS v22.
**Results:** En bloc resection was achieved in all ESD procedures without perforation. The median resected area by the experienced endoscopist was $3.8cm^2$ (min: $1.04cm^2$ max: $7.9cm^2$), which showed no significant difference from that achieved by the novice endoscopist with the median area of 3.3 $cm^2$ (min: $0.86cm^2$ max: $8.25cm^2$) ($p = 0.87$). The median operative time corrected for surface area resected for the experienced endoscopist was 197.9 $s/cm^2$ (min: 60.9 $s/cm^2$ max: 1897.4 $s/cm^2$), which was significantly lower than that of the novice endoscopist (median resection speed = 434.7 $s/cm^2$ (min: 217.2 $s/cm^2$ max: 1544.2 $s/cm^2$)) ($p = 0.05$). For both participants, resection speed plateaued after the third ESD procedure. The learning curve can be summarize by the equation $y = 1183.4x^{-0.807}$ ($R^2 = 0.6927$).

| Trial | Experienced ($s/cm^2$) | Novice ($s/cm^2$) |
|---|---|---|
| 1 | 1897.4 | 1544.2 |
| 2 | 1066.1 | 332.2 |
| 3 | 236.0 | 337.5 |
| 4 | 201.1 | 358.0 |
| 5 | 194.8 | 217.2 |
| 6 | 74.8 | 679.8 |
| 7 | 119.1 | 568.6 |
| 8 | 60.9 | 511.4 |

**Conclusion:** This preclinical bench study illustrated that the use of prototype 3D endoscope may shorten the learning curve for ESD. 3D images improved depth perception for the endoscopist and resulted in better en-bloc resection as well as preventing perforation. This will especially be useful for low experience endoscopists to master ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1226 PRACTICAL STRATEGY FOR INVASION DEPTH PREDICTION OF EARLY GASTRIC CANCER BY CONVENTIONAL ENDOSCOPY AND ENDOSCOPIC ULTRASONOGRAPHY

**J. Cheng**, X. Wu, X. Lu, A. Yang
*Digestive Department, Peking Union Medical College Hospital, Beijing/China*

**Contact E-mail Address:** chengjieyaosan@163.com

**Introduction:** Conventional endoscopy (CE) and endoscopic ultrasonography (EUS) are useful approaches for predicting the depth of invasion in early gastric cancer (EGC), but the diagnostic accuracy were unsatisfatory.

**Aims & Methods:** This study aimed to propose an effective strategy by combining CE and EUS for therapuetic decision.

**Methods:** A total of 150 patients (156 lesions) with superficial gastric cancers underwent both CE and EUS before therapy at Peking Union Medical College Hospital from January 2006 to December 2015. All the lesions were resected either endoscopically (n = 98) or surgically (n = 58), and divided into two histologic groups: superficial invasion referred cancers that limited in mucosal layer or less than 500$\mu$m into the submucosal layer (m/sm1, n = 126) and deep invasion referred those which were more than 500$\mu$m into the submucosal layer or deeper ($sm^2$ or deeper, n = 30). Endoscopic images of CE were reviewed by one experienced endoscopist who was blind to the clinical information, and invasion depth were predicted. The EUS-based tumor depth was reported according to the EUS records, which combined the endoscopic features and ultrasonographic images in practice. Diagnostic accuracy of each method was compared with the histology of the resected specimen. And impact factors for diagnosis were investigated.

**Results:** The overall accuracy rates in invasion depth of superficial gastric cancer were 80.1% for CE and 83.3% for real EUS respectively (P = 0.73). But in the subgroup with more observer confidence, diagnostic accuracy of CE was significant higher than that with unconfidence (92.1% vs. 72.0%, $P < 0.01$). Impact factors associated with CE mis-staging included: unclear images (OR = 418.4, $P < 0.01$), remarkable redness of lesions (OR = 16.2, P = 0.01), histological $sm^2$ or deeper invasion (OR = 1830.7, $P < 0.01$) and undifferentiated carcinoma (OR = 60.7, P = 0.01). Nine of 17 lesions (52.9%) were over-staged by CE, which were expected as surgical candidates. 41.2% of the over-staging lesions avoided surgery by additional EUS assessment.

**Conclusion:** Both CE and EUS are useful for T-staging of superficial gastric cancers. Observer confidence is associated with higher accuracy of CE. Sequential EUS may avoid overtreatment for the lesions with superficial invasion.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1227 EVALUATION OF ENDOSCOPIC TREATMENT FOR SUPERFICIAL DUODENAL NEOPLASM

**Introduction:** Superficial duodenal neoplasm is a rare disease. Recently, the improvement of endoscopic technologies has been suggested to lead to better recognition of duodenal adenoma and early cancer. Duodenal ESD has not been standardized because of difficulty and a very high risk of complications. However, the surgical treatment loads a large burden and functional disorder may remain depending on the location. Thus, minimally invasive treatment is needed.

**Aims & Methods:** In this study, the outcomes of 183 duodenal tumors treated at our hospital between July 2010 and February 2016 were investigated, and the safety and efficacy of EMR and ESD were evaluated.

**Results:** The subjects were patients at a mean age of 62.4 years old (29–85), and the sex ratio (male/female) was 115/56. The location of the lesion was bulb in 24, SDA in 19, descending part in 124, LDA in 10, and horizontal part in 6, circumferentiality was <1/2 in 163 and >1/2 in 20, and the macroscopic type was elevated in 141 and depressed in 42. The treatment method employed was EMR in 62, ESD in 106, circumferential EMR in 5, EMRL in 3, and resection by forceps in 5. The mean tumor diameter was 18.3 mm (2–60), and the lesion was adenoma in 126, cancer in 47, carcinoid in 6, and others in 4. The cancer-bearing rates exceed with the tumor size. By the procedure, in 62 lesions treated with EMR (excluding large Brunner gland adenoma in the bulb treated with planned piecemeal resection), the mean tumor diameter was 9.1 mm (2.5–21), and the lesion was adenoma in 56, adenocarcinoma in 3, carcinoid in 1, and another in 2. The en bloc resection rate was 95% (59/62), and the complete en bloc resection rate was 75% (47/62). No complication occurred (delayed bleeding: 0, perforation: 0). In the 106 lesions treated with ESD, the mean tumor diameter was 24.6 mm (2–75) and mean procedure time was 77.5 minutes (10–360). The lesion was adenoma in 60, adenocarcinoma in 43, carcinoid in 2, and another in 1. The en bloc resection rate was 97% (103/106), and the complete en bloc resection rate was 81% (82/106). Regarding complications, delayed bleeding and perforation occurred in 9 (8%) and 13 (13%), respectively. All delayed bleeding cases were conservatively treated by endoscopic hemostasis. Perforation required surgical treatment in 2 (2%).

**Conclusion:** This study clarified that the cancer-bearing rate of duodenal tumors rises with an increase in the diameter. For small lesions, EMR with a simple procedure causing fewer complications may be sufficient, but reliable resection is needed for the treatment of large lesions. Although duodenal ESD is very difficult with a high risk, when it is performed by experienced experts at advanced high-volume centers, it may be minimally invasive treatment for which marked efficacy while retaining safety can be expected.

## P1228 CREATION OF GASTROINTESTINAL SUBMUCOSAL TUNNEL UPON SUBMUCOSAL INJECTION OF A PLGA-PEG-PLGA THERMOGEL IN A PORCINE MODEL: THE NEXT GENERATION OF TUNNEL ENDOSCOPY? (WITH VIDEO)

**M. Min**, Y. Liu, L. Wang, Y. Bi
*Gastroenterology And Hepatology, Affiliated Hospital of Academy of Military Medical Sciences, Beijing/China*

**Contact E-mail Address:** minmin823@sina.com

**Introduction:** Tunnel endoscopy is an innovative endoscopic technique which plays a crucial role in multiple endoscopic interventions. The creation of a gastrointestinal submucosal tunnel is, however, still technically challenging and time consuming, which significantly limits its clinical applications.

**Aims & Methods:** To evaluate the use of a biocompatible and biodegradable poly (lactic acid-co-glycolic acid)-poly (ethylene glycol)-poly (lactic acid-co-glycolic acid) (PLGA-PEG-PLGA) thermogel (a physical hydrogel formed simply by body heating after injection) as the submucosal injection agent for facilitating the establishment of a submucosal tunnel in esophagus, stomach, and colon.

**Results:** Submucosal tunnels were established successfully in all three sites for all three minipigs without any complications. The PLGA-PEG-PLGA aqueous solution was easily injected into colonic submucosa and then transformed into a semi-solid gel due to contacting with warmer surroundings, resulting in the formation of a thick submucosal cushion. The cap-fitted endoscope was introduced into submucosal space and moved forward gradually by suctioning the in situ-formed thermogel until the tunnel was completed. There was no need for additional electrocautery or blunt dissection. Neither bleeding nor perforation occurred. The median procedure time was only 13.6 mins, 11.5 mins, and 9.6 mins, respectively.

**Conclusion:** Our experiments confirmed that PLGA-PEG-PLGA thermogel was suitable as a submucosal injection substance to establish tunnels safely, conveniently, and rapidly in digestive tract, and had a significant advantage by conducting submucosal auto-dissection in the cushion along the inherent anatomical layer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** matantau@gmail.com

**Introduction:** In patients with achalasia, peroral endoscopic myotomy (POEM) is now the proposed method to replace other endoscopic treatments, having a low morbidity and similar or even higher efficacy than its surgical counterpart, the Heller myotomy. However, balloon dilatation is still performed by many.

**Aims & Methods:** The aim of the present study was to test the effectiveness, the outcome at one year and complications of POEM in consecutive patients with symptomatic achalasia in comparison with pneumatic balloon dilatation. All patients who presented with symptomatic achalasia were treated with either pneumatic dilatation or POEM, depending on the age, comorbidities, previous esophageal surgery or patient's wish. Symptoms were assessed using the Eckardt score (0–12). Endoscopic and radiological assessments were performed in all patients before treatment and at 1 month after treatment. In patients undergoing POEM, a manometry was also carried out before and 1 month after treatment. The patients were regularly contacted for follow-up at 1, 6 and 12 months after treatment. Patients with failure of the initial procedure were treated again, depending on the initial response and the patient's wish.

**Results:** From November 2013 to May 2015, 46 consecutive patients were treated with either POEM (n = 35) or pneumatic dilatation (n = 11). No patient had previous surgical myotomy in the POEM groups, while 4 patients had previous Heller myotomy in the dilatation group. There were significant improvements in the Eckardt scores of all patients treated, in both the POEM group (before 7.8, after 0.8) and the dilatation group (before 7.5, after 1.7). We recorded 5 incidents in the POEM group, 3 esogastric microperforations, closed safely with endoscopic clips, 1 subcutaneous emphysema, for which temporary cessation of the intervention was necessary, and 1 pneumoperitoneum, for which transumbilical decompression using a Veres, needle was necessary. We also recorded 2 complications in the form of postprocedural endoscopic clip slippage, which required endoscopic reintervention. No incidents or complications were noted in the dilatation group. All patients treated with POEM were symptom free at 1, 6 and 12 months after treatment. In the dilatation group, 3 patients relapsed at 3 months after treatment, needing additional dilatation. The 8 other patients remained symptom free at 6 and 12 months. There were no statistical significant differences ($p = 0.083$) with regard to overall treatment failure and outcome at one year between patients treated with POEM and those with balloon dilatation.

**Conclusion:** POEM is an efficacious method for treating achalasia but requires an expert endoscopist with special training. Even in centers where POEM is the standard of care, selected cases could benefit from balloon dilatation, with a similar medium-term efficacy to POEM.

## P1230 A SIMPLE MATHEMATICAL EQUATION FOR RELIABLE PREDICTION OF THE GASTRO-ESOPHAGEAL JUNCTION THROUGH THE SUB MUCOSAL TUNNEL DURING PER ORAL ENDOSCOPIC MYOTOMY – A PROOF OF CONCEPT PILOT STUDY

**Introduction:** Per oral endoscopic myotomy (POEM) is an accepted treatment for achalasia cardia (AC). Accurate estimation of distance to gastro-esophageal junction (GEJ) through the tunnel is often a technical challenge during POEM. Currently employed methods have limited accuracy. Tunneling is often performed by periodically alternating between tunnel and lumen to ensure extension up to and beyond GEJ. An error at this step may lead to an incomplete myotomy; and procedure time may be prolonged. We have observed that distance to GEJ measured through the tunnel is longer than when measured through the esophageal lumen.

**Aims & Methods:** Our hypothesis states that additional distance when traversing the tunnel is directly proportional to the esophageal diameter; and can be calculated by an equation $X = Y + CZ$ (X = GEJ distance through tunnel, Y = GEJ distance through lumen, Z = max. esophageal diameter & C = arithmetic constant). If a reliable C is derived, estimation of GEJ distance during POEM may be possible. This study evaluates accuracy of this hypothesis & the calculated C constant. Patients & methods: Total N = 22: Gr. I – 12 retrospective patients who had undergone POEM; Gr. II – 10 prospective patients undergoing POEM. A single operator performed all POEM procedures. Distance to GEJ (Y) was recorded during screening EGD. Max. esophageal diameter (Z) was measured on Barium swallow / CT scan. In Gr. I, GEJ distance through tunnel was measured and recorded during POEM (X). Using formula $C = (X - Y)/Z$, C was calculated. Mean C +/- 2 SD was calculated for Gr. I. This mean C was substituted in equation $X = Y + CZ$ to predict GEJ distance through tunnel (X1) in Gr. II. Y and Z were calculated as in Gr. I. X1 was predicted pre POEM and values were blinded from operator. During POEM, operator recorded true X (X2). X1 & X2 values were compared.

**Results:** POEM was successfully performed in all. Group I (n = 12, 4 – sigmoid) – mean values (range) for X, Y and Z were 42.58 cm (38 – 47), 39.83 cm (36 –45) and 4.39 cm (2.78 – 6.25) respectively. Mean C (Gr. I data) = 0.63 (SD +/- 0.11). Group II (10 patients, 2 – sigmoid) –mean Y = 40.3 cm (36 – 43), mean Z = 6.19 cm (3.75 – 9.62). Mean estimated X1 = 44.199 (40.49 – 48.06), true X2 = 44 cm (41 – 48). X1 and X2 values showed excellent correlation (Correlation coefficient = 0.991, $p < 0.01$).

**Conclusion:** Disparity in distance to GEJ through lumen and through tunnel is seen during POEM and appears to be proportional to the esophageal diameter. This pilot study suggests an excellent correlation between estimated and actual distances, indicating that the hypothesis & calculated constant C = 0.63 shows excellent reliability throughout current dataset. The equation $X = Y + CZ$ can be used to accurately predict GEJ distance during tunneling. Further studies with a larger database are required to confirm this finding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1231 SAFETY AND EFFICACY OF COLD POLYPECTOMY FOR NONAMPULLARY DUODENAL ADENOMA: A PROSPECTIVE CLINICAL TRIAL

**D. Maruoka**, M. Arai, S. Kasamatsu, H. Ishigami, T. Taida, K. Okimoto, T. Matsumura, T. Nakagawa, T. Katsuno

**Introduction:** Studies have revealed that cold polypectomy (cold forceps polypectomy [CFP] and cold snare polypectomy [CSP]) is an exceptionally safe and effective treatment for colorectal polyps [1, 2]. With regard to the duodenum, the number of nonampullary duodenal endoscopic resections has been gradually increasing [3]. However, duodenal endoscopic resection has a high incidence of complications such as perforation in the endoscopic mucosal resection (EMR) as well as in the endoscopic submucosal dissection (ESD), compared to resection of other parts of the digestive tract. Therefore, relatively safer treatment alternatives such as cold polypectomy should be considered. However, the cases of duodenal cold polypectomy have been unreported. In this prospective study, we aimed to assess the safety and efficacy of nonampullary duodenal cold polypectomy.

**Aims & Methods:** Patients with one or more small nonampullary duodenal adenoma lesions were enrolled in this clinical trial, while those with polyposis syndrome, including familial adenomatous polyposis (FAP); those with coagulation abnormalities; and those receiving antithrombotic drugs were excluded. The study subjects underwent cold polypectomy (CFP or CSP) between March and November 2015, and subsequent upper gastrointestinal endoscopy 3 months after the intervention. The presence of residual tumor was evaluated by conducting endoscopic examination and histopathologic of tissue samples obtained from the cold polypectomy scars. This study was approved by our institutional medical ethics board.

**Results:** A total of 25 lesions in 19 patients were removed using cold polypectomy. Eleven patients (58%) were men and the mean age of the subjects was $62.7 \pm 11.8$ years. The number of lesions was 5, 17, and 3 per lesion location (1st., 2nd., and 3rd. portion), respectively, and 8, 12, 3, and 2 per macroscopic appearance (Is, IIa, IIa + IIc, and IIc), respectively. Nine lesions in 8 patients were resected using CFP, while 16 lesions in 11 patients were resected using CSP. Seven of 9 (77.8%) and 15 of 16 (93.8%) lesions were removed en bloc using CFP and CSP, respectively; other 3 lesions were removed by piecemeal resection in 2 pieces. All specimens resected using both CFP and CSP were successfully retrieved. Histopathologic analysis showed that 22 of 25 lesions (88%) were adenomas; 19 (76%) were low-grade tubular adenoma; and 3 (12%) were high-grade tubular adenomas. The mean size of the adenomatous lesions was $4.0 \pm 1.4$ mm (2–6 mm). Nine of 22 adenomas (41%) were R0 resections; 3 of 9 (33%) and 6 of 13 (46%) were R0 resections using CFP and CSP, respectively. All post-resection ulcers were closed immediately after cold polypectomy by endoscopic clips. Delayed bleeding and intraprocedural/delayed perforation were not observed in any case. In all patients with adenomas, the scars were identified and biopsied at follow-up endoscopy performed 3 months after cold polypectomy. No residual or recurrent tumor was detected morphologically or histopathologically.

**Conclusion:** Cold polypectomy is a safe and effective treatment for small nonampullary duodenal adenomas. A multi-centric long-term follow-up study with a larger sample size should be conducted to confirm the safety and effectiveness of cold polypectomy for nonampullary duodenal adenoma.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1232 ENDOSCOPIC DIAGNOSIS FOR ELEVATED EARLY GASTRIC CANCER THAT SHOWED ADENOMA BY BIOPSY BEFORE ESD

**H. Sawai**, S. Kushida, T. Mimura, Y. Yamamoto, H. Inokuchi
*Hyogo Cancer Center, Akashi/Japan*

**Contact E-mail Address:** h.sawai@hp.pref.hyogo.jp

**Introduction:** Endoscopic differential diagnosis of adenoma and well differentiated adenocarcinoma is considered to be difficult on some gastric elevated tumor. On these lesions, Endoscopic findings of magnified narrow band imaging (M-NBI) was reported to be useful for diagnosis of cancer.

**Aims & Methods:** The aim of this study is to clarify retrospectively details of endoscopic diagnosis for elevated gastric tumor that pathological findings of biopsy performed before endoscopic submucosal dissection (ESD) showed adenoma. From January 2006 to March 2015, 50 lesions in 45 patients were treated by ESD for elevated gastric tumor that pathological findings of biopsy before ESD showed adenoma in our institution. We retrospectively confirmed endoscopic findings, and performed differential diagnosis of gastric adenoma and early gastric cancer (EGC). We defined lesions with redness, depression or rough-surfaced mucosa as cancer on white light imaging and irregular microsurface pattern (IMSV) or irregular microvascular pattern (IMVP) as endoscopic findings of EGC on M-NBI. We clarified clinicopathological features, outcomes of ESD and details of endoscopic diagnosis including sensitivity, specificity, accuracy and so on. In addition, we investigated predictive factors for cancer by uni and multivariate analysis.

**Results:** The clinicopathological features and the details of ESD were as follows; male/female:33/12, median age:72y.o.(57–82) median tumor size:14 mm (4–34) adenoma/EGC:9/41. Histologiacal type of EGC was only well differentiated adenocarcinoma. Sensitivity/specificity/accuracy:75.6%/66.7%/74.0% on WLI and 95.1%/77.8%/92.0% on M-NBI. Among 10 cases that we could not diagnosis as cancer on WLI, nine cases were correctly diagnosed on M-NBI. Positive predictive value of endoscopic findings of cancer: redness:89.5%, depression:100%, rough-surfaced mucosa:88.9%, tumor size (>20 mm):79.2%, IMSP:94.4% and IMVP:100%. On multivariate analysis, IMSP and IMVP were significant predictive factor of cancer.

**Conclusion:** Endoscopic diagnosis by M-NBI is considered to be useful for diagnosis of elevated early gastric cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1233 POEMS POTPOURRI: THE ROUTINE X-RAY AND ENDOSCOPY ARE NOT NECESSARY AFTER POEM; ASPIRIN DOES NOT INCREASE THE RISK OF BLEEDING

**J. Bayer**[1], H. Svecova[2], Z. Vackova[1], J. Krajciova[1], J. Spicak[1], J. Martinek[1]

[2]*Dept. Of Transplant Surgery, IKEM, Prague/Czech Republic*

**Contact E-mail Address:** busta-bayer@web.de

**Introduction:** Peroral endoscopic myotomy (POEM) is a promising new endoscopic method for the treatment of achalasia. The role of several pre-, peri- and postprocedural measures which have been implemented in several centers have not been assessed yet. In our center, we do not require the discontinuation of aspirin before POEM. On the first post-operative day (POD 1), we used to perform both upper GI endoscopy and X-ray with water-soluble contrast to exclude POEM-associated adverse events (AEs), such as a leak or mucosal injury; now, patients are checked by X-ray only.

**Aims & Methods:** The aim of this retrospective study was to analyze 1. the risk of bleeding in patients who had been treated with aspirin before POEM, and 2. to assess the value of routine post-operative examinations (X-ray and upper GI endoscopy) which are usually performed on POD 1.

**Results:** A total of 138 POEM procedures have been performed in 134 patients (4 re-POEMs) in our center since 2012 (mean age 46.5). Only one patient experienced a severe AE (pleural effusion) which required prolonged hospitalization (15 days) with drainage; otherwise, we have not experienced any other severe AE and all patients were discharged on POD 1–2 (mean hospital stay was 1.8 days (SD 1.4)). A total of 10 patients were treated with aspirin (or other antiaggregants) prior to POEM; 3 of these patients had aspirin withdrawn before the procedure. Minor bleeding during POEM occurred in 4 patients (3%) and were successfully managed endoscopically; all occurred in patients without aspirin. We did not experience any bleeding after POEM on POD 1, 2 or later. Upper GI endoscopy on POD 1 was done in 79 patients; out of these, 7 had minor findings such as mucosal injury (all resolved spontaneously) and 3 received additional clips at the site of incision. X-ray on POD 1 was done in 134 cases, and a minor leak was present in 4 of these (2.9%) – these patients were left on nil per mouth and all leaks resolved spontaneously.

**Conclusion:** Routine post-POEM X-ray examination and/or upper GI endoscopy in patients with achalasia are probably not warranted because of the negligible rate of clinically relevant findings. Furthermore, the use of aspirin does not seem to increase the risk of peri- or postprocedural bleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The epidemiology of bleeding from variceal (V) and non-variceal (NV) sources and the risk factors for upper gastrointestinal bleeding has changed over the time. The increased proportion of older patients with different comorbities together with an improved life expectancy modified the risk factors for death by acute upper bleeding.

**Aims & Methods:** We aimed to verify the mortality causes in patients with variceal and non-variceal gastrointestinal sources of bleeding. Data on patients admitted for GI bleeding were collected from Jan 2014 to Jan 2016. Related haemorrhagic death is defined as any death occurred within 30 days from the admission for patients with NV bleeding and within 42 days for those with varices. Mortality due to bleeding episode was defined as any death occurred within 48 hours from the endoscopy.

**Results:** A total of 3224 patients were included. Of these 2,764 (83.1%) had a NV source (mean age 69.1 ± 16.2) and 560 had varices (mean age 63.2 ± 12.3) ($p < 0.000$ for age). Comorbidities were present in 79.8% of the patients with NV and in 55.9% with V ($p < 0000$). The most frequent comorbidity was cardiovascular diseases in NV (38.2%) and neoplasia in V (23.7%). The mean Rockall score was 3.9 (±1.9) in NV and the mean Child-Pugh score was 7.5(±3.0) in V. At admission, mean Hb value was 9.2 gr/dl (±2.6) for NV and 8.9 gr/dl (±2.0) for V ($p < 0.006$) and hemodynamic instability was presented in 7.6% of NV and in 10.1% of V ($p < 0.000$). More than half of the patients were transfused (58.2% of NV and 67.9% of V; $p < 0.000$). The mortality rate was 5.6%. in NV vs 11.9% in V ($p < 0.000$). In both groups, mortality was due to the bleeding episode only in 24% of the patients, while in the rest was related to underlining diseases (e.g. multiorgan failure, respiratory and/or renal failure, table 1).

| | Variceal bleeders | Non Viriceal bleeders |
|---|---|---|
| **Death causes** (%) Related to the bleeding episode Not directly related to the bleeding episode | 24.1 75.9 | 24.4 75.6 |
| **Causes of death (%)** | | |
| Liver failure | 32.3 | – |
| Multiorgan failure | 24.6 | 26.3 |
| Terminal neoplasia | – | 21.8 |
| Respiratory failure | 12.3 | 16.3 |
| Sepsis | 10.8 | – |
| Myocardial infarction | | 8.2 |
| Hepatic encephalopathy | 6.1 | – |
| renal failure | 3.1 | 5.4 |
| Stroke/intestinal infarction | – | 1.8 |

**Conclusion:** Comorbities are common both in variceal and in non-variceal bleeders and negatively impact on the mortality of GI bleeders, accounting for about 75% of the causes of death in this population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1235 FEASIBILITY OF FULL-SPECTRUM ENDOSCOPY GASTROSCOPY, PREVALENCE OF DUODENAL PERIAMPULLARY DIVERTICULA, AND FUTURE OF DIRECT PER-ORAL CHOLANGIOSCOPY

**J. Song Md**, Y.H. Cho, M.A. Kim, J. Kim
*Digestive Disease Center, Department Of Gastroenterology, LCT Hospital, Suwon/Korea, Republic of*

**Contact E-mail Address:** tommymd@naver.com
**Introduction:** The recently developed Full-Spectrum Endoscopy (FUSE) gastroscopy platform, which has two lenses, one at the front and one on the side of the distal tip, has a much wider field of view (245°) than a standard forward-viewing single-lens gastroscope (150°), which facilitates the detection of hidden lesions, such as duodenal periampullary diverticula (PAD) or ampullary lesions. Duodenal PAD is difficult to find with traditional gastroscopy, despite the 11–40% detection rate with endoscopic retrograde cholangiopancreatography (ERCP). However, no study has examined the prevalence of duodenal PAD in the general population using conventional gastroscopy rather than ERCP.
**Aims & Methods:** We were the first to use the FUSE system in Korea and this is the first report of a feasibility study on the use of this new system and on the prevalence of duodenal PAD in a Korean population using FUSE gastroscopy. We suggest that direct per-oral cholangioscopy can be performed with a modified FUSE gastroscope without radiation exposure. We explored the efficacy and safety of FUSE gastroscopy in a retrospective, single-center feasibility study performed between February 1 and December 31, 2015. After excluding 210 cases, 611 subjects (310 males, age 17–81 years) underwent FUSE gastroscopy for screening, surveillance, diagnostic evaluation, or a therapeutic procedure. We also assessed the prevalence and association of duodenal PAD.
**Results:** All of the diagnostic and therapeutic interventions, including endoscopic submucosal dissection (ESD), were performed successfully using the FUSE gastroscope. The insertion and guidance of endoscopic accessories to desired locations were convenient, and no gastroscopy was aborted because of equipment malfunction or failure. The duodenal periampullary portion was detected in all patients by FUSE gastroscopy without adverse events or complications. The prevalence of duodenal PAD was 20.5% (n = 125) and there were 2 (1.6%), 14 (11.2%), and 109 (87.2%) cases of types I, II, and III duodenal PAD, respectively. Gender and age were not associated with duodenal PAD, although subjects with non-specific gastric symptoms (epigastric pain, bloating, or indigestion) and colonic diverticula were more frequent in the duodenal PAD group ($p < 0.05$, Table). If another working channel were made on the side-lens portion then direct per-oral cholangioscopy would be possible with the aid of a baby scope, without radiation exposure.
Basic Charateristics and Prevalence of Duodenal Periampullary Diverticula (PAD)

| | All subjects | Subjects with Duodenal PAD | Subjects without Duodenal PAD |
|---|---|---|---|
| Number (%) | 611 | 125 (20.5%) | 486 (79.5%) |
| M:F | 310:301 | 67:58 | 243:243 |
| Age, mean ± SD | 47.5 ± 12.9 | 48.2 ± 13.3 | 47.4 ± 12.8 |
| ≤ 40, n (%) | 174(28.5%) | 33(26.4%) | 141(29%) |
| 41–60, n (%) | 341(55.8%) | 67(53.6%) | 274(56.4%) |
| ≥ 61, n (%) | 96(15.7%) | 25(20%) | 71(14.6%) |
| With gastric symptoms, n (%) | 337 (55.2%) | 79 (63.2%) | 258 (53.1%) |
| With colonic diverticula, in additional colonoscopy cases, n (%) | 73/364 (20.1%) | 23/73 (31.5%) | 53/291 (18.2%) |

**Conclusion:** This first Korean trial found that FUSE gastroscopy is feasible, safe, and effective. Moreover, using FUSE gastroscopy, the prevalence of duodenal PAD in the general population could be analyzed without using ERCP. In the future, FUSE gastroscopy is expected to be useful in direct per-oral cholangioscopy without radiation exposure.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1236 ENDOSCOPIC PUNCTURE-SUTURE DEVICE IN CLOSING THE DEFECT OF THE GASTRIC WALL AFTER FULL-THICKNESS RESECTION: SURVIVAL PORCINE STUDY

**J. Guo**, S. Sun
*Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/China*

**Contact E-mail Address:** guojt@sj-hospital.org
**Introduction:** Closure of gastric wall defects after endoscopic full-thickness resection remains a clinical challenge. We aimed to introduce an endoscopic puncture-suture device (EPSD) for the closure of such defects. To evaluate the safety and efficacy of the EPSD in gastric wall defect closure by comparing outcomes after the metallic clips closure method after endoscopic full-thickness resection.
**Aims & Methods:** Twenty-four mini pigs (weight range 20–25 kg) were randomly divided into two groups. The EPSD was used in the experimental group and metallic clips were used in the control group. Twelve pigs were randomly assigned to each group. Six pigs underwent endoscopic full-thickness resection (EFTR) on the anterior wall of the gastric body, while the other six pigs underwent the same procedure on the posterior wall. The diameter of the resection margin was 2 cm. The EPSD and metallic clips were applied to close the defects. Pre- and postoperative routine blood testing, serum ions, C-reactive protein, duration of the resection and closure, incidence of operative complications, and wound recovery were compared and analyzed according to the closure approach.
**Results:** For defects in the same sites, compared with the metallic clips method, EPSD significantly reduced closure time (27.5 minutes vs. 8 minutes in the anterior wall and 26.8 minutes vs. 7.8 minutes in the posterior wall). Both groups had comparable chemical examination index. The incidence of pneumoperitoneum in anterior-wall full-thickness resection was 83.3% (10/12). In the posterior wall full-thickness resection group, this incidence was 8.3% (1/12). Wound recovery in all subjects was satisfactory.
**Conclusion:** The EPSD is a device which can quickly, easily, safely, and effectively close the gastric wall defect after EFTR.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1237 PRELIMINARY REPORT OF A NEW SCISSOR-LIKE DEVICE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR SAFE AND EFFECTIVE TREATMENT OF ZENKER'S DIVERTICULUM

**H. Neumann**[1], S. Ishaq[2], A. Nägel[1]
[1]*Department Of Medicine I, University Hospital Erlangen, Erlangen/Germany*
[2]*Dept. Of Gastroenterology, Russell Hall, Birmingham/United Kingdom*

**Contact E-mail Address:** helmut.neumann@uk-erlangen.de

**Introduction:** Endoscopic therapy of Zenker's diverticulum is based on cutting the septum between the diverticulum and the esophageal lumen by using lasers, staplers, harmonic scalpels, argon plasma coagulation, or needle knives. Most recently, a new scissor-like device with serrated jaws for endoscopic submucosal dissection (ESD) was introduced. The device is fully rotatable and available in different lengths. In addition, the outer edges are insulated to minimize the risk of damaging tissue.
**Aims & Methods:** First study to prospectively assess the potential of the new scissor-like ESD device for treatment of Zenker's diverticulum. Therefore, patients with Zenker's diverticulum were prospectively enrolled. With the patient under conscious sedation a conventional feeding tube was first placed through the nose of the patient. A single channel endoscope with a clear distal cap was used for all examinations. The scissor like device allows for selective grasping and cutting of the septum and the muscle fibers. Performance characteristics, complications and follow-up data were recorded.
**Results:** Five patients were treated yet (mean age 74 years, Range 65–80 years; 3 female). Mean diameter of Zenker's diverticulum was 32 mm (Range 20–50 mm). Mean procedure time was 4.8 minutes (Range 3–7 minutes). No bleeding was recorded. In one case opening of the deep muscle layer occurred which was closed with 3 hemoclips. Postprocedural course was uneventful in all cases. All patients described significant symptom improvement without any relapsing symptoms (mean follow up time 10 months).
**Conclusion:** Endoscopic treatment of Zenker's diverticulum with the new scissor-like ESD device is fast and efficient. These preliminary findings should now be evaluated in future prospective, controlled multicenter Trials.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1238 THE USE OF A NOVEL EXTRACELLULAR SCAFFOLD MATRIX FOR HAEMOSTASIS DURING ENDOSCOPIC RESECTION IN PATIENTS AT HIGH RISK OF BLEEDING: A LITTLE GOES A LONG WAY

**S. Subramaniam**[1], F.J.Q. Chedgy[1], K. Kandiah[1], S. Thayalasekaran[1], G. Longcroft-Wheaton[2], P. Bhandari[1]
[1]*Gastroenterology, Queen Alexandra Hospital, Portsmouth/United Kingdom*
[2]*Gastroenterology, Portsmouth Hospitals NHS Trust, Hampshire/United Kingdom*

**Contact E-mail Address:** shar811@googlemail.com

**Introduction:** Endoscopic resection (ER) is an effective method for treating early gastrointestinal (GI) neoplasia. ER although safe, carries the risk of bleeding (particularly with deeper dissection) which can be as high as 15%. Conventional methods of controlling bleeding include the use of diathermy and clips. A novel extracellular scaffold matrix (Purastat®) has recently been approved for haemostasis within the GI tract. This self-assembling peptide forms a transparent gel that can be applied over the bleeding area.
**Aims & Methods:** We aimed to evaluate the technical feasibility of delivering this agent at the bleeding site as well as its safety and efficacy as a haemostatic agent. A secondary objective was to ascertain the mean volume of Purastat® required to cover the entire resection base when used as prophylaxis in this high-risk population. This was a prospective observational study of patients undergoing complex ER in a tertiary referral centre from December 2015-March 2016 where Purastat® was used. Purastat® was used prophylactically to prevent bleeding after resection of high risk lesions or for primary haemostasis when active bleeding was encountered during the procedure. Data was collected on patient demographics, lesion characteristics, technical feasibility of Purastat® application, haemostasis and complications. Surface area of the resection base was calculated using the equation: Area = $2*\pi*R*L*\%$circumferential extent/100. R=radius and L=length of lesion.
**Results:** Purastat® was used in 30 patients during the study period. The average age of the patients in this study was 72.3 years with a male:female ratio of 2:1. 25 patients (83.3%) had endoscopic submucosal dissection whilst 5 (16.7%) had endoscopic mucosal resection. 18 (60%) of the lesions were in the oesophagus, 5 (16.7%) each in the stomach and colon and 2 (7.4%) in the duodenum. 3 patients were fully anticoagulated on warfarin which was withheld pre- procedure. 6 patients were on single antiplatelet therapy (not withheld). Mean lesion size was 3.47 cm.
**Conclusion:** Purastat® is a safe device which is easy to use with an effective application system allowing quick and guaranteed delivery during endoscopic resection. Purastat® can limit the use of diathermy needed for intraprocedural bleeding control and reduces the risk of delayed bleeding. Unlike clips, Purastat does not pose a technical challenge to continuing endoscopic resection in view of its transparent nature. In addition, only a small amount of this agent is needed to effectively cover the resection base for prophylaxis in lesions with a high risk of bleeding. Further prospective randomised controlled trials are needed to understand the exact role of this novel haemostatic agent.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1239 ENDOSCOPIC TREATMENT FOR METACHRONOUS EARLY GASTRIC CARCINOMA IN A RECONSTRUCTED GASTRIC TUBE AFTER RADICAL OPEREATION FOR ESOPAGEAL CARCINOMA

**Y. Maeda**[1], H. Takeuchi[1], H. Kawakubo[1], R. Nakamura[1], Y. Kikuchi[1], K. Fukuda[1], K. Suda[1], N. Wada[1], T. Omori[2], Y. Kitagawa[1]
[1]*Surgery, Keio University School of Medicine, Tokyo/Japan*
[2]*Kawasaki Munichipal Hospital, Kawasaki, Kawanagawa/Japan*

**Contact E-mail Address:** yusuke_1015@hotmail.com

**Background:** The incidence of metachronous early gastric carcinoma in a reconstructed gastric tube after radical operation for esophageal carcinoma has increased as a result of the significant advances in both diagnostic procedures and anti-cancer therapy. We investigated the characteristics of the gastric tube cancer with endoscopic therapy and outcome after treatment.
**Patients and Methods:** We assessed 14 patients and 22 cases of metachronous gastric tube cancer reconstructed with a gastric tube after esophagectomy for esophageal cancer at the Department of Surgery, Keio University School of Medicine, from 2009 to 2015. We investigated the timing of tumor origin, therapeutic approach, disease complication, tumor size, invasion depth, histopathology and long-term outcomes.
**Results:** 13 patients were male and 1 patient was female. The median age at which gastric tube cancer was detected was 71.6 years (range 49–81 years).The median time from esophagectomy to detection of gastric tube cancer was 7.9 years. All patients were treated using endoscopic submucosal dissection (ESD). The median size of tumor was 22.7 mm (range 10–70 mm), depth of tumor invasion was M in 15 cases, SM1 in 2 cases, SM2 in 2 cases, and more than SM2 in 1 case. Curative resections were performed in 5 cases (23%) and non-curative resections were in 17 cases (77%). 4 cases were detected recurrences; local recurrence in 3 cases and peritoneal dissemination in 1 case. The post-operative complication observed only in one case with a delayed perforation of a reconstructed gastric tube after ESD. As emergency operation, the resection of gastric tube with transthoracic approach and the thoracic tube drainage was performed. Currently, 13 cases remain alive and only one case has died by recurrence.
**Conclusion:** As recent advances in diagnostic and treatment modalities for esophageal cancer improve patient survival after radical esophagectomy, the occurrence of a gastric tube cancer continues to increase. Surgical removal of the reconstructed gastric tube has been reported to be a more invasive procedure with high risk of postoperative morbidity and mortality. An extended indication of endoscopic resection should be considered for which are possible to non-curative cases. However endoscopic resection is widely used for the treatment, we experienced one case with a serious complication of delayed gastric perforation which was never reported before. Further investigations are required to establishment a treatment strategy for lesions that does not fulfill the indication for endoscopic resection.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1238 Table 1:** Purastat® Use for Prophylaxis and Primary Haemostasis

| Purastat® Use | Mean Lesion Size (cm) | Haemostasis achieved with Purastat® only | Haemostasis achieved with Purastat® + heat/clips | Delayed Bleeding (1 month) |
|---|---|---|---|---|
| Prophylaxis alone (n = 13) | 3.95 | N/A | N/A | 0 |
| Primary Haemostasis (n = 10) | 3.10 | 8 (80%) | 2 (20%) | 0 |
| Primary haemostasis + prophylaxis (n = 7) | 3.10 | 5 (71.4%) | 2 (28.6%) | 0 |

Purastat® on its own was effective in stopping bleeding in 13/17 cases (76.5%). Purastat® was easy to deliver with no incidences of catheter blockage and apposed well to the ER base during application. The mean surface area of the resection base for the entire cohort was 12.97cm$^2$ requiring a mean Purastat® volume of 2.81mls, equating to 0.22mls/cm$^2$. On follow up in 1 month, there were no postprocedural complications or delayed bleeding in any of the 30 patients.

## P1240 ENDOSCOPIC RESECTION FOR HYPERPLASTIC GASTRIC POLYPS: IS IT JUSTIFIED?

**B. Petit**[1], J. Rivory[2], V. Lepilliez[3], J.C. Saurin[1], T. Ponchon[1], M. Pioche[1]

[3]*Gastroenterology And Endoscopy, Mermoz Private Hospital, Lyon/France*

**Contact E-mail Address:** berepetit@hotmail.com

**Introduction:** A small proportion (1.5%–3% of the cases) of hyperplastic polyps shows dysplasia or intramucosal carcinoma. Thus, it is usually recommended to resect supracentimetric polyps for histologic examination. Recently, we experienced an extensive hyperplastic recurrence following ESD for a large hyperplastic polyp with dysplasia and then we decided to evaluate the results of endoscopic resections for those hyperplastic polyps in order to measure effectiveness and morbidity.

**Aims & Methods:** We conducted a retrospective analysis of all endoscopic resections for hyperplastic polyps over 1 cm performed in two tertiary care centers between 2012 and 2016. Histologic examination and follow up endoscopies were recorded in order to evaluate effectiveness and morbidity of those resections.

**Results:** 59 hyperplastic polyps were resected in 35 patients (23 male, 12 female). Among the 35 patients, 2 were cirrhotic patients and 11 had *H. Pylori* infection. 21 polyps were resected by endoscopic submucosal dissection (ESD), 35 with endoscopic mucosal resection (EMR), 3 were resected by hybrid technique (ESD and EMR). Histologic examination showed 4 dysplastic lesions (7.2%) including 1 adenocarcinoma in situ, 1 high-grade dysplasia and low-grade dysplasia in 2 cases. The mean size of the lesions was 26 mm (6–59 mm). 26 patients had a single polyp although 9 patients had at least 2. Regarding the complications, there was no perforation. Only one patient experienced a severe bleeding (1.8%) two days after EMR with hemorrhagic shock. He had multiple hyperplastic polyps on a watermelon stomach. One of them had been resected by ESD with no adverse event during a first endoscopy procedure and then 8 were resected in a second procedure (4 by EMR technique and 4 by ESD technique) complicated by a hemorrhagic shock. 56 polyps were resected ''in sano'' (healthy margins resection). In the follow up, 5 recurrences appeared after initial resection by EMR in 3 cases, hybrid technique in one case, and ESD in one case. Resection was considered R0 and complete in 4 of the 5 recurrences. Two of them had an infection with *Helicobacter Pylori*. There was no other factor that may explain the recurrence for the other 3 patients (no cirrhosis, no Hp). The first patient was referred for the resection of 3 hyperplastic polyps. He underwent 4 new resections (3 by EMR technique and 1 by hybrid technique), there were hyperplastic polyps every time, never dysplasia and he is followed up every year. The second one underwent a new resection by ESD technique and had no reccurence. The third one underwent 2 new resections (1 by EMR technique and 1 by hybrid technique) and had no recurrence currently. The fourth one underwent a new resection by hybrid technique, and had no recurrence currently. The fifth one underwent a new resection by ESD, and had no recurrence currently.

**Conclusion:** Hyperplastic polyps are benign lesions with rare dysplastic evolution. In our study with 55 lesions, only 7.2% were dysplastic and only 1 adenocarcinoma was found (1.8%). ESD and EMR were relatively safe with only one adverse event with severe bleeding. The main issue of such resections is the local recurrence rate of 7.2% even if the initial resection was curative and R0. Optimal management of these lesions is not yet established but endoscopic resections seem to be a good and safe option but needing a early follow up to detect and resect local recurrences before large extensive relapse.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** gispinz@tin.it

**Introduction:** High-quality endoscopy delivers better health outcomes and a better patient experience (1), but there are clinically important differences in quality of endoscopy and patient outcomes between services across Italy.

**Aims & Methods:** Aim of this work is to describe the accreditation project of endoscopy services in Italy. In 2014 the Italian Society for Digestive Endoscopy (SIED) decided to develop a project for professionally lead service accreditation in collaboration with an independent organization with a special focus on health sector. In the same year SIED created a Quality Assessment Team made up of five endoscopists with a special interest on quality assurance and one representative of the certification company to provide a platform for definition of service and professional standards and leverage to achieve them. The Quality Team, in collaboration with the representatives of the Italian Nurse Association (ANOTE), prepared national endoscopic standards, taken from international professional organizations and guidelines and these standards were published on the SIED's website. Leadership and organization of the service, information and communication, quality and safety of the endoscopy (esophagogastroduodenoscopy, colonoscopy, retrograde colangiopancreatography and percutaneous endoscopic gastrostomy), integration of care, training of trainees and of health professionals entering the service and reprocessing, were included in the accreditation scheme. Performance measures have been applied in the pre, intra and post-endoscopy time periods with a particular interest for process measures and outcome measures rather than structural measures that reflect aspects of healthcare infrastructure harder to change. These performance measures were approved by the SIED's National Committee. Because quality improvement requires political will, we always research, at a local level, support from hospital management. Before the site-visit the endoscopy services used a standard framework as a template for quality improvement. The standard framework took the form of a checklist, which ensured that services did not miss out key aspects of care, enabled them to prioritise work, to evaluate levels of achievement within each domain (such as patient information, safety or reprocessing), to allow tracking of progress and, eventually, to assess readiness of the site-visit for accreditation. Peer review assessors were not reimbursed for the time, but only for travelling and lodging expenses.

**Results:** So far, the peer review components of the accreditation process (two endoscopists, a representative of the accreditation body and a nurse) have locally assessed, against clearly defined criteria, 13 endoscopy services scattered all over the Italian Regions. Seven endoscopy services, that fulffilled the prepared standards, have been accreditated, three have not satisfied the SIED accreditation criteria, and will receive another site-visit in three-six months, two services are under evaluation. One centre has not been accreditated because performance criteria had not been met. Accreditated services will provide informations on a regular basis, between peer visits, to satisfy the accrediting body that standards are being mantained, and to avoid that hospitals may comply with accreditation criteria only during the site-visit period as a ''one-off focused activity'', with doubtful impact on the ability of accreditation to bring about continuous improvements.

**Conclusion:** At the beginning of our program we have observed that external inspection of compliance with standards may improve healthcare organisation and professional behaviour. Considering the time, effort, and resources needed for accreditation programmes, it is essential to collect other data to prove the effectiveness of such programmes and on future improvements.

## P1242 HIGHEST POWER MAGNIFICATION WITH NARROW-BAND IMAGING IS VERY USEFUL TO DIAGNOSE THE MARGINS OF EARLY GASTRIC CANCERS, ESPECIALLY AFTER HELICOBACTER PYLORI ERADICATION

**K. Kojima**[1], K. Uchita[2], R. Daike[1], S. Sasaki[1], K. Iwasaki[1], A. Kawada[1], M. Nakayama[1], M. Okazaki[1], S. Iwamura[1]
[1]*Kochi Red Cross Hospital, Kochi/Japan*
[2]*Dept. Of Gastroenterology, Kochi Red Cross Hospital, Kochi/Japan*

**Contact E-mail Address:** kozikozima22@gmail.com

**Introduction:** It has been reported that a characteristic of gastric cancer which was discovered after eradication of *Helicobacter pylori* (HP) is that diagnosis of the margins of these cancers by magnifying endoscopy is difficult due to the presence of non-neoplastic epithelium (1), but observation conditions such as magnification, etc. were not constant, so in order to examine the diagnosis capability of magnifying endoscopy must be performed under constant observation conditions.

**Aims & Methods:** Aims: To examine diagnostic accuracy for delineation of gastric cancer margins, post HP eradication gastric cancer and HP non-eradication gastric cancer, at different magnification ratios using magnifying endoscopy with narrow-band imagine (NBI). Methods: Out of 125 early gastric cancer lesions removed by ESD consecutively at our hospital from August 2013 to December 2015, 2 lesions were exempted because presence or absence of HP infection was unclear, along with 2 non-differentiated adenocarcinoma lesions, leaving a target 121 lesions which were divided into Group A (post HP eradication gastric cancer group, 42 lesions) and Group B (HP non-eradication gastric cancer group, 79 lesions). For each group the accurate diagnostic rate of delineation by magnifying endoscope was then determined retrospectively at the respective magnifications. Low power magnification was defined as a focal length of approximately 4 mm, using the VS (vessel plus surface) classification system for magnifying endoscope diagnostic criteria of Yao et al (2). Endoscopic examination was conducted in the order of normal endoscopy, NBI low power optical magnification observation, and NBI highest power optical magnification observation, with marking conducted 3–5 mm outside the demarcation line (DL) of lesions. Successful lesion was defined as cases where endoscopically the DL all around the lesion was consistently identifiable and pathologically consistent.

**Results:** Patient background (Group A vs Group B) was average age: 71.4 vs 74.1, tumor diameter (mm): 17.3 vs 18.2, tissue type (tub1/tub2): 32/10 vs 72/7. The accurate diagnosis rate was 95.2% (40/42) for Group A, and 98.7% (78/79) for Group B, with no significant difference seen. In misdiagnosed cases, histologically there was a moderately differentiated adenocarcinoma and a fundic gland mucosa type gastric cancer in Group A, and a moderately differentiated adenocarcinoma in Group B. When evaluated at the respective magnification ratio, successful rate at low power magnification was 59.5% (25/42) for Group A, and 83.5% (66/79) for Group B, with successful rate significantly lower for Group A ($p = 0.0038$). When evaluated histologically, in Group A many cases involved non-cancerous epithelium, and in observation limited to the surface microstructure under low power magnification, diagnosis of the margins of gastric cancer post HP eradication were considered difficult.
**Conclusion:** Highest power magnification with NBI is very useful, and by performing highest power magnification observation it is possible to perform range diagnosis at the same standard as for HP non-eradication gastric cancers. Whereas under low power magnification, there are many post HP eradication gastric cancer lesions for which range diagnosis is difficult.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1243 COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARISPROPRIA

**C.B. Ryu**, M.S. Lee
*Department Of Internal Medicine, Soon Chun Hyang University School Of Medicine, Bucheon/Korea, Republic of*

**Contact E-mail Address:** ryuchb@gmail.com

**Introduction:** Endoscopic resection for gastric subepithelialtumors (SETs) originated from the muscularispropria (GSET-PM) has offered less invasive alternatives to surgical resection.
**Aims & Methods:** The aims of this study were to compare endoscopic subtumoraldissection (ESD) with surgical resection for the removal of GSET-PM. Patients/Methods: This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5 cm and showed an endoluminal growth pattern according to endoscopic ultrasound (EUS) finding.
**Results:** ESD group were more likely to have upper portion (10/17, 58.8%) and surgery group were more likely to have mid portion (41/76, 53.8%)($p = 0.039$). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm, $p = 0.037$) and higher endoluminal ratio ($58.5 \pm 9.1\%$ vs $45.8 \pm 15.4\%$, $p = 0.002$). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52/76, 68.4%)($p < 0.001$). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, $p < 0.001$). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontrolled bleeding) and 1 showed perforation was completely resected with endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group ($p = 0.006$), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two group.
**Conclusion:** ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1244 A COMPARISON OF EFFICACY, OUTCOME AND COMPLICATIONS OF ENDOSCOPIC SUBMUCOSAL DISSECTION WITH THE OLYMPUS SECOND GENERATION ELECTROSURGICAL KNIFE DUALKNIFEJ™ VS OLYMPUS FIRST GENERATION DUALKNIFE™. A SINGLE CENTRE RETROSPECTIVE STUDY

**J. Woo**, J. Matsuoka, Y. Kowazaki, M. Nishimura
*Endoscopy, Tokyo Metropolitan Geriatric Hospital, Tokyo/Japan*

**Contact E-mail Address:** mtjwu888@gmail.com

**Introduction:** Recent improvements in the Olympus second generation electrosurgical knife (Olympus DualKnifeJ™ KD-655) used in endoscopic submucosal dissection (ESD) has the improved features of allowing concurrent injection for mucosal raise in between submucosal dissections. The DualKnifeJ has become available since October 2015. Currently, more evidence is required in determining whether the second-generation knife is indeed superior and safe when compared to its first-generation counterpart.[1,2] Our centre has used the Olympus first generation electrosurgical knife (Olympus DualKnife™ KD 650) till end of December 2015 and had since then changed to using the second generation knife. This study aims to provide further comparative evidence between the two knives.
**Aims & Methods:** A single-centre, retrospective analysis was conducted by analysing the ESD database of our hospital. All patients included in the study had ESD done for either oesophageal, gastric or colonic lesions in between the periods of June 2013 till March 2016. Data compared included average procedure time, midazolam usage, intraoperative complication and en-bloc resection rates.
**Results:** In the first generation DualKnife™ group (A group), there were 266 cases (M:145, F121, age range 35–95, oesophageal ESD 14%, gastric ESD 41%, colonic ESD 45%). In the DualKnifeJ™ group (B group), there were a total of 36 cases (M:16, F20, age range 35–98, oesophageal ESD 3%, gastric ESD 47%, colonic ESD 50%). The average procedure time was 56 minutes in the A group and 59 minutes in the B group, with average midazolam dosage of 3.79 mg and 3.7 mg respectively. The en-bloc resection rates were 94% in the A group (mean lesion size 33.11 mm) and 100% in the B group (mean lesion size 34.1 mm). Intraoperative complications included hypotension (A:65%, B:77%), desaturation (A:40%, B:44%), bradycardia (A:14%, B19%), tachycardia (A:11%, B8%) and Mallory Weiss tear (A:1%, B:5%). Although minor bleeding had occured intraoperatively during dissection in all cases in both groups, there were no related fatal events, all were successfully treated and there was no perforation in both groups. Overall, there was no statistical difference in terms of recorded complications between the 2 groups ($p = 0.49$).
**Conclusion:** Our data provides evidence that the new DualKnifeJ is comparatively as safe as the first-generation dual knife, has better en-bloc resection rate, indifferent in intraoperative complication rate and the cost difference is minimal. From an operator's perspective, with DualKnifeJ, the dual function of submucosal injection during dissection allows much better submucosal visualisation, reduces time and potential scope position loss whilst awaiting change to the injection needle. We conclude that the DualKnifeJ is preferred in comparison with the first-generation dual knife.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[4]*Gastroenterology Deparment, Centro Hospitalar do Porto, Porto/Portugal*

**Contact E-mail Address:** diogolibaniomonteiro@gmail.com

**Introduction:** Foreign body ingestion (FBI) and food impaction (FI) are one of the most frequent emergencies in gastroenterology. It is important to know the proportion of patients in which a foreign body is present in the upper digestive tract, since it is frequently reported that a large proportion of ingested foreign bodies pass throughout the upper digestive tract without clinical consequences. Identification of risk factors for foreign body / food impaction presence is also important in order to define the need for urgent endoscopy and also its timing.
**Aims & Methods:** The aim of this study was to identify predictors of foreign body presence in the upper digestive tract and to assess its management and complications. Methods: This was a prospective unicentric cohort study including consecutive patients with FBI or suspected FI during one year. Continuous variables were compared with independent samples t-test while chi-square test was used for categorical variables; relative risks were computed where adequate.
**Results:** 262 patients were included (171 with FBI, 91 with suspected FI). FI patients were more frequently female and were significantly older when compared with patients with suspected food impaction ($p < 0.05$). Dysphagia was significantly more frequent in the FI group, while odynophagia and foreign body perception were the predominant symptoms in FBI. In the FBI group, the foreign body was identified in the upper digestive tract in 43.2%; older age and earlier presentation to the emergency department were significantly associated with foreign body presence in multivariate analysis. Compared with fish bones, meat bones were more frequently found (49% vs 41%), although the difference was not statistically significant. Foreign body extraction was not possible in 4.8% due to technical difficulties and were referred for rigid esophagoscopy. In FI, there was a known esophageal disease (mainly stricture) in 34.4%. Food impaction was confirmed in 81.1% and was successfully solved in 95.8%. Roth net was the most used instrument in FI, while foreign body forceps was preferred in FBI. The need to use a second instrument was more frequent in FI (23.2% vs 11.3%, $p = 0.06$). Overall, anesthesia was required in 6.5% and major complications occurred in 0.4% (1 perforation).
**Conclusion:** Almost half of the patients with FBI have a foreign body found at esophagogastroduodenoscopy; older age and early presentation to the emergency department increase the likelihood of foreign body presence. FB removal and food impaction resolution were achieved in >95%.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1246 AVAILABILITY OF LAPAROSCOPIC AND ENDOSCOPIC COOPERATIVE SURGERY: AN INTERNATIONAL QUESTIONNAIRE SURVEY

**O. Goto**[1], H. Takeuchi[2], T. Akimoto[1], H. Kawakubo[3], M. Sasaki[1], Y. Kitagawa[2], N. Yahagi[1]
[1]*Cancer Center, Keio University, School of Medicine, Tokyo/Japan*
[2]*Surgery, Keio University, School of Medicine, Tokyo/Japan*
[3]*Keio University School of Medicine, Tokyo/Japan*

**Contact E-mail Address:** ogotou-gi@keio.jp

**Introduction:** Laparoscopic and endoscopic cooperative surgery (LECS) has been developed as a minimally invasive surgery for localised gastrointestinal neoplasms, and it uses a combination of both laparoscopy and endoscopy. LECS is applied predominantly for gastric subepithelial tumours at present[1)] and the indication is expected to be further expanded to gastric cancer[2)] or other organs[3)]. However, there are several issues to be addressed in order to establish and disseminate this methodology worldwide.

**Aims & Methods:** We planned to conduct an international survey for availability of LECS by gathering current opinions regarding LECS from overseas experts in the field of gastrointestinal endoscopy and surgery.

In February 2016, a web-based survey was administered to 35 overseas endoscopists who had given or organized international live demonstrations or had conducted endoscopic training courses. The questionnaire included 22 questions, which were mainly multiple choice questions and were related to the feasibility, efficacy and acceptability of this procedure, e.g. the respondent's opinion on and experience in performing LECS as well as other relevant issues. The responses were collected within 1 month and assessed thereafter.

**Results:** A total of 25 experts (71%) responded to this survey. A main affiliation of the respondents was gastroenterology and hepatology (76%), endoscopy and endoscopic surgery (16%) or surgery (8%). The concept of LECS was known among 96% of respondents. LECS was considered to be easily accessible (12%), accessible (52%), doable (28%) and to be quite beneficial (84%) or partially beneficial (8%), whereas only 40% of respondents had direct experience in performing LECS. Although the respondents considered that the introduction of LECS would be welcome (84%) or acceptable (16%), they expected an acceptable procedure time to be no more than 1 hour (16%) and 2 hours (64%). Furthermore, they considered the minimum estimated fee to be USD 3,000 (20%), 4,000 (24%) or over 5,000 (8%).

**Conclusion:** LECS was considered feasible, beneficial, and acceptable but currently has limited availability. In the permeation of this procedure, the issue of cost-effectiveness remains to be addressed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** hyuk4385@yuhs.ac

**Introduction:** A few patients with non-curative resection of endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) do not undergo additional gastrectomy due to old age, comorbidities or poor general condition. However, there are concerns about safety and long-term outcomes of patients with non-curative resection.

**Aims & Methods:** Of 1,525 patients who underwent gastric ESD for EGC, 291(19.1%) patients with non-curative ESD from 2007 and 2014 were reviewed retrospectively. Non-curative resection is defined as histologically positivity of the resected margins, lymphovascular infiltration, piecemeal resection or beyond expanded criteria for ESD. Recurrence was defined as local and residual recurrence of EGC after non-curative resection.

**Results:** A total 291 patients with more than 6 months follow-up periods were analyzed and the mean (± S.D.) follow up duration was 43.4 (± 22.9) months. Of them, 160 patients (55.0%) and 37 patients (12.8%) underwent surgery and endoscopic treatment after non-curative resection, whereas 94 patients (32.3%) were observed. 75 (25.8%) patients had lymphovascular infiltration, 150 (51.5%) patients had EGCs that had margin positive resection, 36 (12.4%) patients had EGCs that had not en bloc resection. The disease-free survival (DFS) rates was higher in patients with endoscopic treatment than with observation group (86.5% and 81.9%, $p < 0.001$). When we compared three subgroups, the 5-year overall survival (OS) was statistically significant in patient with additional surgery group, additional endoscopic treatment group, and observation group (97.5%, 94.6% and 90.8%, respectively, $p = 0.031$). Among additional endoscopic treatment group, 4 patients (10.8%) developed recurrence of EGC. Interval for additional endoscopic treatment after 3 months was an independent predictor of recurrence in multivariate analysis (HR 30.000, 95% CI, 1.834 – 490.786, $p = 0.017$).

**Conclusion:** In this study showed that compared to observation group, additional surgery or endoscopic treatment improved overall survival and disease-free survival in patients with non-curative ESD. Also, early additional endoscopic treatment within 3 months, was favorable to DFS and OS.

## P1248 DO VISIBLE VESSELS WITHIN THE POST-ENDOSCOPIC MUCOSAL RESECTION (EMR) DEFECT PREDICT POST-EMR BLEEDING?

**L. Desomer**, D. J. Tate, F. Bahin, B. Holt, M. J. Bourke
*Gastroenterology And Hepatology, Westmead Hospital, Westmead/Australia/NSW*

**Contact E-mail Address:** lobkedesomer@gmail.com

**Introduction:** Clinically significant post EMR bleeding (CSPEB) is the most frequent serious complication after wide-field endoscopic mucosal resection (EMR) of laterally spreading lesions ≥ 20 mm (LSLs). Visible vessels within the post EMR defect (PED) present themselves as logical targets for prophylactic treatment to prevent CSPEB. However the clinical significance of these vessels is largely unknown. In the majority of studies risk factors identified for CSPEB include right colon location, lesion size and aspirin use.

**Aims & Methods:** We aimed to evaluate the clinical significance of the various endoscopic features of the post EMR defect including visible vessels. A prospective study of LSLs ≥ 20 mm referred for EMR at a single tertiary referral center was performed. Data collection included patient and lesion characteristics, defect features including submucosal vessels, submucosal haemorrhage, fibrosis, fat and exposed muscle, and the rate of CSPEB. CSPEB was defined as any bleeding occurring after the completion of the procedure necessitating emergency department presentation, hospitalization or reintervention. CSPEB was compared to features of the PED to detect significant associations, using $chi^2$ or Fisher's exact tests. Significant univariate variables were taken forward for binomial logistic regression modelling.

**Results:** Over 60 months, to April 2016, 576 lesions (51.5% located proximal to the transverse colon) in 576 patients (mean age 66.8 years, 50.7% male) were eligible for analysis. The frequency of CSPEB was 35/576 (6.1%). Defect features and statistical analysis are outlined in table 1.

No features of the PED, including number of visible vessels (median 3, IQR 0.25–7.75, $p = .308$), diameter of largest vessel (14/165 >0.5 mm (8.5%), $p = .853$) and herniation of vessels (12/146 (8.2%), $p = .620$), were significantly associated with CSBEP at univariate analysis and were therefore not used in the multivariate model. However, vessels were more often seen in the left colon (76% vs 63.9%, $p = .002$), and these were significantly larger (19.6% vs 9.2% ≥ 1 mm, $p = .008$), more numerous (median 4 (IQR 2–6) vs 3 (IQR 1.25–4.1) vessels, $p < .001$) and showed more often herniation (32.6% vs 21.7%, $p = .005$).

**Table 1:** Defect and procedural features in patients with clinically significant post EMR bleeding (CSPEB) as compared with patients with no CSPEB.

| | Lesions (N = 576) | Univariate P | Multivariate P |
|---|---|---|---|
| **Defect features** | | | |
| Presence of visible vessels (%) | 402 (69.8) | .314 | / |
| Presence of arteries | 34 (5.9) | .713 | |
| Presence of veins | 394 (68.4) | .141 | |
| Number of visible vessels (median, IQR) | 3 (0.25–7.75) | .187 | / |
| Herniation of vessels (%) | 12/146 (32.6) | .620 | / |
| Estimated diameter of largest vessel (in comparison to snare wire) (%) ° ≤1 mm ° >1 mm | 21 (60.0) 6 (17.1) | .446 | / |
| Intraprocedural bleeding (%) | 182 (31.6) | .429 | / |
| Submucosal haemorrhage | 58 (10.1) | .787 | / |
| **Procedural features** | | | |
| Aspirin use within 7 days (%) | 53 (9.2) | .009 | .005 |
| Lesion size ≥ 40 mm (%) | 26 (4.5) | .001 | .002 |
| Lesion location in the right colon (%) | 23 (7.8) | .051 | .017 |

On multivariate analysis CSPEB was associated with use of aspirin within 7 days (RR 3.31, 95% CI 1.5–7.6, $p = .01$), size ≥ 40 mm (RR 3.54, 95% CI 1.6–7.8, $p = .001$) and right colon location (RR 2.508, 95% CI 1.177–5.344, $p = .017$).

**Conclusion:** Number, size or presence of herniation of vessels within the PED does not predict CSPEB. Vessel number, size and herniation is significantly greater in the left colon however the bleeding rate is less. Other features within the PED also do not predict CSPEB, including submucosal haemorrhage and intraprocedural bleeding.

The visible vessels within the PED should not be considered a therapeutic target for prevention of CSPEB and should not be used for risk stratification of CSPEB. Lesion location and size are the dominant risk factors for CSPEB.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic submucosal dissection is currently the reference method to achieve an en bloc resection for large lesions of the digestive tract. Nevertheless, it is a difficult and risky technique with a long learning curve. To reduce the morbidity related to the first procedures, it is recommended to attend training courses with animal models. Self-training programs could have a role in parallel to simplify access to training and at least to learn the initial skills. Self-learning software to assist students in the first steps of ESD has been recently developed. We designed this study to evaluate the impact of such a tool on the ESD learning curve for French and Japanese students using a bovine colon model.
**Aims & Methods:** A prospective randomized comparative study enrolled 39 students (31 in France and 8 in Japan) experienced in interventional endoscopy but not in ESD. Each student was randomized in one of the two groups and performed 30 ESD on a 30 mm large simulated rectal lesion in a retroflexed endoscopic view. The software group used the self-learning software whereas the control group only observed an ESD procedure movie. No other technical explanation was given to both groups. Procedure duration, resection completeness, perforation rate and the specimen size and surface were assessed.
**Results:** 39 students performed 1170 ESD (software group: 19 students, 570 ESD) (control group: 20 students, 600 ESD) with respectively 404 (71.0%) successes (resection of a specimen in less than 75 min) in the software group versus 367 (61.0%) in the control group ($p = 0.030$). Amongst the 1113 successes, the complete resection rate was 76.2% in the software group versus 67.4% in the control group ($p = 0.031$). Among the successes, the perforation rate and the procedure duration were not significantly different with 22 (3.8%) vs 29 (4.8%) ($p = 0.271$) and 34.1 (+/- 13.4) versus 32.3 (+/- 14.0) min ($p = 0.517$) respectively. Regarding only the 30$^{th}$ procedure of each student, the rate of complete resection was superior in software group with 84.2%versus 50.0% ($p = 0.005$). The rate of success in the French group was 77.3% versus 21.7% ($p = 0.001$) in the Japanese group. This significant difference was not explained by the lower experience of Japanese students but probably linked to the learning design (5 consecutive days versus non consecutive Saturdays). For the animal model training, a minimum number of 20 procedures seems required.
**Conclusion:** The use of this ESD self-learning software is effective to improve the quality of resection compared to a standard teaching method with procedure movies for trainees experienced in endoscopy but not in ESD. This result suggests to incorporate such self-learning software in the ESD teaching program.

**Introduction:** Deep learning algorithms and convolutional neural network (CNN) is recently applied in many areas related to medical imaging. Automated computer assisted differentiation between neoplastic and non-neoplastic colorectal polyps based on digital chromoendoscopy pictures could support resect and discharge strategy after polypectomy of minute polypoid lesions detected during colonoscopy.
**Aims & Methods:** The aim of our present preliminary study was to evaluate the usefulness of deep structured learning algorithms for automated computer-based differentiation of hyperplastic and adenomatous colorectal polyps. Patients referred for screening colonoscopy were prospectively enrolled and 100 polyps of 75 patients were detected. All colonoscopies were accomplished with HD zoom colonoscope of Fujinon EC-590ZW/L series. Based on our previous results FICE-filter 4 with 50 times digital magnification [red, green, and blue (RGB) wavelengths of 520, 500, and 405 nm, respectively] provided the best images for evaluating the vascular and surface (pit) pattern for colorectal adenomas. Therefore, optical zoom and HD surface pictures of the colorectal polyps were digitally stored with FICE-filter 4 and with 50 times magnification. Histopathology of the lesions was classified after pathological evaluation from endoscopic resection, polypectomy or biopsy specimens. Regions of interests (ROI) sized of 275x275 pixels were manually selected on captured digital pictures of the surface of the colorectal polyps, and then uploaded to the ERSATZ labs cloud-based deep learning platform.
**Results:** According to the histopathological results, 59 adenomas (5 with severe dysplasia), and 41 hyperplastic polyps were captured, classified and selected for further computer analysis. From the 100 images, 60 images are selected as a training set, and the remaining 40 images are selected as a validation set. Training images were fed to the cloud-based CNN with automatic parametric variables and cropped into pixels with the proposed deep structured learning algorithm. During validation, 91.60% of the test pictures are classified correctly as neoplastic or non-neoplastic polyp region.
**Conclusion:** Computer-assisted differentiation of colorectal polyps is a promising tool to assist differentiation of hyperplastic and adenomatous polyps detected with digital zoom chromoendoscopy. Further improvement of accuracy of the deep learning algorithms may be achieved by increasing the total number of polyps uploaded to the training set and also tuning the parametric variables of the CNN.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1251 COLD SNARE POLYPECTOMY DOES NOT INCREASE THE POSSIBILITY OF RESIDUAL POLYP: A PROSPECTIVE SINGLE-ARM OBSERVATIONAL TRIAL

**Y. Takeuchi**[1], N. Matsuura[1], N. Uedo[2], T. Ito[1], T. Yamashina[3], K. Aoi[1], T. Kanesaka[1], F. Matsui[1], M. Fujii[1], N. Hanaoka[2], T. Akasaka[2], K. Higashino[2], R. Ishihara[1], H. Iishi[2]

**Contact E-mail Address:** takeuti-yo@mc.pref.osaka.jp

**Introduction:** Generally, cold snare polypectomy (CSP) is considered a safe procedure for subcentimetric polyps, although incomplete assessment of the horizontal margin (HM) can often occur [1].
**Aims & Methods:** This study aimed to investigate the residual polyp rate after CSP for resecting subcentimetric neoplastic polyps. This was a prospective, single-arm observational study conducted at a referral cancer center in Osaka, Japan, between March and December 2013. The protocol of these prospective trials was registered in the University Hospital Medical Network Clinical Trials Registry (UMIN-CTR, UMIN 000010879). Patients aged 20 years or older with adenomas smaller than 10 mm (1–9 mm) in diameter were enrolled in this study. CSP was performed until no polyp was visible. Each polyp base was then resected

using additional endoscopic mucosal resection (EMR), leaving a clear margin of 1–3 mm of surrounding non-neoplastic mucosa. The removed polyps and marginal specimens were retrieved with suction through a working channel of the colonoscope and trapped in a bottle attached to the suction route.Each trapped specimen (polyp and marginal specimen) was stored in separate jar containing formalin 20% without pinning on a plate. The fixed specimen were sectioned serially at 2-mm intervals and subjected to histological examination. Any neoplastic tissue observed in the marginal specimen was considered residual polyp. The primary endpoint was residual polyp rate after CSP, compared with historical data of conventional EMR.

**Results:** Of the total 138 patients screened, 126 patients, with 362 subcentimetric polyps diagnosed as neoplastic lesions, were enrolled. The additional EMR could not be performed on 10 (2.8%) of the 362 lesions because of technical difficulties. Two marginal specimen could not be retrieved, and one marginal specimen was contaminated with a removed polyp. Additionally, two additional EMR were recognized as protocol violation, resulting exclusion from the analysis. Therefore, we assessed 347 subcentimetric polyps. The median age of the patients was 71 (IQR 64–75) years. Patients were 83 (65.9%) men and 43 (34.1%) women. Their morphologies were 279 (77.1%) protruded/sessile (0–Is) lesions and 83 (22.9%) superficial/elevated (0–IIa) lesions. The median (IQR) size of the detected polyps was 5 (3–6) mm. Of these polyps, 269 (74.3%) were diminutive (1–5 mm) and 93 (25.7%) were small (6–9 mm). Among 347 evaluable marginal specimens, histopathological diagnosis indicated that 332 (95.7%) were non-neoplastic lesions and 15 (4.3%) were neoplastic polyps. Thus, we considered the unadjusted incidence (90% confidence interval [CI]) of residual polyp after CSP was 4.3 (2.5–6.1)%. No differences were observed in polyp size, age, location, morphology, or operator experience between lesions with and without residual polyp. In the removed polyps, polyp involvement at the lateral margin could not be assessed correctly (HM X) in 229 (68.8%) polyps.

**Conclusion:** The incidence of residual polyp after CSP was 4.3% and did not increase compared with conventional EMR in the previous report.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Internal hemorrhoids are the most common cause of colonic bleeding in ambulatory outpatients [(1)]. However, the prevalence and clinical outcomes of patients hospitalized with severe hematochezia from bleeding internal hemorrhoids have not been reported.

**Aims & Methods:** Our aim was to compare demographics and outcomes of patients hospitalized with severe hematochezia from internal hemorrhoids compared with other colonic diagnoses. For methods, consecutive patients with severe hematochezia admitted between 1995 and 2015 to our two tertiary referral academic medical centers, seen by the GI consultation services, and having urgent colonoscopy after colon purge, were prospectively evaluated. Clinical, laboratory, endoscopic and outcome results (rebleeding, surgery, time to discharge and death) up to 30 days or hospital discharge were retrospectively analyzed. SAS was used for data management and analysis. Bivariate analyses were carried out, using Chi-square and $p < 0.05$ was considered statistically significant.

**Results:** A total of 709 patients with colonic or hemorrhoidal causes of severe hematochezia were included, 76 patients with internal hemorrhoids (10.7%) and 633 patients with other colonic diagnoses (89.3%). Internal hemorrhoids were the third most common cause of colonic hematochezia after colonic diverticular disease (32.4%) and ischemic colitis (12.1%). For the hemorrhoid group, bleeding started as outpatient in 62 patients (81.6%) and as inpatient after admission for unrelated co-morbidity in 14 patients (18.4%). In the 76 patients with internal hemorrhoids compared to patients with other colonic diagnoses, gender, ethnicity, number of red blood transfused for resuscitation or hemoglobin were not significantly different. In the hemorrhoids group, there was significantly lower mean age ($62.3 \pm 15.5$ vs $66.6 \pm 15.5$, $p = 0.02$), Aspirin use (25.0% vs 40.7%, $p = 0.0079$), shock or hypotension (13.2% vs 24.3%, $p = 0.030$), cardiac failure (59.2% vs 79.0%, $p = 0.0006$) and metabolic history (42.1% vs 59.2%, $p = 0.018$). Prevalences of alcohol and liver disease were significantly higher in the hemorrhoid group (respectively 29.0% vs 10.7% $p < 0.0001$ and 40.8% vs 20.7%, $p = 0.0002$). Emergency endoscopic treatment rates were significantly lower in the hemorrhoid group (23.7% vs 38.1%, $p = 0.0449$) and consisted of banding (77.8%) or Bicap (22.2%). For clinical outcomes, see table 1. Internal hemorrhoid patients had significantly better results than patients with other colon diagnoses. Table 1: Clinical outcomes after endoscopic diagnoses of patients with internal hemorrhoids compared to patients with other colonic diagnoses.

**Conclusion:** 1) Internal hemorrhoidal bleeding was the third most common cause of severe hematochezia in hospitalized patients. 2) Compared to other colonic causes of severe hematochezia, patients with internal hemorrhoidal bleeding were younger; fewer used aspirin before bleeding, had cardiac failure, hypotension or metabolic disorders, but more drank alcohol or had liver disease. 3) Outcomes were better for the hemorrhoid group with reduced time to discharge and lower rates of rebleeding or urgent endoscopic treatment.

### P1253 WHAT IS THE CULPRIT LESION FOR INTERVAL CANCER AFTER COMPLETE COLONOSCOPY?

**T. Fujii**
*Dept. Of Gastroenterology, TF Clinic Dept. of Gastroenterology, Tokyo/Japan*

**Contact E-mail Address:** tfclinic@khaki.plala.or.jp

**Introduction:** Interval cancer (IC) has become a focus of attention as likely representing ''missed'' or ''rapidly growing'' lesions in colonoscopic screening for colorectal cancer (CRC), and it is currently assumed in Western countries that sessile serrated adenoma/polyps (SSA/P) may be the likely culprit lesion for IC in many cases.

**Aims & Methods:** To determine the culprit lesion for IC. This study included a total of 6163 patients (females/males, 2334/3829) undergoing complete colonoscopy (CC) procedures performed by the same single endoscopist (TF) at TFCL during the period between 2003 and 2015. IC was defined as all T1/T2 tumors detected during CC within 3 years following the CC procedures with removal of all neoplastic lesions.

**Results:** In the 6163 patients, CC detected 76 traditional serrated adenoma (TSA), 373 SSA/P, and 9025 adenomas, with the cancer stage being Tis in 411 lesions, T1 in 45, and $\geq$ T2 in 93. Of these, 8 were determined as cases of IC and were detected during CC examinations performed at a mean interval of 19 months (9–29 months), with the gross appearance of IC in these cases being all flat and depressed (IIa + IIc, 3; LST-NG with pseudo-depression, 4; and IIc, 1). Again, of the 8 cases of IC, 1 was located in the cecum, 1 in the ascending colon, 3 in the transverse colon, 1 in the descending colon, and 2 in the rectum, with the mean tumor diameter being 22.6 mm (13–35 mm) and the depth of invasion being T1 (slight invasion) in 3, T1 (massive invasion) in 3 and T2 in 2, therapeutic endoscopic procedures required in 5 (EMR, 2; P-EMR, 2; and ESD, 1), surgical resections required in 4, and lymph node metastasis found in 1. In this last case, the lesion was shown to be a IIa + IIc T2 lesion measuring 18 mm and present in the recto-sigmoid curve and. In this patient, a total of 5 polyps were removed in the CC performed 1 and 2 years ago, while a mean total of 3 polyps were found prior to detection of IC, with 3 lesions found to be T0.

**Conclusion:** Flat-depressed lesions may represent the likely culprit lesion for interval cancer, given their morphological features that make them difficult to detect by colonoscopy. As detection of these lesions is thought likely to be affected by such factors as blind spots in colonoscopy and bowel preparation and the lesions may be characterized as rapidly growing, colonoscopic examinations for CRC need to be performed with these lesions in mind.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colorectal cancer screening strategy is based in France on the search for occult bleeding in the stool. However, 13% of patients with a positive test never undergo further colonoscopy. These patients are then recontacted by the management structure but if they don't answer at the end of the complete process of recovery, they are not further invited to the screening program. This study conducted with the screening associations of Rhône « Ademas- 69» and Loire « Vivre » aimed to compare randomly the invitation to perform colonic capsule or virtual colonoscopy in those patients in order to propose them a less invasive strategy.
**Aims & Methods:** Patients identified by the two associations of screening who had a complete recovery procedure without any answer were targeted and receive solicitation offering a re-examination or by colonic capsule or Virtual Colonoscopy after randomization. The objectives of the study were to assess the rate of response, their participation in the proposed additional examination and the results in terms of detection and consequences on the future management of the patient.
**Results:** 756 patients (388 females, 368 males) were targeted with 378 proposals of colonic capsule and 378, Virtual Colonoscopy. Among them, 139 responses were obtained: 70 patients (9.2%) accepted to come for a new examination (38 in the colonic capsule group, 32 in the colonoscopy virtual group), 69 patients/families (9%) called to explain their refusal (26 had already had a colonoscopy, 22 refused categorically any new procedure, 17 wanted to consult their doctor for more information and 4 had died). After 70 patients having made an appointment, only 47 patients (31 females, 66%) finally realized examination with respectively 19 colonic capsules (14 females) and 28 virtual colonoscopies (18 females). 5 patients finally chose an optical colonoscopy instead of the examination proposed. 17 patients (28%) did not come to the scheduled examination including 14 in the colonic capsule arm. Among the 19 colonic capsules performed, 6 adenomas or cancers were detected, as well as 6 hyperplastic polyps and 4 other bleeding lesions. Among the 28 virtual colonoscopies, 5 adenoma or cancer and 3 hyperplastic polyps were detected as well as 4 other potentially bloody lesions. Taking into account these results, 15/19 colonic capsules versus 10/28 virtual colonoscopies have resulted in an additional indication of colonoscopy, 1/19 capsule an indication of proctoscopy against 1/28 virtual colonoscopies and 2/19 against 11/28 gave rise to a new screening two years later by FOBT. Actually, only 6 of the 29 patients (20.7%) with colonoscopy indications finally accepted to perform the procedure.
**Conclusion:** An additional reminder offering a less invasive (colonic capsule or colonoscopy virtual) examination for patients with FOBT + without previous colonoscopy is not effective since only 9.2% of patients responded positively. Among them, only 66% finally underwent the proposed examination or the colonoscopy originally proposed. Contributions to the colonic capsule and Virtual Colonoscopy were not different. The number of lesions detected by the colonic capsule (n = 12/19) was slightly more important than in Virtual Colonoscopy (n = 12/28) as several comparative studies have previously shown. In addition, the colonic capsule leads to propose optical colonoscopy or proctoscopy in 57.4% of the patients examined, which seems to support the importance of optical colonoscopy in first intention in these patients detected by FOBT +.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1255 ENDOSCOPIC TREATMENT OF GASTROINTESTINAL TRACT PERFORATIONS, ANASTOMOTIC LEAKAGES AND FISTULAS USING THE OVER-THE-SCOPE-CLIP SYSTEM (OVESCO): TWO-CENTRE EXPERIENCE

**I. Kildušienė**, G. Radziunas
*Oncosurgery, National Cancer Institute, Vilnius/Lithuania*

**Contact E-mail Address:** inga.kildusiene@gmail.com
**Introduction:** Anastomotic leakages, fistulas and iatrogenic perforations of gastrointestinal tract remain the mayor problems in gastrointestinal surgery and endoscopy. An over-the-scope clip (OTSC) OVESCO has been developed for the closure of small mural defects and bleeding ulcers (1). The OTSC produces more durable closure than standard endoclips because of its ability to grasp more tissue, include the entire thickness of the visceral wall, and apply a greater compressive force (2).
**Aims & Methods:** A retrospective analysis of prospectively collected data in cases of restitution of the digestive tract integrity with OTSC System in two Lithuanian hospitals was performed. Data including technical aspects, clinical outcomes and closure rates were recorded.
**Results:** 20 patients from two Lithuanian hospitals (Vilnius University Hospital Santariskiu Klinikos and National Cancer Institute) were treated applying OTSC clip. Overall 24 procedures were made, and 27 clips were applied between 2013 and 2016. Indications: anastomotic leak and fistula – 13 cases (9 cases - esophageal fistula); iatrogenic lesion of the colon – 4 cases; perforation due to necrotic pancreatitis after multiple operations – stomach and duodenum – 2 cases; leak of the esophageal suture after perforation with the foreign body – 1 case. Mean age of the patients (8 female, 12 male) was 65 years (range 35–85 years). Mean size of the fistula/leak was 1.2 cm (range 0.2–4.0 cm). We achieved complete defect closure at initial procedure in 15/20 of the cases (75%). The completeness of the closure has been checked radiologically and/or by injecting methylene blue solution immediately after the clip application. In 3 cases two clips were applied during initial procedure. In 4 cases clip application was repeated when clinically and radiologically signs of fistula recurrens appiered. In cases of big (> 2.0 cm) lesion closure clinical outcome revealed worse compared to small (< 1.2 cm) defects. At the remote period in 13/20 patients (65%) fistulas remained closed. We argue that unsuccessful clinical outcome is affected not only by technical details, but also by severe general patient condition (for example caused by sepsis or poor nutritional status). Iatrogenic perforation of the colon was closed successfully in all cases.
**Conclusion:** 1. OTSC® System could replace or supplement in certain cases traditional surgical approach in the treatment of fistula, perforation or anastomotic leak. 2. At the remote period in 65% cases fistula remained closed. 3. OTSC® should be available in the endoscopy units where interventional procedures are carried on.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Survival for Cystic Fibrosis (CF) patients has greatly increased over the past 30 years. However, with increasing survival, CF patients also become at risk for other diseases. Recent studies, for example, showed that CF patients have a 7-fold higher risk of colorectal cancer (CRC) compared to the general population. Screening has the potential to reduce the burden of CRC in CF patients. The aim of this study is to estimate costs and benefits of CRC screening in CF patients and determine the optimal screening strategy from a cost-effectiveness perspective.
**Aims & Methods:** The Microsimulation Screening Analysis (MISCAN)-Colon micro-simulation model was adjusted to reflect CRC risk and life-expectancy in CF patients and subsequently used to simulate a cohort of 10 million 30-year old CF patients in 2017. Costs and benefits of 50 colonoscopy screening strategies with various age to start (30,35,40,45,50) and end screening (55,60,65,70,75) as well as screening intervals (5 and 10 years) were evaluated. We performed incremental cost-effectiveness with a willingness to pay threshold of 100,000$ per life-year gained to determine the optimal CRC screening strategy.
**Results:** Without screening, the model predicted 8 per 1,000 CF patients to die of CRC. Colonoscopy screening every 10 years from age 45 to 65 was predicted to prevent more than 60% of these deaths. The optimal screening strategy was colonoscopy every 5 years between ages 40 and 75 with an incremental cost-effectiveness ratio of 92.547$ per life-year gained. The amount of CRC cases and death prevented with this strategy were 8.74 and 5.70 per 1.000 CF patients, respectively and representing an incidence reduction of 41% and a mortality reduction of 72% relative to no screening.
**Conclusion:** This study suggests that CRC screening in CF patents is cost-effective, and because of their higher risk, the CF patients could be screened from an early starting age with a shorter screening interval.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1257 MODIFIABLE FACTORS ASSOCIATED WITH PATIENT-REPORTED PAIN DURING AND AFTER SCREENING COLONOSCOPY

**Contact E-mail Address:** p.wieszczy@gmail.com
**Introduction:** Pain associated with colonoscopy is a major barrier to participation in colorectal cancer screening.
**Aims & Methods:** The aim of this analysis was to identify modifiable factors associated with patient-reported pain during and after colonoscopy performed in programmatic screening setting. We performed a cross-sectional analysis of database records from a population-based colonoscopy screening program (PCSP) in Poland. Since 2014 a validated tool for assessment of patients' experience with colonoscopy (the Norwegian Gastronet project) is being routinely used in centers enrolled in the PCSP. The Gastronet is a questionnaire assessing patient-reported pain during and after colonoscopy, rated on a 4-point scale (no, little, moderate and severe pain). The Gastronet is to be filled in by all screenees on the day after colonoscopy. For the purpose of this analysis we included a derivation cohort of screening colonoscopies performed in 2014 in 17 centers by 44 endoscopists and validation cohort of screening colonoscopies performed in 2015 in 23 centers by 85 endoscopists. All endoscopists included contributed at least 100 procedures. We used ordered multivariable logistic regression models adjusted for age to estimate odds ratios (OR) and 95%CI for one point increase in pain scores associated with patient body mass index (BMI), previous abdominal surgery, endoscopists experience, specialty, cecum intubation rate (CIR) and adenoma detection rate (ADR), endoscope generation, type of screening facility, bowel preparation and use and type of sedation.
**Results:** Of 8760 screening colonoscopies included in 2014 and 26,626 in 2015, 5412 (62.6%) and 17,176 (65.2%) valid Gastronet questionnaires were returned. Overall 2573 (47.28%) in 2014 and 8595 (49.83%) patients in 2015 reported no pain during colonoscopy. A significant variation based on use and type of sedation was observed (for 2014 cohort, 38.38% of patients in case of no sedation, 46.58% of patients in case of sedation without anesthesiologist and 85.98% of patients in case of sedation with anesthesiologist). Results for 2015 cohort were similar. Several patient, procedure, endoscopist and center factors were independently associated with lower odds of painful colonoscopies. On the other hand, surgical specialty of endoscopist and public type of endoscopy center were associated with higher odds of painful colonoscopies (Table 1). As for pain after colonoscopy, an association of lower odds for pain with male sex, sedation and endoscope generation was observed. Contrary, higher odds were observed for surgical specialty of endoscopist and public type of center (Table 1). Previous abdominal surgery, preparation method, endoscopist adenoma detection rate (ADR) and endoscopist experience were not associated with pain during and after colonoscopy. The kappa value for the agreement between endoscopist- and patient-reported pain was 0.23 and 0.22 for 2014 and 2015 cohort respectively. Moreover, endoscopists tended to report better procedure tolerance than reported by patient.
**Conclusion:** Several independent, modifiable factors associated with pain during and after colonoscopy were identified. There was poor agreement between endoscopist- and patient-reported pain scores.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1258 A REVIEW OF CURRENT PRACTICE IN FLEXIBLE SIGMOIDOSCOPY - CAN WE DO BETTER?

**J. P. Jacob**[1], J. Leeds[2]
[1]*Gastroenterology, Freeman Hospital, dn/United Kingdom*
[2]*Department Of Gastroenterology, Freeman Hospital, Newcastle-upon-Tyne/United Kingdom*

**Contact E-mail Address:** jpjacob@doctors.org.uk
**Introduction:** In March 2013, the British Society of Gastroenterology produced a position statement on indications for flexible sigmoidoscopy. We wished to assess whether or not referral practice in our large teaching hospital trust was adhering to this guidance.
**Aims & Methods:** We undertook a retrospective audit to examine referral practice for flexible sigmoidoscopy. We identified all flexible sigmoidoscopies performed between 2nd January 2015 and 1st April 2015 from our endoscopy reporting system. From 816 identified cases, we excluded 136 cases which included Bowelscope, ileal pouch anal anastomosis and rectal stump surveillance as well as erroneous duplicate entries. The remaining 680 cases were then assessed as being appropriate or not according to the BSG criteria.
**Results:** The average age of the study population was 53.7 with an age range of 16–95. There were 321 males and 359 females. Of 680 symptomatic cases referred for flexible sigmoidoscopy, we found that 229 (33.7%) were not appropriate. The test was incomplete in 212 cases (31.2%). The most common reason for an incomplete test was inadequate bowel preparation in 87/212 cases (41%). 498/680 flexible sigmoidoscopies were abnormal. 18 cases resulted in a diagnosis of colorectal cancer with 6 de novo diagnoses. Of the 229 patients in whom flexible sigmoidoscopy was deemed to be an unsuitable first line investigation, 66 went on to have further radiological or endoscopic investigation, but 155 had no further investiagtion, of whom 86 were dicharged with no further follow up after the index sigmoidoscopy. The average time interval between the index sigmoidoscopy and a further appropriate test was 73.7 days with a range of 3 to 268 days.
**Conclusion:** Unfortunately, in this study, approximately one-third of flexible sigmoidoscopy requests were not consistent with current best practice guidelines. Furthermore, completion rates are poor and time intervals to more appropriate investigation appear too long. Better case selection has the potential to lead to more appropriate utilisation of endoscopic resources. In this study, this translated to an additional capacity for 460 colonoscopies or equivalent endosopic investigations per annum.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1259 PREDICTED ADENOMA DETECTION RATE (ADR) AND COMPARISON TO ACTUAL PHYSICIANS' ADR

**Introduction:** The proportion of patients in whom at least one adenoma is detected during colonoscopy, i.e. adenoma detection rate (ADR), is inversely associated with the development of interval colorectal cancer (CRC). Current guidelines recommend an ADR of ≥25% (≥30% for male, and ≥20% for female patients). However, the strict definition (screening, average risk) and

variation in physician panels, especially gender, makes it challenging to compare individual ADRs. We therefore aimed to develop a prediction model for adenoma detection and subsequently ADR.
**Aims & Methods:** Colonoscopy and demographic/risk factor data was used from the cross-sectional multicenter randomized EQUIP-3 study (NCT02325635) in which the GIQuIC national database was used. Patients ≥50 years undergoing screening or surveillance colonoscopy with adequate bowel preparation were included. Colonoscopy for genetic family cancer syndromes and surveillance of inflammatory bowel disease were exclusion criteria in the present study. The dataset was split into two cohorts based on performing center for geographical validation. We developed a prediction model for adenoma detection per patient using multivariable logistic regression. Missing data was handled by multiple imputation (20 multiple imputed datasets). The final model was selected by stepwise backward selection based on Akaike's information criterion and internally validated in the derivation cohort using bootstrap resampling (500 data sets). Goodness-of-fit was evaluated with calibration plots. The model was used to compare predicted and observed physicians' and centers' ADR. We present the development and internal validation of the model, with future geographical validation to be performed.
**Results:** A total of 10152 patients (male: n = 4839 [48%], median age: 60 [range: 50–90] years), undergoing colonoscopy in 5 centers by 35 physicians were included in the derivation cohort. The overall ADR was 36%, with a median of 35% (range: 19–53) per physician, and a median of 37% (range: 28–40) per center. The final model (table) showed only modest discriminative ability for adenoma detection (optimism-adjusted C-statistic: 0.62) based on five predictors. Interestingly, surveillance vs. screening, race, ethnicity and personal or family history of colorectal carcinoma were not selected in the model. The model slightly overestimated adenoma detection in patients with low and high observed prevalence of adenomas. The observed ADR per endoscopist and per center was lower than predicted for the lowest observed ADRs and higher than predicted for the highest observed ADRs.

**Table:** Prediction model for the detection of ≥1 adenoma.

| Predictor | Corrected[a]multivariableOR [95%-CI] |
|---|---|
| Age (per year increase | 1.02 [1.02–1.03] |
| Male sex | 1.72 [1.59–1.87] |
| BMI (per 1 kg/m$^2$ increase) | 1.02 [1.01–1.03] |
| ASA I ASA II ASA III or IV | ref 1.27 [1.15–1.40] 1.57 [1.33–1.86] |
| History of colorectal adenomas None Personal Family | ref 1.41 [1.29–1.55] 1.10 [0.88–1.37] |

OR, odds ratio; CI, confidence interval; BMI, body mass index; ASA, American Society of Anesthesiology physical status class [a]Corrected after internal validation using bootstrap resampling with shrinkage factor 0.97.

**Conclusion:** Patient risk factors, such as age, sex, ASA category and history of colorectal adenomas, could not completely predict adenoma detection and observed ADRs. Additional predictors which were not included in the database, e.g. smoking, alcohol and medication use, could possibly have added to the performance of the model. This data suggests that variation in raw ADR between physicians could likely be due to other factors, e.g. physician, procedural or technical factors, and not patient risk factors alone.

[4]*San Gerardo Hospital, monza/Italy*
[5]*ASST Rhodense, Rho And Garbagnate Milanese/Italy*

**Contact E-mail Address:** m.dinelli@asst-monza.it
**Introduction:** The over-the-scope clip (OTSC) system has showed promising results in the management of gastrointestinal (GI) fistulas, iatrogenic perforations, and bleedings. In addition, the OTSC-assisted endoscopic full thickness resection (EFTR) has been proposed as a therapeutic option for GI epithelial and submucosal tumors. Recently, a new OTSC device (Padlock Clip™, Aponos Medical, Kingston, NH, United States) has been introduced into clinical practice.
**Aims & Methods:** We retrospectively reported the results in the treatment of 14 patients in a 18-month period. The Padlock clip is a hexagonal nitinol ring with six inner prongs released by a delivery system that consists of an applicator cap, similar to the variceal band-ligation cap. The clip is preassembled in an opened position on the delivery system and it is released by a trigger cable parallel to the scope that is connected to a handle. After the suction of tissue within the cap to obtain adhesion to the instrument tip, the clip is released by the handle pushing wire within the cable. When deployed, the shape-memory effect and the high elasticity of nitinol cause the closure of the clip. Its six inner prongs penetrate and pull the tissue inward resulting in a pseudo-polyp of closed tissue. When performing EFTR, the tissue entrapped was resected with an oval snare above the closed clip applying cutting current.
**Results:** 8 out of 14 patients were treated for closure of GI fistulas (n = 4) or iatrogenic GI perforations (n = 2) and hemostasis of post-polipectomy bleeding (n = 2). Site of clipping was lower GI tract (rectum and sigma) in 5 cases and upper GI tract (stomach, duodenum) in the remaining cases. The clip was successfully delivered in 7 out of 8 cases and clinical success (closure of GI defect or bleeding resolution) was achieved in all cases. Endoscopic full thickness resection (EFTR) was performed to treat 6 patients with recurrent adenoma (n = 4), recurrent adenocarcinoma at ileorectal anastomosis (n = 1) and neuro-endocrine tumor of rectum (n = 1). Technical success was recorded in all cases. A complete intestinal wall resection and a R0 resection were achieved in 50% and 83.3% of cases, respectively. No complications were recorded. Endoscopic follow up ranged from 3 to 15 months and no recurrence was demonstrated either macroscopically or microscopically when the scars were biopsied.
**Conclusion:** This novel OTSC systems seems to be an effective and safe tool to treat GI deep wall lesions or GI bleeding and to perform EFTR. However, further studies are needed to confirm our preliminary results and to explore further indications in clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1261 SPLIT VS SAME-DAY REGIMES FOR BOWEL PREPARATION BEFORE COLONOSCOPY: A META-ANALYSIS OF PUBLISHED STUDIES

**C. Bucci**[1], R. Marmo[2]
[1]*Dept Gastroenterology, University Of Salerno, Cristina Bucci, Salerno/Italy*
[2]*Hospital Curto, Polla/Italy*

**Contact E-mail Address:** cristinabucci@hotmail.it
**Introduction:** An adequate colon cleaning is essential for a good-quality colonoscopy and the split regimens (S) are actually considered the standard of care. However, 15–20% of patients still have an inadequate bowel cleansing after a split preparation. Recently a new regimen (same-day, SD) in which the purge is assumed the morning before the colonoscopy has been introduced, but published studies are underpowered and report controversial results.
**Aims & Methods:** Our aim was to assess the colon cleansing rate of split vs. same-day regimens. Published randomized clinical trials (1960–2015) comparing S vs. SD preparations in adults undergoing colonoscopy were selected using MEDLINE, the Cochrane Central Register of Controlled Trials, clinical trial.gov, ISI Web of Science. Search terms included bowel, preparation, colon, cleaning, colonoscopy, same-day and split. Rate difference (RD) of the degree of colon cleaning between split and same-day was the primary measure of treatment effect. Compliance (defined as the completion of at least > 75% of both doses of the purge) and presence of adverse events (nausea, vomiting, abdominal pain and abdominal discomfort) were secondary outcomes. **Statistics**: the meta-analyses were performed by computing RD using random-effects model, if heterogeneity was present. Egger's-Hardbord regression test was pre-defined statistical tests for publication bias assessment.
**Results:** From 122 initially screened abstracts, 11 full text studies were retrieved and a total of 12 treatment arms were analysed (1837 patients). Seven studies compared PEG vs. PEG, 1 sodium picosulfate vs sodium picosulfate, 1 sodium picosulfate vs. PEG and 3 PEG vs. sodium picosulfate. Overall, 88% (621/719) patients in the S group vs. 86% (570/688) in the SD group had an adequate bowel cleansing. Pooled RD was 2% [ (C.I.95% -1.6 to 5.6), heterogeneity chi-squared= 13.88 (d.f. = 8) p = 0.085; I-squared (variation in RD attributable to heterogeneity)= 42.4%, p = 0.280, Fig.1) ]. In all but one studies, split preparation was more effective than SD. Also, patients were more compliant and had slightly less adverse events with the split preparations but significant heterogeneity was present.
**Conclusion:** Data shows that split preparations give a similar adequate colon preparation compared with same-day preparations and with a better compliance and less adverse events.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endocytoscopy (EC) is a next-generation endoscopy that enables diagnostic imaging at 450× magnification. To date, excellent results have been achieved using EC classifications for qualitative diagnosis and assessment of depth of invasion of colorectal lesions (neoplasia/non-neoplasia accuracy: 96.5%; accuracy for carcinomas with massive submucosal invasion (SM-m): 96.3%).(1, 2)

**Aims & Methods:** In the EC classifications, lesions diagnosed as EC3a vary extensively from adenoma to SM-m, including some lesions that are unsuitable for endoscopic treatment. Therefore, to improve the accuracy of assessing the depth of invasion based on the EC classification, we investigated the presence or absence of certain endoscopic factors in EC3a findings that could be indicators of SM-m. Among lesions that were observed by EC between May 2005 and January 2015, we retrospectively examined 277 lesions diagnosed as EC3a or EC3b, according to the EC classification. Patients with unclear glandular lumen were excluded. The presence or absence of four findings that are indicators of SM-m were examined by EC. The four factors were: (1) high degree of nuclear enlargement (HNE); (2) multilayered nuclei (MN); (3) marked dilation of vessels (MDV); and (4) fine granular structures (FGS). Based on the results, we thoroughly examined the diagnostic accuracy of EC3a findings in the diagnosis of depth of invasion.
**Results:** Based on the results of multiple logistic regression analysis, the factors useful for the diagnosis of SM-m were HNE ($p < 0.01$), MN ($p < 0.01$), and FGS ($p < 0.05$). Of these, HNE and MN had odds ratios $> 10$ and were considered important predictors of SM-m invasion. So we diagnosed the lesions which were positive for HNE and MN as EC3a-high grade, whereas lesions negative for such findings were diagnosed as EC3a-low grade. As a result, 32 of 119 lesions were diagnosed as EC3a-high grade. Of these, the final pathological diagnosis was SM-m in 19 lesions, and muscularis propria cancer (MP) in five lesions. The diagnostic efficiency was as follows: sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and positive likelihood ratio of 88.9%, 91.3%, 75.0%, 96.6%, 90.8%, and 10.2, respectively. In the EC diagnosis above, interobserver validation ($\kappa$) of the three endoscopists were 0.63, 0.64, and 0.69, whereas good values were obtained for intraobserver validation ($\kappa$) at 0.73, 0.79, and 0.67.
**Conclusion:** In the diagnosis of colorectal lesions by EC, EC3a findings of HNE and MN are important indicators of SM-m. Results also suggested that taking into consideration the findings as for EC3a may improve the diagnostic accuracy for SM-m.

### P1263 UNDERWATER EMR IS A SAFE AND A WELL-TOLERATED PROCEDURE: THE EXPERIENCE OF TWO UK CENTRES

**A. Yusuf**[1], N. Suzuki[1], H. Htet[2], N. Gautam[2], S. Thomas-Gibson[1], S. Ishaq[3]

**Introduction:** Underwater Endoscopic Mucosal Resection (UEMR) is a relatively new technique, which has been developed for endoscopic resection of colonic lesions. In this technique, air or $CO_2$ insufflation is not required when performing EMR of lesions. We present here the experience of two UK centres.
**Aims & Methods:** The aim of this study was to assess the 1) feasibility of UEMR by endoscopists trained in traditional EMR, and 2) to assess the safety, tolerability, and effectiveness of UEMR. All of the procedures were performed by two experienced interventional endoscopists. Patient data was collected prospectively. A Hybrid technique, i.e. injection of lifting solution or use of Argon Plasma Coagulation (APC) together with UEMR, was employed if the lesion was traversing a fold/removed in retroflexed position or if there was remnant tissue post resection, respectively.
**Results:** From May 2015 to April 2016, a total of 41 patients (mean age 65.7 years, range 35–85, males n = 24) have had UEMR of 43 lesions performed by the two operators. The lesions (mean size 32.6 mm, range 7–160 mm) were located in right colon (n = 9), transverse colon (n = 2), left colon (n = 10), and rectum (n = 22). Seven of the lesions (16.3%) were recurrence post previous traditional EMR. The morphology of the lesions were either flat (n = 25) or sessile (n = 18). Hybrid technique was employed as following: Lifting (n = 20), APC (n = 4), and a combination of lifting and APC (n = 2). Histopathology of the lesions demonstrated low grade dysplasia (n = 34), high grade dysplasia (n = 6), and other (n = 3; One cancer and two serrated lesions). Complete endoscopic resection (at index procedure) was achieved in 42 out of the 43 lesions (97.7%); a large lesion (160 mm in size), which was crossing over two folds, was resected at two planned sessions. There were no perforations; however there were two cases of immediate bleeding (4.9%), which were controlled endoscopically during the procedure, and one case of delayed bleeding (2.4%), which was treated with Endoclot powder spray. The procedures, which were performed either with no sedation or analgesia (n = 12), with light sedation and analgesia (n = 22), or with Entonox inhalation as required (n = 7), were well-tolerated with a pain score of zero or one (zero = no pain; one = minimal pain).
**Conclusion:** In our experience, underwater endoscopic mucosal resection seems to be an effective, safe and a well-tolerated procedure, which can be performed by an endoscopist trained in traditional EMR. It can be an alternative to the traditional EMR, which requires either air or $CO_2$ insufflation. However, the insufflation of air or $CO_2$ significantly thins the colonic wall during the EMR, which may increase the risk of complications, but endoscopic ultrasound studies of the water-filled colon have shown that the colonic wall retains its natural thickness[1]. Follow-up data is required to assess the short- and long-term recurrence rate associated with UEMR.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1264 RANDOMIZED TANDEM COLONOSCOPY OF NARROW BAND IMAGING (NBI) AND WHITE LIGHT ENDOSCOPY IN PATIENTS WITH SERRATED LESIONS

**F. Riu Pons**[1], M. Andreu[2], D. Naranjo[3], M. A. Álvarez-González[1], A. Seoane[1], J.M. Dedeu[2], L. Barranco[1], X. Bessa[2]

**Introduction:** Detection of serrated polyps is difficult due to their morphology and appearance. Sometimes, in patients with few serrated polyps, diagnostic criteria of Serrated Polyposis Syndrome (SPS) depends on identification of few additional polyps (e.g. 5 or more serrated polyps, 2 >= 10 mm). Patients with SPS are considered to be at increased risk of colorectal cancer and requires a close endoscopic follow-up. We hypothesize that NBI could improve the detection rate of serrated polyps compared with High Definition White Light Endoscopy (WLE) in patients not fulfilling completely the SPS.
**Aims & Methods:** We performed a randomized, cross-over trial at our institution from March 2015 to April 2016 of tandem colonoscopy using NBI and WLE in patients with at least 1 serrated polyp $\geq$10 mm, or in individuals with $\geq$3 serrated polyps independtly of the size, both proximal to the sigmoid colon. (ClinicalTrials.gov, NCT02406547). Patients were evaluated back-to-back by the same endoscopist, using both techniques randomly (1:1) NBI-WLE or WLE-NBI. All detected polyps were resected in each withdrawal. The main goal was to compare the rate of detected polyps between both techniques, the polyp miss rate and when it was possible, reassessing the diagnosis of SPS for an appropriate surveillance interval.
**Results:** A total of 41 patients were included. Mean age was 59.6 yrs (SD: 8.6); 53.7% males. The median time from last colonoscopy was 5 months (IQI: 3–7). Baseline characteristics were not different between NBI-WLE (n = 21) or WLE-NBI (n = 20). 246 suspected polyps were detected. Histology was obtained in 238, 28 (11.8%) with normal histology, 106 (44.5%) hyperplastic polyps, 28 (11.8%) sessile serrated polyps and 57 (23.5%) adenomas. No significant differences were observed in the median number of detected polyps by NBI (NBI-WLE group) and WLE (WLE-NBI group), 3 (IQI: 2–8) vs 2.5 (IQI: 1–4), respectively ($p = 0.15$). Moreover, there were no differences in the polyp miss rate of NBI and WLE, with 21.3% and 26.1% (OR 0.77, 95% CI: 0.43–1.39) respectively. An additional colonoscopy, independently of the technique identified 9 (22%) individuals that fulfilled the criteria for SPS.
**Conclusion:** NBI has a similar detection rate to WLE in patients with serrated lesions. A close follow-up to these patients could change the diagnostic to SPS about 1 in every 5 patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Reports in Japan indicate that the type II-open pit pattern is a useful endoscopic finding for sessile serrated adenomas/polyps (SSA/Ps). The Japan Society for Cancer of the Colon and Rectum (JSCCR) has proposed the pathological diagnosis of SSA/Ps. Thus, although this criterion can be used to diagnose most typical SSA/Ps, consensus has not yet been reached on the treatment of the diagnosed lesions; the treatment is currently determined at the discretion of each institution. The absolute indication for resection (i.e., lesions that can be called high-risk lesions in advanced colorectal cancer) currently includes carcinoma in SSA/Ps and SSA/Ps with cytological dysplasia (advanced SSA/Ps); this clinicopathological characteristic is a very important index for establishing future SSA/P treatment.
**Aims & Methods:** The purpose of this study was to examine whether all SSA/Ps need to be resected. This study included 225 lesions in 183 SSA/P patients who

underwent endoscopic or surgical resection in our hospital between January 2008 and December 2015. There were 12 cases of carcinoma in SSA/Ps and 9 cases of SSA/Ps with cytological dysplasia. In addition to the conventional-pit pattern diagnosis, type II pit subclassification was used for magnifying endoscopic diagnosis. The pathological diagnosis of SSA/Ps was determined in accordance with the criteria proposed by the JCCCR. Patient characteristics (age and gender), conventional endoscopic findings (size, location, macroscopic type, color, and the presence or absence of mucus), and magnifying endoscopic findings were compared with the histopathological diagnosis. Molecular biological analysis was also performed for advanced SSA/Ps (A-SSA/Ps).

**Results:** Patient characteristics: The mean age was 64 years in the SSA/P group and 73 years in the A-SSA/P group. There were more men in the SSA/P group (56%; 116/204) and more women (76%; 16/21) in the A-SSA/P group. Conventional endoscopic findings: As found in earlier reports, in the A-SSA/P group, the lesions were more commonly on the right side of the colon, they were normal-colored or pale mucosa, and had abundant mucus; however, the lesion was macroscopically flat type with a higher elevation in 57% (12/21) of the patients of the A-SSA/P group. The lesion diameter was a median length of 10 mm in the SSA/P group and 20 mm in the A-SSA/P group. Magnifying endoscopic findings: Lesions exhibited several pit patterns in approximately 14% (30/204) of the SSA/Ps and all A-SSA/Ps. Particularly, 75% of carcinomas in SSA/Ps exhibited the type V pit pattern, with elevation and redness at the same site. Molecular biological analysis: Red, elevated lesions that were 15 mm in size in the ascending colon with a depression in the lesion center were analyzed. Most lesions exhibited type II-open pit and type IV pit patterns; however, type V pit pattern was observed in the depressed area. Upon diagnosis of SSA/P cancerization, endoscopic mucosal resection was performed. The pathological results were adenocarcinoma with SSA/Ps and depth was pTis. Analysis of sections containing cancer revealed BRAF mutation, MLH1 methylation, and microsatellite instability. These results appear to support the serrated pathway currently considered. Because we are also presently analyzing other cases of cancerization, we will report on this together with these results.

**Conclusion:** In the present study, the rate of concurrent SSA/Ps and cancer was 5.3%. Because resection was not necessarily performed of all SSA/Ps, we believe that the rate of concurrence is actually lower. Furthermore, carcinomas in SSA/Ps and SSA/Ps with cytological dysplasia present several surface microstructures compared to SSA/Ps and are highly likely to be elevated. Based on these results, if endoscopic diagnoses are carefully performed and A-SSA/Ps are effectively detected, not all SSA/Ps will require treatment. Further examination via a multicenter prospective study (with a larger subject sample, molecular biological analysis, and minimal bias) is anticipated.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Successful colon cleansing enables effective colonoscopy. PEG based split dosing preparations are traditionally seen as the gold standard in cleansing, but many still require a high preparation volume intake. NER1006 is the first 1 L PEG3350 and ascorbate bowel preparation in phase 3 clinical development. The low volume of NER1006 is achieved through the use of ascorbate in the second dose only.

**Aims & Methods:** This phase 3, randomised, multicentre, colonoscopist-blinded, non-inferiority study assessed the efficacy, safety and tolerability of a day before split-dosing regimen of either NER1006 (NDB; evening time) or sodium picosulfate + magnesium citrate (SPM; regimen per label) in patients undergoing colonoscopy. Two alternative primary endpoints were evaluated: overall bowel cleansing success and 'Excellent plus Good' cleansing rate in the ascending colon including the caecum using the Harefield Cleansing Scale (HCS). Secondary endpoints included hierarchical evaluation of adenoma/polyp detection rates, and cleansing assessment using the Boston Bowel Preparation Scale (BBPS). Patient tolerability, acceptability and compliance were assessed using a questionnaire. Safety was monitored through adverse events reporting and clinical laboratory evaluation. The threshold for statistical significance in this study was $P < 0.025$.

**P1266 Table 1:** Patients, efficacy and safety

| Abstract legend | NER1006 day before split-dosing NDB | Comparator: sodium picosulfate/magnesium citrate SPM | CI for the difference [P value] NDB vs. SPM |
|---|---|---|---|
| **PATIENTS** | | | |
| Randomised patients [n] | 258 | 257 | |
| Mean age [years (SD)] | 54.6 (11.64) | 52.9 (13.35) | |
| Males / females [n] | 90 (34.9%) / 168 (65.1%) | 83 (32.3%) / 174 (67.7%) | |
| **EFFICACY** | **Primary analysis set, n = 250** | **Primary analysis set, n = 251** | |
| Primary endpoint: Patients with successful overall bowel cleansing efficacy (HCS) [n] | 155 (62.0%) | 135 (53.8%) | −0.50%* [0.038] |
| Supportive secondary endpoint: Patients with successful overall bowel cleansing efficacy (BBPS) [n] | 146 (58.4%) | 115 (45.8%) | n.a. |
| Primary endpoint: Excellent plus Good cleansing rate in colon ascendens [n] | 11 (4.4%) | 3 (1.2%) | −5.56%* [0.027] |
| Key secondary endpoint: Adenoma detection rate, colon ascendens | 6.4% | 4.0% | −6.35%; 11.12%** [0.154] |
| Key secondary endpoint: Adenoma detection rate, overall colon | 22.0% | 18.7% | −5.56%; 11.91%** [0.212] |
| Key secondary endpoint: Polyp detection rate, colon ascendens | 12.0% | 7.6% | −4.36%; 13.10%** [0.064] |
| Key secondary endpoint: Polyp detection rate, overall colon | 39.2% | 36.3% | −5.96%; 11.51%** [0.278] |
| Compliance rate (min 75% of both doses taken) [n] | 193 (77.2%) | 229 (91.2%) | n.a. |
| **SAFETY** | **Safety set, n = 235** | **Safety set, n = 241** | |
| All treatment-emergent adverse events [n] | 64 | 30 | n.a. |
| Patients with any related treatment-emergent adverse event [n] | 28 (11.9%) | 10 (4.1%) | n.a. |

* = 97.5% 1-sided CI; ** = 95% 2-sided CI; n.a. = not applicable

The confidence interval (CI) for the difference between the groups used a 10% margin to demonstrate non-inferiority vs. SPM.
**Results:** Patients were randomised to receive either NDB (n = 258) or SPM (n = 257). Demographic characteristics were similar between the two groups, as shown in Table 1. For both alternative primary endpoints, NDB was non-inferior (lower CI limit ≥ -10%) to SPM. NDB was also non-inferior to SPM in detecting adenomas and polyps, both in the ascending colon and in the overall colon (Table 1). Despite lower compliance rates for NDB vs. SPM, the overall bowel cleansing of NDB was non-inferior to SPM (Table 1). NDB had more treatment-emergent adverse events (TEAEs) than SPM, however the total numbers of patients with related TEAEs were low and no related event was serious. The most frequently reported related TEAEs were vomiting and nausea (NDB), and headache (SPM).
**Conclusion:** NER1006 as a day before regimen was non-inferior to SPM in achieving overall bowel cleansing success and an 'Excellent plus Good' cleansing rate in the ascending colon. NER1006 also showed non-inferior adenoma and polyp detection rates. Both treatments were well tolerated; most TEAEs were mild or moderate in severity and reflected the expected safety profile of respective treatments. The 1 L NER1006 administered the evening before colonoscopy offers comparable efficacy and safety to SPM.

## P1267 HIGH MENTAL WORKLOAD EXPERIENCED DURING COLONOSCOPY IS ASSOCIATED WITH POOR ENDOSCOPIST PERFORMANCE

**I. Rahman**, P. Boger, P. Patel
*Gastroenterology, University Hospital Southampton, Southampton/United Kingdom*

**Contact E-mail Address:** imdi81@hotmail.com
**Introduction:** Studies have shown that there are a multitude of factors that affect the quality of colonoscopy. However, the effect of the endoscopist mental workload on their performance has been neglected. It is shown that health professionals exposed to excessive workloads and fatigue show degraded performance. The aim of this study was to measure the effect of mental workload as represented by the National Aeronautics and Space Administration-Task Load Index (NASA-TLX), on colonoscopic performance relative to the experience of the endoscopist and colonoscopy scheduling.
**Aims & Methods:** Procedures were observed prospectively in one institution for 3 groups; trainees, consultants and bowel cancer specialist programme (BCSP) endoscopists. On reaching the caecum the endoscopist marked on a validated pro-forma their corresponding workload on six subscales; mental demand, physical demand, temporal demand, effort, frustration and own performance, to generate a NASA-TLX score. Data on performance which included caecal intubation times (CIT), patient comfort and polyp detection rate (PDR) were noted. In addition, withdrawal times, time of day (am or pm) and queue order for procedures were recorded.
**Results:** A total of 202 procedures were undertaken between 6 endoscopists with a mean CIT of 9.2 minutes and PDR of 42%. Increasing mental workload was associated with increasing CIT ($r = 0.61$, $p = 0.07$) and inversely associated with withdrawal time ($r = -0.72$, $p = 0.03$). The mean mental workload during colonoscopy was lower in BCSP endoscopist v consultants v trainees (188 v 254 v 352 $p < 0.01$). On multivariate analysis, absence of polyp detection was associated with a procedure that was undertaken in pm with an above mean mental workload (OR 1.62, 95% CI 1.38–2.07) and withdrawal time of < 5 minutes (OR 1.53, 95% CI 1.32 – 1.91). Increased patient discomfort was associated with increased frustration on the subscale of the NASA-TLX score (OR 1.59, 95% 1.37 – 1.93) and being a trainee (OR 1.11, 95% 1.03 – 1.22). The use of ScopeGuide reduced the mental workload of consultants (227 v 282 $p < 0.01$), but not trainees or experts. Queue position had no impact on any of the markers of performance.
**Conclusion:** This study shows that high mental workload experienced during colonoscopy has a significant detrimental effect on the performance of endoscopists. Drop in PDR in pm procedures when only associated with high mental workload may explain some of the conflicting results of daily variations of PDR in other studies. Further studies are now required to look into measures that may reduce excessive mental workload.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1268 NARROW BAND IMAGING VERSUS WHITE LIGHT ENDOSCOPY IN THE CHARACTERIZATION OF RESIDUAL NEOPLASIA AFTER ENDOSCOPIC PIECEMEAL MUCOSAL RESECTION, A RANDOMIZED CONTROLLED TRIAL

**F. Riu Pons**[1], M. Andreu[2], J. Gimeno[3], M. A. Álvarez-González[1], A. Seoane[1], J.M. Dedeu[2], L. Barranco[1], X. Bessa[2]

[2]*Department Of Medicine, Autonomous University of Barcelona, Barcelona/Spain*
[3]*Pathology Department. Hospital del Mar-IMIM, Barcelona, Barcelona/Spain*

**Contact E-mail Address:** 61111@parcdesalutmar.cat
**Introduction:** Endoscopic Piecemeal Mucosal Resection (EPMR) of large or difficult sessile polyps in the colon is commonly used but it is associated with a recurrence of up to 25%. There is no evidence regarding whether Narrow Band Imaging (NBI) instead of High Definition White Light Endoscopy (WLE) could improve the detection of residual tumorat the follow-up after an EPMR polypectomy.
**Aims & Methods:** We conducted a randomized, controlled trial at our institution to assess the accuracy of NBI and WLE for the detection of residual neoplasia in the scar of a previous EPMR. (ClinicalTrials.gov, NCT02448693). During real-time colonoscopy, the same endoscopist evaluated the polypectomy scar using both techniques randomly (1:1) NBI-WLE or WLE-NBI. Any suspected neoplasia was classified independently by each technique as low/high confidence. An apparently normal scar was also evaluated and biopsied. The remainder of the colon was inspected as usual with WLE.
**Results:** A total of 120 lesions from 111 patients were included. Mean age was 67.8 yrs (SD:10.1); 57.5% males. Median size 20 mm (IQI:12–30); 80% right-sided. The mean time for scar review from initial resection was 4.8 months (SD: 1.8). Baseline characteristics were not different between groups (NBI-WLE or WLE-NBI). For each lesion, at most 3 biopsies were taken (total number of evaluated sites 142). NBI compared to WLE demonstrated an 87.8% vs 78.0% sensitivity, 85.1% vs 86.1% specificity and 85.9% vs 83.8% overall accuracy, respectively. This slight increase in sensitivity was not significant ($p = 0.125$). Regardless of the technique, 41/113 (36.3%) had neoplastic lesions on histologic assessment. Residual dysplasia was related at univariate analysis with size, body weight and Body Mass Index (BMI). In a multivariate analysis, polyp size ≥25 mm (OR 2.73, 95% CI: 1.15–6.47) and BMI ≥27kg/m$^2$ (OR 3.03, 95% CI: 1.34–6.89) were independently predictive factors of residual dysplasia, with and AUC of 0.69 (95% CI: 0.59–0.79).
**Conclusion:** NBI has a similar accuracy to WLE for residual dysplasia detection after EPMR. Patients with lesions over 25 mm have a high risk of residual neoplasia.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Background and study aims: Cold snare polypectomy (CSP) for small colorectal polyps has lower incidence of adverse events, especially delayed post-polypectomy bleeding (DPPB). However, few data are available on comparisons of the incidence of DPPB of CSP and hot polypectomy (HP).
**Aims & Methods:** The aim of this study was to evaluate the incidence of DPPB after CSP and compare it with that of HP. A propensity score model was used as a secondary analysis. This was a retrospective cohort study conducted in a municipal hospital. We identified 539 patients with colorectal polyps from 2 mm to 11 mm in size who underwent CSP (804 polyps in 330 patients) or HP (530 polyps in 209 patients) between July 2013 and June 2015.
**Results:** There was no case of DPPB in the CSP group. Conversely, DPPB occurred in 4 patients (1.9%) after HP, resulting in a significant difference between the CSP and HP groups ($P = 0.025$). [KMD1] [t2] Propensity score-matching analysis created 402 matched pairs, yielding a higher DPPB rate in the HP group than CSP group ($P = 0.06$). However, significantly more patients in the CSP group had unclear horizontal margins that precluded assessment (83 vs 38 cases, $P < 0.001$). The retrieval failure rate was significantly higher in the CSP group than in the HP group (3% vs 0.7%, $P = 0.01$).
**Conclusion:** DPPB tended to be less frequent with CSP than HP, as selected by the propensity score-matching model; however, special care should be taken during polyp retrieval and horizontal margin assessment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1270 COLORECTAL SURVEILLANCE PROGRAM IN PORTUGUESE FAMILIES WITH LYNCH SYNDROME: A SINGLE-CENTRE COHORT STUDY

**R. Vale Rodrigues**[1], I. Claro[2], J. Pereira Da Silva[3], P. Lage[4], S. Ferreira[4], I. Rosa[4], I. Francisco[5], B. Filipe[5], C. Albuquerque[5], P. Chaves[6], A. Dias Pereira[3]

**Introduction:** Lynch syndrome (LS) is associated with a high risk of colorectal cancer (CRC). Colonoscopy enables the identification and removal of adenomas or early cancers and is the mainstay of secondary prevention in LS patients.
**Aims & Methods:** To assess the cumulative risk for the development of colorectal adenomas and the prevalence of high-risk adenomas (HRA) or CRC during colonoscopic surveillance in LS. Single-centre cohort study; asymptomatic LS mutation carriers (MC) in a surveillance program (SP) between 2005–2015 were evaluated, with review of the colonoscopic reports (range 12–18 months). Patients with previous colectomy, who declined screening or received follow up in another hospital were excluded from the analysis. HRA were defined as $>=10$ mm, high-grade dysplasia or villous component. Statistics analysis: SPSS.V20.
**Results:** Among 331 MC, 184 were excluded from the study (previous colectomy: n = 130; declined screening: n = 8; surveillance in another hospital: n = 46). Therefore, 147 MC (from 73 families) were included (88 female/59 male), MLH1/MSH2/MSH6 mutations: 51/83/13. A total of 897 colonoscopies (mean 6.1 per person, range 1–13) were performed. In 161 colonoscopies (18%), 232 adenomas were detected. Adenomas were mainly found in the proximal colon (right colon-59.9%, left colon-29.8%, rectum-10.3%, $p < 0.001$). The cumulative risk of adenomas at 30, 40, 50 and 60 years of age was 6.2%, 20.5%, 34.2% and 43.8%, respectively, with a significantly positive correlation ($p = 0.002$). HRA or CRC were identified in 48 colonoscopies from 39 MC (26.5%); mean age was 49.4 years (24–80). Among these, 17/39 (43.6%) had HRA or CRC detected in the index colonoscopy. Eleven MC presented CRC (7.5%), right colon/left colon/rectum: 7/1/3; AJCC stage I/II/III: 8/1/2; four occurred at 12 (n = 2), 16 (n = 1) and 17 (n = 1) months from the previous colonoscopy and the remaining 7 were detected in the first screening colonoscopy or in the absence of compliance to the SP; no patient died from CRC.
**Conclusion:** Colonoscopic surveillance program in LS patients allowed the detection of adenomas in a large group of MC and adenoma cumulative risk increased steadily over the age range, as expected. Only 4/11 CRC occurred during regular surveillance protocol and most of them were diagnosed in early stages. These results validate an intensive SP in LS supporting that CRC-related mortality can be reduced.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1271 THE EFFICACY AND SAFETY OF ENDOSCOPIC MUCOSAL RESECTION WITH A CAP FOR RECTAL NEUROENDOCRINE TUMOR COMPARE TO ENDOSCOPIC SUBMUCOSAL DISSECTION

**Introduction:** Rectal neuroendocrine tumor (NET) are found incidentally during surveillance of colonoscopy. They can be resected using various endoscopic techniques.
**Aims & Methods:** The aim of this study is to compare efficacy of endoscopic mucosal resection with a cap (EMR-C) with those of endoscopic submucosal dissection (ESD) for rectal NETs. Methods: Between August 2006 and February 2016, 93 patients (93 lesions) underwent either EMR-C (n = 61) or ESD (n = 32) for rectal NETs at Gachon University Gil Medical Center. The endoscopic complete resection rate, procedure time, pathological complete resection, and procedure complications were analyzed retrospectively.
**Results:** Mean age was $49.7 \pm 10.6$ year in the EMR-C group and $50.3 \pm 11.5$ year in the ESD group. Mean tumor size was $4.63 \pm 2.40$ mm in the EMR-C group and $6.59 \pm 3.56$ mm in the ESD group. Endoscopic complete resection rate was 100% in both groups. Lateral margin involvement rate was significantly greater in the ESD group (25%) than in the EMR-C group (1.6%) ($P < 0.001$). The procedure time was significantly longer in the ESD group ($14.3 \pm 7.8$ min) than in the EMR-C group ($8.0 \pm 4.4$ min) ($P < 0.001$). Overall complication rate was not significantly different between the EMR-C group (4.9%) and the ESD group (15.6%).
**Conclusion:** Compared with ESD, EMR-C may be easy, simple, shorter and more effective procedure in removing rectal NETs. Therefore, EMR-C may be considered the treatment of choice for small rectal NETs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The role of ESD in the therapeutic algorithm of the colorectal cancer as the less invasive approach to surgery to treat superficial neoplasms with a negligible risk of lymph node metastasis has been officially recognized in Japan and East Asia. Actually, its technical difficulty is an obstacle for its adoption and diffusion in the West, and the definitive identification of the prognostic variables of colorectal ESD difficulty would have important implications to improve ESD feasibility; promote its training and adoption.
**Aims & Methods:** Prospective study conducted in a nonacademic center by a single endoscopist with an experience of 60 colorectal ESDs. Inclusion criteria: colorectal neoplasms $\geq$15 or $\geq$20 mm with and without a scar of previous resection; no features of SM-deep invasion (Kudo pit pattern type V and Sano microcapillary pattern type 3B). ESD was performed by the standard technique. The ESD was defined as difficult if not en bloc and with an operating speed $>13$ min/cm$^2$ (threshold: 90 min for a 30-mm lesion). The prognostic role of preoperative and intraoperative variables was evaluated according to the neoplasm location in the rectum and colon. Operator experience was stratified in consecutive groups of 30 colorectal procedures.
**Results:** From 1.2012 to 7.2015, 140 ESDs were included: 110 (79%) in the colon, 30 (21%) in the rectum. Lesions had a median size 9cm$^2$ (range 1.2–33); were LST-G in 85 (61%); had a nodule $>20$ mm in 38 (27%), a scar in 31 (22%). Colonic neoplasms were significantly more frequently located on a semilunar fold ($P < .0001$). Rectal neoplasms had significantly more frequently a nodule $>$ 20mm ($P = .03$) and a scar ($P = .004$). Colonic ESDs were achieved with a higher en bloc resection rate (85%) and a lower difficulty rate (40%) than in the rectum (73% and 50%, respectively) with no statistical difference. Ineffective gravity counter traction was significantly more frequent in colonic ESD (22% vs. 3%; $P = .016$); SM fibrosis was significantly more frequent in rectal ESD (44% vs. 31%; $P = .045$). Preoperative variables of difficulty. In the rectum, the scar was the only prognostic variable (OR 12.3; $P = .03$). In the colon, prognostic variables were (in ascending order): operator experience $< 120$ procedures (OR 0.19; $P = .025$); size 7–12 cm$^2$ (OR 0.2; $P = .016$); sessile (OR 3.1; $P = .024$) and LST-NG (OR 10.5; $P < .005$) morphology; the scar (OR 12.7; $P = .038$). Intraoperative variables of difficulty. In the rectum, no variable was identified although severe SM fibrosis occurred only in difficult procedures. In the colon, prognostic variables were (in ascending order): perpendicular SM access (OR 5.1; $P = .042$); ineffective gravity counter traction (OR 12.3; $P = .002$); severe SM fibrosis (OR 21.9; $P = .010$).
**Conclusion:** This is the first study that evaluated the prognostic variables of colorectal ESD difficulty in the Western setting and demonstrated that there are qualitative differences according to the neoplasm location. The evaluation of the full spectrum of the preoperative and intraoperative variables confirmed that the level of ESD difficulty has to be evaluated on both the pre- and intraoperative variables. The combination of independent prognostic variables can be used to guide training and feasibility of ESD performed by Western endoscopists. Difficult neoplasms should be avoided until an expert level of competency has been achieved for easy neoplasms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1273 ENDOSCOPIC MANAGEMENT OF LARGE RECTAL POLYPS

**H.H. Nietsch**
*Division Of Gastroenterology, St. Elisabeth Medical Center, Halle/Germany*

**Contact E-mail Address:** h.nietsch@krankenhaus-halle-saale.de
**Introduction:** Since implementation of screening colonoscopy as primary method for the detection of early colorectal neoplasia in Germany many large ($>5$ cm in diameter) rectal lesions are found. Almost all of those are amenable to endoscopic resection via EMR or ESD.
**Aims & Methods:** We report our 3-year experience resecting those large rectal lesions endoscopically.
**Results:** Our patient cohort includes 46 patients (age 45–84 years) with rectal polyps from 5 to 11 cm in size. Some lesions spread in a circumferential

manner. All of those polyps were resected successfully after careful assessment using the Paris classification. EMR, ESD and hybrid methods were used. All procedures were performed on an outpatient basis. 4 patients did present with a post-polypectomy haemorrhage 24–72 hours after resection, which could be treated with endoscopic haemostasis (clips and APC). All patients were enrolled in an endoscopic surveillance program at 3–6 months after resection: 4 patients had evidence of polyp recurrence of up to 10 mm in diameter (all after piecemeal EMR). Repeat polypectomy did achieve complete histological resection.
**Conclusion:** Endoscopic resection of extensive rectal polyps is safe and effective on an outpatient basis. ESD is associated with a lower recurrence rate compared to piecemeal EMR. Post-interventional bleeding is quite frequent, but can be successfully managed endoscopically.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1274 THE DISCREPANCY IN PATHOLOGY RESULTS BETWEEN ENDOSCOPIC FORCEPS BIOPSY AND RESECTED SPECIMEN OF COLORECTAL POLYP

**K. Kim**[1], D.E. Jeong[1], M.J. Hwang[1], B.I. Jang[1], T.N. Kim[1], C.H. Yang[2]

**Introduction:** There are reports about discrepancy in results of histology between endoscopic forceps biopsy and resected specimens in gastric neoplasms. However, there are few studies in colorectum. The aims of this study were to investigate the decree of discordance in pathology result and to analyze the risk factors of underdiagnosis before complete removal co colorectal polyp.
**Aims & Methods:** Among 1171 patients who underwent endoscopic resection of colorectal polyp, 240 patients with pathology report prior to endoscopic resection were included in the study. We reviewed the medical records and endoscopic findings retrospectively and assessed the frequency and type of discordance in histology.
The baseline characteristics of the patients, morphology, size of the polyp and histology were compared between groups. Among the discordant group, risk factors of under-diagnosis were analyzed. Under diagnosis was defined as the cases when final pathology of total specimen showed more advanced type than those of biopsy specimen before resection.
**Results:** Mean age was 59.3 years and male to female ratio was 1:0.518 (158:82). Colorectal polyps were detected in the recto-sigmoid colon most frequently (53.75%). Mean size of the polyp was $18.5 \pm 9.8$ mm and 94.2% of them were removed by endoscopic mucosal resection. En-bloc resection rate was 97.9% and tubular adenoma with low-grade dysplasia was most common histology in 144 cases (58.8%). Change of the final histology after endoscopic resection was noted in 121 cases (50.4%). Among them, change to malignancy from benign after complete removal was noted in 25 cases (10.4%) and high-grade dysplasia to malignant was most common in 14 cases (5.8%). There noted under diagnosis in 80 (66.1%) and over-diagnosis was in 41 (33.9%). In under-diagnosis group, polyps above 10 mm in diameter and flat type morphology was significantly more common. By multivariate analysis, size above 10 mm was the only predictive factors of under- diagnosis after endoscopic resection.
**Conclusion:** The histology discrepancy between before and after endoscopic resection was noted in 50.4% of colorectal polyp and among them, 66.1% of them were under diagnosed nefore procedure. The rate was higher in flat morphology and increased with size increase. We need more attention for complete removal especially in case of larger than 10 mm flat type polyps.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** Brand.Eelco@mayo.edu
**Introduction:** Detection of subtle recurrences after colorectal endoscopic mucosal resection (EMR) is challenging. High-definition colonoscopy with narrow band imaging (NBI) and near-focus features may help in differentiating residual neoplasia from granular tissue and could thereby potentially reduce the need for pathologic assessment during EMR follow-up. The main objective is to evaluate the diagnostic value of high-definition white light and NBI with and without near-focus in the optical detection of residual neoplasia after EMR.
**Aims & Methods:** This multicenter prospective study started at one site in Florida in January 2016. Consecutive patients undergoing follow-up colonoscopy after a previous EMR of a ≥20 mm colorectal neoplasia were eligible for inclusion. Endoscopists predicted the presence of recurrence and their level of confidence (high or low) based on visual assessment of the previous EMR site with 1) high-definition white light colonoscopy without and 2) with near-focus, and 3) NBI without and 4) with near-focus. From each EMR-site tissue was obtained and histology, as reference standard, was assessed blinded to colonoscopy. A preliminary analysis was planned after enrollment of 50 patients. Negative predictive value (NPV), positive predictive value (PPV), sensitivity, specificity and diagnostic accuracy including 95% confidence intervals were calculated for all diagnostic modalities.
**Results:** Per-protocol analysis included 50 patients (males: n = 32 [64%], median age: 67 [range: 48–90] years) with 52 scar sites, with a median follow-up of 16 (range: 3–66) months. The prevalence of residual neoplasia was 37%. Diagnostic values for all EMR-scar sites and EMR-scar sites assessed with high confidence are summarized in table 1. The NPV of high confidence diagnosis was 100%, except for white-light (96%).

**Table:** Diagnostic value of optical detection of residual neoplasia during EMR follow-up.

| **All EMR-sites**, n = 52 | **White light** | **White light with near-focus** | **NBI** | **NBI with near-focus** |
|---|---|---|---|---|
| NPV | 97% [81–100] | 97% [81–100] | 97% [81–100] | 93% [76–99] |
| PPV | 86% [63–96] | 82% [59–94] | 82% [59–94] | 77% [54–91] |
| Sensitivity | 95% [72–100] | 95% [72–100] | 95% [72–100] | 89% [65–98] |
| Specificity | 91% [75–98] | 88% [71–96] | 88% [71–96] | 85% [67–94] |
| Accuracy | 92% [81–98] | 90% [78–96] | 90% [78–96] | 87% [74–94] |
| **High confidence diagnosis**, n (%) | 42 (81%) | 43 (83%) | 41 (79%) | 45 (87%) |
| NPV | 96% [80–100] | 100% [84–100] | 100% [84–100] | 100% [83–100] |
| PPV | 93% [64–100] | 88% [60–98] | 87% [58–98] | 80% [56–93] |
| Sensitivity | 93% [64–100] | 100% [73–100] | 100% [72–100] | 100% [76–100] |
| Specificity | 96% [80–100] | 93% [76–99] | 93% [75–99] | 86% [67–95] |
| Accuracy | 95% [83–99] | 95% [83–100] | 95% [82–99] | 91% [78–97] |

[.-.], 95%-confidence interval; n, number of EMR-sites.

**Conclusion:** These preliminary results suggest a very high NPV and good PPV for the optical diagnosis of residual neoplasia with NBI with near-focus when assessed with high confidence, in a setting with a surprisingly high residual neoplasia rate. These advanced imaging modalities may improve real-time decision making in follow-up after colorectal EMR, particularly the avoidance of biopsy.

## P1276 ACCURACY OF COLORECTAL POLYP SIZE ESTIMATION BY ENDOSCOPY

**A. Huerta Madrigal**, A. Fernández Atucha, M.S. Argueta, S. Torres Burgos, A. Bernal Martinez, J.L. Cabriada Nuño
*Gastroenterology Service, H. Galdakao-Usansolo, Galdakao/Spain*

**Contact E-mail Address:** alainhuerta@gmail.com
**Introduction:** The size of colonic polyps affects postpolypectomy surveillance interval, 3 years if ≥10 mm, and the implementation of strategies based on real-time histological diagnosis, in those < 6 mm.
**Aims & Methods:** The aim of the study was to assess overestimation and underestimation of the endoscopic size (ES) compared to histological size (HS) of colon polyps, in cutoffs of 5and 10 mm, and associated factors. Prospective consecutive outpatient colonoscopies of single endoscopist (May 2014 - November 2015). Only polyps resected in toto with ES and HS available with single fragment in a single pot. Logistic regression analysis to assess factors associated with the over/underestimation of HS, reference method, with ES (dichotomized ≤5 vs >5 mm and ≥10 vs <10 mm); OR (95%CI).
**Results:** In 511, of the 720 colonoscopies, ≥1 polyp was resected. 52.37% (961/1835) of resected polyps were excluded by the absence of valid HS; factors associated with the exclusion were age (y) OR 1.015(1.003–1.028); non 0-Ip morphology, 0-Is OR 3.717(2.007–6.884) and 0-II OR 3.866(2.098–7.121); and resection with forceps OR 4.763(3.822 - 5.936). 874 polyps were included, of 375 colonoscopies, ES Md 5 mm (ICR 3–8): 62.57% <6 mm, 25.3% 6–9 mm and 12% ≥10 mm. HS Md 4 mm (ICR 3–6); 79.1% (691/874) adenomas and 20.9% (183/874) hyperplastic/serrated lesions. 19.05% (20/105) with ES ≥10 mm were overcalled; non screening (iFOBT) indication OR 4.687(1.352–16.255) and proximal to splenic flexure localization OR 6.715(1.741–25.902).

3.25% (25/769) with ES <10 mm were undercalled; female OR 2.082(0.902–4.803) and non 0-II morphology, 0-Is OR 3.89(1.524–9.933) and 0-Ip OR 11.543(3.424–38.913). 34.4% (112/326) with ES ≥6 mm were overcalled, 3 villous component; suboptimal bowell cleaning OR 2.662(1.224–5.79); non 0-Ip morphology, 0-Is OR 4.296(1.861–9.917) and 0-II OR 5.259(2.095–13.201); and proximal to splenic flexure localization OR 1.726(0.968–3.077). 8.39% (46/548) with ES <6 mm were undercalled, null advanced histology; non screening (iFOBT) indication OR 4.141(1.598–10.73); and non 0-II morphology, 0-Ip OR 3.035(0.328–28.123) and 0-Is OR 2.216(1.177 - 4.174). 42 colonoscopies show ≥1 polyp with ES and HS discordance in 10 mm cutoff, 45 polyps. Posptpolypectomy surveillance changed in 0.3% (11/375) of the included colonoscopies: 10 to 3 years in five and 3 to 10 years in six.
**Conclusion:** In colorrectal polyps ES overestimation, compared to HS, is greater than the underestimation, cutoffs of 5 and 10 mm. The clinical relevance is residual in the postpolypectomy surveillance, but it can affect the impact of policies of discard and resect polyps <6 mm.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1277 ANALYSIS OF COLONOSCOPY TO CONTINUOUS AMBULATORY PERITONEAL DIALYSIS (CAPD) PATIENTS

**S. Kawamura**[1], N. Toda[1], S. Kurosaki[1], K. Funato[2], Y. Karasawa[1], S. Maeshima[1], K. Kojima[1], S. Furuse[3], T. Ohki[1], K. Saito[3], M. Seki[1], N. Mise[3], K. Tagawa[1]

**Introduction:** There have been several case reports on peritonitis following colonoscopy in continuous ambulatory peritoneal dialysis (CAPD) patients. Then antibiotic prophylaxis for patients undergoing colonoscopy while on CAPD is recommended. And, in general, colonoscopy in patients with peritoneal adhesion is considered to be difficult. However, whether CAPD is risk factor for complications or incomplete study of colonoscopy is unclear. We conducted a study to investigate preparation, difficulty and complication of colonoscopy to CAPD patients on the basis of single-center experience in Japan.
**Aims & Methods:** 52 CAPD patients were enrolled. They underwent 93 colonoscopies between August 1982 and October 2015. Demographic and clinical data, use of antibiotics before colonoscopy, preparation status, difficulty of intubation, procedure performed and complication were retrospectively analyzed. Preparation was evaluated by Aronchick scale (1: excellent – 5: inadequate). These patients were then compared with a control group with normal renal function matched 2:1. For statistical analysis, $\chi^2$ or Fisher's exact test was used.
**Results:** In 93 colonoscopy procedures to CAPD patients, prophylactic antibiotics were given in 11. Regarding colon preparation quality, 13% of colonoscopies were judged poor or inadequate. Average intubation time was 16.8 ± 13.5 mins and cecal intubation rate was 94%. No post-operative complication was observed. Aronchick scale was higher in CAPD patients (2.5 ± 1.1 in CAPD group vs 1.8 ± 0.7 in control group, $p < 0.001$). Longer intubation time (16.8 ± 13.5 in CAPD group vs 10.6 ± 8.2 in control group, $p = 0.005$) and lower cecal intubation rate (94% in CAPD group vs 100% in control group, $p = 0.042$) were observed in CAPD group. Colonoscopists felt difficulty more occasionally in procedures for CAPD patient (35% in CAPD group vs 15% in control group, $p = 0.010$).

| Patient Characteristics | CAPD Group (N = 52) | Control Group (N = 104) | p Value |
|---|---|---|---|
| Age | 64.1 ± 9.4 | 65.6 ± 11.9 | 0.422 |
| Male sex, n (%) | 35 (67) | 69 (66) | 0.717 |
| BMI, kg/m$^2$ | 21.3 ± 3.0 | 22.2 ± 3.1 | 0.073 |
| Inpatient status, n (%) | 23 (44) | 46 (44) | 1.000 |

**Conclusion:** We found CAPD was associated with insufficient preparation and difficult intubation of colonoscopy. No complication after colonoscopy was observed either in patients with or without prophylactic antibiotics. In our study, we cannot demonstrate a necessity of prophylactic antibiotics in colonoscopy for CAPD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1278 TRACTION ASSISTED COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION USING CLIP AND LINE: A FEASIBILITY STUDY

**Y. Yamasaki**, Y. Takeuchi, N. Uedo, T. Kanesaka, T. Akasaka, N. Hanaoka, K. Higashino, R. Ishihara, H. Iishi
*Department Of Gastrointestinal Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka/Japan*

**Contact E-mail Address:** yasshifive@yahoo.co.jp
**Introduction:** Colorectal endoscopic submucosal dissection (C-ESD) is a challenging procedure because it is often difficult to maintain good visualization of the submucosal layer. To facilitate C-ESD, we designed a novel traction method, namely "Traction assisted C-ESD using clip and line (TAC-ESD)", and investigated its feasibility.
**Aims & Methods:** We retrospectively analyzed 67 patients with large colorectal superficial lesions who had undergone TAC-ESD between October 2014 and July 2015. The main outcome was the procedural success rate of TAC-ESD, which we defined as successful, sustained application of clip and line to the lesion until the end of the procedure. TAC-ESD was performed as follows. Before the colonoscope was inserted, a polyester line was inserted into its accessory channel by grasping the line with hemostatic forceps, and pulling it up through the working channel. Then we tied the ends of the line together outside the colonoscope. After that, the colonoscope was inserted as usual and the actual C-ESD procedure started. After submucosal injection, the mucosa was incised on the anal side of the lesion. Next, the line was cut externally at the hand control end of the colonoscope and the accessory channel end of the line tied to the teeth of the clip attached to an applicator. At this stage, it was important not to fully open the clip. The clip and line were then retracted into the applicator and the applicator inserted into the accessory channel. The clip was fully opened in the colon and used to grasp the anal side of the specimen, after which the line was pulled gently by hand to provide good visibility of the submucosal layer. Finally, the submucosal layer was dissected easily under direct visualization [1,2]. In the rectum, TAC-ESD was performed as follows. First, a polyester line was tied to the teeth of a clip, which was attached to an applicator. The clip and line was then retracted into the applicator as in preparation. Next, the colonoscope was inserted into the rectum. After a mucosal incision on the anal side of the lesion was performed, the colonoscope was withdrawn outside of the rectum. The applicator was inserted into the accessory channel of the colonoscope, and the line was pulled back up through the working channel. Then, the colonoscope was reinserted into the rectum. The clip was fully opened within the rectum and used to grasp the anal side of the lesion. Since then, the procedure was same as above [3].
**Results:** Study subjects were 34 men and 33 women with a median age of 70 years (range 41–89 years). Forty-six (69%) lesions were located in the proximal colon, 11 (16%) in the distal colon, and 10 (15%) in the rectum. Thirty-four (50%) lesions were a granular type of laterally spreading tumor. The median lesion size was 27 mm (range 14–125 mm). The median resected specimen size was 34 mm (range 20–135 mm). The overall median procedure time was 64 min (range, 18–291 min). The clip and line was successfully attached to the lesion in all cases, thus good visibility of the submucosal layer was obtained in all cases in the initial part of TAC-ESD. However, in seven cases, the clip and line detached from lesion during submucosal dissection, all of which were in the proximal and the procedure times over 70 minutes. Therefore, the procedural success rate of TAC-ESD was 90% (60/67). En bloc resections of all lesions were achieved and R0 resections confirmed in 61/67 lesions (91%). Intra-procedual perforation occurred in two lesions (2.9%) and was treated successfully with endoscopic clipping. There were no fatal adverse events.

**Conclusion:** TAC-ESD is feasible and safe for C-ESD and may improve the ease of performing C-ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Current clinical guidelines do not favor a specific diet the day before a screening colonoscopy. Participants in a screening program are usually healthy and motivated patients who comply adequately with instructions; on the other hand good tolerability is very important in asymptomatic participants to improve adherence to surveillance colonoscopies.
**Aims & Methods:** Main objective: to compare the efficacy of a low-fiber diet (LFD) versus liquid diet (LD) the day before a screening colonoscopy. - Secondary objectives: to compare the adenoma detection rate (ADR) and tolerability. This is a randomized controlled clinical trial to show non-inferiority of LFD versus LD. 276 participants of the colorectal cancer screening program in Barcelona came for a personal interview to schedule the colonoscopy date and to receive instructions on bowel preparation and were randomized to LFD or LD. Both groups were given 4 liters of poliethylenglicol in split fashion. The main outcome measure was inadequate bowel preparation measured with the Boston Bowel Preparation Scale (<2 points in any segment). The endoscopists were blinded for the diet received. The sample size was calculated estimating 4% of inadequate bowel preparation with LD (our previous data) with a differential of 6%, to keep inadequate bowel preparation <10%. The patients were given questionnaires on tolerability and acceptability to be filled during the bowel preparation. Analogic visual scale was used.
**Results:** 276 consented patients were randomized from January to June 2015 (3% nonappearance) and 267 patients fulfilled the protocol. 132 were included in LD and 135 in LFD, both groups were similar in baseline variables. Inadequate bowel preparation was 6.8% (95% CI: 3.6%-12.5%) for liquid diet and 2.2% (95% CI: 0.8%-6.3%) for LFD ($p = 0.07$). ADR was 53% for LD and 60% for LFD ($p = 0.3$). LDF participants referred less hunger ($p = 0.006$) and less perception of excessive volume of laxative ($p = 0.04$), without differences in bloating or nausea. Acceptability was 85% (LD) and 88% (LFD), $p = 0.6$.
**Conclusion:** The efficacy of a screening colonoscopy following a low fiber diet is excellent, with less than 10% of inadequate bowel preparations. It also improves hunger and perception of excessive volume. This study shows that low fiber diet is the ideal dietary recommendation for the day before a screening colonoscopy.

**Introduction:** A retrospective review of a single centre's adoption of pocket creation method in colorectal ESD.
**Aims & Methods:** Patients' records from all colorectal ESD cases performed in our institution were selected from June 2014 to January 2016. A total of 55 colonic ESD cases were performed and nine cases were excluded as they were deem unsuitable on examination.
**Results:** A total of 46 patients underwent colonic ESD in which the average age was 68.4(47–85). 22 cases were done via pocket creation method and 24 via hybrid/others. 12 out of 22 cases achieved complete en bloc resection whereas the remaining 10 cases required endoscopic piecemeal resection (EPMR). The complication rate of the pocket creation method was 4.6% (1/22) versus the hybrid group 8.3% (2/24). The size of the lesion resected in the pocket creation method ranged from 23–60 mm x 20–55 mm with the largest en bloc resection specimen at 60 mm x 55 mm x 7 mm.
**Conclusion:** Overall pocket creation method is safe, effective and facilitates submucosal dissection to achieve en bloc resection of colonic lesions. Safety and success rates can be improved via development of new strategies, training system and equipment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Little is known about the long-term outcome of early colorectal cancer with submucosal invasion following endoscopic resection. The present study addressed determine the long-term outcome of endoscopically resected sm+ colorectal cancer.
**Aims & Methods:** Aim of this monocentric retrospective study was to evaluate the follow-up of patients after endoscopic resection of colorectal carcinoma with submucosal invasion Patients who benefits of an endoscopic resection (ER) of a submucosal invasive colorectal carcinoma between 2006 and 2012, were included in this study. Submucosal invasion was stratified using the Paris classification1 (sm1, $sm^2$, sm3). If the exact depth of submucosal invasion couldn't be assessed on the specimen, lesion was stratified as "smX". Complementary surgical resection was purposed if the submucosal invasion was either superior to 1000$\mu$m or inferior to 1000$\mu$m with poor prognosis criteria (budding, low differentiation, lympho-vascular invasion). In another situation, clinical and endoscopic follow-up was recommended.
**Results:** Forty-one patients (16 female, mean age = 30 yrs [35–88] were treated endoscopically for 43 submucosal invasive colorectal carcinomas (rectum = 17, colon = 26). Endoscopic mucosal resection was performed in 35 cases (81.5%), submucosal dissection in 5 (11.5%) or hybrid technique in 3 (7%). Mean diameter was 30 mm (10–50 mm). ER was macroscopically complete in all cases, en-bloc in 51%. Morbidity was 14% (bleeding = 4, perforation = 2), treated conservatively in all cases. Histology showed well or moderately differentiated carcinoma in respectively 49% and 35% (7 missing datas). Budding, lymphatic or vascular invasion were identified respectively in 5%, 11% and 2%. Deep margin was superior to 1 mm in 58% of cases. Lateral margin was clear in 77% after en-bloc resection (unevaluable after piecemeal resection). Submucosal invasion was stratified sm1, $sm^2$, sm3 or smX respectively in 32%, 28%, 5% or 35%. Follow up after ER was obtained in 29 patients (71%). Surgical resection was performed for 11 patients (4 $sm^2$, 6 smx, 1 sm1 with budding), 9 patients being followed (surgical contraindication or refusal). None residual adenomatous tissue was found on the surgical specimen in all patients operated, but 2 patients with early rectal cancer were N+. Definitive classification of patients treated surgically was: pT0N0 = 9, pT0N1 = 1, pT0N2 = 1. No metastasis occurred during a median follow up of 48 months [12–84 m]. Eighteen patients were included in a follow-up program for a mean duration of 54 months [12–96 m]: sm1 = 8, sm1 with budding = 1, $sm^2 = 3$, sm3 = 1, smx = 5. Local recurrence occurred in 1 patient but was treated endoscopically. No metastasis occurred during follow up.
**Conclusion:** ER is an efficient and safe treatment for submucosal invasive colorectal adenocarcinoma without high risk criteria. Local recurrence is spare and most often treatable endoscopically. Clear margins of the resected site on endoscopic examination seems superior to microscopic analysis of lateral margins to predict complete resection.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Desmoplastic reaction (DR), characterized by stromal myofibroblast infiltration of the tumor, is thought to initiate in response to the invasion of carcinoma cells into the submucosal (SM) or deeper layers. DR expression increases as cancer invades, hence immerging to the surface of cancer. Reports in the past have shown that the presence of DR in the surface of early colorectal cancer suggests deep invasion into the submucosa. Therefore, the pathological determination of a DR in colorectal carcinoma is useful for predicting massive submucosal invasion.However, no previous study have reported in vivo assessment of DR using EC thus far. We have recently demonstrated that some submucosal invasive colon cancer represents fine granular structure (FGS) on endocytoscopy (EC) (not published).
**Aims & Methods:** The aim of this study was to determine the usefulness of EC in detecting DR. From May 2005 to August 2013, 72 lesions were diagnosed at our institution as EC3b according to the EC classification[(1)], suggesting submucosal or deeper invasion. For judging DR, these lesions were diagnosed by single pathologist. Pathological definition of DR were as follows: 1) the presence of carcinoma is required for the detection of DR; 2) a DR involves an area of collagen fiber accumulation and myofibroblast proliferation; 3) carcinoma and inflammatory infiltration does not signify the presence of DR; and 4) histological findings were determined by HE staining alone[(2)].FGS on EC was defined as granular aggregate formed by round nuclei which are smaller than cancer nuclei. We hypothesized that FG represents inflammatory cell and myofibroblast cell infiltration. The area with FGS on EC were pathologically examined in hematoxylin and eosin-stained specimen. We calculated positive ratio of FGS among subject lesions and overall accuracy of the identification of FGS on EC.
**Results:** Among the 72 lesions, 26 were positive for FGS, and 88.5% of the lesions (23/26,) had a DR. The overall accuracy of FGS on EC that was predictive of a DR was 86.1% (table1).

**Table 1:** Correlation between the presence of FGS and a superficial exposing desmoplastic reaction.

| | DR (+) | DR (-) | total |
|---|---|---|---|
| **FGS (+)** | 23 | 3 | 26 |
| **FGS (-)** | 7 | 39 | 46 |
| **total** | 30 | 42 | 72 |

N = 72; DR, desmoplastic reaction; FGS, fine granular structure

**Conclusion:** In conclusion, the presence of FGS in EC may be useful for predicting the presence of a DR, suggesting the clinical usefulness of EC in informing treatment for colon cancer with SM invasion.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** According to current recommendations[1] antibiotic prophylaxis is not recommended when an ERCP is likely to achieve complete biliary drainage. However, clinically significant post-ERCP bacteremia (PEB) occurs in up to 5% of cases and other risk factors are not fully established.
**Aims & Methods:** The aim of this study was to evaluate specific risk factors for PEB. This was a retrospective cohort study of 1.082 consecutive ERCP procedures performed in the Tel-Aviv Medical Center between January 2012 - December 2013. Exclusion criteria: a) age < 18 years; b) positive bacterial blood culture before ERCP; c) scheduled full antibiotic treatment prior to ERCP; d) hospitalization > 14 days before ERCP and e) missing critical data. Stepwise Logistic Regression analysis and Decision Tree algorithms were used for prediction modeling of PEB.
**Results:** A total of 626 ERCPs performed in 434 patients were included. Mean age- 66.49 ± 15.4 years and male:female ratio 46.5%/53.5%. The rate of clinically significant PEB was 3.7% (23/626). The bacteria cultured were: Enterobacteriaceae (1.8%), Extended spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae (1.3%), Pseudomonas aeruginosa (0.3%) and Acinetobacter baumannii (0.3%). In a case by case review by a blinded endoscopist, antibiotic prophylaxis was administrated in 22.2% of the cases but was indicated only in 7%. Prophylaxis was not indicated in any of the PEB cases. Demographic and procedure characteristics were comparable between the PEB and non-PEB groups except for ERCP duration (PEB 40.87 ± 42.7 min vs. non-PEB 28.64 ± 24.3 min, P = 0.02) and the prevalence of tandem EUS/ERCP (PEB 21.7% vs. non-PEB 6.6%, P = 0.006). In a stepwise multivariate logistic regression (ROC 0.716), only 3 variables were included: Tandem EUS/ERCP (Yes vs. No)(OR 3.563, P = 0.027); ERCP duration (minutes)(OR 1.009, P = 0.132) and Age at ERCP (years)(OR 1.031, P = 0.063 borderline significance). In a decision tree model (ROC 0.741) only two cut points were included: duration of the ERCP > 61.5 minutes (PEB probability of 12%) and age > 74.5 years (PEB probability of 6.5%).
**Conclusion:** In a retrospective point of view, antibiotic prophylaxis according to current guidelines was not indicated in any of the cases that resulted in PEB. Moreover, prophylaxis was not indicated in 60% of the cases it was actually administrated, but the prevalence of PEB was similar to previous reports. Thus, better classification of risk factors is required. In our study, ERCP duration over 1 hour, Tandem EUS – ERCP and age above 75 years were found to be significant risk factors for PEB. These factors should be further evaluated as indications for prophylactic antibiotic treatment before ERCP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Stone extraction represents the most frequent reason for performing endoscopic retrograde cholangiopancreatography (ERCP). Since its introduction in 1974 endoscopic sphincterotomy (ES) has been widely considered the choice technique for biliary duct stones removal [1]. Although its universal use, several complications can be caused by ES [2]. In 2003 Ersoz et al. introduced the technique of dilation assisted stone extraction (DASE), consisting of an EPBLD following a limited ES [3]. DASE has been proven to be safe and effective for extraction of large CBD stones, with some evidences of reduced post-procedure complication rates and need for mechanical lithotripsy when compared to ES [4].
**Aims & Methods:** Aim of our study is to evaluate efficacy and safety of DASE for the extraction of large biliary stones in patients with PAD. All patients with evidence of biliary large stones and concomitant peri-ampullary diverticula from 4 Italian ERCP referral centers undergoing a therapeutic ERCP were enrolled in our study. All ERCPs were performed by experienced endoscopists at high volume centers (> 200 ERCPs per year). Peri-ampullary diverticula were classified into three types based on the location of the major papilla with respect to diverticula: type 1, when papilla was located inside the diverticulum; type 2, when papilla was located on the perimeter of the diverticulum; and type 3, when papilla was located towards 1 cm outside the diverticulum. All data concerning procedure and during and post-procedural complications were recorded.
**Results:** A total of 81 patients (36 males and 45 females, median age 75 years old - range, 45 to 93 years old) were enrolled in our study. Follow-up average time was 363 days (92–734 days). A deep biliary cannulation was reached in 78/80 patients (biliary cannulation rate 97.5%). Pancreatic main duct was cannulated in 16/80 patients (pancreatic cannulation rate 20%). A prophylactic pancreatic stent was placed in 3 cases. A successful stone removal was achieved in 74/78 patients (94.8%). Mechanical lithotripsy was successfully used in 2/78 patients (2.6%). An unsuccessful extraction was observed in 5.2% of patients. In all but one papilla was located into the diverticulum (PAD1), in about 50% of patients there were three or more stones, with a maximum diameter of about 20 mm. Two of four unsuccessful patients experienced a complication. A total of 7 complications were observed, of which one mild bleeding during procedure. Post-

procedural complications were 2 mild bleeding, both on anticoagulants within 72 h before (2.5%), 4 mild pancreatitis (5%) and 1 severe perforation (1.2%). Univariate and multivariate analyses of complications for predictors (see table 3 and 4) showed that age, location of stones and stone extraction success were significantly associated with complications ($p < 0.05$). In consideration of the small number of patients referring to hospitals with concomitance evidence of large biliary stones and PAD, sample size presented in our series can be considered statistically adequate for a descriptive analysis for this group of patients.
**Conclusion:** Results from our study show that DASE can be considered a safe technique to obtain a successful removal of large biliary stones. Moreover, DASE can be considered the first choice technique in patients with concomitant evidence of large biliary stones and PAD, avoiding use of ML and reducing risks of biliary bacterial contaminations.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Cholangioscopy provides direct visualization of the biliary tract by using ultra-slim endoscopes that can be introduced into the bile duct. The SpyGlass system is a catheter-based technology which can be used for diagnostic and therapeutic purposes by a single operator. Recently, a new generation of this technology has been launched.
**Aims & Methods:** This retrospective study aimed to evaluate the clinical value of SpyGlass cholangioscopy by analyzing consecutive examinations at nine Austrian referral centers for bilio-pancreatic endoscopy. Patients characteristics, indications, image quality from 1 (bad) to 10 (optimal) and outcome were assessed and compared between two SpyGlass generations (SpyGlass Legacy and SpyGlass DS).
**Results:** Over a ten-year period 239 consecutive examinations (161 Legacy, 78 DS) were performed in 205 patients (125 male, 80 female, median age 71 years, range 25–95 years). The main indication was evaluation of indeterminate strictures (68%), followed by cholangiolithiasis (24%). Prior to SpyGlass examinations, a majority of patients (84%) had already undergone a median number of 1 conventional ERCP examinations (range 1 – 10) with inconclusive or insufficient result. In 76% of stricture cases targeted biopsies were taken using the SpyBite biopsy forceps which had a diagnostic accuracy (according to the further clinical course) of 80%. In 85% of stone cases lithotripsy by targeting an endohydraulic or laser probe was successful (57% complete, 28% partial stone resolution). Image quality was rated 4 in median for the Legacy system and 8 in median for the DS system ($p = 0.02$, Fisher's exact test).
**Conclusion:** In this multi-center retrospective analysis cholangioscopy using the SpyGlass system was very effective for diagnosis and therapy of biliary disease. Image quality was rated much better for the new system, potentially resulting in an even higher diagnostic yield in the future.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Bile leak after liver transplantation (LT) is commonly treated with endoscopic retrograde cholangiopancreatography (ERCP); however, there is scarce data in regard to the optimal strategy with this technique. We aimed to examine the role of ERCP in LT recipients with bile leaks at two large institutions.
**Aims & Methods:** We reviewed all ERCPs performed in LT recipients with bile leak and duct-to-duct biliary anastomosis at two high-volume transplant centers (Hospital Clinic-Barcelona and Mayo Clinic-Rochester) from 2003 to 2015. Information on clinical and endoscopic outcome was obtained from electronic health records and endoscopy databases from both institutions. Preoperative and endoscopic variables were evaluated as factors determining outcomes after ERCP.
**Results:** A total of 80 patients were included (45-Hospital Clinic and 35–Mayo Clinic). Location of bile leak was: anastomotic (45%), T-tube (34%), intrahepatic (10%), cystic remnant (9%) and cut surface (2%). Forty-seven (59%) patients underwent ERCP with plastic stent placement and 33 patients (41%) underwent sphincterotomy alone. Complete resolution was obtained in 94% of the stent group vs. 58% of the sphincterotomy group ($p = 0.01$). Resolution occurred in <3 months in 76% of the stent group vs. 37% of the sphincterotomy group ($p = 0.01$). There was no difference in 3-month survival among both groups. Percutaneous transhepatic therapy and surgery were required in 4% and 6%, respectively in the stent group vs. 12% and 42% respectively in the sphincterotomy group ($p = 0.22$ and $p < 0.001$ respectively). The only predictive factor of bile leak resolution was stent placement. Complications of ERCP occurred in 10% (5 mild pancreatitis, 3 mild bleeding).
**Conclusion:** ERCP is a safe and effective therapy for post-LT bile leaks. Combination therapy with sphincterotomy and plastic stent is highly successful and more effective than sphincterotomy alone. These results indicate that ERCP with sphincterotomy and plastic stent placement should be considered the treatment of choice for bile leaks in LT recipients with duct-to-duct biliary anastomosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1288 CAN ULTRASLIM UPPER ENDOSCOPE REPLACE FIVEROPTIC CHOLEDOCHOSCOPE FOR PERCUTANEOUS TRANSHEPATIC CHOLANGIOSCOPY?: A FEASIBILITY STUDY

**Contact E-mail Address:** goong@schmc.ac.kr

**Introduction:** PTCS is useful for evaluation of indeterminate biliary stricture and management of intrahepatic bile duct stone. PTCS using fiberoptic choledochoscopeis limited by unsatisfactory image quality and fragility.
**Aims & Methods:** The aim of this study was to evaluate the feasibility of an ultraslim upper endoscope during PTCS. A total of 16 patients with biliary stricture and/or intrahepatic bile duct stone were included prospectively. All the patients underwent PTCS with ultraslim upper endoscope (distal end outer diameter 5.4 mm, working channel 2–2.2 mm, total working length 110 cm) after by fiberoptic choledochoscope. Primary outcome was technical success, defined as advancement of the ultraslim upper endoscope into the target site. Secondary outcomes were adverse events, quality of image, and success rates of diagnostic and therapeutic intervention.

**Results:** The PTCS using ultraslim upper endoscope was completed in 16 of 16 patients (13 biliary strictures, 3 intrahepatic bile duct stones). NBI observation with targeted biopsy was successfully performed in 9 of 13 patients with biliary strictures. The overall diagnostic accuracy of histologic sampling was 77.8% (2 malignancy, 5 benign). Technical success of lithotripsy was achieved in 3 of 3 (100%) procedures. No adverse event including air embolism and cholangitis was ovserved.
**Conclusion:** PTCS using an ultraslim upper endoscope is feasible and useful for evaluation of biliary stricture and managment of bile duct stone instead of fiber-optic choledochoscope.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1289 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) FOR THE ELDERLY AND EXTREMELY ELDERLY: DOES AGE REALLY MATTER?

**M.A. Kopke Tulio**, L. Carvalho, S. Marques, J. Rodrigues, J. Carmo, B. Charrua, P. Barreiro, T. Bana, E Costa, C. Chagas
*Gastroenterology, Centro Hospitalar Lisboa Ocidental, Lisboa/Portugal*

**Contact E-mail Address:** mariaanatulio@yahoo.com

**Introduction:** The role of endoscopic retrograde cholangiopancreatography (ERCP) in the diagnosis and treatment of biliary diseases is well established. Despite the aging population, few studies have evaluated its efficacy and safety in elderly patients.
**Aims & Methods:** Our aim was to assess ERCP safety and effectiveness in elderly patients and to identify predicting factors for a successful ERCP in the considered patient group. Clinical data from patients >85 years-old that underwent ERCP in our centre during a two years period was retrospectively analyzed. Elderly patients were defined by being 85–90 years-old and extremely elderly by being >90 years-old. Variables analyzed included demographics, comorbidities, ERCP indications, final diagnosis and immediate and delayed complications (within 30 days of the exam).
**Results:** Our sample included 108 patients, 43 (39.8%) male and 65 (60.2%) female, with a mean age of 89 years (85–103). A total of 147 duodenoscopies were performed (98 in elderly and 49 in extremely elderly patients). ERCP indication was suspected lithiasis (25.9%), obstructive jaundice (24.5%), cholangitis (22.4%), acute pancreatitis (12.9%), stent placement/replacement/removal (10.2%) or other (4.1%). Most frequent diagnosis were lithiasis (61.2%) and neoplastic stenosis (27.9%), with 8.5% of normal exams. There was a 93% cannulation rate, in 15.5% of cases after precut papillotomy or double-wire technique. Juxtapapillary duodenal diverticula were identified in 20.4% of patients. Regarding therapeutic procedures performed, there were 62.8% of sphyncterotomies, 8.8% of precut papillotomies, 8.5% of ballon sphincteroplasties, 58.1% of stone removal, 34.9% of biliary stent placements (64% of which plastic) and 7.8% of prophylactic pancreatic duct stent placements. Immediate complications were identified in 7.7% of patients, namely bleeding (9 cases) and bradycardia (1 case). Gastrointestinal bleeding episodes were mild, without hemodynamic repercussion, effectively managed endoscopically and with only one case needing subsequent transfusion. Delayed complications (analyzed in 99 patients with 30 days follow-up), identified in 2% of patients, with 1 case of cholangitis and 1 case of gastrointestinal perforation (treated endoscopically). There were no cases of post-ERCP pancreatitis. Mortality during the 30 days follow-up occurred in 4 patients (4%), with only 1 case due to the procedure (cholangitis/sepsis). There was an association between cannulation rate and the presence of juxtapapillary duodenal diverticula (20% of no cannulation if present vs 3.7% in the remaining cases, $p = 0.002$). There was an association between immediate bleeding and precut execution (44% in patients with precut vs 3.3% in the remaining, $p < 0.001$), but not to previous antiplatelet or anticoagulant therapy (5.4% in medicated patients vs 6.9% in the remaining, $p = 0.771$). No statistical difference was identified regarding immediate (7.1% vs 6.1%, $p = 0.817$) or delayed (1.5% vs 9.1%, $p = 0.071$) complication rates for the two considered age groups.
**Conclusion:** In our sample, ERCP was safe and effective in both elderly and extremely elderly patients. The presence of juxtapapillary diverticula was a negative predicting factor for a successful exam, whereas precut execution was a predicting factor for immediate bleeding. Age and previous treatment with antiplatelet or anticoagulant agents were not associated to an increased risk of complications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1290 EFFICACY OF ENDOSCOPIC GALLBLADDER STENTING IN ACUTE CHOLECYSTITIS

**Y. Kawakami**, K. Suzuki, Y. Hayashi, M. Akahonai, K. Fukuda, T. Yatsu, K. Yonezawa, T. Abe
*Department Of Gastroenterology, Kushiro City General Hospital, Kushiro/Japan*

**Contact E-mail Address:** yujiro.kawakami@gmail.com

**Introduction:** Laparoscopic cholecystectomy is recommended for acute cholecystitis. However, in our hospital, cholecystectomy is performed 2–3 months after presentation, only after the gallbladder inflammation has resolved. Cholecystectomy is occasionally not possible in high-risk elderly patients with comorbidities. Although percutaneous gallbladder drainage (PTGBD) is usually considered an alternative to cholecystectomy, endoscopic gallbladder stenting (EGBS) has recently been shown to be useful.
**Aims & Methods:** We aimed to evaluate the efficacy of EGBS as either a bridge to surgery (BTS) for cholecystectomy or as a permanent placement.We retrospectively studied 35 EGBS procedures performed at our hospital between April 2012 and April 2016. In total, 31 patients (18 men and 13 women; mean age, 72 years [range, 41–88 years]) underwent EGBS, with a 5Fr single pig-tail stent with a thread. The main outcome measure of this study was the efficacy of EGBS.
**Results:** EGBS was performed for BTS in 19 cases and permanent placement in 12 cases. The overall EGBS technical success rate was 88.6%. Clinical success was noted in all the cases wherein technical success was achieved with the EGBS procedure. However, there were 3 cases of recurrence. The mean placement duration was 77 days (range, 23–290 days) in the BTS group and 348 days (range, 6–874 days) in the permanent stent placement group. Complications included damage of the cystic duct ($n = 1$) and pancreatitis ($n = 1$).
**Conclusion:** EGBS can improve quality of life, and may be effective for patients who are poor surgical candidates or those requiring a BTS.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1291 THE USEFULNESS OF ARGON PLASMA COAGULATION ABLATION SUBSEQUENT TO ENDOSCOPIC SNARE PAPILLECTOMY FOR AMPULLARY ADENOMA

**K. Nam**[1], T.J. Song[2], M.K. Cho[2], D. Oh[2], D.H. Park[2], S.S. Lee[2], D. Seo[2], S.K. Lee[2], M. Kim[2]
[1]*Gastroenterology, Dankook University Hospital, Cheonan/Korea, Republic of*
[2]*Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of*

**Contact E-mail Address:** nambag1108@gmail.com

**Introduction:** Endoscopic snare papillectomy (ESP) of major papilla is safe and effective alternative to surgical resection of ampullary adenoma. Argon plasma coagulation (APC) is widely used in ESP as adjuvant method to control bleeding and to ablate residual tumor. However, the safety and effectiveness of subsequent APC ablation during ESP are not fully evaluated. The aim of this study is to evaluate the short-term and long-term outcomes of APC ablation as adjuvant method during ESP.
**Aims & Methods:** The data of patients who had undergone ESP for ampullary adenoma between September 2005 and August 2015 were restrospectively reviewed.
**Results:** The 100 patients underwent ESP for ampullary adenoma with curative intent. The mean patient age was $57 \pm 11$ years old and 70 (70.0%) patients were male. The mean tumor size was $1.63 \pm 0.80$ cm. After ESP, adjuvant APC ablation was performed in 53 (53.0%) patients. There were no significant differences in procedure-related adverse events including pancreatitis (ESP + APC vs. ESP alone; 5.7% vs. 14.9%, $p = 0.183$), cholangitis (ESP + APC vs. ESP alone; 1.9% vs. 10.6%, $p = 0.096$), or perforation (ESP + APC vs. ESP alone; 1.6% vs. 2.1%, $p = 1.000$). However, bleeding events occurred less frequently after APC ablation (ESP + APC vs. ESP alone; 5.7% vs. 21.3%, odds ratio = 0.222, $p < 0.05$). During follow-up period (mean $931 \pm 881$ days), papillary stricture (ESP + APC vs. ESP alone; 9.4% vs. 4.3%, $p = 0.442$) and recurrence rate (ESP + APC vs. ESP alone; 20.8% vs. 23.4%, $p = 0.750$) were not significantly different.
**Conclusion:** During ESP procedure, additional APC ablation may have beneficial effect in decreasing bleeding events.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1292 ETOMIDATE WITH MEPERIDINE VS MIDAZOLAM WITH MEPERIDINE FOR SEDATION DURING ENDODSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAM (ERCP): A SINGLE CENTER, RANDOMIZED CONTROLLED, SINGLE BLINDED STUDY

**B.H. Cha**
*Gastroenterology, Division Of Medicine, Sheikh Khalifa Specialty Hospital, Ras Al Khaimah, UAE/United Arab Emirates*

**Contact E-mail Address:** doctorhyo@hotmail.com

**Introduction:** Endoscopic retrograde cholangiopancreaticography (ERCP) is a crucial technique for specific pancreatobiliary diseases. Maintaining adequate sedation is vital to achieve successful outcome.
**Aims & Methods:** The objective of this study was to compare the efficacy and adverse effects of sedating patients undergoing ERCP with etomidate (ETM) with those of midazolam (MDZ).This was single-institute, prospective, randomized single blinded study. In the MDZ group, the initial dose of MDZ was 0.06 mg/kg with 50 mg of meperidine (MPD), after which 1 mg was added intermittently during ERCP. In the ETM group, 0.1 mg/kg ETM was initially injected with 50 mg of MPD, and an additional dose of 2 mg was added if needed.

**Results:** Of 63 patients undergoing ERCP, 33 and 30 were randomly allocated to the MDZ and the ETM group, respectively. In the ETM with MPD arm, the intervention rates were significantly lower (number of intervention, $p < 0.01$), the satisfaction scores of patients and the endoscopists were significantly higher ($p = 0.015$ and $p < 0.01$, respectively), and there were fewer hypoxic events ($p = 0.013$).
**Conclusion:** We concluded that ETM in combination with MPD is superior to MDZ with MPD for sedating patients during ERCP. Therefore, endoscopists can consider ETM with MPD as a good sedative regimen for therapeutic ERCP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Samsung Medical Center, Seoul/Korea, Republic of*
[3]*Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of*

**Contact E-mail Address:** jurrdoc@naver.com

**Introduction:** Although endoscopic management is useful to treat Post-LDLT anastomotic stricture, the recurrence of the biliary stricture sometimes happen after removal of biliary stricture.
**Aims & Methods:** The aim of our study is to evaluate the risk factors related to recurrence of Post-LDLT biliary stricture. 1106 patients underwent LDLT between May 1996 and May 2014 at Samsung Medical Center (Seoul, Korea). 241 of these patients who were clinically suspected of developing biliary stricture underwent ERCP and 145 of them were performed ERBD successfully. Among the 241, 22 patients were showed normal cholangiogram or minimal stricture which didn't need for ERBD. We followed up the 145 ERBD group for more than 12 months. Among 145 who were performed successful ERBD, 11 were expired, 34 were maintained ERBD due to persistent biliary stricture, and 94 could remove the ERBD stent due to improvement of biliary stricture. 6 persons could remove ERBD also, but they were followed less than 12 months. Among the 94 patients of ERBD removal group, 69 were maintained ERBD removal state, but 20 showed biliary stricture recurrence. 5 recurred below the 3 months, and 20 were recurred after 3 months from time to remove the ERBD. In order to identify the predictors of recurrent biliary stricture after ERBD removal, we analyzed donor factors, recipient factors, surgical factors, endoscopic procedure-related factors, and cholangiography-related factors.
**Results:** The success rate for the endoscopic management of biliary strictures after LDLT was 66.2% (145 of 219 patients), and recurrence rate of the biliary stricture was 21.3% (20 of 94 patients). The recurrence of the biliary stricture was more frequent in patients with in the case of Non-B, Non-C liver cirrhosis, and the elderly age of the donor ($p < 0.05$).
**Conclusion:** At the time to consider the removal of ERBD after endoscopic treatment of post-LDLT anastomotic stricture, we should be careful when the patients have the risk factors for the relapse of biliary stricture.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1294 THE USEFULNESS OF DIRECT PERORAL CHOLANGIOSCOPY COMBINING WITH INTRADUCTAL ULTRASONOGRAPHY FOR THE EVALUATION OF INDETERMINATE BILE DUCT LESIONS

**H.J. Choi**[1], J.H. Moon[1], H.J. Goong[1], Y.N. Lee[1], H.K. Kim[2], M.H. Choi[1], T.H. Lee[1], S. Cha[1], Y.D. Cho[1], S. Park[1]
[1]*Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon and Seoul/Korea, Republic of*
[2]*Department Of Pathology, SoonChunHyang University School of Medicine, Bucheon and Seoul/Korea, Republic of*

**Contact E-mail Address:** joseph@schmc.ac.kr

**Introduction:** The evaluation of indeterminate bile duct strictures or filling defects is clinical challenging. Direct peroral cholangioscopy (DPOC) may be helpful by allowing endoscopic visualization and targeting biopsy. However, the evaluation of bile duct wall layers or extraductal lesions is impossible with DPOC. Intraductal ultrasonography (IDUS) provides high-resolutional ultrasonic findings of the bile duct wall and extraductal structures.
**Aims & Methods:** We evaluated the usefulness of DPOC combining with IDUS in evaluation of indeterminate bile duct lesions. Total 31 patients with indeterminate biliary strictures or undefined filling defects in preceding conventional imaging modalities including ERCP were evaluated by IDUS and DPOC by using an ultra-slim upper endoscope. Inclusion criteria includes dilated distal bile duct more than 8 mm. Asymmetrical irregular wall thickening and intraductal protruding or polypoid lesions with ductal disruption in IDUS findings were diagnosed as malignant lesions. Irregular surface with stricture, tortuous tumor vessels, protruding mass lesions, and granular or papillary mucosal lesions in DPOC findings were diagnosed as malignant lesions. Final diagnoses were confirmed by histopathologic results and/or clinical follow-up outcomes.
**Results:** Evaluated indeterminated bile duct lesions were finally diagnosed as 17 malignant, 1 adenoma and 13 benign lesions. The overall diagnostic accuracy of DPOC visual impression for indeterminate bile duct lesions was 80.6% (25/31). Three nonspecific small polypoid lesions and one flat elevated lesion without dilated vessels or mucosal irregularity in DPOC had been diagnosed as polypoid masses with ductal wall thickening with or without invasion in IDUS. One papillary mucosal lesion in DPOC was showed as symmetrical wall thickening in IDUS. And one intraductal polypoid mass lesion in DPOC was revealed as extraductal invading mass in IDUS. DPOC-guided targeted biopsy was performed in 87.1% (27/31) with diagnostic accuracy of 92.6% (25/27).
**Conclusion:** DPOC with targeted biopsy was useful for differentiating indeterminate bile duct lesions with high diagnostic accuracy. IDUS may provide adjunctive information before performing cholangioscopic evaluation by providing bile duct wall and periductal images of target lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1295 RISK FACTORS AND PROPHYLAXIS OF POST ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY PANCREATITIS

**D. Perdigoto**[1], D. Gomes[2], N. Almeida[3], S. Mendes[4], E. Camacho[3], R. Mesquita[1], A.R. Alves[1], L. Elvas[5], S. Barbeiro[6], S. Giestas[1], A. Fernandes[1], A. Oliveira[3], C. Sofia[2]

**Introduction:** The pancreatitis that happens after an Endoscopic retrograde cholangiopancreatography (ERCP) is still the most frequent complication of this procedure. This post ERCP pancreatitis (PEP) remains an event that can potentially cause considerable harm to the patient.
**Aims & Methods:** The main objective was to study prospectively the risk factors associated with this complication by defining their impact in this condition. We also aimed to evaluate the efficacy of the standard prophylactic methods used to prevent PEP. Methods: we designed a form to collect patient and procedure data from each ERCP executed in the endoscopic unit of a Gastroenterology department. It was registered the duration and number of attempts to catheterize the Vater papilla, execution of needle-knife precut, catheterization of the Wirsung with and without contrast injection, septotomy (trans-pancreatic sphincterotomy) pneumatic dilation and the application of pancreatic protection stents and rectal indomethacin. The patient was followed-up during, at least, 24 hours after the procedure. PEP was defined as

acute onset or increasing intensity abdominal pain that persisted more than 24 hours after ERCP and was associated with increase in amylase and/or lipase more than 3 times the normal cut-off value. The severity of PEP was defined according to the Atlanta 2012 classification. Statistics were done with SPSS v. 20 (SPSS v. 20 Inc., IBM, Chicago IL).
**Results:** In 12 months we prospectively enrolled 329 patients. Then 56 patients were excluded because of incomplete follow-up. Out of the 273 finally included 52.7% were women. Mean age 70 ± 15 years (20 to 95). The PEP rate was 5.9% corresponding to 16 cases. Only 2 were considered severe pancreatitis (one death from those 2 patients). The remaining were all mild pancreatitis. Prophylactic administration of rectal indomethacin was done in 77% cases. It wasn't used in cases of simple/very low risk procedures and in patients with contraindication. In the 16 patients with PEP only one didn't receive indomethacin. None of the risk factors considered revealed correlation with pancreatitis or odds ratio statistically significant for higher risk. The utilization of pancreatic stent (5.9% cases) didn't correlate with lower pancreatitis risk. Whenever septotomy was performed (4.4%) PEP didn't occur (no statistical significance). All the executants had large experience on this procedure and there were no differences in the PEP rate among them.
**Conclusion:** Even with indomethacin prophylaxis there's always a risk of PEP occurrence related to the procedure. This risk can only be partially reduced. We cannot draw conclusions about any of the risk factors. Probably there are also some individual patient related risk factors that make pancreatitis more likely in some patients. Those should be the subject of future studies. Prophylaxis with intensive hydration should also be tested in large clinical trials.

## P1296 SAFETY OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY FOR PATIENTS TAKING ANTITHROMBOTIC AGENTS

S. Nakashita, **C. Nishioka**, T. Kuwashiro, F. Koga, Y. Kawaguchi
*Department Of Hepatobiliary And Pancreatology, Saga-Ken Medical Centre Koseikan, Saga/Japan*

**Contact E-mail Address:** chlkqiko@gmail.com
**Introduction:** In 2012, the Japan Gastroenterological Endoscopy Society published guidelines for the management of gastrointestinal endoscopy for patients using antithrombotic agents. The guidelines were created from the viewpoint of bleeding risk during continuation of antithrombotic agents, as well as thromboembolic risk related to periprocedural interruption of antithrombotic agents. In Japan, there has recently been an increase in the number of patients taking antithrombotic agents who require endoscopic retrograde cholangiopancreatography (ERCP). The aim of this study was to evaluate the safety of ERCP for patients taking antithrombotic agents.
**Aims & Methods:** We retrospectively investigated the records of patients who received ERCP between April 2015 and March 2016 in our institution. Among 320 patients, 70 had taken antithrombotic agents (14 anticoagulant agents, 55 antiplatelet agents, and 1 both agents) (group A), and 250 patients had not taken any antithrombotic agents (group N). We compared the background and treatment outcome between the two groups.
**Results:** Patients in group A were older than those in group N [79.0 (52–93) vs. 72.0 (20–97) years, median (range), $p < 0.001$]. There were no significant differences in sex (group A vs. group N; male 51.4% vs. 60.0%) and causes (biliary stone 41.4% vs. 38.4%, pancreatic cancer 22.9% vs. 27.2%, and biliary tract cancer 21.4% vs. 20.4%). There was a significant difference between the two groups in comorbidity (ischemic heart disease or arrhythmia 22.9% vs. 0.8%, and ischemic brain disease 14.3% vs. 0.4%, $p < 0.001$). Regarding treatment, there were no significant differences in the implementation of endoscopic sphincterotomy (EST) (48.6% vs. 37.2%), and the use of rectal diclofenac (74.3% vs. 68.0%). Regarding complications, there were no significant differences in bleeding after ERCP (2.9% vs. 1.6%), post-ERCP pancreatitis (4.3% vs. 4.8%), and perforation (1.4% vs. 0.8%). Antithrombotic agents were interrupted in nine of 14 (64.3%) patients taking anticoagulant agents, 28 of 55 (50.9%) patients taking antiplatelet agents, and one patient taking both agents. In group A, one of two patients who had bleeding after EST continued taking anticoagulant agents. There were no thromboembolic events during interruption of antithrombotic agents.
**Conclusion:** This retrospective study showed the safety of ERCP for patients taking antithrombotic drugs. However, one should always consider the bleeding risk of the procedure and the risk of thromboembolic events related to discontinuation of antithrombotic agents, especially for procedures with a high risk of bleeding, such as EST.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1297 A PERSONALIZED TREATMENT OF GASTROINTESTINAL STROMAL TUMORS IS ENABLED BY ANALYZING ENDOSCOPIC ULTRASOUND-GUIDED BIOPSIES: A PROSPECTIVE, TEN-YEAR COHORT STUDY

**Introduction:** Gastrointestinal stromal tumors (GIST) are challenging to diagnose preoperatively and the diagnostic sensitivity of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is reported as non-satisfactory. Moreover, accurate information on the tumor mutation profile and on the tumor proliferation rate is important prior to treatment of patients with GIST. The genotype driven targeted therapy with imatinib is highly effective but should be prescribed exclusively to patients carrying tumors with sensitive mutations.
**Aims & Methods:** The aims of this study were to diagnose and characterize GISTs by the use of endoscopic ultrasound (EUS) and to evaluate the tumor response to neoadjuvant treatment. All GIST-patients punctured by EUS in the tertiary center of West Sweden were prospectively and consecutively included between 2006–2015. Fine-needle aspiration (EUS-FNA) was performed in 2006–2011. In 2012–2015 EUS-FNA and an additional fine-needle biopsy (EUS-FNB) were performed on the same lesions according to a randomized protocol. The FNB-biopsies were subjected to Sanger-sequencing of KIT and PDGFRA. The Ki-67-index of the FNB-biopsies ($Ki\text{-}67_{EUS}$) and the resection specimens ($Ki\text{-}67_{SURG}$) was determined.
**Results:** In sixty-four patients included the diagnostic accuracy increased from 50% (EUS-FNA) to 98% (EUS-FNB), $p < 0.001$. Sequencing was successful in 43/44 (98%) of the cases (KIT-mutation 73%, PDGFRA-mutation 18%, wild-type 7%) with full mutation congruence comparing EUS-biopsies with resected specimens. In patients not treated with neoadjuvant imatinib, the $Ki\text{-}67_{EUS}$ was at equal level as the $Ki\text{-}67_{SURG}$, 2.7% vs 2.9%, $p = 0.68$. In treated patients carrying sensitive mutations, the $Ki\text{-}67_{EUS}$ was significantly higher than the $Ki\text{-}67_{SURG}$, 2.5% vs 0.2% $p = 0.005$ with a significant reduction of the Ki-67-index = -91.5% (95% CI: -82.4 – -96.0), $p = 0.005$.
**Conclusion:** A diagnostic and prognostic pretreatment tumor characterization in GIST-patients is achievable by the analysis of EUS-fine needle biopsies. Such a characterization may guide the initiation of imatinib and allows evaluating tumor response to neoadjuvant therapy. EUS should be considered early in the management of GIST to enable a personalized treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1298 EUS-GUIDED CYST-ENTEROSTOMY USING A SELF-EXPANDING METAL STENT IS A MORE COST-EFFECTIVE STRATEGY FOR THE TREATMENT OF PANCREATIC FLUID COLLECTIONS

**S. Kenshil**[1], S. Sandha[2], C. Teshima[3], P. M. D'Souza[1], G. S. Sandha[1]

**Contact E-mail Address:** s.kenshil@gmail.com
**Introduction:** EUS-guided cyst-enterostomy (EUS-CE) has become the mainstay for endoscopic treatment of symptomatic pancreatic fluid collections (PFCs). The traditional approach (Approach I) of inserting multiple double-pigtail plastic stents with sequential dilation of the tract with or without naso-cystic irrigation is successful but requires repeated endoscopic intervention. The comparative effectiveness of newer approaches utilizing a fully covered expandable metal stent (FCEMS, Approach II) is not understood very well.
**Aims & Methods:** Our aim is to compare the clinical efficacy and cost impact of these approaches in the management of PFCs. We included all patients that underwent EUS-CE for PFCs. Clinical efficacy was defined as symptomatic improvement and cyst resolution on cross-sectional imaging. Follow-up was until stent removal. The total cost was calculated for each EUS-CE (including anesthesia and radiology costs), all subsequent procedures and hospital length of stay (HLOS).
**Results:** Between November 2010 and March 2016, 12 patients underwent Approach I and 16 patients underwent Approach II. Patients in Approach I had a mean of 3.9 endoscopic interventions (range 1–8), mean procedure time of 72 min (range 43–130 min) and 11.4 days of HLOS (range 0–33 days) compared with 1 endoscopic intervention, mean procedure time of 39 min (range 16–65 min) and 2.2 days HLOS (range 0–7 days) in Approach II ($p = 0.001$, $p = 0.01$ and $p = 0.02$, respectively). Cyst resolution was documented in 12/12 patients with a mean follow-up of 284 days in Approach I (range 86–628 days) and 15/16 patients with a mean follow-up of 98 days in Approach II (range 1–239 days). There were 6 adverse events in Approach I compared with 2 in Approach II ($p = 0.03$). The average cost of Approach I was $17,590 compared with $6,165 for Approach II ($p = 0.01$).
**Conclusion:** Despite the increased upfront cost of a metal stent, the use of a FCEMS for EUS-CE in the treatment of PFCs is effective, safe and results in significant overall cost savings by reducing the number of endoscopic re-interventions and HLOS.

**Introduction:** Endoscopic management of post-Whipple pancreatic complications with enteroscopy-assisted endoscopic retrograde pancreatography (e-ERP) is associated with high failure rates. EUS guided-pancreatic duct drainage (EUS-PDD) has shown promising results; however, there have been no comparative data looking at these two modalities.
**Aims & Methods:** The goal of this study is to compare EUS-PDD with e-ERP in terms of technical success (PDD through dilation/stent), clinical success (improvement/resolution of pancreatic-type symptoms) and adverse event (AE) rates in patients with post-Whipple anatomy. This is an international multicenter comparative retrospective study at 7 tertiary centers (2 US, 2 European, 2 Asian, and 1 South American). All consecutive patients who underwent EUS-PDD or e-ERP between 1/2010 - 8/2015 were included.
**Results:** 66 patients (mean age 57, 48% female) and 75 procedures were identified with 40 in EUS-PDD and 35 in e-ERP. Technical success was achieved in 92.5% procedures in EUS-PDD compared to 20% procedures in e-ERP (OR49.3, $p < 0.001$). Clinical success (entire cohort) was attained in 87.5% procedures in EUS-PDD group compared to 17% in e-ERP (OR33.8, $p < 0.001$). AEs occurred more commonly in EUS-PDD group (35% vs. 2.9%, $p < 0.001$). However, all complications were rated as mild or moderate. Procedure time and length of stay was not significantly different between the two groups. On multivariable analysis, EUS-PDD was independently associated with increased rate of clinical success and adverse events.
**Conclusion:** EUS-PDD is superior to enteroscopy-ERP in post-Whipple anatomy in terms of efficacy with acceptable safety. As such, EUS-PDD should be considered as a potential first-line treatment in post-pancreaticoduodenectomy anatomy.
**Disclosure of Interest:** T. Moreels: Received free Olympus equipment for procedures

**Introduction:** The use of EUS-guided tissue acquisition (TA) in diagnosing pancreatic malignancy has increased throughout the past two decades. Data on the diagnostic accuracy of this technique have almost exclusively been generated in tertiary referral centers. To our knowledge no data are available on role and quality of EUS guided TA in diagnosing pancreatic malignancy in community hospitals i.e. in general gastroenterology practice neither regarding ways to potentially improve its diagnostic yield.
**Aims & Methods:** To determine quality of EUS-guided TA in diagnosing pancreatic malignancy in community hospitals, in particular after the formation of a regional EUS group interactively discussing cases, techniques and outcomes on a regular basis. First, we retrospectively analysed the yield of 143 EUS-guided TA procedures for suspected pancreatic malignancies from 7 different hospitals in the southwestern part of the Netherlands before the regional EUS interest group was established. Next, after initiating the regional EUS interest group and after having had several meetings discussing cases and the specifics of various EUS-FNA/FNB techniques, we prospectively recorded data on EUS-guided TA procedures from January to October 2015 in 5 of these hospitals. Patient characteristics, size and localization of the pancreatic mass, EUS-characteristics of the mass, size and type of needles, use of suction techniques, number of needle passes, and types of cytology medium for cellblock were recorded. Outcome measures were the results of histo-, and cytopathological analysis, which were compared to a gold standard of 6 months follow-up and histopathology from resected tissue and/or metastatic tissue (1). The results of the first 75 prospective cases were compared to the retrospective data using chi-square and Mann-Whitney U tests when appropriate.
**Results:** Both the increase in procedures diagnostic for malignancy and decrease in procedures yielding insufficient material for diagnosis were significant ($p < 0.05$). Sensitivity, specificity, PPV, NPV and diagnostic accuracy in the retrospective cohort were: 65%, 100%, 100%, 44%, and 72% respectively. In the prospective cohort sensitivity, specificity, PPV, NPV and diagnostic accuracy were: 86%, 100%, 100%, 50%, and 88%. Significant differences between retrospective and prospective series were: the number of needle passes, the use of suction techniques and needle size. In the prospective series less 19 G needles were used, and both more needle passes and more suction were applied. Both groups were comparable with regards to age, gender and final histopathological diagnosis.
**Conclusion:** The establishment of a collaborative regional EUS group with ongoing case reviews and discussions on technical aspects of EUS guided TA has led to a statistically and clinically significant improvement of diagnosing pancreatic cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic Ultrasonography-guided Fine-Needle Aspiration (EUS-FNA) has become a dispensable examination in the clinical fields. Generally Oblique-viewing echoendoscope (OVE) has been employed for EUS-FNA and has elevator and long hard tip, which results in less pushability and less maneuverability. Recently Olympus Medical Systems (Tokyo) has launched a new forward-viewing echoendoscope (FVE). We have investigated its usefulness and limitation of FVE for not only therapeutic EUS but also diagnostic EUS-FNA, especially sucusion method with cap for EUS-FNA of submucosdal tumor.
**Aims & Methods:** We have perfomed 111 cases (averaged 60 y/o, M:F- = 61:49) of EUS-FNA, which includes 37 pancreas tumors etc. 35 submucosal lesions, 10 lymph adenopathy, 3 others and 26 therapuetic EUS-FNA (13 pseudocyst drainage, 9 EUS-biliary drainage, 3 EUS-pancreatic duct drainage, and 1 CPN,) up to now. The specification of FVE is as follows, maximum size of its tip is 14.2 mm in diameter, channel is 3.7 mm in diameter, and 90 degree of ultrasonographic field without elevator and balloon. In case of submucosal tumor, we have used "suction method", in which cap has been attached to the echoendoscope and we are keeping suction during EUS-FNA procedure. Then we have investigated its usefulness and limitation.
**Results:** The image quality and penetration of FVE is nearly of the same as conventional OVE such as GIF-UCT260. Its sampling rate is 88.2% (75/85) and diagnostic rate is also 87.1% (74/85). We had got 85% (17/20) accuracy in submucosal tumors less than 3 cm with "suction method". for EUS-FNA of submucosal tumor. Concerning about therapuetic EUS-FNA, it is rather easy to perform pseudocyst drainage, biliary drainage, and pancreatic duct drainage. Because using FVE, it is easy to puncture the gastrointestinal wall vertically, then it makes good pushability. And we have experienced a strictured case of anastomosis after Child's operation, in which we directly inserted FVE like a enteroscope, and punctured dilated intrahepatic bile duct and inserted metallic stent. We have successfully treated 100% (13/13) for pseudocyst drainage, 88.9% (8/9) for EUS-BD, 100% (3/3) for EUS-PD, 100% (1/1) for EUS-CPN with FVE. Finally We have leakage complications (EUS-BD).
**Conclusion:** We concluded that new FVE is useful not only for therapuetic EUS-FNA but also for diagnostic EUS-FNA, especially "suction method with cap" is useful for EUS-FNA of submucosal tumors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1302 EFFICIENCY OF STYLET CAPILLARY SUCTION AND STANDARD SUCTION TECHNIQUE OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION (EUS-FNA) IN SOLID PANCREATIC CANCER

**Contact E-mail Address:** szepes.zoltan@med.u-szeged.hu
**Introduction:** Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is recommended as the first-line sampling procedure for the histological/cytological diagnosis of solid pancreatic cancer. Currently, there are no evidence-based guidelines about the detailed methods of sampling and processing of samples, therefore, they vary substantially across medical centers.
**Aims & Methods:** To compare the diagnostic yield of EUS-FNA samples obtained with stylet capillary suction technique or with standard suction using a 5 mL syringe based on the classification of Papanicolau Association in 75 prospectively enrolled patients with solid pancreatic masses. The number of diagnostic samples, cellularity and bloodiness were assessed, and considering the result of study, we established a recommendation for sampling.
**Results:** EUS-FNA sampling resulted diagnostic samples in 58 of 75 cases (77.33%): with standard suction in 57 cases (76.00%) and with capillary suction in 52 cases (76.33%). Technical success rate (100% vs. 93.33%) and the number of samples were significantly higher in the standard suction group (1.87 vs. 3.5; $p < 0.001$). Although, there was no difference in the cellularity (1.75 vs. 1.52; $p = 0.2556$), the blood contamination of samples obtained by standard suction was substantially increased (1.57 vs. 2.33; $p < 0.001$), which made the pathological diagnosis difficult, therefore the rate of diagnostic samples was lower (47.36% vs. 33.23%; $p = 0.003$). The cytological examination of fluid obtained by flushing the needle with saline was diagnostic in 29 cases (38.67%). In 40 cases histological samples were obtained, in 22 cases with both of the two techniques, in 11 cases only with capillary suction and in 7 cases only with standard suction. Histological samples were diagnostic in two third of the cases (67.50%). The diagnostic yield of EUS-FNA sampling was not influenced by the needle type, tumor size and location.
**Conclusion:** Both capillary and standard suction are effective in the EUS-FNA sampling of solid pancreatic masses. Due to higher negative pressure, standard suction is recommended in case of fibrotic pancreatic cancer, but the increased bloodiness of vascularized tumors decreases the diagnostic yield of sampling.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1303 CHOLEDOCHOLITHIASIS AND COMMON BILE DUCT ECTASIA: ALWAYS ASSOCIATED?

**J. Pinto**, R. Azevedo, H. Ribeiro, C. Leitão, A. Caldeira, E. Pereira, A. Banhudo
*Gastroenterology, Hospital Amato Lusitano, ULS de Castelo Branco, Castelo Branco/Portugal*

**Contact E-mail Address:** jsdiaspinto@gmail.com
**Introduction:** The diagnosis of choledocholithiasis by abdominal ultrasound (US) has low sensitivity. However, its accuracy for the detection of common bile duct (CBD) ectasia is higher, and the presence of this surrogate finding contributes to the diagnosis of choledocholithiasis. Furthermore, endoscopic ultrasound (EUS), providing high resolution imaging, has significantly improved the understanding of the relationship between the presence of lithiasis and CBD dilation, irrespective of their dimensions.
**Aims & Methods:** We aimed to evaluate and characterize by EUS the presence of CBD dilation on a population of patients with choledocholithiasis. Methods: Retrospective analysis of the EUS procedures done in a single centre over a five-year period. The patients with choledocholithiasis on EUS were selected, and the ones with biliary tract neoplasia or biliopancreatic stents in place excluded. CBD dilation was considered when the calibre measured just above the stone was higher than 6 mm or 8 mm in patients without gallbladder.
**Results:** 109 EUS procedures were selected. Female sex 63.3% (n = 69); average age of 68.06 years (24–96); average number of stones present 2.4 ± 1.5, average size of 7.7 ± 4.4 mm; stone with diameter < 5 mm in 57.8% (n = 63); diameter between 5 and 10 mm in 26.6% (n = 29) and diameter > 10 mm in 15.6% (n = 17). CBD dilation confirmed in 65.1% (n = 71) of patients; with an average CBD diameter of 10.2 ± 4.4 mm. 25.7% (n = 28) of patients had no gallbladder; from the remaining, 22.9% (n = 25) had cholecystitis and 93.6% (n = 74) had evidence of biliary sludge or gallbladder stones. There was a statistical association between the presence of CBD dilation and sex (more males without ectasia) and with the size of the endoluminal stones. Nevertheless there was no association with age, number of stones, previous cholecystectomy, cholecystitis or presence of gallbladder stones.
**Conclusion:** On the population of our study, 34.9% (n = 38) of the patients with choledocholithiasis showed no CBD dilation. These findings support the indication for EUS when CBD lithiasis is suspected, mainly if there is no biliary tract dilation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1304 ENDOSCOPIC ULTRASOUND (EUS) GUIDED CYANOACRYLATE INJECTION FOR VARICEAL OBTURATION AS SECONDARY PROPHYLAXIS FOR PATIENTS AT HIGH RISK FOR RECURRENT GASTROESOPHAGEAL VARICEAL BLEEDING: A PILOT STUDY

**R. S.Y. Tang**[1], J. C. t. Wong[1], M. Kyaw[1], A.Y.B. Teoh[2], Y. Tse[1], T. Lam[1], J. C. y. Wu[1], H. L. y. Chan[1], J. Y. w. Lau[3]

**Introduction:** Patients with hepatocellular carcinoma (HCC) and/or portal vein thrombosis (PVT) are at higher risk for recurrent variceal bleeding and worse clinical outcome. Prior studies reported a rebleeding rate of 28%–42% in patients with HCC and oesophageal variceal bleeding treated with endoscopic cyanoacrylate (CYA) injection or band ligation. Recent evidence suggested prophylaxis against rebleeding may improve outcomes in patients with HCC. However, the optimal approach for secondary prophylaxis in such patients has not been well defined. The utility of endoscopic ultrasound (EUS)-guided CYA injection for variceal obturation in these high-risk patients has not been studied.
**Aims & Methods:** This is a prospective pilot study evaluating EUS-guided CYA injection for variceal obturation as secondary prophylaxis for patients at high risk for recurrent variceal bleeding. Consecutive patients with HCC and/or PVT, or patients with non-HCC malignancy with PVT who had gastroesophageal variceal bleeding within 12 weeks were recruited. EUS-guided CYA injection was performed within 12 weeks of the index variceal bleeding for secondary prophylaxis. Oesophagogastroduodenoscopy (OGD) was performed before EUS to assess for presence of active bleeding or stigmata of recent bleeding from oesophageal varices (OV) and gastric vaices (GV). EUS was subsequently performed with a linear echoendoscope. OV and GV were assessed by B-mode imaging and Doppler on EUS for size measurement and vascular flow. Varices ≥ 3 mm were treated. CYA (0.5 ml of Histoacryl + 0.7 ml of lipiodol per injection) was injected with a 19 G needle under EUS guidance. Doppler was used to confirm variceal obliteration. Chest and abdominal x-rays were obtained to confirm satisfactory position of CYA/lipiodol. Patients were followed for 6 months after EUS or till death if patients died within 6 months of EUS. Follow-up EUS would be performed on day 90 and day 180 during which CYA injection may be repeated for recurrent varices. Outcome measures include cumulative incidence of rebleeding at day 30 and day 90, and complications related to the procedures. Death occurring prior to recurrent bleeding was considered a competing risk event in analysis.
**Results:** 23 patients were initially screened, with 20 patients meeting inclusion criteria and undergone EUS guided CYA injection (mean age 64+/-10; 85.0% male) successfully. 17 patients had HCC + cirrhosis, in which 88.2% also had PVT. Among these patients, the Barcelona Clinic Liver Cancer (BCLC) stage for the HCC were: A (5.9%), B (5.9%), C (88.2%), D (0%), and the Child-Pugh class were: A (41.1%), B (58.8%). The other 3 patients had non-HCC malignancy (gastric cancer, pancreatic neuroendocrine tumour, lymphoma) + PVT. In this cohort, 14 patients had OV bleeding and 6 patients had GV bleeding in the index bleeding episode before recruitment. In the 1st EUS, CYA injection was done for OV, GV, and OV + GV in 12, 6, 2 patients, respectively. 6 had varices ≥ 5 mm on EUS, while 14 had varices < 5 mm on EUS. The mean number of CYA injections performed in EUS was 1.4+/-1. The death adjusted cumulative incidence of rebleeding at 30-day and 90-day after EUS guided CYA injection were 15% (95% CI, 4 – 34) and 20% (95% CI, 6 – 40), respectively. 1 patient had mild dysphagia after CYA injection, but no serious adverse event occurred. Death occurred during the follow-up period were due to malignancy progression, organ failure or infection. 12 patients (60%) were alive and returned for 2nd EUS follow up at day 90 and 3 of the 12 patients (25%) needed additional CYA injection for treatment of recurrent OV or GV.
**Conclusion:** In this pilot study, EUS-guided CYA injection for variceal obturation as secondary prophylaxis for patients at high risk for recurrent variceal bleeding is safe and achieves a lower rate of recurrent variceal rebleeding when compared to previously reported data in the literature.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Malignant hilar obstruction is a common cause of endoscopic retrograde cholangiopancreatography (ERCP) failure or non feasibility for patients with surgical altered anatomy. Percutaneous transhepatic biliary drainage (PTBD) has poor results in re-intervention rate and quality of life.
**Aims & Methods:** A monocentric prospective study had been conducted in a tertiary-care-referral center (Cochin Hospital, Paris, France) including patients with modified surgical anatomy or after ERCP failure. Primary outcomes were technical and clinical success defined by decrease of 50% of total serum bilirubin level at 7 and 30 days. Secondary outcomes were procedure-related complications, administration rate of chemotherapy, hospital length stay, reintervention rate and overall survival rates.
**Results:** 18 patients had hepaticogastrostomy and 27.7% of them had transhilar stenting. Cause of obstruction were: local recurrence of primitive malignancy (33.3%), primitive pancreatic mass (22%), Klastkin tumor (16.7%) and carcinosis (16.7%). 61.1% of patients presented surgical modified anatomy and 30.8% presented proximal duct obstruction after ERCP failure. Technical success was achieved in 94% of patients, early clinical success in 72.2% of patients and late clinical success in 68.8% of patients. Procedure-related complication rate was 16.7%, chemotherapy administration rate was 55.6%, hospital length stay was 16 (7–45) days, reintervention rate at three months was 16.7% and mean overall survival rate was 79 (5–345) days.
**Conclusion:** EUS-HGS is a feasible technique for hilar obstruction after ERCP failure or for patients with surgical altered anatomy. Moreover EUS-HGS is a helpful technique in chemotherapy administration for patients with advanced disease
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1306 PROSPECTIVE STUDY FOR COMPARISON OF ENDOSCOPIC ULTRASOUND-GUIDED TISSUE ACQUISITION USING 25- AND 22-GAUGE CORE BIOPSY NEEDLES IN SOLID PANCREATIC MASSES

**S.W. Park**
*Department Of Internal Medicine, Hallym University College of Medicine, Gyeonggi-do/Korea, Republic of*

**Contact E-mail Address:** britnepak@outlook.com
**Introduction:** Although thicker needles theoretically allow more tissue to be collected, their decreased flexibility can cause mechanical damage to the endoscope, technical failure, and sample blood contamination. The effects of needle gauge on diagnostic outcomes of endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) of pancreatic mass lesions remain unknown.
**Aims & Methods:** This study compared procurement rates of histologic cores obtained from EUS-FNB of pancreatic masses using 25- and 22-gauge core biopsy needles. From March 2014 to July 2014, 66 patients with solid pancreatic mass underwent EUS-FNB with both 25- and 22-gauge core biopsy needles. Among them, 10 patients were excluded and thus 56 patients were eligible for the analyses. Needle sequences were randomly assigned, and two passes were made with each needle, consisting of 10 uniform to-and-fro movements on each pass with 10 mL syringe suction. A pathologist blinded to needle sequence evaluated specimens for the presence of histologic core.
**Results:** The mean patient age was $65.8 \pm 9.5$ years (range, 44–89 years); 35 patients (62.5%) were men. The mean pancreatic mass size was $35.3 \pm 17.1$ mm (range 14–122.3 mm). Twenty-eight patients (50%) had tumors at the pancreas head or uncinate process. There were no significant differences in procurement rates of histologic cores between 25-gauge (49/56, 87.5%) and 22-gauge (46/56, 82.1%, $P = 0.581$) needles or diagnostic accuracy using only histologic cores (98% and 95%). There were no technical failures or procedure-related adverse events.
**Conclusion:** The 25-gauge core biopsy needle could offer acceptable and comparable outcomes regarding diagnostic performance including histologic core procurement rates compared to the 22-gauge core biopsy needle, although the differences were not statistically significant.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1307 A RANDOMIZED CONTROLLED TRIAL COMPARING EARLY DEPLOYMENT OF A VIDEO CAPSULE VERSUS CONVENTIONAL WORK-UP OF NON-HEMATEMESIS GASTROINTESTINAL BLEEDING: INTERIM ANALYSES

N. Marya, S. Jawaid, A. Foley, K. Patel, S. Han, A. Rupawala, D. Kaufman, C. Marshall, K. Bhattacharya, J. Tennyson, **D. Cave**
*Medicine-gastroenterology, University of Massachusetts Medical School, Worcester/United States of America/MA*

**Contact E-mail Address:** david.cave@umassmemorial.org
**Introduction:** Gastrointestinal bleeding (GIB) is a common diagnosis in the emergency department (ED). For hematemesis, the diagnostic algorithm is non-controversial. For non-hematemesis GIB (NHGIB), the algorithm is less clear, since the bleeding can originate anywhere in the gastrointestinal (GI) tract. For NHGIB, clinicians use signs and symptoms to assess where the most likely source of bleeding is and then choose the most appropriate endoscopic procedure. If, during this workup, a clinician is able to localize active bleeding or the likely source of bleeding (SOB) this may permit therapeutic intervention and reduce readmission rates for rebleeding. Our hypothesis is that early deployment of a video capsule (VCE) in patients presenting with NHGIB will shorten time to diagnosis, improve diagnostic yields, and improve visualization of SOB compared to the current standard of care.
**Aims & Methods:** Study inclusion criteria are > 18 years old, admission to the hospital, hemodynamic stability, no contraindications to VCE, and presentation with new onset NHGIB. If eligible they are consented and randomized into either the early capsule group (EC) or the standard of care group (SC).
Patients in the EC group swallowed an EC-10 Olympus VCE immediately following consent. The EC-10 real time viewer (RTV) was used to confirm entry into the stomach and to look for gastric bleeding. After completion images were processed, reviewed, and the further procedures were performed based on the findings. The SC group received care and procedures at the direction of the GI attending.
**Results:** A total of 150 patients were screened and 42 were enrolled. Baseline characteristics of the study patients are described in Table 1. The EC group had a significantly higher rate for detecting active bleeding or stigmata of recent bleeding (73.9% vs. 15.8%; $p < 0.001$) and rate of diagnosis (78.3% vs. 36.8%; $p = .006$) compared to the SC group. There was no significant difference between the EC and SC group in the rate of therapeutic intervention (30.4% vs. 15.8%; $p = 0.267$), total number of invasive procedures performed (1.0 vs. 1.1; $p = 0.463$), and length of stay (103 hours vs. 99 hours; $p = 0.913$). Kaplan-Meier curves analyzing time to diagnosis in both groups were significantly different (log-rank test, $p = 0.01$). Subgroup analysis of patients in the study found to have SOB demonstrated that a significantly larger percentage of those patients had a therapeutic procedure (45% vs. 4.5%, $p = 0.002$) and significantly less likely to have recurrence of bleeding in 30 days (0% vs. 19%, $p = 0.04$) compared to patients not found to have SOB. Elevated admission BUN, decreased admission systolic blood pressure, elevated Glasgow-Blatchford score, and receiving an early capsule were all significantly associated with finding SOB. Using these factors, a multivariate logistic regression was performed demonstrating that early capsule endoscopy was the only significant factor for predicting the presence of SOB (OR 94.3, 95% CI 4.6–1917.6).

**Table 1:** Descriptive statistics of patients based on cohort.

| n | Early Capsule 23 | Standard of Care 19 |
|---|---|---|
| Age (years), mean (SD) | 66.5 (10.9) | 74.1 (12.9) |
| Male, n (%) | 11 (47.8) | 12 (63.2) |
| Prothrombin time at admission (seconds), mean (SD) | 14.6 (6.2) | 22.8 (16.6) |
| Blood urea nitrogen at admission (mg/dL), mean (SD) | 30.6 (22.9) | 29.1 (20.7) |
| Hemoglobin at admission (g/dL), mean (SD) | 9.6 (3.0) | 9.3 (1.9) |
| Medication use prior to study, n (%) | | |
| Antiplatelet agent | 6 (26.1) | 10 (52.6) |
| Anticoagulation agent | 5 (21.7) | 8 (42.1) |
| NSAID agent | 4 (17.4) | 3 (15.8) |
| Reason for admission, n (%) | | |
| Guiac positive stool with anemia | 3 (13.0) | 0 (0.0) |
| Hematochezia with anemia | 6 (26.1) | 4 (21.1) |
| Melena | 13 (56.5) | 14 (73.4) |
| Unexplained anemia | 1 (4.3) | 1 (5.3) |
| Systolic blood pressure (mm Hg) at admission, mean (SD) | 119.6 (18.6) | 130.2 (17.8) |
| Heart rate (beats per minute) at admission, mean (SD) | 74.5 (10.2) | 77.1 (11.1) |
| Recent syncope, n (%) | 3 (13.0) | 0 (0.0) |
| Glasgow-Blatchford Score, mean (SD) | 8.4 (4.6) | 8.7 (3.7) |

**Conclusion:** Our study demonstrates that the early capsule has significant benefits compared to standard of care with regards to diagnostic efficiency and

locating signs of bleeding. In order to continue to evaluate additional outcomes more patients need to be studied and a multi-centered trial should be considered.

## P1308 VALIDATION OF SPICE, A METHOD OF DIFFERENTIATING SMALL BOWEL SUBMUCOSAL LESIONS FROM INNOCENT BULGES ON CAPSULE ENDOSCOPY

**J. P. Rodrigues**, R. Pinho, A. Rodrigues, J. Silva, A. Ponte, M. Sousa, J. Carvalho
*Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia/Portugal*

**Contact E-mail Address:** jaimepereirarodrigues@gmail.com
**Introduction:** Small bowel submucosal lesions (SBSL) and innocent bulges, smooth protrusions of normal mucosa resulting from loop angulation and/or the impression of an adjacent loop, may have an identical appearance and can be difficult to distinguish on small bowel capsule endoscopy (SBCE), mainly if we exclude protrusions with alarm signs. Recently, Girelli et al proposed a score, smooth, protruding lesion index on capsule endoscopy – SPICE, in order to differentiate both.[1]
**Aims & Methods:** We aimed to evaluate and validate SPICE as a differentiation method between innocent bulges and SBSLs. We evaluated all SBCEs performed in our department between January 2005 and September 2015, and selected the ones with a smooth, round, protruding lesion in the small bowel. Lesions with alarm signs were excluded. A video clip of the region of interest was created and SPICE was assigned blindly and independently by two endoscopists. We evaluated demographic and clinical data and determined the discriminative ability of SPICE, using the definitive diagnosis of each patient as the standard criteria.
**Results:** We included 30 SBCEs of 28 patients (mean age $54.5 \pm 18.3$ years; 53.6% male), corresponding to 12 SBSLs (4 gastrointestinal stromal tumors, 2 neuroendocrine tumors, 4 lipomas and 2 polypoid lymphangiectasias) and 18 innocent bulges. SPICE scores ranged from 0 to 4, allowing the distinction between SBSLs and innocent bulges ($p < 0.001$). SPICE $> 2$ had 66.7% sensitivity, 100.0% specificity, 100.0% positive predictive value and 78.3% negative predictive value and the area under the curve was 0.88 (95% CI, 0.73–1.00; $p < 0.001$) for the diagnosis of SBSL.
**Conclusion:** Our data support SPICE, namely a score $> 2$, as a predictive method of SBSLs. Taking into account its simplicity, it may be very useful in the distinction between SBSLs and innocent bulges at SBCE.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** aymericbecq@gmail.com
**Introduction:** Colon capsule endoscopy (CCE) does not possess an objective and reliable scoring system to assess the quality of visualization of the colon mucosa. A previously published study (1) showed a computed assessment of small bowel mucosal visibility based on the ratio of color intensities of the red and green channel of the tissue color bar to be feasible and reproducible.
**Aims & Methods:** The aim of this study was to establish and validate a colonic Computed Assessment of Cleansing (C-CAC) score, based on the intensity of diverse ratios of color intensities of CCE still frames, to discriminate the 'adequately cleansed' from the 'inadequately cleansed' ones, with the highest performance. Twelve CCEs, using the Pillcam® Colon 2 system (Medtronic), were prospectively selected amongst a database, irrespective of the indication. All exams had allowed visualization of the entire length of the colon. All exams were considered normal. Subsequently, a C-CAC score, defined as the ratio of color intensities such as red over green (R/G ratio), and red over brown (a mixture of red and green, $R/(R+G)$ ratio) was calculated for each of the 79496 extracted colonic frames. Eighteen and sixteen intervals of a variable width (0.05 and 0.01, for each type of ratio, respectively) were then determined, ranging from the smallest to the largest ratio amongst the extracted frames. Then, twelve frames were randomly selected in each of these intervals, for both types of ratio. Two sets of 216 and 192 still frames were thus obtained (for R/G and $R/(R+G)$, respectively). These images were shuffled, and analyzed twice in a random order, by two experienced CCE readers, blinded to the C-CAC scores. A qualitative evaluation was performed based on criteria in the setting of small bowel CE (2): each image with a visualization of over 90% of the mucosa, with no, minimal or mild fluid and debris, bubbles, and bile/chyme staining, and with no, minimal or mild reduction of brightness, was considered to be 'adequately cleansed'. Any image failing to fulfill these criteria was considered as 'inadequately cleansed'. Images were subsequently classified as being 'adequately' or 'inadequately' cleansed (according to an experts' agreement when necessary). A receiver operating characteristic (ROC) curve was forged for both types of ratios. Thus, a C-CAC score threshold was established, yielding the highest diagnostic performance in terms of adequate cleansing assessment.
**Results:** In the first dataset (R/G ratio), 37 frames (17.1%) were 'adequately cleansed', the remaining 158 being 'inadequately cleansed' (82.9%). According to the ROC curve, a C-CAC score threshold of 1.55 was most performant to discriminate adequately from inadequately cleansed frames, with a sensitivity of 86.5%, a specificity of 77.7%, a positive predictive value of 44.4%, and a negative predictive value of 96.5%. In the second dataset ($R/(R+G)$ ratio), 22 frames (11.5%) were 'adequately cleansed', the remaining 170 being 'inadequately cleansed' (88.5%). According to the ROC curve, a C-CAC score threshold of 0.58 was most performant to discriminate adequately from inadequately cleansed frames, with a sensitivity of 95.5%%, a specificity of 62.9%, a positive predictive value of 25.0%, and a negative predictive value of 99.1%.
**Conclusion:** The two proposed C-CAC score based on the ratio of color intensities (R/G and $R/(R+G)$ ratios) come with high sensitivities and negative predictive values to discriminate 'adequately cleansed' from 'inadequately cleansed' CCE still frames, but they lack specificity. Further refinement, with implementation of additional image parameters, will overcome this limitation. These findings set path to future studies assessing the proportion of 'adequately cleansed' frames of CCEs, allowing to compare different colon-cleansing regimens in a objectve manner.
**Disclosure of Interest:** X. Dray: I have received lecture fees from Given Imaging / Covidien / Medtronic

**Contact E-mail Address:** ccarretero@unav.es
**Introduction:** Colon capsule is a non-invasive device primarily designed for colonic visualization. However, a slight modification of the ingestion protocol may allow both the visualization of the small bowel and colon with only one prep and one capsule. This pan-enteroscopic study might be useful for those patients who may have pathology in the small and large intestine (for instance in Peutz Jeghers syndrome) but also for those patients with gastrointestinal bleeding who are high-risk patients for anesthesia or for endoscopy.
**Aims & Methods:** We have included all pan-enteroscopic capsule procedures performed in our unit, from October 2011 to January 2015. We have retrospectively reviewed the clinical history, reason for referral and capsule findings. Creatinine and electrolytes pre and post procedure have also been gathered. All patients underwent the same colon prep, with PEG in split dose (2 liters + 2 liters) and sodium phosphate as capsule booster (30 ml + 15 ml).
**Results:** 68 patients were included (64.7% male). The mean age was 67 years old (21–90) and 45.6% were inpatients. The reason for referral was occult-obscure gastrointestinal bleeding (OGIB) in 14.9% of cases, overt-OGIB in 16.2%, 38.8% were high-risk patients for anesthesia/endoscopy (53.7% because of cardiac conditions) and had iron deficiency anemia, in 4.5% a Peutz Jeghers syndrome was suspected and 25.6% of patients underwent pan-enteroscopic for other reasons (diarrhea, abdominal pain...) The most frequent small bowel findings were angiodysplasia (23.5%), erosions/ulcers (13.2%) and polyps (8.8%). The most frequent colonic findings were diverticula (46.8%), polyps (50%), angiodysplasia (27.4%) and colon cancer (3.2%). In 38% of cases, the pan-enteroscopic capsule had a therapeutic impact, mainly referring the patient to balloon enteroscopy, colonoscopy or surgery. Despite of having several cardiac patients and even patients with renal insufficiency, no abnormalities were detected in post prep creatinine and electrolytes. We had one complication, as the capsule was retained in a small bowel bleeding stricture that was not suspected. This patient needed surgery to remove the stricture and the retained capsule.
**Conclusion:** The election of performing a pan-enteroscopic capsule had a therapeutic impact in almost 40% of cases. The pan-enteroscopic capsule is a relatively safe procedure, with no effect on renal function despite the use of sodium phosphate in high-risk patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1311 DEVELOPMENT AND VALIDATION OF A HIGHLY SENSITIVE AND HIGHLY SPECIFIC COMPUTED ASSESSMENT OF CLEANSING SCORE FOR SMALL BOWEL CAPSULE ENDOSCOPY

**Introduction:** An objective and reliable scoring system is much needed to assess the quality of visualization in small bowel (SB) capsule endoscopy (CE), for both clinical practice and research purposes. A previously published study showed a computed assessment of SB mucosal visibility based on the ratio of color intensities of the red and green channels of the tissue color bar to be feasible and reproducible (1).

**Aims & Methods:** Thirty-three SB-CE were selected amongst a database of cases of obscure gastro-intestinal bleeding. The SB2 Pillcam® system (Medtronic) had been used. All exams had allowed full visualization of the small bowel. All were considered normal. For every SB-CE, the red, green and blue (R, G, B) components were extracted from each still frames of these videos. Subsequently, the SB-CAC score, defined as the ratio between the red and green pixels (R/G ratio), was calculated for each of the 443,141 extracted frames. Twenty-four intervals of R/G values of a 0.05 width were then determined, ranging from the smallest to the largest R/G ratio amongst the extracted frames. Then, twelve frames were randomly selected in each of these intervals. A first set of 288 still frames was thus obtained. These images were shuffled twice into a random order, and analyzed twice by two experienced SB-CE readers, blinded to the SB-CAC score of each image. A qualitative evaluation was performed based on the criteria previously used by Brotz et al. (2): each image with a visualization of over 90% of the SB mucosa, with no, minimal or mild fluid and debris, bubbles, and bile/chyme staining, and with no, minimal or mild reduction of brightness, was considered to be 'adequately cleansed'. Any image failing to fulfill these criteria was considered as 'inadequately cleansed'. Images were thereby analyzed as being 'adequately' or 'inadequately' cleansed (3 or 4 concurrent assessments out of 4 reads). In cases of discrepancy after initial analysis, an agreement was reached between the two readers and the image was subsequently classified. Once an 'adequately cleansed' or 'inadequately cleansed' qualification was allotted to every still frame (each of which with a previously calculated R/G ratio), a receiver operating characteristic (ROC) curve was forged. Thus, a SB-CAC score (R/G ratio) threshold was established, yielding the highest diagnostic performances in terms of adequate cleansing assessment. A second dataset of 288 different SB still frames was then generated, as described above, and read twice in a random order by two other experienced SB-CE readers, using the same blinded methodology. The diagnostic performances of the SB-CAC score threshold were then calculated, allowing validation of this score.

**Results:** In the first dataset, 130 frames (45.1%) were analyzed as being 'adequately cleansed'. According to the ROC curve, a SB-CAC score threshold of 1.6 achieved best to discriminate adequately from inadequately cleansed frames, with a sensitivity of 91%, a specificity of 91%, a positive predictive value of 89.4%, and a negative predictive value of 92.9%. In the second dataset, 114 frames (41.0%) were analyzed as being 'adequately cleansed'. The SB-CAC score threshold value of 1.6 was validated using this second dataset, yielding the following performances: sensitivity 93.6%, specificity 88.0%, positive predictive value 83.6%, and negative predictive value 95.5%.

**Conclusion:** The SB-CAC score based on the R/G pixels ratio has a threshold value of 1.6 with the highest sensitivity and specificity to discriminate 'adequately' from 'inadequately' cleansed SB-CE still frames. This constitutes an objective, reproducible, reliable, automated and comprehensive cleansing score for SB-CE. These findings set path to future studies assessing the proportion of 'adequately cleansed' frames of SB-CEs, allowing to compare different bowel-cleansing regimens. A similar CAC score in the setting of colonic CE is currently being generated. Further research is warranted in order to determine which proportion of 'adequately cleansed' frames defines an acceptable overall SB-CE quality in clinical practice.

## P1312 CLINICAL UTILITY OF THE PATENCY CAPSULE

**A. Peixoto**, M. Silva, R. Coelho, R. Gaspar, R. Liberal, R. Castro, A. Albuquerque, M. Marques, H. Cardoso, G. Macedo
*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*

**Contact E-mail Address:** armandoafp5@gmail.com

**Introduction:** In patients with suspected or known obstructive gastrointestinal pathology, the use of patency capsule (PC) aims to minimize the risk of subsequent retention of the endoscopic capsule. However, its clinical utility is not consensual.

**Aims & Methods:** Our aim was to evaluation of the indications, results and safety profile of the PC. We performed a retrospective analysis of PCs (Agile patency Capsule) conducted between 2011 and 2015. Patency evaluation was performed after 30 hours, with radiological confirmation if PC was detected.

**Results:** We included 369 PCs, 54% female. The average age was $42 \pm 16$ years. Main indications included suspected Crohn's disease (CD) (45%), CD staging (32%), neoplastic diseases (9%), radic enteritis (3%), prior surgery (3%), NSAIDs enteropathy (2%) and anemia (2%). Before the exam 5% of patients were taking constipation-induced medications and 5% reported occlusive symptoms. 38% of patients had previous abdominal surgeries, most often ileal resection due to CD (24%). 42% of patients had previous imaging studies, revealing strictures in 20% and bowel dilation in 11%. Patency capsule was negative (patent gastrointestinal tract) in 73% of cases at 30 h and 2% of PCs were fully recovered in the following days. Seven patients (2.5%) showed self-limiting occlusive symptoms during the procedure. All patients with negative PC subsequently performed capsule endoscopy with no cases of retention. History of occlusive symptoms ($p = 0.023$) and strictures in imaging studies ($p = 0.029$) were associated with the detection of the PC at 30 hours.

**Conclusion:** PC is a safe and effective exam. Occlusive symptoms and imaging strictures were significantly associated with the retention. The retention rate was 25%, a similar result to that described in other series but higher than expected for the various indications, suggesting the importance of new research studies.

## P1313 SMALL BOWEL MALIGNANCY IN PATIENTS UNDERGOING CAPSULE ENDOSCOPY IN A TERTIARY CARE ACADEMIC INSTITUTION

C. Johnston[1], **D. E. Yung**[2], A. Koulaouzidis[2], J.N. Plevris[2]
[1]*College Of Medicine And Veterinary Medicine, The University of Edinburgh, Edinburgh/United Kingdom*
[2]*The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom*

**Contact E-mail Address:** diana.e.yung@gmail.com

**Introduction:** Cancer of the small-bowel (SB) is rare, accounting for < 5% of all gastrointestinal (GI) neoplasms [1].Furthermore, diagnosis of SB cancer is often delayed [2]. Capsule endoscopy (CE) has become the procedure of choice for non-invasive diagnosis of SB diseases [3]. Nevertheless, data on the use of CE in diagnosis of SB cancer is limited [4].

**Aims & Methods:** Retrospective study; the records of all patients who underwent SBCE at our centre from Mar 2005 – Oct 2015 were reviewed; we retrieved those whose CEs were reported as suggestive of neoplasia. Further data was gathered on preceding and subsequent investigations, management and outcomes of these patients.

**Results:** From a total of 1949 CE studies (1082 PillCam™/867 MiroCam™), SB neoplasia was diagnosed in 8 patients (0.41%; 2 F/6 M; median age 56, range 34–72). Two had lymphoma, 3 gastrointestinal stromal tumours (GIST), 2 duodenal adenocarcinomas, 1 jejunal metastasis from a sarcomatoid lung tumour. In these patients, CE was performed for: iron-deficiency anaemia (IDA) ($n = 6$), diarrhoea ($n = 1$) & suspicion of SB lymphoma ($n = 1$). 7/8 patients had priornegative bidirectional GI endoscopies; 1 had a normal gastroscopy. Prior to CE, two patients had abdominal USS, 4 had CT scan, 2 had SB follow-through and 1 had a bone marrow aspirate. Two patients had capsule retention; one was removed with a gastroscope, the other with push enteroscopy. All 8 patients had further investigations after CE. Six had a chest, abdomen & pelvis CT scan for staging. Two patients had push enteroscopy, both of whom were diagnosed with duodenal adenocarcinoma. One had double balloon enteroscopy (DBE), two had colonoscopy, two had UGIE; there was one abdominal USS and one bone marrow aspirate. Four patients underwent SB resection. Following resection, 1 patient with GIST had imatinib chemotherapy. Of the two individuals with duodenal adenocarcinoma, one underwent gastroenterostomy and the other had an elective Whipple procedure. Four patients passed away. Two remain under follow up with oncology and two with the GI team.

**Conclusion:** SB cancers are rare and our experience is in agreement with other studies. The median age of 56 indicates that SB malignancy is more common in relatively younger patients. Unexplained iron deficiency anaemia was the main presenting complaint in our patients which triggered further investigation despite negative bidirectional endoscopies. CE is effective in picking up SB neoplasia where other imaging modalities have failed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The paradigm in the treatment of obesity and metabolic disease is changing from surgical therapies to minimally invasive endoscopic procedures. Therefore, endoscopic treatment such as duodenal-jejunal bypass liner has emerged as alternative therapies to bariatric surgery or medical therapy for weight loss. Although various materials (silicon, fluoroethylene, propylene, etc.) would be available for medical device, the optimal material for duodenal-jejunal bypass liner was not fully investigated. In this study, we compared the physical properties and characteristics of the materials for the duodenal-jejunal bypass liner.
**Aims & Methods:** Four test membranes were made of hydrophobic silicone, thin e-PTFE (Poly-tetra-fluoroethylene), thick e-PTFE, and FEP (Fluorinated ethylene-propylene). We performed the test for anti-tensile ability, durability, and the experimental aging test in pH2 and pH7 buffer solutions. The features of test materials were shown by using scanning electron microscopy (SEM) and infrared spectroscopy (FT-IR).
**Results:** The debris and cracks in surface on hydrophobic silicone were significantly increased after accelerated aging test with pH 2, 7 by SEM image. And it showed about 50% reduction in tensile force after the test. Thin-PTFE and thick e-PTFE showed the small amounts of debris on the surface after accelerating test by SEM. FEP had minimal changes on surface morphology after accelerating test. Anti-tensile ability of e-PTFE (thin and thick) was 10 times more than silicone, and 5 times than FEP in pH7 environment. The difference of anti-tensile ability between e-PTFE and FEP decreased in pH2 environment. There was no significant difference of anti-tensile between thin and thick e-PTFE. In the experimental aging test, FEP had better aging resistance and superior chemical stability than e-PTFE under corrosion environment. FEP showed a minimal FT-IR curve change on graph presenting a chemical property.
**Conclusion:** FEP and e-PTFE showed acceptable results in tensile force test and chemical resistance test. Whereas FEP material had a good chemical stability, both thin and thick e-PTFE had a superior tensile strength. Because of its poor anti-tensile force and durability, hydrophobic silicone material would not be appropriate for duodenal-jejunal bypass liner. It would be recommendable materials both FEP and e-PTFE for making the liner of new endoscopic duodenal-jejunal bypass stent.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1315 EUS-GUIDED ENTERO-ANASTOMOSIS WITH LUMEN APPOSING METAL STENT: PRELIMINARY ASSESSMENT OF INDICATIONS, EFFECTIVENESS AND SAFETY

**Introduction:** Endoscopic Entero-Anastomosis (EEA) is a novel procedure performed in animal models and exceptionally in patients, without a case series published to date.
**Aims & Methods:** We want to present a retrospective study of 16 patients in whom EEA has been done in our center, describing the type of anastomosis performed, complications encountered and the results obtained. We identified retrospectively from a prospective database from 01/01/12 to 30/06/15, 16 patients with a mean age of 71.1 years (SD 11) underwent EEA. A prosthesis Axios® 15x10 mm was used in all patients, and its were placed under Echoendoscopy control. Sedation was performed with Propofol. One patient was excluded from the analysis due to lack of window.
**Results:** In 10 patients with post-surgical anatomy it was performed to access the bile duct: via gastro-jejunostomy (40%), jejuno-jejunostomy (40%) and percutaneous jejunostomy (20%). We obtained technical success in 80%, and clinical success (defined as the possibility of access to the bile duct) in 60%, with 20% of complications (jejunal tear, perforation) and stent migration due to the passage of the duodenoscope through the stent. In 5 patients, all oncologics, EEA was performed because of gastric outlet obstruction, with failure of conventional endoscopic treatments. 80% by gastro-jejunostomy, the remaining 20% by gastro-duodenostomy. Technical success in 60%, clinical success in 40% (clinical success was defined as the ability of the patient to tolerate an oral diet). The complication rate was 20% (1 patient) with perforation, peritonitis and subsequent death. There was no migration of the stent during trans-stent procedure with a pediatric or convencional endoscope.
**Conclusion:** EEA seems a safe procedure to facilitate biliary access in patients with postsurgical anatomy and to solve the gastric outlet obstruction in cases of malignant obstruction in patients with null surgical possibilities.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1316 SURVEILLANCE IN ESOPHAGEAL ATRESIA PATIENTS: ENDOSCOPY SHOULD BE A ROUTINE IN POST OPERATIVE?

**Introduction:** Esophageal strictures remain the most frequent complication after surgical repair of esophageal atresia (EA) and occurs in 18% to 50% of patients. It is controversial whether the endoscopy is performed routinely after EA repair or only in symptomatic patients.
**Aims & Methods:** The aim of this study was to assess the frequency of esophageal stenosis in EA patients operated in a pediatric hospital in Rio de Janeiro, Brazil. A retrospective longitudinal study was carried out on patients with EA who were submitted to surgical repair in a period of 5 years in a pediatric hospital in Rio de Janeiro, Brazil. The data collected were age, sex, type of EA, associated congenital anomalies, type of surgery performed, evaluation of esophageal stenosis and recanalization of the tracheoesophageal fistula, time between first endoscopy and surgery and treatment performed for complications. The characteristic of these patients were collected from charts, operative and endoscopy reports. Symptoms suggestive of stenosis included dysphagia, vomiting, cough, poor or slow feeding, foreign body obstruction, recurrent respiratory tract infections, and/or poor weight gain. All patients presenting symptoms underwent digestive endoscopy. When stenosis was diagnosed, anastomotic dilatation were carried out.
**Results:** Forty-one patients were included in this study, and twenty-four were male (58.5%). Thirty-six children (87.8%) had EA with distal fistula and 5 (12.2%) EA with proximal fistula. Thirty-four patients (82.9%) were submitted to surgical repair with ligation of the fistula and 7 were submitted to gastric transposition after esophagostomy and gastrostomy. The surgery was performed on average nine days after birth. Eighteen (43.9%) children had congenital anomalies associated.
Twenty-one patients (51.2%) underwent digestive endoscopy, the first endoscopy was perfomed on average 11 months after surgery. Fourteen patients (34.1%) had stenosis of anastomotic and were submitted to esophageal dilatation. Four (9.8%) had recanalization of the tracheoesophageal fistula and were referred to surgery.
**Conclusion:** Esophageal stricture occurred in nearly one-third of patients in this series. Recanalization of the tracheoesophageal fistula is rare, but requires early treatment to avoid complications. Sometimes the symptoms are non-specific and the infant may develop serious complications before diagnosis. In our study, endoscopy was performed on average 11 months after surgery in symptomatic patients. Endoscopy performed by an experienced professional has a low index of complications, and although further studies are needed to follow up these patients, we recommend early routine endoscopy in all infants after EA repair to detect complications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Radioactive stents have shown improvement in survival for patients with terminal esophageal cancer (1). However, loading brachytherapy seeds into current brachytherapy stent designs is a manually intensive process that can result in direct seed-esophagus contact, dose hotspots and mucosal ulceration or perforation.

**Aims & Methods:** Our aim is to develop an improved radioactive stent design that can achieve, using a porcine preclinical model, a conventionally acceptable dose of 60 Gy to the esophageal tumor while preserving the health and structural integrity of the surrounding esophagus and peri-esophageal normal tissues. Monte Carlo calculations of radiation transport simulations (MCNP6) were performed to optimize the stent design in terms of dose uniformity and surface hotspots. Using standard endoscopy techniques, 20 mm diameter stents were implanted in 3 minipigs (31–39 kg) with a radiation dose target of 60 Gy at a 5 mm mucosal/submuscosal depth. Over the 60 day implant the pigs were regularly monitored, including endoscopy and radiography. After 60 days, the stents were removed and the pigs were sacrificed at 1, 2, and 3 months following stent removal to assess short-term side effects. A full gross necropsy and histopathological analysis was performed on each pig.
**Results:** Monte Carlo simulations showed that increasing the number of seeds, using a polymeric stent instead of a metal stent, and placing the seeds inside the stent wall improved dose uniformity at the prescription distance, while reducing hotspots at the mucosa. The stent was constructed with 6 interior channels designed to accept 6 strands with 10 seeds each for a total of 60 seeds per stent (model 6720 I-125 Seeds-in-Carrier, GE Healthcare).The I-125 source strength (0.5 U/seed) was determined for a 2-month implant. This design also allowed for fast and safe loading of the radioactive seeds. During stent assembly, extremity exposure was less than 2 mSv. Whole body exposure was much less given use of Pb gowns and a transparent L-block shield. Each stent was safely loaded with the radioactive seeds, deployed in the esophagus within 1 cm from the intended location, and sutured to the esophagus through a neck incision to prevent stent migration. The maximum radiation exposure rate at 1 meter from each implanted pig was less than 0.004 mSv/h, thus not introducing concerns for radiation safety during pig monitoring over the course of the study. Follow up from this study will be completed by the time of the meeting, and late-breaking results on histopathological results will be reported.
**Conclusion:** A novel stent design was combined with stranded brachytherapy seeds to produce a radioactive stent for eventual treatment of esophageal cancer in humans. Initial results of this preclinical study suggest that the stent design is capable of delivering the desired target dose to an esophageal tumor.

## P1318 ENDOSCOPIC TREATMENT OF POST-LAPAROSCOPIC SLEEVE GASTRECTOMY LEAKS WITH A SPECIFICALLY DESIGNED METAL STENT

V. Bove, **A. Tringali**, R. Landi, V. Perri, I. Boskoski, P. Familiari, F. Barbaro, G. Costamagna
*Digestive Endoscopy Unit, Catholic University, Gemelli University Hospital, Rome, Italy, Rome/Italy*

**Contact E-mail Address:** andrea.tringali@unicatt.it

**Introduction:** Laparoscopic Sleeve Gastrectomy (LSG) is one of the most used restrictive surgical procedures for the treatment of morbid obesity. Leak of the surgical suture at the level of the esophago-gastric junction is the main complication of LSG; endoscopic therapy of such a complication has been achieved using clips, fibrin glue, bioprosthetic plug, plastic and metal stents (1, 2). The role of non-specifically designed Self-Expandable Metal Stent (SEMS) in the treatment of post-LSG leaks is not well established and reported results are not satisfactory (stent migration, ulcer impaction, stent incarcerations) (1). The efficacy of a specifically designed fully covered SEMS (FC-SEMS) as a first-line therapy in post-LSG leaks, is evaluated.
**Aims & Methods:** Patients referred to our Endoscopy Unit from January 2013 to November 2015 for the treatment of post-LSG fistula underwent insertion of a specifically designed FC-SEMS (Niti-S Beta stent, Taewoong Medical, Seoul, Korea). This stent has a small cell meshes, a specific design with anti-migration features (outer double layers coated with silicone) and a length between 18 and 23 cm to extend from the esophagus to the antrum, in order to bypass the leak; stent diameter is 24 mm (32 mm proximal flared end) to have an optimal adherence to the esophagus.
**Results:** Ten patients (5 males, mean age 32.1 years, range 20–53) (mean BMI 43.11, range 31–66) with a post-LSG leak were treated. Characteristics and results for each patient are shown in **Table 1**. A total of 11 SEMS were inserted. In 2 patients a bioprosthetic plug (Surgisis, Cook Inc.) was also placed. In 8 patients (80%) the fistula healed after stent removal. Two patients (20%) had fistula recurrence after 8 and 14 days from stent insertion; these 2 cases were treated with a FC-SEMS with wide cells meshes. In one case proximal dysfunction of the stent was diagnosed, the stent was removed and replaced with the same FC-SEMS but with small meshes design, obtaining subsequent fistula healing. The second patient had also proximal stent dysfunction leading to the development of an infected 4 cm collection; 2 double-pigtails plastic stents (diameter 8.5 French, length 2 cm) were inserted from the leak to the collection obtaining an internal drainage; fistula healing was observed after plastic stents removal. In 2 patients (20%) gastric ulcerations secondary to impaction of the distal end of the stent were observed at stent removal; it was an incidental finding without any adverse event. After a mean follow-up of 13 months (range 5–37) all the patients are asymptomatic.
**Conclusion:** A specifically designed esophago-gastric FC-SEMS with a small cells design, is an effective and promising treatment for post-LSG leaks, but needs further evaluation in large series and in the setting of clinical trials.

## P1319 ULTRA-LONG BENIGN ESOPHAGEAL STRICTURES HAVE POOR OUTCOME

M. Pang, M. J. Bartel, C.R. Simons Linares, E.C. Brand, M. Raimondo, M. Wallace, **T.A. Woodward**
*Gastroenterology, Mayo Clinic, Jacksonville/United States of America/FL*

**Contact E-mail Address:** woodward.timothy@mayo.edu
**Introduction:** Strictures of ≥2 cm length are also termed complex esophageal strictures. In contrast to non-complex short esophageal strictures, only few information is available on the outcome of long (≥2 cm) and ultra-long esophageal strictures (≥5 cm). In the context of emerging esophageal endoscopic techniques (EMR, ESD, RFA) we expect that post-procedure strictures as well as post radiation will account for the majority of long and ultra-long esophageal strictures in the future. Their treatment is currently not evidence based, however relies on expert opinion from small case series.
**Aims & Methods:** We aimed to investigate the outcome of long (≥2 cm) benign, intrinsic esophageal strictures. 83 consecutive patients were identified who underwent endoscopic treatment of benign, intrinsic esophageal strictures of ≥2 cm length at a single tertiary between 7/2010 and 5/2014. Strictures and dilations of these patients prior to this time interval where evaluated based on retrospective review of outside hospital records and patient recollection. Data collected from the time interval 7/2010 and 5/2014 was abstracted also by retrospective chart review, including stricture etiology, duration of presence of stricture, endoscopic procedures and long-term outcome. The main endpoints were to calculate the treatment success defined as improved dysphagia score and resolution of dysphagia, as well as the rate of gastrostomy-dependent patients and patients requiring esophagectomy.
**Results:** 83 patients (mean age 63 years, SD 16.9; 54% female) were followed over 17 months (mean) at our facility for esophageal strictures of 53 months (mean) duration. Stricture etiology included peptic 23%, radiation 26%, anastomotic 11%, post-ablation 11%, post-EMR 10%, dermatologic conditions 10% and others 9% strictures, with a mean length of 43 mm [range 20–200] and mean diameter of 8.4 mm [range 1–11]. Median dysphagia score at presentation to our facility was 2 (able to swallow semi-solid only). Patients underwent a median of 7 dilations, which correspondents with 0.3 dilations per months. Only a minority of patients underwent in addition to dilation argon plasma tissue vaporization, stent placement, steroid and Mitomycin-C application. Median dysphagia score remained unchanged at 2, with 14% of patients having resolution of dysphagia, whereas 61% patients experienced unchanged or worsened dysphagia. 25% were eventually gastrostomy-dependent and 4% required esophagectomy. Stricture length and diameter remained not significantly changed at end of follow up. Kaplan-Meier analysis delineated resolution of dysphagia according to stricture length: 50% in strictures 20–49 mm, 12.5% in 50–99 mm and 0% in ≥100 mm. Limitations: Single center, retrospective study, heterogeneous cohort.
**Conclusion:** Endoscopic treatment is effective in only 50% for long (≥2–5 cm) esophageal strictures as reflected by improvement of dysphagia score. However, dysphagia remained unchanged in most ultra-long strictures (≥5 cm). Gastrostomy or esophagectomy were long-term required in 29% of strictures ≥2 cm.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1320 OUTCOMES OF SELF-EXPANDABLE METAL STENTS IN THE PALLIATIVE TREATMENT OF GASTRODUODENAL OBSTRUCTION: A SINGLE-CENTRE EXPERIENCE

**J. Carvalho**, E. Branco[1], L.C.C. Lourenço[1], V. Anapaz[1], A. Oliveira[1], R. Carvalho[1], D. Horta[2], J. Reis[1]

**Contact E-mail Address:** cbranco.joana@gmail.com
**Introduction:** Malignant gastric outlet obstruction (MGOO) affects patients with advanced gastric, duodenal, periampullary and pancreatic cancers and causes significant morbidity with resultant impairment of quality of life[1]. This condition may be resolved with palliative interventional procedures, either endoscopic or surgical; surgical procedures are associated with a prolonged hospital stay and sometimes with poor function of the gastroenterostomy[2]. Endoscopic placement of a self-expandable metallic stent is an option in these patients. It is well-tolerated and associated with shorter hospital stay, low complication rate and a rapid symptom relief, allowing the intake of food in these patients[2]. This efficacy can be measured by the gastric outlet obstruction (GOOS) score.
**Aims & Methods:** We performed a retrospective single-center study including consecutive patients with malignant gastric outlet obstruction who underwent an uncovered metallic stent placement in our Department from January 2012 to December 2015. We collected data from patients' records. Our primary outcomes were technical and clinical success (this one measured by GOOS score); secondary outcomes were duration of stent patency and survival. Statistical analysis was executed on SPSS® version 20.0.
**Results:** Twenty-seven patients were included: 17 (62.3%) were men, with an age of 69 ± 10 years (44–99 years). The type of tumor was: gastric adenocarcinoma (14 patients - 52%), pancreatic adenocarcinoma (10 patients – 37%) and cholangiocarcinoma (3 patients – 11%). The location of the obstruction was: pylorus (14 patients - 52%), the bulb (5 patients – 19%) or the other duodenum portions (8 patients – 29%). The technical success rate of the procedure was 100%. The clinical success rate was achieved in 23 patients (85%), with 18 patients with a GOOS > 1 (able to eat solid or semi-solid food). Patients restarted oral intake 35.5 hours after stent placement (24–168 hours). The median hospital stay was 17 ± 10 days. There weren't complications related to the procedure. Stent restenosis occurred in 5 patients (19%) during the follow-up period and was resolved with the placement of a second stent. The mean survival of the patients was 58 days.
**Conclusion:** Metallic stent placement is an effective and relatively safe procedure in the palliative treatment of patients with MGOO allowing a better quality of life. Our primary outcomes results' are in accordance to recently published results, which report a technical success of 95–100% and a clinical success of 90–95%[2–3].
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1321 FEATURES OF ESOPHAGEAL STENTING USING ULTRATHIN ENDOSCOPE

**D. Gusev**
*Endoscopy, Yaroslavl Regional Cancer Hospital, Yaroslavl/Russian Federation*

**Contact E-mail Address:** denis_gusev83@mail.ru
**Introduction:** Self-expanding metallic stents (SEMS) is a well-established form of palliative treatment for dysphagia in esophageal cancer. Different methods of esophageal stenting have its own features, advantages and limitations. Ultrathin endoscopes (UTE) guided SEMS placement is simple and time-saving technique [1]. It is safe, effective, and not requires fluoroscopic assistance.
**Aims & Methods:** The aim of this study was to assess the features and safety of UTE-guidance technique stent placement under direct vision, and compare it with standard stenting techniques using X-rays. The study included 182 patients (143 M/39F, mean age 72) who were undergoing stent placement for malignant esophageal strictures, between July 2010 and April 2016. 58 patients (32%) had cardioesophageal cancer, 106 (58%) – tumor in the distal part of esophagus and 18 (10%) - in the proximal part of esophagus. All patients were incurable. Stent was placed by a standard procedure using direct visual control with standard endoscope and fluoroscopy in 40 patients (group A). 142 patients were undergone by UTE-guided SEMS placement without fluoroscopy (group B). We used ultrathin endoscope with a diameter of 4.7 mm (GIF N180, Olympus Comp.). Partially SEMSs from 80 mm to 140 mm in length was used.
**Results:** In all cases the technical success rate was 100%. In group A, in 7 cases (17.5%) the length of the stent was selected incorrectly. We could not pass the endoscope through the "waist" of stent immediately after expansion and to assess the distal flanges of the stent in most cases. We had to re-reposition of stent in 3 cases (7.5%). The technical success rate of UTE-guided SEMS placement (group B) was in all cases. It allowed us to avoid intraoperative complications and significantly simplified the technical stent placement procedure. The use of ultrathin endoscope allows accurately assess the length of malignant stenosis, even tortuous esophagus lumen [2,3,4]. UTE-guided SEMS placement does not require fluoroscopy to demarcate the proximal and distal extent of the lesion. In all patients, the proximal and distal stent positions could be seen and corrected at once. The mean time required for SEMS placement was 25 minutes in group A, and 15 minutes in group B.
**Conclusion:** The standard procedure for SEMS insertion requires fluoroscopic guidance for accurate stent deployment and adjustment of positioning during the procedure. SEMS placement using ultrathin endoscopes might have some advantages over with standard method. UTE-guided SEMS placement without fluoroscopy improves the conditions for precise positioning of stent; It allows to select stents individually with minimal risk of complications for the patient; It allows to control the stent installation process, which affects the technical success of stenting.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The self-expandable metallic stent (SEMS) in upper gastrointestinal (GI) tract has been used for palliative treatment of malignant conditions. Recently, the use of SEMS is expanded to the benign esophageal or gastroduodenal strictures. Also its temporary use in patients with postoperative complication, such as anastomosis site leak or stricture, was reported. However, there are scarce data available regarding efficacy, long-term complications and outcomes with use of SEMS in benign disease, especially postoperative complications.

**Aims & Methods:** We retrospectively analyzed 39 patients who underwent a self-expandable metallic stent insertion in upper GI tract for postoperative complications between March 2009 and December 2015. All patients underwent curative gastrectomy for gastric cancer. Data collected included patient demographics, indication for procedure, type of stent used, complications, and patient outcomes.

**Results:** SEMS placement was technically successful in all patinets. At 2.5 years mean follow-up, no severe adverse events were observed after the procedures. Of 39 patients, 21 patients (53.8%) had SEMS placed for anastomosis site leakage, 8 (20.5%) for anastomosis site stricture, 10 (25.6%) for luminal narrowing due to angulation, such as E loop or A loop syndrome. After SEMS placement, symptomatic improvement was achieved in 37 of 39 patients (94.9%), while no improvement was noted in 2 patients (5.1%). Among 37 patients with symptomatic improvement, 2 patients (5.4%) had recurrent symptom and underwent repeated stent insertion and balloon dilatation respectively. After SEMS placement, mean timing of initiating diet was 7.2 days, and mean duration of hospitalization was 17.1 days. Migration was only reported complication, and developed in 9 (23.1%) patients. SEMS endoscopic removal or spontaneous expulsion was failed in 5 patients (12.8%); 1 pateint underwent sugery for SEMS removal due to migration, 1 patient failed due to stent overgrowth, and 3 were remained SEMS in place due to patient's will.

**Conclusion:** SEMS placement is effective and safe treatment for post-gastrectomy anastomosis site leaks, stricture and obstruction due to E loop or A loop syndrome. It can lead to decrease burden and risk of re-operation related mortalities and modalities.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Self-expandable metal stent (SEMS) implantation may rapidly improve the symptoms of malignant esophageal stenosis and tracheoesophageal fistulas (TEF). However, dysphagia often returns subsequently and repeated endoscopic intervention may be necessary.

**Aims & Methods:** We analyzed retrospectively the clinical data of 212 patients with locally advanced esophageal cancer who underwent SEMS implantation. The risk factors of complications, frequency and efficacy of repeated endoscopic interventions were examined.

**Results:** 238 SEMS implantations were performed with 99.06% technical success and 0.01% procedure related deaths rate in the enrolled 212 cases. Complications occurred in 84 patients (39.62%) and in 55 cases (25.94%) repeated endoscopic procedures were required. Early re-intervention 24–48 hours after the stent implantations was necessary due to stent migration (12 cases), arrhythmia (2 cases), intolerable retrosternal pain (1 case) and dyspnea (1 case). An average of 1.98 (range 1–6; median: 2) repeated gastroscopies 13.58 (range 1.5–48; median: 11) weeks after the stent implantation were performed during the follow-up period: 37 stent repositions, 23 re-stent implantations, 15 endoscopic esophageal dilations and 7 stent removals. In 48 cases (87.3%) oral feeding of patients made possible by endoscopic interventions.

**Conclusion:** In one quarter of SEMS implantations the occurrence of complications, that can successfully manage by endoscopic interventions, has to be reckoned with. Our experiences have shown that the individualized stent choice may substantially reduce the complications rate and make repeated endoscopic interventions easier.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1324 PREDICTORS OF COMPLICATIONS AND MORTALITY IN SELF-EXPANDING METAL STENTS FOR PALLIATION OF MALIGNANT COLONIC OBSTRUCTION

**M. Sousa**[1], R. Pinho[2], L. Proença[1], J. Silva[2], A. Ponte[2], J. P. Rodrigues[2], J. Carvalho[2]

[2]*Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia/Portugal*

**Contact E-mail Address:** mafalda_m_p_sousa@hotmail.com

**Introduction:** Self-expanding metal stents (SEMS) for palliative purposes in malignant colonic obstruction is an alternative to surgery, that has gained popularity over times, since surgery is associated with high mortality and morbidity, as well as detrimental impacts on a patient's quality of life.

**Aims & Methods:** Retrospective study of patients submitted to SEMS for palliation of obstructing malignant colorectal cancer from 2005 to 2015. Chi-square test and Student's t-test were used to compare non-continuous and continuous data, respectively. Survival and progression-free survival were calculated using Kaplan-Meier method and Log-Rank test. Multivariate analysis using Cox proportional hazard models was used to evaluate the predictors of survival and complications.

**Results:** 45 patients were included with high rates of technical and clinical success (97.7% and 95.5% respectively), with complications occurring in 18% of the patients (8.8% perforations, 4.4% obstruction and 4.4% migration). The length of the stenosis was superior in the patients with complications (74.3 vs 54.7 mm, $p = 0.02$) but the local of the stenosis was not associated with complications. 11.1% of the patients had a re-intervention (2.2% surgery and 8.8% colocation of other SEMS). The median duration of the hospitalization was 5 days after SEMS. The mortality rate was 37.2% at 30 days, 56.5% at 60 days and 87.5% at 1 year. There were no identified predictors of survival, including age, sex, stage of the tumor, metastasis or complications of the procedure.

**Conclusion:** In this study, SEMS placement was associated with high rate of technical and clinical success, with low rate of complications, giving an option for palliate patients with obstructive neoplasia. The length of the stenosis was associated with a greater risk of complications and although the majority of SEMS procedures were performed in rectosigmoide colon, the right colon obstruction was also managed endoscopically without increasing number of complications.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1325 ENDOSCOPIC GASTRODUODENAL SELF-EXPANDABLE METAL STENT PLACEMENT: REVIEW OF OUTCOME IN A LARGE ACUTE UK HOSPITAL

T. Riley[1], **T. Hollingworth**[1], R. Ellis[2], A. Fowell[1], P. Goggin[2]

[2]*Dept. Of Gastroenterology, Queen Alexandra Hospital Dept. of Gastroenterology, Portsmouth/United Kingdom*

**Contact E-mail Address:** TWHollingworth@GMail.com

**Introduction:** Gastroduodenal obstruction is commonly a late sign of locally advanced or metastatic cancer with a poor prognosis (mean survival 100 days[1]) and a poor associated quality of life[1]. Current treatment strategies include the placement of self-expandable metal stents, a palliative gastrojejunostomy or placement of a venting percutaneous gastrostomy tube. Placement of gastroduodenal self-expandable metal stents has emerged as the leading treatment option for gastroduodenal obstruction.

**Aims & Methods:** The aim of the study was to review the outcome of endoscopic SEMS placement for malignant gastroduodenal obstruction in a large acute UK hospital. All patients who underwent gastroduodenal self-expandable metal stents placement between January 2009 and October 2015 were identified using the hospital endoscopy reporting system (HICSS). The electronic records for these patients were reviewed, recording the underlying pathology, sedation used, time between procedure and death and all complications occurring within 30 days that were a cause of death.

**Results:** A total of 115 gastroduodenal self-expandable metal stents were placed in 103 patients (35 uncovered and 80 partially covered). Stent dysfunction occurred in 11.7% of cases with 11 patients undergoing repeat procedures due to tumour overgrowth (4), stent fracture (3), stent displacement (2), and failure of stent to expand (2). One patient underwent two repeat procedures due to tumour overgrowth. 60 cases were performed under general anaesthetic and the remainder (55) under conscious sedation. The underlying pathology included pancreatic adenocarcinoma (37), gastric adenocarcinoma (17), duodenal adenocarcinoma (5) cholangiocarcinoma (4), ampullary cancer (3) and carcinoid tumours (3). The remainder of cases were metastatic disease (18) or unknown (16). Median survival following gastroduodenal self-expandable metal stents placement was 53 days (range 2–805 days). Three patients died within 30 days of self-expandable metal stents placement; two from pneumonia and one from perforation of the caecum unrelated to the stent. The remaining patients died as a result of the underlying primary malignancy.

**Conclusion:** Endoscopic gastroduodenal self-expandable metal stents placement appears a feasible and effective treatment option for patients with malignant gastroduodenal obstruction. Stent dysfunction and complications rates, and median survival in our series were similar to previously published data[2]. Further data on quality of life following gastroduodenal self-expandable metal stents insertion and cost-effectiveness are required.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Current guidance for UK Certificate of Completion of Training (CCT) in general surgery from the Joint Committee on Surgical Training (JCST)[1] recommends trainees with a colorectal interest to have performed 15 haemorrhoidectomies and to have achieved three procedure-based assessments (PBAs) rated at level four. We aimed to determine the experience of current UK surgical trainees in performing haemorrhoidectomy and the relationship between operative numbers and PBA levels achieved.

**Aims & Methods:** We used data from the Intercollegiate Surgical Curriculum Programme (ISCP) database[2] linked to the eLogbook[3] for all UK trainees from August 2007 to October 2014. Trainees awarded CCT during the period studied and those still in training were included. We identified all trainees undertaking a haemorrhoidectomy PBA and operative records for all trainees for haemorrhoidectomy.

**Results:** In total we identified 1431 trainees. Trainees performed 23182 haemorrhoidectomies with 65% (n = 15160) either under supervision or performed. Some 585 trainees recorded a total of 1289 PBAs for haemorrhoidectomy with a median of 2 (inter quartile range (iqr) 1–3, range 1–15) per trainee. PBA performance was graded as level four in 42% (543), level three in 38% (493), level two in 20% (252) and one as level one. Over 88% (66/75) of trainees recording three level four PBAs had performed more than 15 haemorrhoidectomies. The median number of procedures performed prior to achieving three level four PBAs was 33 (iqr 21–44).

**Conclusion:** Current indicative operative numbers for haemorrhoidectomy do not reflect the number of procedures that are reported prior to obtaining three level four PBAs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Although a temporary ileostomy is widely used in protecting the anastomosis after middle and low rectal cancer surgery, some of the patients do not fully achieve stoma closure after primary surgery.

**Aims & Methods:** Thus, the aim of this study was to identify risk factors for permanent stomas following low anterior resection or inter-sphincteric resection with a temporary ileostomy for rectal cancer and to develop a nomogram that can predict non-reversal ileostomy within a year. To develop a nomogram, we reviewed retrospectively the clinical data of 212 consecutive rectal cancer patients who underwent low anterior resection or inter-sphincteric resection with or without a temporary stoma between April 2012 and June 2015 at the University of Tokyo Hospital. The predictive accuracy and discriminative ability of the nomogram were determined using concordance index (C-index) and a calibration curve. Statistical evaluations were done using the multivariate analysis and Cox hazard model.

**Results:** Among 212 patients with rectal cancer, 116 had a temporary ileostomy, 11 had a temporary colostomy, and 85 were without stoma creation. Among temporary ileostomy cases, 90 (77.6%) patients showed stoma reversal, the median period for which was 6.9 months from the time primary resection surgery was performed for rectal cancer. The temporary and permanent stoma groups consisted of 87 and 29 patients, respectively. The nomogram included the depth of invasion (p = 0.037), other metastatic organs (p = 0.017), and preoperative chemo-radiotherapy (p = 0.086), which were based on the multivariate analysis and results obtained from the Cox hazard model. The calibration curve showed good concordance between the predicted and actual probabilities of one-year stoma non-reversal rates. The C-index of the nomogram was 0.635.

**Conclusion:** Permanent stoma risk for the rectal cancer patients, who had temporary stomas after low anterior resection or inter-sphincteric resection, was characterized by higher depth of invasion and metastasis in other organs. In this study, the nomograms could identify rectal cancer patients with a higher risk of long temporary ileostomy, helping surgeons in correctly choosing the type of stoma.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Small Bowel Adenocarcinoma (SBA) is a rare tumor and the therapeutic management is not well established. The curative treatment of resecable tumor and its metastases is carcinological surgery. Metastatic surgery has never been studied. SBA at a metastatic stage is usually treated with an exclusive palliative chemotherapy (CT) with overall survival (OS) between 8 and 22 months. The benefit of metastases resection has not been demonstrated. The aim of our study was to assess a medical-surgical strategy including carcinological surgery of metastases.

**Aims & Methods:** The study cohort included 34 patients with SBA at a metastatic stage with a carcinological resection of the primary tumor and metastase (s). Patients included in the study came from the NADEGE prospective cohort (n = 27) and additional patients were included through the AGEO network (n = 7) (French Association of Gastroenterologists and Oncologists). The primary endpoint was OS. Secondary endpoints were the assessment of progression-free survival (PFS) and survival prognostic factors in univariate analysis, and the description of metastases' localizations.

**Results:** Thirty-four patients were enrolled, including 25 with synchronous metastases and 9 metachronous. Patient characteristics were similar to those of the entire NADEGE cohort except for the localization of the primary tumor which was more frequently ileal (29.5% vs. 16%; p = 0.049) and less frequently duodenal (41% vs 59% p = 0.043). Metastases' localizations were peritoneal (n = 10), liver (n = 9), lymph node (n = 4), lung (n = 1), multiple (n = 5) and other (n = 5). For the metastatic carcinological resection, seven patients had invaded resection margins (R1 n = 4 and R2 n = 3) and 24 had healthy margins. The median OS was 25.1 months and PFS was 13.6 months. Four patients received neoadjuvant CT. CT adjuvant after resection of the metastases was performed on 29/34 (85%) of patients, mostly by FOLFOX (n = 25). In univariate analysis, factors associated with decreased OS were: poorly differentiated histology (15.1 vs 28.1 months p = 0.004), resection margins invaded at surgery in the metastatic stage (16.6 vs 27.6 p = 0.014) and lymph node involvement at surgery of the primary tumor (23.3 vs 43.2 p = 0.040). The best prognosis factor was adjuvant CT with oxaliplatin compared with adjuvant CT without oxaliplatin (29.5 vs 16 months p = 0.034).

**Conclusion:** SBA's surgery metastases was for the first time assessed with this study. Overall survival appeared greater compared with non-operated patients with metastatic SBA observed in the literature. Tumor differentiation, possibility of an R0 resection and existence of an initial nodal involvement should be considered for a better selection of surgical indications.

## P1329 SURGICAL TREATMENT OF ENTEROVESICAL FISTULA – DOES SUTURING URINARY BLADDER MATTER?

**M. Wlodarczyk**[1], A. Sobolewska-Włodarczyk[2], L. Dziki[1], A. Dziki[1]
[1]*Department Of General And Colorectal Surgery, Medical University of Lodz, Lodz/Poland*
[2]*Department Of Gastroenterology, Medical University of Lodz, Lodz/Poland*

**Contact E-mail Address:** dr.mwlodarczyk@gmail.com
**Introduction:** Enterovesical fistula (EVF) is a rare chronic disease represented by an abnormal communication between the bladder and the intestine. Management of EVFs is mainly dependent on the underlying pathology, site of the bowel lesion, and patient's preoperative clinical status. The EVF's treatment involves the conservative approach and surgical procedures. The aim of the most frequently used operative method is to resect and reanastomose the offending bowel segment and to close the bladder. However, recent studies express debut whether the closure of defect in the urinary bladder wall is always needed. The aim of this study was to analyze the most appropriate surgical treatment approaches in patients with EVF. We would like to underline the problem of intraoperative suturing of the bladder defect.
**Aims & Methods:** Fifty-nine patients with EVF, who underwent surgical treatment, were enrolled. A surgical one-stage procedure with resection and anastomosis of the offending bowel segment in all enrolled patients was performed. After the separation of the offending bowel segment, the permeability of the bladder was checked by feeding a methylene blue through a catheter into the bladder lumen. In all patients a drainage of the bladder by a Foley catheter was made for seven days after the operation.
**Results:** The most common intestinal fistula involving urinary bladder was colovesical fistula observed in 52.5% cases. The most often observed primary disease related with the EVF involving colon was diverticulitis: 67.7% of patients. The statistical analysis showed no differences between EVF with urinary bladder sutures and without them in terms of all perioperative complications. During a median follow-up of 48 months (range 3 to 103) the recurrent episode of EVF formation in one patient with urinary bladder suturing and in two patients without suture were observed ($p = 0.913$); all in CD patients.
**Conclusion:** Nowadays surgery seems to be the treatment of choice in patients with EVF. Our study showed that the closure of bladder defect is not necessary in cases without intraoperative leakage of liquid delivered by catheter to bladder lumen.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1330 NEW SURGICAL APPROACH IN PREVENTION OF ANASTOMOTIC LEAKS IN PATIENTS WITH COLON OBSTRUCTION

**S. Grytenko**
*Surgery №1 Withurology, Ternopil State Medical Unibersity, Ternopil/Ukraine*

**Contact E-mail Address:** stepan_grytsenko@ukr.net
**Introduction:** Anastomotic leakage remains an urgent problem in colorectal surgery. In elective surgery on colorectal cancer, it is 10–17.9%, while complicated forms - 3–32%, mortality - 10–50% [1,2,3]. Surgeries on obstructive ileus in 26–85% are closed by overlapping colostomy. The majority of patients with stoma become socially and psychologically disadaptaited disabled. The second stage - reconstructive surgery is one of the most difficult operation in abdominal surgery with a high percentage of postoperative complications. The frequency restoration of physiologic passage through the colon can be perfomed only in 30–40% of patients.
**Aims & Methods:** Aim of study was to evaluate the safety, outcomes in patients with colon obstruction after resection with primary nonfunctional anastomosis (PNA) comparing with primary anastomosis. 155 patients with cancer of proximal rectum and sigmoid colon, complicated with acute ileus (included 12 patients with local peritonitis) were included and divided into 2 groups. In basic group ($n = 95$) PNA with preventive transversostoma (patent №72889) after resection of the rectum was performed. In comparing group ($n = 60$) resection of the colon with primary anastomosis was performed. We have worked out rate score of risk factors of anastomotic dehiscence. After resection proximal end of colon was sutured by stapler, through the colon was imposed two welt ligatures in cross direction which was lowered into the distal lumen. Traditional end-to-end anastomosis was supplemented. On 7–8 day welt ligatures were dragged out, afterwards necrosis of stitched stapler area of colon has been advanced, as result anastomosis has become passable. Stoma was closed in 2–2.5 month after operation.
**Results:** In the basic group, in 7 causes (7.4%) during the operation peritonitis were found (vs 5 cases (6,7%) in comparing group). 84 patients (88.4%) were radically operated (vs 57 patients (95%) in comparing group) and palliative operations were performed in 11 patients (11.4%) (vs 3 patients (5%) in comparing group). Combined operation with resection of posterior wall of the bladder, hysterectomy, small bowel resection was performed in 12 patients (12.6%) (vs. 16 patients (26.4%) in comparing group). General complications have arised in 5 (5.3%) of basic group and in 11 (18.4%) patients of comparing group. Anastomotic leakage have arised only in 1 (1.1%) patient of basic group and in 7 (11.7%) patients of comparing group. In all patients of comparing group with anastomotic leaks reconstructive operation wasn't performed. The average length of stay in hospital patients and control group was 15.2 and 16.0 days, to operations 2.2 and 3.2 days respectively.
**Conclusion:** PNA with preventive transversostoma provides adequate decompression of the colon, reliable prevention of colorectal anastomotic leakage, avoids complex reconstructive operations and is good alternative for Hartman's procedure. Application of primary nonfunctional anastomosis is not limited to colon obstruction, but is also appropriate to the presence of peritonitis. The anastomotic leakage appeared only in 1 patient (1.1%), indicating the high reliability of developed and applied in the primary nonfunctional anastomosis. Application of primary nonfunctional anastomosis is indicated if significant technical difficulties blending primary anastomosis in patients with multiple risk factors for anastomotic leak seams and anatomic features of the blood supply or the length of the mesentery or bowel segment proximal anastomosis, which may be risk of anastomotic leakage in the postoperative period.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** alain.fiorot@yahoo.it
**Introduction:** Colorectal cancer (CRC) is infrequent in patients under 50 years. According to recent studies [1], in this age group CRC could have more aggressive histopathological features but better survival outcome than older (over 50 years old) patients.
**Aims & Methods:** The aim of this study was to understand why younger patients with CRC have a better survival outcome in spite of worse clinical and pathological features. We retrospectively enrolled 26 patients under 50 years with CRC operated on in our Unit from January 2006 to December

2010. We matched them 1:2:2 with 52 patients from 50 to 70 years and with 52 patients over 70 years old. The matching was done according tumor site, stage and gender. Details about pre-operative parameters, laboratory data, surgical operation, histology and follow-up were retrieved. Non parametric statistics, ROC curve analysis and survival analysis were used.
**Results:** Patients under 50 years had a significantly longer overall survival ($p = 0.001$) and disease-free survival ($p = 0.05$) than older groups. However, they had more frequently lymphovascular invasion than the older groups ($p = 0.006$) and they more frequently developed metachronous CRC at follow up ($p = 0.03$). Nevertheless, preoperative lymphocytes blood count/white blood count ratio (LBC/WBC) inversely correlated with age at operation (rho = -0.21, $p = 0.04$) and it predicted CRC recurrence with an accuracy of 70%, $p < 0.001$ (threshold value LBC/WBC = 0.21%). Patients with a LBC/WBC ratio over this threshold had a significantly better overall and disease survival ($p < 0.0001$ and $p < 0.0001$, respectively). At multivariate analysis, stage and LBC/WBC ratio, but not age at operation, resulted independent predictors of disease free survival ($p = 0.0001$ and $p = 0.01$, respectively).
**Conclusion:** Patients under 50 years had a significantly longer overall survival and disease free survival than older groups. Overall survival is probably related to the presence of co-morbidities. On the contrary, better disease free survival, in spite of worse pathological features, of younger patients seems to be due to a higher LBC/WBC ratio. These results suggest a more efficiently functioning immune system and thus, a possible role of immunosurveillance in neoplastic control.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1332 FEASIBILITY AND SAFETY OF LAPAROSCOPIC AND ENDOSCOPIC COOPERATIVE SURGERY FOR GASTRIC SUBMUCOSAL TUMORS

**K. Matsumoto**
*Gastroenterology, Kobe City Medical Center General Hospital, Kobe/Japan*

**Contact E-mail Address:** kmatsumoto0418@yahoo.co.jp
**Introduction:** Laparoscopic and endoscopic cooperative surgery (LECS) is a newly developed concept for the dissection of gastric submucosal tumors (gSMT), enabling preservation of the stomach or minimization of the extent of partial resection.
**Aims & Methods:** We aimed to evaluate the feasibility and safety of LECS.
The medical records of 27 patients with gSMT less than 5 cm in diameter who underwent LECS between June 2008 and January 2016 were retrospectively reviewed. Data evaluated included the demographic and clinical characteristics of patients and tumors; total procedure time and postoperative hospital stay; and success, complication, and recurrence rates.
**Results:** The 27 patients included 16 men and 11 women, aged 20–89 years (mean 62 years). These patients had 28 tumors, 23 in the upper third (U), three in the middle third (M) and two in the lower third (L) of the stomach. Median tumor size was 32.5 mm (range 13–55 mm). Of these 28 tumors, 21 were diagnosed postoperatively as gastrointestinal stromal tumors (GISTs), five as leiomyomas, and one each as a schwannoma and an aberrant pancreas. The R0 resection rate was 100%, with no patient requiring conversion to open surgery. The median total procedure time was 148 min (range 94–222 min), and the median postoperative hospital stay was 5 days (range 4–14 days). One patient (3%) experienced a complication, ileus. During a median follow-up period of 39 months (range 6–60 months), one patient (3%) experienced tumor recurrence, consisting of peritoneal dissemination.
**Conclusion:** LECS, which combines the advantages of both laparoscopy and endoscopy, completely resected all tumors without conversion to open surgery and achieved short postoperative hospital stay.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1333 LAPAROSCOPY ENDOSCOPY COOPERATIVE SURGERY (LECS) PROCEDURE TO BREAKTHROUGH THE LIMITATION OF ESD AND EMR FOR COLORECTAL TUMORS

**Y. Tamegai**[1], Y. Fukunaga[2], H. Osumi[1], T. Kishihara[1], A. Chino[1], S. Saito[1], M. Igarashi[1]
[1]*Dept. Of Endoscopy, Cancer Institute Hospital, Tokyo/Japan*
[2]*Dept. Of Surgery, Cancer Institute Hospital, Tokyo/Japan*

**Contact E-mail Address:** yoshiro.tamegai@jfcr.or.jp
**Introduction:** We established the Laparoscopy Endoscopy Cooperative Surgery (LECS) procedure to overcome the limitation of colorectal ESD and EMR. We will report the usefulness of this epoch-making procedure from the viewpoint of safety and curability.
**Aims & Methods:** In this report, we will clarify the usefulness of LECS procedure applied with ESD technique to complete a safe one-piece resection with adequate surgical margin. We performed ESD on 1,229 colorectal tumors in 1,197 patients (male: female = 700:497; mean age, 65.9 years). Among these cases, 278 cases were accompanied by SM fibrosis. These cases were divided into three groups; absence of fibrosis (Type A), fibrosis due to benign causes (due to biopsy, recurrence after EMR, etc. Type B), and fibrosis due to cancer invasion in the SM layer (type C). The degree of fibrosis was classified into mild (grade 1), moderate (grade 2), and severe (grade 3) degree. In this study, we examined the limitation of ESD and established the indication of LECS procedure.
**Results:** The one-piece resection rates were as follows: Type A; 925/951(97.3%), Type B-1; 84/87(96.6%), B-2:46/52(88.5%), B-3:25/43 (58.1%), Type C-1:46/46(100%), C-2:19/20(95.0%), C-3:18/31(58.1%). We experienced four cases (0.3%) of perforation in Type B. In cases with Type B-3, one-piece resection becomes more difficult due to the risk of perforation. The limitation of ESD is thought to be existed in these lesions from the viewpoint of safety and curability. From these results, we established the LECS procedure applied with ESD technique to overcome the limitation of ESD. Indications of the LECS procedure for colorectal tumors were thought to be as follows; Intra-mucosal carcinoma and adenoma accompanied by wide and severe degree fibrosis due to tumor recurrence after endoscopic and surgical resection, submucosal tumors, tumors involved appendix or diverticle. We performed one-piece resection for 11 cases using LECS procedure, 3 case of mucosal cancer accompanied by severe degree fibrosis, and 2 cases of adenoma involved diverticle, 3 cases of mucosal cancer involved appendix, 2 case of submucoal tumor, and 1 case of poor endoscopic operability. We experienced no complications, and average hospital stay was 7.7(6 to 12) days.
**Conclusion:** We developed a LECS procedure to overcome the limitation of ESD and EMR, and completed one-piece resection of the tumors considered as high risk of perforation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1334 LAPAROSCOPIC NO-TOUCH PANCREATICODUODENECTOMY

**L. Pererva**, V. Kopchak, K. Kopchak, I. Khomiak, A. Duvalko, S. Andronik, I. Skrypnychuk
*Pancreatic Surgery And Reconstractive Surgery Of Bile Duct, Shalimov National Institute of Surgery and Transplantology, Kyiv/Ukraine*

**Contact E-mail Address:** perervalunet@bigmir.net
**Introduction:** One of the techniques, becoming more and more popular in open pancreatic surgery is no-touch pancreaticoduodenectomy (PD). Laparoscopic access could bring some advantages to pancreatic resections.
**Aims & Methods:** The aim was to determine possibility and safety of laparoscopic no-touch PD in patients with periampullary tumors. In the period 2013–2015 we performed 51 no-touch PD in our institute. Laparoscopic PD was completed in 6 patients, including 4 no-touch PD. Inclusion criteria at the learning stage were periampullary tumors without any potential contact to the main arterial and venous vessels, no signs of lymph node enlargement, no previous surgery on the upper level of the abdomen, no history of acute pancreatitis. The laparoscopic no-touch PD was completed in 4 patients. There were 2 male and 2 female patients aged from 36 to 63 years (mean age was 53 + 10 years). Tumors were localized in the ampulla of Vater in 1 patient, in pancreatic head- in 1 patient and in intrapancreatic portion of distal bile duct- in 2 patients.
**Results:** The mean duration of surgery was 443 ± 44 minutes (from 370 to 490 minutes). The mean blood loss was 650 ± 269 ml (from 300 to 1000 ml). In 3 patients (75.0%) postoperative complications were recorded in the form of pancreatic fistula grade B. Mortality was zero. In all patients R0 resection was achieved. One patient died 3 months after the surgery from the reasons neither connected to the surgery. 1 patient has been alive for 13 months being diagnosed a metastatic disease on the 9-th month. 2 patients are alive without signs of recurrence (20 months and 14 months).
**Conclusion:** No-touch technique could be done from laparoscopic access in a selected group of patients. Potential advantage is fast rehabilitation of patients with early start of adjuvant chemotherapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** A key pathogenetic feature of ulcerative colitis (UC) is an intrinsic low mucus phosphatidylcholine (PC) content. Recently a paracellular transport for PC across lateral tight junctions (TJ) has been described.

**Aims & Methods:** We aimed to prove the hypothesis that disruption of lateral TJ causes diminished luminal PC transport and induces an UC phenotype. We examined adult C57BL6 wildtype and mutated mice with tamoxifen inducible villin-Cre dependent intestinal deletion of kindlin 1 and 2 which were assumed to present with disrupted lateral TJ.
**Results:** Electron microscopy of mucosal biopsies of both mutants revealed loosening of lateral TJ with expansion of the mucosal crypt lumina. PC secretion into mucus was reduced by > 65% and the mucus PC content dropped from 80 in controls to 39 and 27 nmol mg mucin $2^{-1}$ in kindlin 1 and $2^{(-/-)}$ mice, respectively. In parallel the hydrophobicity was reduced from 72° in controls to 30° and 35° in kindlin 1 and $2^{(-/-)}$ mice, respectively. Accordingly microbiota penetrated into the submucosa. Later on, a full blown intestinal inflammation was present in both mutants with loose bloody stools as well as macroscopic and histologic features of colitis. The inflammation could be reversed by oral PC supplementation. In analogy, colonic biopsies of patients with UC also showed TJ disruption revealing widened crypt luminal diameters and functionally an impaired luminal PC secretion.
**Conclusion:** Genetic mouse models with intestinal deletion of kindlin 1 and 2 resulted in TJ disruption and revealed pathophysiologic features of impaired PC secretion to the mucus leading to mucosal inflammation compatible with human UC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1338 ROLE OF SLC26A3 (DRA) ION TRANSPORTER IN ENHANCING INTESTINAL EPITHELIAL BARRIER IN COLITIS

M. Li, D. Tian, X. Ding, **Y. Qin**
*Gastroenterology, Huazhong University of Science and Technology, WuHan/China*

**Contact E-mail Address:** monica77@163.com
**Introduction:** Slc26a3 ion transporter also known as DRA (downregulated in adenoma), is a $Cl^-/HCO_3^-$ exchanger, it absorbs $Cl^-$ and exports $HCO_3^-$ in a partly CAII-dependent fashion, and it contributes to intestinal fluid absorption and enterocyte acid/base balance. Recent research showed that loss of DRA impairs mucosal $HCO_3^-$ secretion and it may occur due to inflammation induced changes in the crypt and villous architecture or the effect of proinflammatory cytokines on epithelial ion transporters. And previous study indicated that Slc26a3 deficiency is associated with absence of a firm mucus layer and $HCO_3^-$/mucus barrier impairment in mice, thus $Slc26a3^{-/-}$ mice is susceptible to dextran sodium sulphate (DSS)-induced colitis. However, whether Slc26a3 had an effect on intestinal epithelial barrier is not clarified yet.
**Aims & Methods:** To elucidate its impact on epithelial barrier in colitis, we studied the role of DRA in epithelial barrier in acute dextran sulfate sodium (DSS) induced colitis in vivo and in Caco2BBE cells in vitro, then explored the potential mechanisms. The expression of DRA, TNF-$\alpha$ and tight junction (TJs) were detected in DSS-induced colitis mice by RT-qPCR, Western blot assay and Immunofluorescence staining. Then the colonic epithelial ultrastructure was investigated by transmission electron microscope. Next, after transfected DRA siRNA or lentiviral-mediated DRA overexpression in Caco2BBE cells, the expression of TNF-$\alpha$ and tight junction (TJ) proteins were measured by RT-qPCR and Western blot assay. The changes of TJs also measured when different dosage of TNF-$\alpha$ affect DRA overexpression Caco2BBE cells. Cell apoptosis was detected by FACscan flow cytometer (FACS) analysis.
**Results:** Transmission electron microscope results showed that tight junction was destroyed in distal colon of DSS treated mice. Compared to control group, mice treated with DSS showed a higher TNF-$\alpha$, much lower expression of DRA, Occludin, ZO-1 and Claudin1, inversely Claudin4 and Claudin5 were markedly increased. Knockdown of DRA in Caco2BBE cells reduced the expression of Occludin, ZO-1 and Claudin-1, and increased Claudin-5 expression, serum TNF-$\alpha$ level was also markedly elevated. On the contrary, overexpression of DRA resulted in the high expression of Occludin, ZO-1 and Claudin-1, decreased Claudin-5 expression and serum TNF-$\alpha$ level was significantly decreased. In addition, TNF-$\alpha$ could affect the expression of DRA and TJs in overexpression DRA Caco2BBE cells in dosage-dependent way. However, there's no significant difference between siDRA transfected and DRA overexpressed Caco2BBE cells in cell apoptotic rate.
**Conclusion:** These results suggest that DRA exhibit therapeutic potential against colitis and preserve intestinal epithelial barrier integrity through changing TJs expression which may be regulated by TNF-$\alpha$.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1339 CLINICAL CHARACTERISTICS OF INFLAMMATORY BOWEL DISEASE DIAGNOSED BEFORE OR AFTER OF PRIMARY SCLEROSING CHOLANGITIS (PSC): EFFECT ON PSC OUTCOME

**A. Hellström**[1], M.A. Färkkila[2]
[1]*Doctoral Programme In Clinical Research, University of Helsinki, Helsinki/Finland*
[2]*Dept. Of Gastroenterology, Helsinki University Hospital, Helsinki/Finland*

**Contact E-mail Address:** alec.hellstrom@helsinki.fi
**Introduction:** Primary sclerosing cholangitis (PSC) is associated with inflammatory bowel disease (IBD) in 50–80% of cases, usually (80%) with ulcerative colits. Ulcerative colitis associated with PSC is characterised by backwash ileitis, rectal sparing, quiescent pancolitis and an increased risk of colorectal cancer compared to IBD without PSC (1). IBD-PSC has been regarded as a unique, distinct disease entity. However, many of the patients have had IBD long before the diagnosis of PSC (2). To this date, there are no data on clinical differences of IBD-PSC patients based on the preceding diagnosis. We evaluated the role of PSC as a disease modifier of IBD by studying the differences of PSC and IBD phenotypes based on the preceding diagnosis.
**Aims & Methods:** Patients were recruited from the PSC-registry of Helsinki University, consisting of 612 PSC patients. Inclusion criteria was met in 424 patients; the diagnosis of both diseases and a minimum follow-up time of 12 months. Patient recruitment was performed on tertiary care referral to ERCP procedure at primary PSC diagnosis or follow-up into registry. ERC findings were scored according to modified Amsterdam score [Helsinki score] (3). Routine colonoscopy was done for all patients at least at the time of PSC diagnosis.
**Results:** PSC preceded IBD in 20 (4.7%) patients, while PSC and IBD were simultaneously diagnosed in 84 (19.8%). Three-quarters of the patients had IBD preceding PSC and 75% of patients also had ulcerative colitis and nearly all of them presented with pancolitis (92.5%). The median age at time of diagnosis of IBD was 23 years in patients with diagnosis before PSC and 28 years in those diagnosed simultaneously or after. The median ERC score in patients with PSC preceding IBD was 6 (IQR 3–9) compared to 5 (IQR 2–8.25) in patients without PSC as preceding diagnosis ($p = 0.08$). Respectively, histological liver fibrosis stage 3 or 4 was observed in 6 (15.0%) and 10 (8.5%) patients ($p = 0.24$). Data on clinical characteristic are presented in Table 1.
**Conclusion:** Our study population is one of the largest on this topic. Our findings support previous studies on IBD often preceding PSC. PSC preceding IBD was associated with higher ERC score and more advanced liver fibrosis stage. Endoscopic and histologic IBD data are warranted to assess if PSC modifies the clinical course of IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1340 ENDOSCOPIC INJECTION OF MESENCHYMAL STROMAL CELLS INTO THE BOWEL WALL ATTENUATES EXPERIMENTAL COLITIS

**M. C. Barnhoorn**, **E. S. .**, M. De Jonge-Muller, M. A.c. Mierement-Ooms, D. Van Der Helm, M. L. Van Gulijk, J. D. Hoogenboom, I. Molendijk, A. E. Van Der Meulen-De Jong, L. J.a.c. Hawinkels, H.W. Verspaget

**Introduction:** Mesenchymal stromal cells (MSCs) are a new potential therapeutic modality in inflammatory bowel diseases because of their immunomodulatory properties and their participation in tissue repair processes. However, when injected intraperitoneally or intravenously only a small part of the cells, if any, reaches the inflamed colon. In previous experiments MSCs as spheroids administered intraluminally as enema into the colon were found to alleviate experimental colitis. In the present study we assessed whether endoscopically injected MSCs, as singe cells or in spheroids, into the intestinal wall of the inflamed distal colon also affect the course of experimental colitis.
**Aims & Methods:** A total of $2.0 \times 10^6$ green fluorescent protein (GFP)-positive single MSCs or 2000 GFP-positive MSC spheroids, formed from 1000 MSCs, were injected in every quadrant of the distal colon of C57BL/6 mice with established dextran sulphate sodium (DSS)-induced colitis ($n = 8$ per group). Body weight was measured daily and disease activity scored (i.e. loose stool, visible faecal blood and macroscopic inflammation) at time of sacrifice. Endoscopy was performed for injection of the MSCs and before sacrifice. The murine endoscopic index of colitis severity (MEICS) was used to evaluate mucosal damage. A subgroup of mice received luciferase transfected MSC

**P1339 Table 1:** Comparison of clinical characteristics and outcomes of PSC-IBD patients based on timing of IBD diagnosis.

| Variable | $N_{total}$ | Patients (n,%); median [IQR] | IBD preceding PSC (n = 320) | IBD diagnosed simultaneously (20) or following (84) PSC (n = 104) | p-value |

spheroids to trace the spheroids ex vivo by bioluminescence (BLI). Paraffin embedded tissue was used for immunohistochemical localization of injected MSCs. Differences in expression profiles of relevant regulatory genes between MSCs grown in monolayer or in spheroids were assessed by quantitative PCR (qPCR) on mRNA isolated from MSCs and MSC spheroids in vitro.
**Results:** Endoscopically injected MSCs and MSC spheroids both alleviated DSS-induced distal colitis, as shown by a higher relative body weight (% body weight at the start) from day 3 up to day 6 after treatment compared to controls, with significant differences at day 5 (MSCs $88 \pm 3\%$ and MSC spheroids $87 \pm 2\%$ vs controls $79 \pm 2\%$, both $p < 0.05$). Furthermore, mice treated with single MSCs or MSC spheroids had a lower disease score compared to control mice (MSCs $1.8 \pm 0.3$, $p = 0.05$ and MSC spheroids $1.4 \pm 0.3$ vs controls $2.8 \pm 0.4$, $p = 0.01$), particularly due to less macroscopic inflammation. However, no differences in the MEICS were found. MSCs and MSC spheroids were found in the bowel wall by BLI and GFP staining 6 days after treatment. qPCR analysis showed transforming growth factor (TGF)-$\beta$1, TGF-$\beta$3, hepatocyte growth factor and C-X-C chemokine receptor type 4 to be upregulated whereas cyclo-oxygenase-2 and insulin-like growth factor-1, were downregulated in MSC spheroids compared to single MSCs.
**Conclusion:** Local injection of MSCs, into the inflamed distal colon as single cells as well as spheroids, is able to attenuate DSS-induced colitis and these MSCs remain in the bowel wall for at least 6 days after installation. Despite differential expression of several genes involved in immune regulation, tissue repair and trafficking, MSCs as single cells or spheroids give a similar efficacy. These data indicate the beneficial potential of local treatment with MSCs for distal colitis.

**Introduction:** Crohn's disease (CD) is a chronic and disabling inflammatory disorder of the intestine, and its prevalence and incidence are increased in developed countries. CD involves an interplay between intestinal microbiota, host genetics and environmental factors. Among factors associated with a Western lifestyle, changes in dietary habits and especially, the escalating consumption of fat and sugar parallels increased incidence of CD.
**Aims & Methods:** In this work, we aimed at better understanding the potential relationships between nutrition, gut microbiota composition and host's health by means of a suitable animal model. Thereby, we evaluated the potential protective effect of a G-protein-coupled receptor 43 (GPR43) agonist on gut inflammation following chemically-induced colitis or Adherent-Invasive E. coli (AIEC) infection in mice. Mice were fed a high-fat high-sugar (HF/HS) diet or a conventional diet for 18 weeks. E. coli populations associated with colonic and ileal mucosa were quantified using a culture-dependent method and confocal microscopy. Gut microbiota composition was analyzed by Illumina sequencing. Production of short-chain fatty acids (SCFAs) by microbiota was measured by gas chromatography in fecal samples of mice. GPR43 receptor was visualized by confocal microscopy after immunostaining of colonic mucosa tissues and in biopsies from CD patients. Mice treated or not with a GPR43 agonist were infected with AIEC bacteria or received DSS to induce colitis. Inflammatory parameters were measured to evaluate the effectiveness of GPR43 agonist treatment in the control of gut inflammation.
**Results:** Abnormal proportions of *E. coli* bacteria were recovered from colonic and ileal mucosa of mice under a HF/HS diet, compared to mice fed a conventional diet. Interestingly, intestinal mucosa dysbiosis was observed after Illumina sequencing characterized by a reduction of bacterial richness, but also an overgrowth of pro-inflammatory proteobacteria and a decrease in protective bacteria in mice fed a HF/HS diet. This was correlated with a significantly decrease of SCFAs concentrations. Moreover, GPR43 receptor expression was reduced in mice treated with a HF/HS diet and reduced in CD patients compared with controls. Mice treated with an agonist of GPR43 were protected against DSS-induced colitis and AIEC infection, showing a decrease of Disease Activity Index (DAI), lipocaline-2 level, cytokine release and mucosa-associated-AIEC bacteria.
**Conclusion:** Western diet creates an intestinal dysbiosis characterized by a decrease of protective SCFAs producing bacteria, favoring the overgrowth of opportunistic pathogenic *E. coli* which could aggravate the inflammatory process resulting in chronic inflammation. Moreover, regulation of GPR43 receptor expression could be used as a new strategy to treat patients abnormally colonized by AIEC bacteria.

**Introduction:** Transcriptome profile from ileocolectomy performed on non-affected margin of the ileum of the Crohn's disease (CD) patients showed changes in NOTCH signalling that could be implicated in early post-surgical recurrence (PSR). Comparing transcriptome profile from inflamed vs healthy margin could reveal new knowledge about the CD recurrence.
**Aims & Methods:** Objectives: To identify specific biologic functions between non-affected and affected margins of surgical samples from CD patients which will develop recurrence >18 months of the surgery. Material and methods: Transcriptomic profile study (CodeLink© microarrays, USA) among nonaffected and affected margins of ileocolestomy from CD patients with PSR (n = 5) or not PSR (n = 10) were performed. Ten controls were also included in this study and compared to different intestinal margins. Raw data from microarray analysis undergone quality control, normalization and clustering. Next analysis of gene differentiation was done with following statistical criteria: FDR < 0.05 or FDR < 0.01 and abs (log (FoldChange)) >2. The most relevant genes were grouped in co-expression modules using WCGNA (selection power=13, r2 > 0.92). GeneSet databases were used to perform enrichment analysis to screen biological and molecular functions in each module. The modules linked to recurrent or not recurrent CD were identified based on high correlation (abs (r2) > 0.75; p < 0.05).
**Results:** After quality control procedures a total of 53 samples and 20,902 gene expression probes mapping one gene were identified and included in further analysis. No single gene expression probe was identified when recurrent and no recurrent patients within the inflamed or non-affected margins were compared. However, 222 probes (69 with FDR < 0.01) were identified among non-affected and inflamed margins from CD recurrent patients, and 342 probes (95 with FDR < 0.01) showed different expression non-recurrent patients. These individual probes were grouped in 5 modules, three of them involved specifically in recurrent patients. Modules related to oxygen levels and protein amidation had a positive correlation between PSR and non-PSR (abs (r2) >0.96 and >0.83; p < 0.0003, respectively), while centriolecentriole cohesion showed a negative correlation (abs (r2) = -1; p = 10–9).
**Conclusion:** PSR in CD show highlighted biological functions related to hypoxia and protein amidation, while centriole-centriole adhesion displays an antagonistic function compared to non-recurrent patients
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1343 THE GUT MICROBIOTA PROFILE AND HOST ANTI-MICROBIAL RESPONSE AT ONSET OF ULCERATIVE COLITIS IS ASSOCIATED WITH DISEASE COURSE

**Contact E-mail Address:** lena.ohman@microbio.gu.se
**Introduction:** The clinical disease course of ulcerative colitis (UC) is unpredictable; some patients have mild symptoms whereas others suffer from frequent and severe flares and the reason for this is unknown. The gut microbiota and the host immune defense are key players for gut homeostasis and may be linked to disease severity.
**Aims & Methods:** Our aim was to determine the gut microbiota profile and mucosal anti-bacterial response in newly diagnosed patients with UC and correlate these data to disease course during the first three years. To do this we obtained rectal biopsies and fecal samples at onset of the disease from 44 therapy-naïve patients with UC. Patients were followed for 3 consecutive years and disease severity was assessed annually. Patients defined as having a mild disease course had ≤1 flares per year, whereas patients with a relapsing disease course had >1 flare per year at least one of the three years during follow-up. Microbiota analysis of fecal samples was performed for patients where fecal samples were present using the GA-map™ Dysbiosis Test (Genetic Analysis AS, Oslo, Norway). Gene expression in biopsies was analyzed by RT$^2$ Profiler PCR array for 84 genes involved in "Anti-bacterial response" (Qiagen) and confirmed by regular quantitative rtPCR. Multivariate factor analysis using orthogonal partial least squares discriminant analyses (OPLS-DA) (SIMCA-P+ software; Umetrics, Umeå, Sweden) was used to examine the relationship between bacterial content and mRNA expression to disease severity. The quality of the OPLS-DA was based on the parameter R2, defining the goodness of the fit of the model (good fit R2 > 0.5, best possible fit, R2 = 1).
**Results:** No demographic or disease specific parameters at disease onset discriminated between patients having mild (n = 23) or relapsing (n = 21) disease. Microbiota analysis of fecal samples (relapsing n = 11, mild n = 7) revealed differential clustering between the groups for the total set of bacteria (R2 = 0.55). However, no significant differences for bacterial species of phyla were found. Exploratory mRNA array analysis performed for a subset of patients (mild n = 5, relapsing n = 8) to get an insight into the mucosal anti-bacterial response showed distinct discrimination between the groups (R2 = 0.87). Bactericidal/permeability-increasing protein (BPI) and chemokine (C-X-C motif) ligand 2 (CXCL2) were the most important nominators for the discrimination. These data were confirmed in a larger cohort of patients and showed that BPI was increased (0.0002 (0.0001–0.0004) vs. 0.00009 (0.00005–0.0002), (median (IQR), p < 0.0001) and CXCL2 decreased (0.091 (0.048–0.154) vs. 0.119 (0.102–0.217), p = 0.02) in patients with mild disease vs. patients with a relapsing disease course (mild n = 23, relapsing n = 21). BPI levels correlated negatively to the total numbers of flares during the three years (r = -0.52, p = 0.0003).
**Conclusion:** The mucosal anti-bacterial response in patients with newly diagnosed UC is associated to the disease course during follow-up. This indicates that patients with a non-favorable anti-microbial expression pattern could benefit from an intensified treatment regime.

## P1344 THE ROLE FOR T CELLS IN THE PATHOGENESIS OF CROHN'S DISEASE-ASSOCIATED FISTULAE

**R. S. Bruckner**, M. R. Spalinger, S. Lang, G. Rogler, M. Scharl
*Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland*

**Contact E-mail Address:** Ramona.Bruckner@usz.ch
**Introduction:** Fistulae represent a frequent complication in Crohn's disease (CD). Surgical intervention is often required, as medical treatment outcome with conventional drugs is frequently insufficient. We have previously demonstrated that epithelial-to-mesenchymal transition (EMT) plays a critical role for fistula development. The cytokines tumor necrosis factor (TNF), interleukin (IL)-13, interferon (IFN)$\gamma$, IL-17 A and IL-22 are highly expressed in transitional cells along fistula tracts in CD patients. Similar to transforming growth factor (TGF) $\beta$, TNF is able to induce EMT and the expression of molecules being associated with cell invasiveness and migration. IL-13 induces expression of genes being associated with invasive cell growth, such as SLUG transcription factor and $\beta$6-integrin. Here, we analyzed the implication of the T cell-derived cytokines IFN$\gamma$, IL-17 A and IL-22 in the event of EMT. Moreover, we investigated if there are differences in the composition of lymphocytes in the blood of CD patients suffering from fistulae compared to patients without fistulae or healthy controls.
**Aims & Methods:** Three-dimensional intestinal epithelial cell (IEC) constructs (spheroids) were stimulated with IFN$\gamma$, IL-17 A and IL-22 to investigate the effects on EMT development. Further, CD4+ and CD25+ T cells were isolated from fistulizing CD patients' blood or control blood samples and co-cultured together with HT29 cells. Afterwards, mRNA expression levels of EMT-associated genes were analyzed.
**Results:** Treatment of the spheroid model with IFN$\gamma$ resulted in a loss of the well-defined globular spheroid shape after day 7. We observed a clear separation of IECs, while mRNA levels for EMT-related transcription factors like SNAIL-1 and ETS-1 were not up-regulated. IL-17 A and IL-22 had no effect on cell morphology suggesting that they do not induce EMT in our cell model. On a molecular level, both cytokines had no effect on the mRNA expression of EMT-associated genes, but prevented the TGF$\beta$-induced up-regulation of e.g. SNAIL-1 or ETS-1. The sorting of T cells isolated from blood of CD patients with fistulae revealed an elevated expression level of CD4+ and CD25+ T cells compared to healthy controls.
**Conclusion:** Our data demonstrate that T cell derived cytokines may play a crucial role in the pathogenesis of CD-associated fistulae. Th1 cell-derived IFN$\gamma$ may be involved in the event of EMT in IECs, however Th17 cell-derived cytokines IL-17 A and IL-22 are likely not implicated in EMT onset, and may prevent EMT-associated effects of TGF$\beta$. This observation supports the hypothesis that Th17 cell-derived cytokines exert a pivotal role for maintaining intestinal homeostasis. The different lymphocyte composition in CD patients' blood represents a further hint for the importance of these cells in fistulae formation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1345 CAN TISSUE AND PERIPHERAL EOSINOPHILIA BE USED AS PREDICTORS FOR DISEASE OUTCOME IN CHILDREN WITH ULCERATIVE COLITIS?

S. Morgenstern[1], E. Brook[1], F. Rinawi[2], R. Shamir[2], **A. Assa**[2]
[1]*Department Of Pathology, Rabin Medical Center- Beilinson Campus, Petach Tikva/Israel*
[2]*Institute Of Gastroenterology, Nutrition And Liver Diseases, Schnider Children's Medical Center, Petach Tikva/Israel*

**Contact E-mail Address:** dr.amit.assa@gmail.com
**Introduction:** Eosinophils are implicated in the pathogenesis of ulcerative colitis (UC).
**Aims & Methods:** To evaluate the magnitude of mucosal and blood eosinophils in newly diagnosed pediatric UC patients and to investigate its clinical significance in predicting the long-term disease outcome.We retrospectively evaluated colorectal biopsies of 96 patients. Samples were taken from diseased areas of the colon and examined by a gastrointestinal pathologist. The most inflamed site was used for assessment of mucosal eosinophils. Demographic data, disease characteristics and long-term outcomes were extracted from medical charts. Associations between histologic features and clinical outcomes were analyzed.
**Results:** Samples from 96 diagnostic colonoscopies as well as 70 follow-up colonoscopies (49 patients) were evaluated. Median age was 13.3 years (IQR 10.1–15.3). Median duration of follow-up was 12.8 years (IQR 7.2–17.1). Median number of tissue eosinophils at diagnosis was 45 (IQR 22–73) compared to 10 eosinophils (IQR 8–25) during histologic remission (p < 0.0001). Peripheral absolute eosinophil counts correlated significantly with tissue inflammation (p = 0.001) and with tissue eosinophilia (P = 0.001). Severity of

both mucosal eosinophilic infiltration ($p = 0.02$) and peripheral eosinophilia ($p = 0.04$) was associated with clinical severity of UC at diagnosis. Multiple logistic regression analysis showed that severe eosinophilic infiltration is associated with corticosteroid therapy following diagnosis ($p = 0.04$) but not with a long-term risk for step-up therapy or colectomy.
**Conclusion:** Tissue and peripheral eosinophilia in pediatric UC patients correlate with disease severity at diagnosis and with the risk for corticosteroid requirement following diagnosis. However, for our cohort, these did not serve as predictors for poor long term outcome including colectomy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1346 IL-33/ST2 AXIS SUSTAINS GUT MUCOSAL WOUND HEALING AND CANCEROGENESIS IN COLITIS-ASSOCIATED COLORECTAL CANCER

**Contact E-mail Address:** lopetusoloris@libero.it
**Introduction:** IL-33 and its receptor, ST2, are important factors in IBD pathogenesis. Emerging evidence also suggests its potential role in epithelial proliferation inflammation-driven tumorigenesis.
**Aims & Methods:** To characterize the precise contribution of IL-33/ST2 axis in the DSS and AOM/DSS model of colitis. C57/BL6 wild-type (WT), IL-33 KO and ST2 KO mice were given a single dose of AOM and two cycles of 3% DSS for 7 d. Body weight, occult blood test, and stool consistency were measured to calculate the Disease Activity Index (DAI), and endoscopic and histological evaluation of colons were performed. Aged-matched WT mice, injected with vehicle and given regular drinking water were used as controls (CT). At 8 wks post AOM injection mice were sacrificed. IHC, immunofluorescence (IF) and qPCR were done on full-thickness colons for IL-33 and ST2 localization and identification, and mRNA expression. FACS analysis was performed on resected, isolated polyps in order to functionally characterize ST2+ cells. Moreover, in order to characterize the precise role of the IL-33/ST2 axis following acute epithelial injury and mucosal repair, 3% DSS was administered for 5 d to C57/BL6 WT, IL-33 KO and ST2 KO mice. DSS was then replaced with drinking water for 2 wks (recovery period). Another group of WT mice received DSS for 5 d and IL-33 or vehicle (VEH) every other day during the recovery period. Mice were sacrificed either after DSS challenge or after 1 or 2 wks of recovery.
**Results:** In AOM/DSS models, IL-33, ST2L, and sST2 mRNA transcripts were dramatically elevated in WT vs. CT mice. IHC of treated WT mice revealed localization of IL-33 to the colonic epithelium and to cells within the LP morphologically consistent with tissue macrophages. ST2 staining was localized to the intestinal epithelium in tissues immediately adjacent to tumors, while within the tumors themselves, ST2+ cells displayed a spindle/fibroblast-like morphology with a unique distribution throughout the polyps. Little to no staining for both IL-33 and ST2 was present in CT. Using IF, ST2 co-localized with αSMA in polyps; however, ST2 staining was not exclusive for αSMA+ cells. FACS analysis showed a distinct population of CD45+ hematopoietic cells consisting of CD3/CD8+ cytotoxic T cells (CTLs), CD19+ B-lymphocytes, CD11b+CD11c- and CD11b+CD11c+ myeloid cells. ST2 was mainly expressed by CTLs, and CD11b+CD11c- and CD11b+CD11c+ myeloid cells. Non-hematopoietic cells (CD45-) also expressed ST2. DSS challenge in WT mice resulted in increased body weight loss and DAI vs. IL-33 KO and ST2 KO mice. At 5 weeks post AOM injection, experimental mice underwent survival colonoscopy. WT had already developed protruding lesions with abnormal vascular patterns, suggesting pre-tumorous lesions, while IL-33 KO and ST2 KO mice showed the absence of pre-tumorous lesions with a more impressive mucosal inflammation, likely due to reduced epithelial proliferation and repair caused by the absence of IL-33 signaling. At sacrifice, increased number and size of polyps were observed in WT vs. IL-33KO and ST2KO mice. In DSS model, more severe colitis was observed following DSS+1wk recovery vs. after 5 d of DSS, which decreased after DSS+2wks recovery. ST2 staining was more evident during the recovery phase following DSS, notably localized to subepithelial myofibroblasts in close proximity to areas of re-epithelialization. Both IL-33 and ST2 KO mice showed increased colonic inflammation after 2 wks recovery compared to after 5 d DSS and vs also WT. IL-33 treatment of WT mice resulted in increased body weight, reduced DAI, and decreased colonic inflammation after 2 wks recovery vs. VEH.
**Conclusion:** Our results suggest that activation of the IL-33/ST2 axis sustains mucosal healing promotes epithelial repair and mucosal healing following acute epithelial injury during DSS-induced colitis. On the other side, it is also crucially involved in tumorigenesis in the murine model of colitis-associated CRC. Further studies are underway to determine mechanisms of action that support these findings.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1347 CEACAM1 REGULATION OF BCR SIGNALING IN THE ACTIVATED B CELLS

**Introduction:** It has been recently shown that the carcinoembryonic antigen-related adhesion molecule 1 (CEACAM1) expressed in T cells may regulate immune responses in the gut.[1,2] In addition to T cells, B cells are also one of the major populations in the gut-associated lymphoid tissue that orchestrates mucosal homeostasis. However the role of CEACAM1 in B cells has not been elucidated.
**Aims & Methods:** We analyzed B cell subsets in the lymphoid tissues of wild type C57BL6 mice as well as a murine B cell line, A20, to determine the expressions and functions of CEACAM1.
**Results:** FACS analysis of the lymphocyte subsets isolated from lymphoid tissues such as spleen, mesenteric lymph nodes and Peyer's patches of C57BL6 revealed that CEACAM1 expression on B cell surface was more than that of T cells. Bone marrow analysis showed that the expression level of CEACAM1 was increased during maturation and differentiation process of B cells. When splenic B cells were stimulated with either LPS, anti-CD40, or anti-m chain antibodies (Abs) in the presence or absence of agonistic anti-CEACAM1 Ab, the increased cytokine production such as IL-4 and IL-5 by activation via B cell receptor (BCR) signaling was specifically suppressed by CEACAM1 signaling rather than B cell activations via either TLR4 or CD40 signaling. Immunofluorescent studies revealed that the expression of CEACAM1 aggregated and co-localized with BCR expression under the confocal microscope when B cells were activated with anti-m chain Ab. Given these results, A20 cells were transfected with CEACAM1 cDNA. Immunoblotting showed that the overexpression of CEACAM1 suppressed BCR signaling in these cells when compared to that of vector alone-transfected control. Moreover, the overexpression of CEACAM1 in these cells resulted in reduced expressions of activation markers such as CD69, CD80, CD86, MHC-1 and -2 on the cell surface. These observations were associated with decreased $Ca^{2+}$ influx and suppressed cytokine production by the overexpression of CEACAM1 after BCR signal activation.
**Conclusion:** These results suggest that CEACAM1 may regulate B cell activation and differentiation specifically via BCR signaling.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Few studies have focused on identifying predictive response biomarkers in patients with inflammatory bowel disease (IBD) treated with infliximab (IFX)[1,2]. With the advent and feasibility of proton nuclear magnetic resonance ($^1$H NMR) spectroscopy-based metabolic profiling[3,4] of serum in IBD, metabonomics presents itself as an obvious tool for differential diagnostics and identification of predictive response biomarkers
**Aims & Methods:** This study aims at performing a longitudinal cohort study of $^1$H NMR spectroscopy-based metabolic profiling of serum from IBD patients treated with IFX 1) to substantiate the potential use of spectroscopy as a semi-invasive diagnostic tool, 2) to provide insight into the disordered metabolism during active and quiescent IBD, and 3) to identify metabolic changes during treatment with IFX in order to explore markers of favorable outcomes. Successive serum samples collected during IFX induction treatment (weeks 0, 2, 6, and 14) from 87 IBD patients and 37 controls were analyzed by $^1$H NMR spectroscopy. Patients were divided into three different response types in accordance with disease activity at 14 weeks: Remission (Mayo score $< 2$, Harvey Bradshaw (HB) score $< 5$, and/or PDAI score $< 5$), Responder (reduced Mayo score, HB score, and/or PDAI score, but Mayo score $\geq 2$, HB score $\geq 5$, and/or PDAI score $\geq 5$), and Non-responder (no clinical response). Data were analyzed with principal component analysis and orthogonal-projection to latent structure-discriminant analysis using SIMCA-P+ 12 and MATLAB.
**Results:** The metabolic profiles were significantly different between active ulcerative colitis (UC) vs. controls; active Crohn's disease (CD) vs. controls, and quiescent CD vs. controls. The metabolites holding differential power primarily belonged to a range of lipids and phospholipids with pro-atherogenic characteristics, and metabolites involved in the pyruvate metabolism suggestive of an

intense inflammation-driven energy demand. All remaining models were insignificant including the models comparing different IFX treatment response types, i.e. remission, responder, and non-responder, as well as successive serum samples across the duration of induction within each of these response types.
**Conclusion:** In conclusion, $^1$H NMR spectroscopy-based metabonomics on successive serum samples from patients with IBD has proven to be a potentially powerful semi-invasive diagnostic tool in flaring UC and CD providing unique insights into the metabolic changes taking place during induction treatment with IFX. No applicable response biomarkers could be identified, but the identification of a reversible pro-atherogenic lipid profile in IBD patients with active disease might be of clinical importance in terms of statin treatment of IBD patients with continuous inflammation or frequent flares.

**Introduction:** Post-operative recurrence is a major concern in Crohn's disease (CD).
**Aims & Methods:** The aim of this study is to identify a molecular signature associated with post-operative recurrence in the neo-terminal ileum and the biological pathways associated. The REMIND Post-operative study has been performed in 9 centers of the REMIND group, collecting data at time of surgery and of endoscopy (performed at 6 months), associated with an extensive bio-banking. Clinical, biological and endoscopic parameters (description and location of elementary lesions, Rutgeerts score) were collected at month 6. Endoscopic recurrence was defined by a Rutgeerts score$\geq$1. Baseline factors (demographic and phenotypic variables) associated with endoscopic recurrence were searched by univariate and multivariate regression analysis. Biopsies of ileal mucosa were collected on surgical specimen and by endoscopy six months after surgery. Whole genome expression analysis was performed using microarray study and followed by Gene Ontology and clustering analyses.
**Results:** Thirty patients representative of the whole REMIND cohort were selected: 53% were male, median age at surgery was 30 years old. One third of patients (33%) were active smoker at time of surgery. Twenty patients (66.6%) received pre-operative anti-TNF therapy, while 10 (33%) received anti-TNF after surgery. Nineteen (63%) patients had an endoscopic recurrence as defined by a Rutgeerts score$\geq$1. Principal component analysis (PCA) showed two clusters of patients according to their transcriptional profiles, which highly correlated with post-operative recurrence. Indeed in the first cluster, 12 patients out of 13 had endoscopic recurrence; while 10 out of 17 patients had no endoscopic recurrence in the second cluster. Endoscopic recurrence was associated with significant regulation of inflammatory genes such as S100A8, S100A9, IL1B, IL6, CCL2, CCL8 and GZMA. Remarkably, the molecular signature of non-recurring patients was not similar to non-IBD healthy controls (ileal biopsies; n = 9). Moreover, study of samples at time of surgery defined different types of transcriptional profiles.
**Conclusion:** This study revealed a correlation between gene expression profiling and recurrence of mucosal inflammation after surgery in CD. Analysis of the whole data set (in progress) could lead to the identification of important pathways involved in post-operative recurrence in CD.

**Introduction:** Immune modulating antibodies targeting a specific cytokine signal (e.g. TNF-$\alpha$, IL-6) are the mainstay in therapeutic control of a broad and heterogeneous group of chronic inflammatory diseases, including rheumatoid arthritis (RA) and inflammatory bowel disease (IBD). Pathogenesis of these diseases is argued around microbial driven activation of immune cascade and cytokine imbalance; however the impact of such targeted cytokine blockade on intestinal microbial communities is poorly understood.

**Aims & Methods:** This study aims to determine the impact of anti TNFa therapies on microbiota in patients with rheumatoid arthritis and with inflammatory bowel disease. We enrolled patients with RA (n = 38) and IBD (n = 14) and healthy volunteers (n = 24) for this longitudinal study. Patients enrolled were naïve to previous biological therapy. Fecal samples were collected at baseline of therapy induction and on 1 day, 3 day, 1 week, 1 month and 6 months of therapeutic interventions. DNA was extracted from fecal samples and V4 region of the 16 S rRNA gene was sequenced using MiSeq Illumina platform.
**Results:** Compared to healthy control, IBD and RA patients display a specific microbial pattern of luminal gut microbiota at baseline. Moreover, in response to therapy induction we observed significant differences in the proportion of major bacterial groups (*Firmicutes* and *Actinobacteria*) in a time dependent manner. Likewise microbial composition and structure (beta diversity) was significantly altered after therapy if compared to the changes in healthy volunteers within same time frame. The observed microbial changes could not specifically attributed to TNFa inhibition in different disease types but rather seemed to reflect the overall changes of systemic immunity in response to therapy induction
**Conclusion:** Our data suggests a marked influence of biological therapies on microbial composition and structure, irrespective of underlying disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1351 GAMMADELTA T CELL DEFICIENCY IN THE PERIPHERAL BLOOD OF PATIENTS WITH CROHN'S DISEASE: RELATIONSHIP WITH CLINICAL AND ENDOSCOPICAL ACTIVITY

**Introduction:** Crohn's disease (CD) is a chronic relapsing systemic disease affecting the gastrointestinal tract. An altered immune reponse to commensal intestinal bacteria takes place in genetically predisposed individuals, and it can be considered an immune deficiency condition. Gamma delta T lymphocytes (GDTL) are considered key cells in the first line of defense against infections and can stimulate wound healing. Murine studies have shown their protective role against colitis in IBD models. Their clinical role in CD pathogenesis and prognosis is largely unknown.
**Aims & Methods:** We aimed to determine the numbers of GDTL in the peripheral blood (PB) of a large cohort of CD patients and matched controls and study its relation with the clinical and endoscopical activity. A prospective study of 102 patients with CD compared with 102 healthy subjects (control group) matched by age and sex was undertaken. Lennard-Jones criteria were used for the diagnosis of CD. Disease activity was measured with the Crohn's disease activity index (CDAI) and endoscopical activity by the SES-CD index. New patients, patients in remission, and patients with active disease were evaluated. Lymphocytic populations of CD3+, CD4+, CD8+, CD56+, and $\alpha\beta$ and $\gamma\delta$ subsets were measured in the PB of all participants.
**Results:** The number of total CD3+, CD4+, CD8+ and CD56+ lymphocytes was decreased in CD patients compared with the control group ($p < 0.001$, 0.003, $<0.001$, and 0.001, respectively). Although both $\alpha\beta$ and $\gamma\delta$ T lymphocytes were lower in patients, GDTL subsets showed the lowest levels in CD patients (mean 0.0332 x $10^9$/l) vs controls (mean 0.0753 x$10^9$/l), $p < 0.001$. This decrease was significant for both CD4+$\gamma\delta$, CD8+$\gamma\delta$ and CD56+$\gamma\delta$ subsets ($p < 0.001$), and for all the clinical scenarios studied (new patients, remission or active disease) $p < 0.001$. In addition, we found and inverse correlation between the numbers of CD3 + $\gamma\delta$ and CD8 + $\gamma\delta$ (and not the $\alpha\beta$ T lymphocytes) with the clinical (-0.304 and -0.249; $p = 0.014$ and $p = 0.017$ respectively) and endoscopical activity (-0.275 and -0.249; $p = 0.017$ $p = 0.017$).
**Conclusion**: This study confirms a decrease in the global lymphocyte population in the peripheral blood of patients with CD. This decrease is more evident in gamma-delta T lymphocytes. Our results show for the first time an inverse correlation between GDTL numbers in PB and disease activity, highlighting the importance of these cells in the pathogenesis of the disease with potential therapeutical implications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The gut microbiota is believed to play a central role in the development of the inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC). Recently has been suggested that live commensal intestinal bacteria are present in the adipose tissue and the peripheral blood where they can induce inflammation. Since this process can trigger inflammation the aim of the present study was to evaluate the intestinal bacteria concentration and translocation of bacteria in IBD.
**Aims & Methods:** Both blood and tissue biopsy samples were collected from children (n = 6) and adult patients with active CD (n = 3) and UC (n = 6), as well as from healthy individuals (n = 9) underwent screening colonoscopy. Most of the patients were newly diagnosed and none of them received antibiotics. All of the adults received 5-ASA and three of them anti-TNF. Samples were taken before starting and after 12–20 weeks of anti-TNF treatment. For each samples (tissue and blood) the purified DNA was eluted and analyzed for total bacteria using suitable primers targeting 16S rRNA gene by Real-Time PCR. Reference microbial strain E.coli used for standard curve construction. Total tissue and blood bacterial DNA were determined by interpolating the Ct values obtained from the samples into the appropriate standard curve.
**Results:** The total bacterial count was similar in tissue biopsies and blood samples. However, adult UC patients had increased bacterial count ($87.02 \pm 1.02$ ng/ul in tissues and $84.53 \pm 0.5$ ng/ul in blood) compared to CD ($74.58 \pm 0.52$ ng/ul in tissues and $75.55 \pm 0.51$ ng/ul in blood) ($p < 0.05$). In children samples bacterial count, in both tissue ($48.38 \pm 7.74$ ng/ul) and blood ($49.15 \pm 5.89$ ng/ul) samples, was significantly lower than adult's samples ($p < 0.001$). In all cases adult and children patients, the bacterial count was significantly higher than in controls ($34.02 \pm 0.03$ in tissues and $43.1 \pm 0.14$ ng/ul in blood) ($p < 0.001$). Interestingly, when we compared the samples of patients who received anti-TNF treatment before and after the treatment we shown that the bacterial count diminished significantly after anti-TNF treatment, in the levels to control samples in both tissues (before anti-TNF $81.4 \pm 9.4$ vs after anti-TNF $29.43 \pm 6.54$ ng/ul, $p < 0.01$) and blood samples (before anti-TNF $80.12 \pm 6.33$ vs after anti-TNF $50.32 \pm 7.03$ ng/ul, $p < 0.01$).
**Conclusion:** Our results idicate the translocation of bacteria from gastrointestinal system in the circulation in IBD cases and the bacterial count in bloodstream could be a less invasive indicator of response to anti-TNF treatment. Further studies to identify the bacterial species in this cases are in process.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** giuseppelos@alice.it
**Introduction:** The pathogenesis of inflammatory bowel disease (IBD) is complex, with multiple interactions between genetics, infections, microbiota and diet. Diet pattern has been observed as a possible environmental trigger for IBD. On the other hand, the activity of the disorder may affect dietetic intake. Therefore, we evaluated diet macronutrients in IBD and correlated them with disease activity.

**Aims & Methods:** A hundred and fifty IBD patients (84 Crohn's disease-CD and 66 ulcerative colitis-UC) and 100 healthy volunteer controls were enrolled. All patients answered a 24-hour recall questionnaire/personal interview to evaluate macronutrient intakes (total calories, carbohydrates, refined sugars, lipids, proteins, total fibers, insoluble/soluble fibres). Data were elaborated by a dedicated software (WinFood). Disease activity was estimated by global Mayo and Harvey Bradshaw index-HBI. We evaluated the association of dietetic factors with disease activity as well as with immunomodulator or biologic therapy using both univariate and multivariate analysis with linear regression.
**Results:** We did not observe any difference in total calories, proteins and carbohydrates intake among controls, IBD receiving immunomodulators and IBD under biologics. Controls assumed less lipids in diet than patients with IBD and more fibres, both soluble and insoluble. For CD, HBI score was directly correlated to carbohydrate intake ($b = 6.752 \pm 3.25$, $p = 0.04$), however the multivariate analysis did not confirm this finding ($b = 0.65 \pm 1.12$, $p = 0.26$). For UC, the disease activity directly correlated with total caloric intake ($b = 2.72 \pm 1.7$, $p = 0.008$) and inversely with carbohydrates ($b = -3.02 \pm 2.53$, $p = 0.03$), and multivariate analysis confirmed such findings both for carbohydrates ($b = -1.1 \pm 0.17$, $p = 0.03$) and total calories ($b = 1.19 \pm 0.04$, $p = 0.049$). Type of drug medications was not a confounding factor in the correlation between dietary intakes and disease activity.
**Conclusion:** We found that the assumption of carbohydrates Is correlated with disease activity directly for CD and inversely for UC. Mayo score was then directly correlated to total caloric intake in UC. A direct cause-effect relationship cannot be demonstrated by our study since the study does not allow to establish whether the diet affects the disease or the disease affects dietetic habit.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Intrafamilial cases of Crohn's disease (CD) are well documented; they may be linked to genetic susceptibility and/or transmissible agents. Adherent-invasive *E. coli* (AIEC) has been consistently implicated as a pro-inflammatory species in CD.
**Aims & Methods:** The aim of our study was to investigate similarities between different *E. coli* strains isolated from stools of CD cases and their healthy relatives issued from a French population-based CD registry. 246 strains from 38 individuals belonging to 17 families with at least one case of CD were checked for invasive ability by infecting Intestine-407 (ATCC CCL-6) epithelial cells during three hours by the E.coli strains at a multiplicity of infection of 10 bacteria per cell. After cell-rinsing by PBS (3 times), fresh medium containing 100 $\mu$g/mL of gentamicin was added and further incubated for 1 hour (in order to kill extracellular bacteria). The cells were then lysed with 500 $\mu$L of 1% Triton X-100 and intracellular bacteria are outnumbered. The isolates were considered invasive when (intracellular bacteria / initial inoculum) $\times$ 100 was $\geq$0.1%. Two controls were systematically tested, a non-invasive *E. coli* strain (K12 C600) and the AIEC reference strain LF82. Strains belonging to the AIEC pathovar were further typed by Pulsed Field Gel Electrophoresis (PFGE) using XbaI as restriction enzyme.
**Results:** A total of 82 AIEC strains from 38 individuals (19 CD patients and 19 healthy relatives) belonging to 17 families were isolated. They generated 71 different PFGE profiles, indicating a high variability both in patients and their healthy relatives. One person can harbor up to three different profiles of AIEC strains.
**Conclusion:** The AIEC population is rather heterogeneous and different AIEC profiles can be found in the same sample. On the whole profiles are different in healthy persons and CD patients belonging to the same family. These observations are in agreement with a low risk or intrafamilial transmission. ## P1355 IMPROVEMENT OF HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC INFLAMMATORY BOWEL DISEASE AFTER 4 WEEKS OF ADDITIVE TREATMENT WITH MENTHACARIN – A RANDOMIZED, PLACEBO-CONTROLLED TRIAL

**M. A. Engel**[1], B. Stracke[2]
[1]*First Department Of Medicine, Friedrich-Alexander-University Erlangen Nürnberg, Erlangen/Germany*
[2]*Clinical Research, Dr. Willmar Schwabe GmbH & Co. KG, Karlsruhe/Germany*

**Contact E-mail Address:** matthias.engel@uk-erlangen.de
**Introduction:** Since the early 1950s, a rise in the incidence of inflammatory bowel disease (IBD) has been observed. In Western Europe, IBD affects 0.5–1.0% of the population during their lifetime[1]. The main symptoms of IBD are diarrhea in connection with stools containing blood and mucus as well as pain and abdominal cramps. The most common types of IBD are ulcerative colitis and Crohn's disease. We analyzed data from a prospective, randomized, placebo-controlled, double-blind, parallel-group, multi-center clinical trial in outpatients with IBD, defined here as ulcerative colitis and Crohn's disease. The results of health-related quality of life (QoL) in patients with chronic inflammatory bowel disease after 4 weeks of additive treatment with Menthacarin* will be reported here.
**Aims & Methods:** The trial was performed by 27 internists, gastroenterologists, and general practitioners in Germany. In total, 135 male or female, adult outpatients suffering from IBD were randomized and treated for 4 weeks with Menthacarin capsules or placebo (2 x 1 capsule/day) - as an additive treatment. The patients' medication for treatment of IBD had to be administered in constant dosage. Baseline-values for health-related QoL, as rated by the patient using the validated 'Inflammatory Bowel Disease Questionnaire' (IBDQ)[2] were compared with QoL-results at the end of trial.
**Results:** There was an improvement in the total score of IBDQ by $25.6 \pm 30.2$ points (from $149.1 \pm 24.1$ to $175.8 \pm 24.6$ points) under Menthacarin-treatment (full analysis set, mean $\pm$ SD; $n = 61$) compared to an improvement of $11.0 \pm 22.5$ points (from $149.4 \pm 32.4$ to $160.2 \pm 30.0$ points) in the placebo group (full analysis set, mean $\pm$ SD, $n = 64$). This results in a corresponding p-value of 0.0012 (full analysis set, U-test, one-sided). All the four dimensions of the IBDQ (bowel symptoms, systemic symptoms, emotional and social function) demonstrate the significant improvement in the Menthacarin-group compared to the placebo group as well.
**Conclusion:** Menthacarin significantly improved health-related QoL in patients affected by IBD and was well tolerated. _____ *Menthacarin® is a proprietary combination of essential oils of a specified quality from Mentha x piperita L. (90 mg Peppermint oil WS® 1340) and Carum carvi (50 mg Caraway oil WS®1520)
**Disclosure of Interest:** M.A. Engel: I received honoraria from Dr. Willmar Schwabe GmbH & Co. KG, Karlsruhe, Germany.
B. Stracke: I am an employee of Dr. Willmar Schwabe GmbH & Co. KG, Karlsruhe, Germany.

## P1356 PROPHYLACTIC AND CURATIVE POTENTIAL OF THE HERBAL PREPARATION STW 5 IN AN EXPERIMENTAL MODEL OF CROHN'S DISEASE

**M.T. T. Khayyal**[1], W. Wadie[1], D. Abdallah[1], M. J. Schneider[2], T. Efferth[2], O. Kelber[3], H. Abdel-Aziz[3]

**Contact E-mail Address:** mtkhayyal@gmail.com
**Introduction:** STW 5 is a standardized multi-component herbal preparation consisting of extracts of bitter candy tuft, lemon balm, chamomile, Angelica, peppermint, milk thistle, caraway, celandine and liquorice. It has been used clinically in functional dyspepsia[1] and irritable bowel syndrome[2] and showed efficacy in experimental dextran sulphate induced colitis as a model of ulcerative coitis[3]. The present study was conducted to investigate its potential usefulness in 2,4,6 - trinitrobenzene sulfonic acid (TNBS) induced colitis as an established experimental model for Crohn's disease.
**Aims & Methods:** Colitis was induced by instilling TNBS in the colon of male Wistar rats under light ether anaesthesia. In a prophylactic setting, STW 5 was given orally1 week before induction of colitis and continued for 3 days after induction. Twenty-four hours later, rats were sacrificed. In the curative setting, STW5 was given orally 48 h after colitis induction daily for 1 week and the rats sacrificed 24 h later. Mucosal colonic damage was assessed macroscopically. Sulfasalazine was used as a reference drug. Colon homogenates and serum samples were used to assess levels of inflammatory and oxidative stress parameters. Immuno-histochemical staining of colon sections was used to assess calprotectin and IL-17 A levels, reported to be pertinent markers for IBD in man.
**Results:** TNBS colitis was evidenced by severe ulcerative damage, inhibition of reduced glutathione and a rise in myeloperoxidase in colon homogenates. Relevant cytokines TNF$\alpha$, IL-1$\beta$, ICAM-1 were elevated as well as LT-$B_4$

**P1357 Table1:** Cost of UC – 24 months prior to first NE admission to 24 months following first NE admission

| Age group | Cost of first admission | Admission post diagnosis | Outpatient gastroenterology | Inpatient endoscopy | Outpatient endoscopy | A&E gastroenterology |
|---|---|---|---|---|---|---|
| 0–15 | £278,009.21 | £55,316.54 | £254,193.76 | £184,155.33 | 0 | £6,291.61 |
| 16–30 | £1,791,556.72 | £2,771,071.82 | £1,116,013.46 | £1,184,373.75 | £13,640.77 | £58,800.8 |
| 31–50 | £3,341,371.68 | £3,010,543.24 | £1,251,378.49 | £1,212,658.85 | £18,713.65 | £51,713.99 |
| 51–75 | £5,779,692.95 | £4,789,813.5 | £1,100,563.6 | £1,612,289.53 | £21,181.86 | £62,492.72 |
| 75+ | £4,708,529.46 | £2,754,053.05 | £40,713.1 | £96,841.35 | £8,023.53 | £34,812.16 |

Total costs per patient per year were calculated using data from Table 1. For age group 0–15, this was £4,76.07. For ages 16–30, cost was £3,280.73. For ages 31–50, cost was £2,704.32. For ages 51–75, cost was £2,867.02 and for 75+, cost was £2,872.24. Patients below the age of 30 utilised more cost per patient than those above the age of 30.

and $PGE_2$. Immuno-histochemical examination showed a rise in calprotectin and IL-17 A. Pre-treatment with STW 5 prevented such effects in a similar manner to sulfasalazine. In the curative setting, STW 5 tended to normalize changes in reduced glutathione and myeloperoxidase and in ulcerative indices induced by TNBS.
**Conclusion:** Present findings provide good supportive evidence for the potential usefulness of STW5 in Crohn's disease.

### P1357 THE TRUE COST OF ULCERATIVE COLITIS IN THE UK

**A. Soubieres**, A. Poullis
*Gastroenterology, St George's Hospital London, London/United Kingdom*

**Contact E-mail Address:** anet.soubieres@gmail.com

**Introduction:** Inflammatory Bowel Disease (IBD) has a prevalence of around 400 in 100,000 in the UK, with the prevalence of Ulcerative Colitis (UC) specifically of around 243 per 100,000. This gives a figure of 146,000 people in the UK living with UC. Around 30% of IBD patients are under regular hospital follow-up. Luces C et al found lifetime costs of IBD to be comparable to other major chronic illnesses such as heart disease and cancer.[1] In recent years there has been much focus on costs associated with new biologic agents for treatment of IBD. There are few studies looking at healthcare costs in terms of out patient assessments, admissions and diagnostics in Ulcerative Colitis. One recent Dutch study found healthcare costs of IBD to be stable over a 2-year period. [2] There are, in addition, inevitable costs incurred in the lead up to the eventual diagnosis of UC. This is a poorly researched area, which is likely to have a significant impact on total healthcare costs attributable to UC.
**Aims & Methods:** We aimed to determine the true costs attributable to UC over a 48-month period, spanning from 24 months leading up to the first non-elective admission for UC up to the 24 months following the first non-elective admission for UC. Hospital Episode Statistics data for 2011/2 for all clinical commissioning groups in England were analysed to calculate the cost of UC. The data used were obtained from the AXON Database, a health data warehouse that provides interrogative analysis and health intelligence on Hospital Episode Statistics (HES). Costs were calculated using national tariffs linked to Healthcare Resource Group (HRG) codes associated with each HES record. HES data from all the clinical commissioning groups in England for the year 2011 and 2102, 24 months up to the day prior to the first non-elective (NE) admission and 24 months following the first NE admission for UC were analysed. International Classification of Diseases – 10 (ICD-10) diagnosis codes related to UC were used to identify patients.
**Conclusion:** In the 48 months commencing 24months prior to the first NE admission for UC and ending 24 months after the first NE admission, there are significant costs in terms of admissions, outpatient assessments and diagnostics. Non-elective admissions, associated inpatient diagnostics in addition to attendance in A&E make up a high proportion of total cost. Non-elective care is often unplanned and more expensive than elective care. Better access to secondary care may reduce the cost burden of UC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The risk of developing inflammatory bowel disease (IBD) is dependent on the surrounding environment as a contributing factor. Smoking is associated with complicated Crohn's disease (CD), but it has a protective role in ulcerative colitis (UC). Processed food, caffeine and sugar intake are also likely to influence IBD.
**Aims & Methods:** All patients diagnosed with IBD between 2012 and 2014 at Mater Dei Hospital in Malta were included in this study as part of ECCO-EpiCom inception cohort. Each patient was then asked to fill in a questionnaire related to environmental factors.
**Results:** 152 patients (mean age 42.4 years SD ± 17.7; mean age at diagnosis 39.8 years SD ± 17.7) were included in this study. 55.9% were male. 65.8% patients suffered from UC.
Association of type of IBD with environmental factors: Patients with UC (38.1 years) had a mean older age at stopping smoking when compared to CD (30.3 years).($p < 0.027$) More UC patients were former smokers at the time of the study ($p < 0.01$) and at diagnosis ($p < 0.015$) and were ongoing smokers at diagnosis ($p < 0.033$). Whereas less UC patients were ongoing smokers at the time of the study ($p < 0.027$). Most patients with CD exercised daily or weekly. Most patients with UC exercised weekly or less. ($p < 0.013$) The higher the consumption of juices, the more likely the diagnosis of UC over CD. ($p < 0.007$) Patients with UC had an older mean age at the time of the study ($p < 0.003$) and at diagnosis ($p < 0.002$) and had a higher mean weight ($p < 0.001$) and BMI ($p < 0.007$).
Association of environmental factors with age at diagnosis: Patients with CD who had ever smoked ($p < 0.044$) and were exposed to passive smoking ($p < 0.032$) had a higher mean age at diagnosis than those who had never smoked and were never exposed to passive smoking. Those who were former smokers at diagnosis ($p < 0.008$) and at the time of study ($p < 0.026$) and those who smoked more than 20 cigarettes daily ($p < 0.008$) were older at diagnosis than. Those who had resumed smoking at diagnosis had a younger age at diagnosis.($p < .056$) CD patients on contraceptives ($p < 0.004$), those who consumed non-wholemeal bread ($p < 0.057$), those with the highest sugar consumption in coffee ($p < 0.01$) and tea ($p < 0.060$) and those who consumed most fast food ($p < 0.003$) had a younger age at diagnosis. Contrary to this, those with highest coffee ($p < 0.009$) and tea consumption ($p < 0.013$) were oldest at diagnosis. On constructing a general linear model, use of contraceptives ($p < 0.049$), consumption of fruit ($p < 0.022$), vegetables ($p < 0.033$), eggs ($p < 0.022$), bread ($p < 0.006$), cornflakes ($p < 0.014$), sugar in coffee ($p < 0.023$), sugar in tea ($p < 0.054$), fast food ($p < 0.030$), juices ($p < 0.048$), soft drinks ($p < 0.009$), tea ($p < 0.018$), pack years ($p < 0.028$) retained statistical significance. Patients with UC who had ever smoked ($p < 0.005$), were former smokers at diagnosis ($p < 0.0001$) and at the time of the study ($p < .0001$), smoked more than 20 cigarettes per day ($p < .029$) were older at diagnosis. Those with the highest consumption of fast food were youngest at diagnosis ($p < 0.001$). Those with the highest consumption of coffee ($p < 0.098$) and tea ($p < 0.024$) were oldest at diagnosis. On constructing a general linear model, pack years ($p < 0.001$) and total fast food ($p < 0.004$) consumption retained statistical significance.
**Conclusion:** A sedentary lifestyle, a higher consumption of juices and a higher BMI predispose to a diagnosis of UC. Smoking was protective in both UC and CD leading to an older age at diagnosis as was caffeine intake. Fast food consumption was also common to both types of IBD, leading to a younger age at diagnosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory bowel diseases (IBD-Crohn's disease (CD); ulcerative colitis (UC)) are lifelong inflammatory conditions of the gastrointestinal tract. IBD-associated colorectal cancer (CRC) accounts for approximately 1–2% of all cases of CRC. Although data on mortality rates in IBD patients are controversial, CRC has been shown to account for approximately 10–15% of all deaths among IBD patients.

**Aims & Methods:** The aim of our nationwide registry was to prospectively collect IBD-related mortalities and all types of malignancies diagnosed in the Hungarian IBD population. Data on all death and malignancies developed from January 2015 in IBD patients were recorded. Each members of the Hungarian Society of Gastroenterology were prospectively interviewed 3 monthly by personal emails to report both death and malignancies observed in their patient population. Demographic and clinical data including previous immunosuppressive and biological therapy were also collected.

**Results:** Twenty-one newly diagnosed malignancies were reported (mean age: 48.2 years old, mean disease duration was 18.5 years; male/female ratio was 14/7) 14 CRC (mean age: 48.7 years, mean disease duration: 20.9 years, male/female ratio was 11/3; 1 pouch cancer previously colectomized because of sigmoid tumor), 1 with gallbladder, 1 with cervix, 1 with lung, 1 with esophagus, 1 with salivary gland, 1 with skin and 1 with tonsil cancer throughout the examined period. Eleven of the 14 CRC cases were associated with UC, 81% with pancolitis and chronic disease course. Eleven of the 14 cases were located on the rectosigmoid region, 2 had multiple localization (5 and 2 cancers simultaneously). Fifteen patients with treated IBD died during the examined period. Seven cases were related to IBD (5 males 2 females; 1 CD patient with rectal cancer, 1 patient with pouch cancer, 1 CD patient with interstitial pneumonia, 1 UC and 1 CD patients with septic complications, 1 UC patient with meningitis, 1 UC patient with hemorrhagic shock). Age of death was significantly lower in case of IBD-related mortality compared to the other patients and general population (44 vs. 65 vs. 73.4 (data from Central Statistical Office 2013, Hungary) years, $p = 0.02$). Immunosuppressive and/or biological therapy was ever given for 6 patients with IBD-related mortality.

**Conclusion:** The most frequently observed IBD-related malignancy is CRC, which can be multifocal and mainly involved the distal part of the colorectum typically in UC patients with pancolitis and chronic activity. Malignancy and septic complications were the leader causes of IBD-related mortality characterized by earlier death than in the rest and in the non-IBD population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1360 CROHN'S DISEASE BEHAVIOR AND LOCATION IS ALTERED WHEN ASSOCIATED WITH PRIMARY SCLEROSING CHOLANGITIS

**Introduction:** Primary sclorising cholangitis (PSC) is diagnosed in up to 7.5% of ulcerative colitis (UC) patients and less frequently (up to 3.4%) in Crohn's disease (CD) patients. The intestinal disease is usually milder but more extensive in patients UC-PSC patients compared to patients with no PSC. However, data on clinical characteristics of patients with PSC-CD are scarce. It has been suggested that CD-PSC patients have an extensive colonic involvement, leading in many cases to a diagnosis of indeterminate colitis. Classification of patients by phenotype is important for prediction of clinical outcome, tailoring therapy and for future understanding of disease pathogenesis, especially if they progress differently from isolated CD patients.

**Aims & Methods:** A retrospective case control analysis was performed on 18 patients with PSC and an established concomitant diagnosis of CD, who attended the IBD Center at the Tel Aviv Medical Center, between the years 2011–2014 (PSC-CD patients). PSC-CD patients were matched (by age, gender, and disease duration) to 90 CD patients (with no PSC) as controls. Disease phenotype (according to the Montreal classificaiton), demographic and clinical data were compared between the two groups. We aimed to clinically characterize Crohn's disease in patients who have concomitant primary sclerosing cholangitis.

**Results:** Disease in PSC-CD patients was more frequently limited to the colon (L2) compared to controls (50% vs 16%, $P = 0.004$). In contrast, a disease limited to the small bowel disease (L1) was noticed in only one PSC-CD patient as opposed to 30 of controls (6% vs 33%, $P < 0.05$). A non-stricturing-non-penetrating inflammatory phenotype was significantly more prevalent (83% vs 33%, $P = 0.0001$) in PSC-CD patients, while a penetrating phenotype (B3) was documented in only one patient with PSC-CD, signifacntly lower compared to controls (6% vs 33% $P < 0.05$). Use of 5-ASA agents as a single therapy was significantly more prevalent among PSC-CD patients compared to controls (39% vs 7% $P < 0.005$). In contrast, biologic therapy was significantly less common among PSC-CD patients compared to controls (17% vs 52%, $P = 0.0086$).

**Conclusion:** Patients with PSC-CD are clinically distinct from patients with isolated CD, and are characterized by a predominant colonic involvement and an inflammatory, non-stricturing-non-penetrating phenotype. These findings, if repeated in larger cohorts, may aid in strategising therapeutic interventions in these patients and in research of disease pathogenesis.

**Introduction:** The course of inflammatory bowel disease (IBD) is highly heterogeneous. The available data on the impact of obesity in IBD patients is limited (1, 2). Therefore, we examined the impact of body mass index (BMI) on disease course and on therapeutic failure in a large single-center cohort of IBD patients treated with biological therapy.

**Aims & Methods:** We retrospectively analysed data from 894 IBD patients (60.4% Crohńs disease (CD); 39.6% Ulcerative Colitis (UC)) treated between 2002 and 2014 in the Department of Gastroenterology, University Hospital Münster. 317 (35.5%) patients received biological therapy with either Infliximab or Adalimumab (72.6% CD; 27.4% UC). Extent of disease, medical treatment and disease severity was analysed using Partial mayo score (UC patients) or Harvey-Bradshaw Index (CD patients), as documented in medical records. Bodyweight was categorized applying WHO definitions: underweight (BMI $< =18.49$), normal weight (BMI 18.5–24.99), overweight (BMI 25–29.99), and obesity (BMI $> 30$). Additionally, the time to therapeutic failure defined as new course of steroid treatment, escalation/change of medical therapy, hospitalization or surgery, was assessed. Statistical analyses performed were Kaplan-Meier estimator, Cox proportional hazards model and log-rank test.

**Results:** (1) Comparing BMI subgroups of all 894 patients, irrespective of disease severity or mode of therapy, overweight patients had a therapeutic failure latest (18 month, 95%CI: 10.4–25.6), followed by obese (14 month, 95%CI: 5.5–22.5) and normal/underweight patients (9 month, 95%CI: 6.4–11.6; Log Rank $P < 0.05$). To the contrary, an altered BMI was not predictive for an earlier or later therapeutic failure in the group of anti-TNF$\alpha$ treated patients: overweight patients failed after 24 month (95%CI: 12.5–35.5), obese after 19 month (95%CI: 0–38.5) and normal/underweight patients after 16 month (95%CI: 7.5–24.5; Log Rank $P = 0.76$). (2) Multivariate Cox regression of all IBD patients revealed BMI ($P = 0.04$), age at onset of disease ($P < 0.01$), nosologic entity ($P = 0.02$), and disease severity ($P < 0.01$) best predicted therapeutic failure; no associations regarding these variables were found in IBD patients treated with anti-TNF$\alpha$. (3) Assessing the time from start to therapeutic failure in Infliximab and Adalimumab-treated patients, no significant differences were detected between the two most commonly administered anti-TNF$\alpha$ antibodies.

**Conclusion:** In our large single-centre cohort study, BMI correlated strongly with therapeutic success in IBD patients, with rise in BMI reducing the risk of therapeutic failure. However, treatment success in the subgroup of anti-TNF$\alpha$ treated patients was not BMI-dependant. Prospective studies are warranted to further elucidate the impact of body weight on therapeutic success in IBD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Although influenza vaccinations are generally recommended by several guidelines in patients with inflammatory bowel disease (IBD) treated with immunosuppressive and/or biological therapy, the vaccination rate is low. This might be due to the fear of the potential negative effects of the vaccine on the activity of IBD.
**Aims & Methods:** The aim of the study was to assess the influence of the seasonal flu vaccine on the disease activity. Vaccination with the seasonal influenza vaccine was offered to patients. Stool samples were collected from each patient in order to detect calprotectin: one sample at the time of the immunization, and another one a month later. We recorded demographic and clinical data too.
**Results:** We enrolled 36 patients with IBD on immunosuppressive treatment (24 Crohn's disease / 12 ulcerative colitis; 13 male / 23 female, mean ages: 40 years, mean disease duration: 13 years.) Eleven patients received azathioprine monotherapy, 15 patients received biological monotherapy (infliximab/adalimumab) and 10 patients were on combination therapy. The median value of fecal calprotectin was 300 $\mu$g/g at the time of the flu vaccination and it was 330 $\mu$g/g a month later. This difference was not significant ($p = 0.3657$). No significant deviation was found in the laboratory parameters (erythrocyte sedimentation rate, C-reactive protein, leucocytes, haematocrit, thrombocytes) before and after vaccination. Complications after the vaccination were mild: Four patients had local skin reaction (pain, erythema, itches), 6 patients reported "common cold" like symptoms (nasal discharge, dry coughing, fatigue), 2 patients experienced mild relapse. Only one patient perceived "flu like" symptoms such as fever and arthralgia at the 6$^{th}$ week after the vaccination.
**Conclusion:** In our pilot study flu vaccination proved to be safe and did not increase the activity of IBD in patients with immunosuppressive and/or biological therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1363 SATISFACTION WITH LIFE AND COPING IN CROHN'S DISEASE: A GENDER PERSPECTIVE

**Introduction:** Satisfaction with Life (SWL) and Strategies for Coping with disease form important psychological resources in chronic diseases, but are not adequately researched in Crohn's disease (CD). Our aim was to measure these resources and determine their inter-relationships in Crohn's disease, while exploring gender differences.
**Aims & Methods:** CD patients (aged 18 years or greater) completed a questionnaire incorporating demography, Patient Harvey-Bradshaw Index (P-HBI), treatments, Satisfaction with Life Scale and Brief Cope Inventory (COPE). COPE was sub-classified as Emotion-focused Coping (EFC), Problem-focused Coping (PFC) and Dysfunctional Coping (DYS). We used univariate analysis to compare demographics, disease severity, SWL, and coping strategies between genders, and multiple linear regression analysis to construct gender-specific predictor models of SWL.
**Results:** The cohort comprised 402 subjects; men 39.3% and women 60.1%, respective mean ages $36.5 \pm 12.6$ and $40.1 \pm 14.7$ years ($p = .02$), and P-HBI 4.75 and 5.74 ($p = .01$). Economic status, smoking status, medical treatments and hospitalizations did not differ between genders, but men had more surgeries than women (43% vs. 29.5%, $p = .005$). Men and women had similar SWL scores, 22.27 and 22.38. Men and women had similar scores for EFC, $24.61 \pm 5.63$ and $23.66 \pm 5.65$. PFC was used more by women than men, $16.54 \pm 4.61$ vs. $15.02 \pm 4.56$ ($p = .003$). DYS was used more by women than men, $22.62 \pm 5.24$ vs. $21.04 \pm 6.12$ ($p = .002$). P-HBI was correlated significantly with DYS in men (Pearson correlation coefficient .230) and women (.172). SWL was correlated negatively with P-HBI in men (-.281) and women (-.241). SWL was correlated with EFC in women (.246), and with PFC in men (.246). SWL was negatively correlated with DYS in men (-.364) and women (-.214). PFC correlated with EFC, and DYS with EFC and with PFC, in both genders. SWL was correlated positively with economic status in men (.493) and women (.396). Disease duration, patient age and education were not correlated with SWL. When patients were stratified by disease remission (P-HBI) vs. active disease, the significant differences between men and women with respect to PFC and DYS were confined to the patients in remission. Economic status was the principal predictor of SWL in models constructed separately for men (32.6% of explained variance, model adjusted R square = 0.411) and women (15.2%, 0.335) (both $p < 0.001$).
**Conclusion:** SWL in the CD cohort was only moderate, and associated with economic status but also medical and COPE variables. Women used more dysfunctional and problem-focused coping than men, but with active disease these differences were no longer evident. Physician awareness of these attributes may improve patient care.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1364 PREGNANCY DOES NOT AFFECT FAECAL CALPROTECTIN CONCENTRATION IN HEALTHY PREGNANT WOMEN

**Contact E-mail Address:** balint.anita86@gmail.com
**Introduction:** Fecal calprotectin (CP) is a promising activity marker in the differentiation of inflammatory bowel diseases (IBD) vs. functional gastrointestinal diseases. Non-invasive activity markers are extremely important in conditions, like pregnancy, when endoscopy is not recommended to be performed. Few data is available on the alteration of fecal CP concentration during pregnancy.
**Aims & Methods:** The aim of this prospective study was to determine fecal CP concentrations in healthy non-pregnant and pregnant women and in patients with IBD. Healthy women, pregnant women and patients with active and inactive IBD were prospectively enrolled in the study. Demographic and clinical parameters, clinical disease activity scores in case of patients with IBD were recorded. Blood and stool samples were obtained from every patient to determine C-reactive protein (CRP) and fecal CP levels. Fecal CP concentration was quantified by use of enzyme-linked immunosorbent assay.
**Results:** One hundred and thirty-five subjects were enrolled in the study (24 healthy women, 48 healthy pregnant females, 40 patients with active and 23 patients with inactive IBD). Between subjects with IBD (mean: 788 $\mu$g/g, SD: 1215 $\mu$g/g) and without IBD (mean: 36 $\mu$g/g, SD: 23 $\mu$g/g) was shown significant difference regarding to FC ($p < 0.001$). Mean fecal CP and CRP levels were 36.9 $\mu$g/g (SD: 20.4 $\mu$g/g) and 5.53 mg/l (SD: 4.1 mg/l) in pregnant women. FC was significantly higher in active IBD compared to pregnant ($p < 0.001$) and non-pregnant healthy women ($p < 0.001$). No difference could be detected in the fecal CP concentrations between pregnant and non-pregnant healthy women.
**Conclusion:** Since fecal CP levels did not change during pregnancy, it seems to be useful noninvasive diagnostic tool in pregnancy and maybe beneficial in the future for monitoring disease activity in pregnant patients suffering from IBD. Further studies are necessary to confirm these results.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1365 CLINICAL PREDICTORS OF INTESTINAL BOWEL DAMAGE AND DAMAGE PPROGRESSION ASSESSED BY THE LÉMANN INDEX IN PATIENTS WITH CROHN'S DISEASE

**Introduction:** Crohn's Disease (CD) frequently shows a gradual progression, leading to accumulation of structural bowel damage (BD), loss of function and disability. The Lémann Index (LI) is an instrument developed to assess the cumulative BD according to stricturing or penetrating lesions detected at endoscopic and radiological evaluation as well as history of surgical resections [1].
**Aims & Methods:** The aim of this study was to evaluate BD progression by LI scoring in patients with CD, in the attempt to identify factors likely to predict its changes. We retrospectively evaluated all consecutive patients with a diagnosis of CD who received 2 or more serial CT or MR enterographies at at least a 6 months time-distance from 2010 to 2015 at our Hospital. Two gastroenterologists and two radiologists reviewed patients' history, endoscopic examinations and cross-sectional images respectively. Two serial LI evaluations were calculated for each patient and matched with CRP levels, Clinical Disease Activity Index

(CDAI), disease location, disease behavior, medical treatments, CD-related hospitalizations and surgeries using the Spearman correlation, the Wilcoxon or the Mann-Whitney tests, as appropriate.
**Results:** Twenty-eight patients were enrolled (15 men, median age 40.3 years). Most of them had a small-bowel (39%) or ileo-colonic (46%) involvement and a luminal (36%) or a stricturing behavior (43%) at baseline. The median LI was 7.7 (interquartile range [IQR] = 2.7–17.9) at baseline and 9.1 (IQR = 4.1–17.7) after a median of 20.7 months (IQR = 10–27.5). History of surgical resections ($P < 0.0001$), stricturing or penetrating behaviors ($P = 0.0041$) and a disease duration $\geq 10$ years ($P < 0.0001$) were predictive of higher LI value at first evaluation. At follow-up, LI increased in 13, remained unchanged in 9 and decreased in 6 patients. LI was more likely to increase in colonic locations (median delta LI 2.5 versus 0.0; $P = 0.34$) and in patients with a disease duration $< 10$ years (median delta LI 0.625 versus 0.0; $P = 0.059$). LI's progression showed no correlation with CRP levels and CDAI. Anti-TNF$\alpha$ treatments were associated with higher LIs at baseline (median LI 25.5 vs 6.3, $P = 0.0175$), and no improvement at the follow-up evaluation (Delta LI 0.6 vs 0.0; $P = 0.0872$).
**Conclusion:** This study confirms that surgical history, complicated disorders or long duration are independent predictors of BD. These data suggest for the first time that patients with colonic locations or with a recent diagnosis of CD have an increased risk of BD progression, thus suggesting that early therapeutic intervention should be taken into account to reduce damage progression. Further studies should now focus on the possible impact of assessing LI in the evaluation of standard and experimental therapeutic strategies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Optimal patient care in life-long Inflammatory Bowel Diseases (IBD) benefits from the action of a multidisciplinary team. IBD-nurse can help with assessment and management of patients in remission or with active disease.
**Aims & Methods:** We evaluate the concordance between IBD-nurse and physician in computing Clinical Activity Scores in IBD-patients treated with biologics. From July to September 2015 we enrolled all consecutive IBD-patients treated with biologics at our Unit. For each patient a gastroenterologist and a nurse blindly filled-out a form to assess Harvey-Bradshaw Index (HBI) in Crohn's Disease (CD) or partial MAYO score in Ulcerative Colitis (UC). Each index enable to categorize each patient in one among four classes (remission, mild activity, moderate activity, severe activity). All data were recorded in an electronic database to assess beyond chance agreement (concordance) by k statistic.
**Results:** Eighty-seven patients were enrolled (male 45%, female 55%, CD 61%, UC 39%, infliximab 80%, adalimumab 20%). The agreement in all IBD patients by k value was good (66%), ranging from moderate to substantial (95% CI from 51 to 80%). The main reason of disagreement was about scoring of remission versus mild activity and mild activity versus moderate activity, both in CD and UC patients. The prevalence of severe disease activity was too low in the sample to lead to reliable analysis. With regard of single items of HBI the best agreement was for well-being in the previous day (k 62%, 95% CI 39 to 84%) and the less for abdominal mass (k 35%, 95% CI < 0 to 71%).
**Conclusion:** Our study shows a moderate strength of agreement among nurse and gastroenterologist in evaluating disease activity of IBD-patients through calculation of scores largely used in clinical practice. Despite known simplicity of score administration, there is a need to improve concordance in order to optimize patient care.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1367 SYSTEMATIC REVIEW WITH META-ANALYSIS: THE EFFECT OF TOBACCO SMOKING ON THE NATURAL HISTORY OF ULCERATIVE COLITIS

N. To[1], A.C. Ford[1], **D.J. J. Gracie**[2]
[1]*Leeds Gastroenterology Institute, Leeds Teaching Hospitals NHS trust, Leeds/United Kingdom*
[2]*Leeds Gastroenterology Institute, Leeds Teaching Hospitals, Leeds/United Kingdom*

**Contact E-mail Address:** djgracie1982@doctors.org.uk
**Introduction:** It is well established that tobacco smokers are less likely to develop UC than non-smokers. However, evidence for the role of tobacco smoking on the clinical course of UC is less definitive, with conflicting evidence as to whether this influences the likelihood of needing surgery, rates of relapse of disease activity, proximal extension of disease location, or the development of pouchitis. Despite this, recent data suggests that up to 40% of patients perceive tobacco smoking to have a beneficial effect on disease outcomes in UC. (1) These patients may continue to smoke, exposing themselves to the harmful effects of tobacco smoke without any tangible benefit in UC outcome. We have therefore conducted a systematic review and meta-analysis to examine the effect of tobacco smoking on the clinical course of UC. If tobacco smoking does lead to a less complicated disease course in UC, then this may provide the impetus for researchers to investigate the components of tobacco that are beneficial in UC. However, if there is no effect of tobacco smoking on the natural history of UC, then healthcare professionals can be confident in encouraging smoking cessation in patients with UC, due to the multiple other health benefits provided by quitting smoking.
**Aims & Methods:** To conduct a systematic review and meta-analysis of the effects of tobacco smoking on the natural history of UC A search of MEDLINE, EMBASE and EMBASE classic was carried out (up to December 2015) to identify observational studies reporting data on smoking and rates of colectomy, flare of disease activity, proximal disease extension, and development of pouchitis following panproctocolectomy and ileal pouch-anal anastomosis in patients with UC. Dichotomous data were pooled to obtain odds ratios (ORs), with 95% confidence intervals (CIs).
**Results:** The search identified 16 eligible studies: five (2615 patients) studying colectomy; four (620 patients) reporting on flare of disease activity; four (687 patients) examining proximal disease extension; and three (355 patients) assessing development of pouchitis. Compared with non-smokers, the odds ratio (OR) of colectomy (OR = 0.89; 95% confidence interval (CI) 0.62–1.26), flare of disease activity (OR = 1.26; 95% CI 0.65–2.44), proximal extension of disease (OR = 0.57; 95% CI 0.20–1.66), or the development of pouchitis (OR = 0.57; 95% CI 0.21–1.53) were not significantly lower in smokers.
**Conclusion:** This systematic review and meta-analysis has demonstrated that tobacco smoking, when compared with non-smoking, does not appear to have any effect on colectomy rates in UC. Furthermore, smoking was not associated with any reduction in the rates of flare of disease activity, proximal disease extension, or the development of pouchitis. Given the high morbidity and mortality associated with smoking, and the high proportion of patients who may, falsely, perceive a benefit of smoking on disease outcomes in UC, these data reinforce the need for smoking cessation advice to be provided to all patients with IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1368 USEFULNESS OF CONSECUTIVE FECAL CALPROTECTIN MEASUREMENTS TO PREDICT RELAPSE IN INFLAMMATORY BOWEL DISEASE PATIENTS UNDER MAINTENANCE TREATMENT WITH ANTI-TNF DRUGS

**R. Ferreiro Iglesias**[1], M. Barreiro-De Acosta[1], A. Lorenzo-González[2], J.E. Domínguez-Muñoz[2]
[1]*Gastroenterology, University Hospital of Santiago de Compostela. Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain, Santiago de Compostela/Spain*
[2]*Gastroenterology, University Hospital of Santiago de Compostela, Santiago de Compostela/Spain*

**Contact E-mail Address:** rocioferstg@hotmail.com
**Introduction:** Monitoring inflammatory bowel disease (EII) patients with fecal calprotectin (FC) could be useful to predict relapse in clinical practice. Few studies have examined the changes in FC levels during treatment.
**Aims & Methods:** The aim of the study was to evaluate the predictive value of a rapid test of FC to predict flares in IBD patients under maintenance treatment with anti-TNF drugs.
**Methods:** A prospective, observational cohort study was designed. Inclusion criteria were IBD patients in clinical remission for at least six months under a continuous standard dose of 40 mg/eow adalimumab therapy or 5 mg/kg infliximab therapy. Fresh FC was measured using a rapid test (Quantum blue®). FC levels were measured at 4-month intervals for sixteen months. Serum C-reactive protein, erythrocyte sedimentation rate and platelet counts were evaluated in all patients on the same day of faecal sample collection for FC quantification. Relapse was defined as a Harvey–Bradshaw score > 4 in Crohn's disease and a partial Mayo score > 3 in ulcerative colitis. The receiver-operating characteristic (ROC) curve was drawn for diagnostic-accuracy analysis. The optimal cut-off point was that providing the highest sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), positive likelihood ratio (LR +) and negative likelihood ratio (LR-).
**Results:** One hundred and six patients were included (median age 44 years, 51% female), 75% with CD and 25% with UC. After sixteen months of follow-up, 68.4% patients remained in clinical remission whereas the disease relapsed in 31.6% of the patients. FC concentration was significantly higher in those patients who relapsed during the follow-up (477 µg/g, range 131–1800) than in those who maintained in remission (65 µg/g, range 30–880) ($p < 0.001$). The optimal cut-off of fecal calprotectin to predict remission was 130 µg/g according to the ROC analysis. Sensitivity, specificity, positive and negative predictive value of FC to predict relapse were 100%, 80%, 62% and 100%, respectively. FC concentration higher than 300 µg/g resulted in a sensitivity of

66.7%, specificity of 93.8%, positive predictive value (PPV) of 78.3% and negative predictive value (NPV) of 89.4%. The positive likelihood ratio (LR+) is 10.8. Two consecutive FC measurements > 300 µg/g were identified as the best predictor for flare with a PPV of 86%, NPV of 72.7% and LR + 12.9. According to ROC analysis, FC was significantly better to predict relapse than C-reactive protein or erythrocyte sedimentation rate.
**Conclusion:** In IBD patients under anti-TNF therapy, FC is useful to monitor patients for relapse. FC levels lower than 130 µg/g exclude relapse over at least the following four months with a negative predictive value of 100%. FC levels higher than 300 µg/g predict relapse within the following four months with a positive predictive value (PPV) of 78.3%. Two consecutive FC measurements higher than 300 µg/g are the best predictors of flare with a PPV of 86%.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1369 DEVELOPMENT AND VALIDATION OF A DEVICE FOR RAPID MONITORING OF ADALIMUMAB IN SERUM OF INFLAMMATORY BOWEL DISEASE PATIENTS

**Contact E-mail Address:** sumin.bian@kuleuven.be
**Introduction:** Therapeutic drug monitoring of adalimumab is recommended to improve therapeutic outcomes in patients with inflammatory bowel disease. To do this, we previously developed the MA-ADM28B8/MA-ADM40D8 ELISA to measure adalimumab serum concentrations and showed an equal performance of this ELISA compared to TNF-coated adalimumab assays[1]. The disadvantages of ELISA are the rather long time-to-result and the necessity of collecting multiple samples in order to decrease the price per adalimumab determination. Recently, a fiber-optical surface plasmon resonance (FO-SPR)-based sensor was combined with gold nanoparticles to measure infliximab in serum[2].
**Aims & Methods:** To develop and validate an assay for measuring a single adalimumab serum sample within 45 minutes. Similar to ELISA, the capture antibody MA-ADM28B8, was immobilized on a gold-sputtered fiber surface; and the detection antibody MA-ADM40D8 was conjugated to gold nanoparticles to amplify the detection signal. Different concentrations of adalimumab were spiked in buffer and serum diluted 1/400 with the same buffer. Here, a calibration curve was measured using one FO probe which was regenerated between each sample. Infliximab was applied to test the assay's specificity. Performance of the FO-SPR sensor was compared with ELISA using six serum samples of adalimumab-treated patients.
**Results:** A dose-response curve ranging from 2.5 – 40 ng/ml was obtained in buffer and 1/400 diluted serum, allowing quantification of 1 to 16 µg/ml adalimumab in serum. Non-specific infliximab concentrations up to 16 µg/ml showed no significant signals. Using a pre-functionalized fiber, the sensor requires less than 45 min for measuring a single adalimumab serum sample. Comparison of measurements between FO-SPR and ELISA revealed excellent correlation (Pearson r coefficient of 0.994 and intraclass coefficient of 0.993).
**Conclusion:** A rapid bioassay using the FO-SPR platform was established and revealed excellent correlation with ELISA. The reduced assay time and the possibility of measuring a single sample are major advantages compared to ELISA. Considering its full automation and miniaturization, it would be a valuable point-of-care diagnostic tool for adalimumab measurements.

**Introduction:** Serologic nuclear and antimicrobial antibodies have been proposed as predictive markers of disease course and complications in inflammatory bowel disease (IBD), however their stability over time have been questioned.
**Aims & Methods:** The aim of the study was to compare antibody titres before and after treatment in newly diagnosed adult IBD patients with regard to gender, age, disease distribution and grade of inflammation. Patients were included as a part of a prospective population based study (IBSEN II). All diagnoses were revised at follow up. Selected antibodies (ASCA IgA, ASCA IgG, Anti-OmpC IgA, Anti-CBir1 IgG, Anti-I2 and pANCA) (Prometheus laboratories Inc., San Diego) were evaluated at inclusion and follow-up within 2 years. C-reactive protein (CRP) and fecal calprotectin were used as markers for inflammation.
**Results:** In total 221 patients were included. Initially 60 patients were diagnosed as ulcerative colitis (UC), 36 as Crohns disease (CD), 8 as IBD-U, 7 as possible IBD and 110 as non-IBD (controls). All patients, except non-IBD, were invited to follow-up with re-examination within 2 years and 89 accepted. At follow-up 17 patients did not have data on antibodies, reducing the numbers for paired comparison to 36 (UC) and 21 (CD). **Reference values:** (EU/ml, ELISA) for antibodies were: ASCA IgA < 8.5, ASCA IgG < 17.8, Anti-OmpC IgA < 10.9, Anti-CBir1 IgG < 78.4, Anti-I2 < 368, and for pANCA detected (positive) or not detected. UC patients 75% (27/36) was pANCA-positive at diagnosis and 64% (23/36) patients did not change their status at follow-up while 36% (13/36) did. The percentages of positive values of the other antibodies were as follows: Anti-I2 (53%), Anti-OmpC (6%), ASCA IgA (25%), ASCA IgG (3%), and Anti-CBir1 (8%). Additionally they had not changed significantly at follow-up. CD patients ASCA IgA was positive in 38% (8/21) and 43% (9/21) at diagnosis and follow-up, respectively. 24% (5/21) changed their status. pANCA was positive in 48% (10/21) and 33% (7/21) at diagnosis and follow-up, respectively. 33% (7/21) changed their status. Anti-I2 was positive in 71% (15/21) and 67% (14/21) at diagnosis and follow-up, respectively. 14% (3/21) changed their status. Positive values in the remaining antibodies at diagnosis: Anti-OmpC (0%), ASCA IgG (24%, 5/21), and Anti-CBir1 (19%, 4/21). Moreover, no significant changes occurred at follow-up. Phenotype: There were no statistically significant associations between positive serological biomarkers and grade of inflammation, gender and age, nor disease distribution in the IBD study sample. (all $p > 0.60$)
**Conclusion:** Our results suggest that pANCA and ASCA are not stable in IBD patients, in contrast to previous studies. An explanation could be that children are excluded in our study and that there are differences between adults and children with regard to antibody stability. Further, there were no statistical associations between positive serological biomarker (s) as tested and disease phenotype nor gender and age. Our results do not support the use of serological biomarkers as diagnostic nor prognostic tools in an adult clinical practice as a routine practice, however our findings are based on small numbers.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1371 ACQUIRED VON WILLEBRAND SYNDROME IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**Introduction:** Acquired von Willebrand syndrome (AvWS) is observed in numerous diseases, including immunological and cardiovascular disorders, malignancies, myeloproliferative disorders, infections. It can occur as well as a side-effect of some medications. Bleeding from gastrointestinal tract is one of the most important clinical symptoms of AvWS. The diagnosis of the AvWS type 2a is based on the same criteria as the diagnosis of von Willebrand disease type 2 – the ratio of ristocetin cofactor activity (vWF:RCo) to vWF antigen concentration (vWF:Ag) (vWF:RCo/vWF:Ag) or vWF collagen binding test (vWF:CB) to vWF:Ag (vWF:CB/vWF:Ag) should be less than 0.7.
**Aims & Methods:** The study aimed to assess the risk of AvWS occurrence in patients with inflammatory bowel disease (IBD). 85 patients with IBD, including 47 patients with ulcerative colitis (UC) and 38 with Crohn's disease (CD) as well 50 healthy volunteers were involved in the study. In all the patients disease activity, localization of inflammatory changes and presence of complications has been assessed. vWF:Ag, vWF:RCo, vWF:CB, leucocytes, platelets, C reactive protein (CRP), fibrinogen, albumin, haematocrit were measured in all subjects. The ratio of vWF:RCo/vW:FAg and vWF:CB/vWFAg as well the odds

ratio (OR) of vWF:RCo/vWF:Ag or vWF:CB/vWF:Ag less than 0.7 in comparison to the control group was calculated.
**Results:** Plasma vWF:Ag was higher in CD and UC patients than in controls (for both $p < 0.0001$). Additionally, in the IBD group approximately 50% of patients had vWF:Ag higher than 150%, whereas in the control group only 8%. In the UC group the OR of vWF:Ag higher than 150% was 8.7 (95%CI: 2.7–28.1), and in the CD group - 16.2 (95%CI:4.8–54.0) in comparison to the control group. vWF:CB was lower in the UC group in comparison with both CD as well the control group. Such differences were not observed for vWF:RCo. In IBD group there was 13 patients with vWF:RCo/vWF:Ag < 0.7, whereas in the control group there was not any. In UC group OR for vWF:RCo/vWF:Ag < 0.7 was 18.7 (95%CI: 1.0–337.4) in comparison to the control group and in CD group - 20.2 (95%CI: 1.1–370.8). In UC group OR for vWF:CB/vWF:Ag < 0.7 was 11.9 (95%CI: 4.4–32.4) and in CD group 13.3 (95%CI: 4.6–38.1) in comparison to the control group.
**Conclusion:** This is the first study to show that in UC and CD patients there is an increased risk of AvWS occurrence. In spite of tendency to hypercoagulability in IBD patients, in some cases an increased risk of bleeding might be observed. However, research involving a larger number of patients is required to confirm this observation.

## P1372 7-ALPHA-CHOLESTENONE AND FAECAL CALPROTECTIN IN PATIENTS WITH COLLAGENOUS COLITIS

R. Trimble[1], **D. E. Yung**[2], A. Koulaouzidis[2]
[1]*College Of Medicine And Veterinary Medicine, The University of Edinburgh, Edinburgh/United Kingdom*
[2]*The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom*

**Contact E-mail Address:** diana.e.yung@gmail.com
**Introduction:** Collagenous colitis (CC) causes chronic, watery diarrhoea [1]. Bile acid malabsorption (BAM) often accompanies CC [2,3] and CC can respond to treatment with bile acid sequestrants [4]. The European Microscopic Colitis Group (EMCG) advises that BAM should be sought in investigation for CC [1]. The selenium-labelled homocholic acid taurine (SeHCAT) test is considered the gold standard for BAM diagnosis; however, serum 7-alpha-hydroxy-4-cholesten-3-one (7aC) is simpler and less expensive, with comparable sensitivity [5]. Faecal calprotectin (FC) is well established as a biomarker of bowel inflammation, but data on CC is scant [6]. We present data from a tertiary referral centre on 7aC and FC in patients with CC.
**Aims & Methods:** Pathology records were interrogated for patients diagnosed with CC (2000–2015), extracting results on 7aC and FC. Results are presented as mean (±SD) or median (range).
**Results:** Over 15 years, 399 patients were diagnosed with CC (280 F/119 M). Of these, 164 were excluded from further analysis due to lack of appropriate data. 7aC was available in 83 (20.8%) patients, mean levels of 11.5 ± 9.70 ng/ml. 11/83 (13.3%) patients had elevated 7aC. FC levels were measured in 101 (25.3%) patients, mean levels 251.89 ± 282.62 µg/g. Of these, 76/101 (75.2%) had elevated FC ≥ 50 µg/g (FC ≥ 100 µg/g: 63/101; FC ≥ 200 µg/g: 30/101). Of the 101 patients with FC measurement, 76 had FC results ± 30 days from the point of histological diagnosis. In this group, median FC was 165 µg/g, range 20–1375 µg/g.
**Conclusion:** This is the first cohort data on 7aC in CC. Our findings confirm that a significant proportion of CC patients have co-existing BAM; however, the incidence is lower than that reported in other studies using SeHCAT. The high incidence of raised FC in our cohort supports the position that FC is a useful marker of histologic inflammation in CC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Crohn's disease (CD) is a chronical and progressive condition. It has been established that even during remission a subclinical inflammation persists. This condition may lead to stricturing or penetrating lesions and at least surgical resection. To date, the Lémann Index (LI), is the only instrument developed and validated to assess structural bowel damage related to disease evolution. This Index was recently applied in a retrospective study to demonstrate that biological therapy was able to halt CD progression.
**Aims & Methods:** The primary aim of our prospective study was to evaluate the capability of biological therapy to halt or decrease LI in a series of consecutive CD patients. The secondary aim was to correlate delta LI to Harvey Brashaw Index (HBI) and PCR values during a long-term follow up period. We prospectively enrolled consecutive CD patients who were starting biological therapy at our IBD center and we followed-up them every 6 months by means of clinical and biochemical evaluation and every year by radiological and endoscopic assessment in order to calculate the LI. Clinical activity was measured according to HBI (remission defined by HBI < 5) and a CRP < 5 mg/L was considered normal.
**Results:** We prospectively enrolled 39 CD patients (26 Male, median age 38 years, range 18–67) with a median follow-up of 19 months (range 6–28 months). Out of them, 24 (61.5%) were on Adalimumab therapy and 15 (48.5%) patients were on Infliximab therapy. Median LI at the beginning of follow-up and every years for the subsequent two years was respectively 4.6 (0.9–29.8), 4.6(0–29.4) and 2.7 (0–26.2) with no significant difference during these years compared to baseline ($P = 0.53$, $P = 0.25$). There was no significant difference in terms of median LI at the beginning [4.7, (0.9–29.8) vs. 3.2 (1.6–26.5), $p = 0.36$] and end [4.6 (0–29.4) vs. 2 (0–26.2), $p = 0.67$] of follow-up between patients with mild disease compared to patients with moderate/severe disease at baseline. Moreover, there was no difference in terms of median LI comparing patients with an increased CRP values (> 5 mg/L) to patients with normal CRP values both at the start [3.8 (0.9–29.8) vs. 5.7 (1.3–26.6), $p = 0.67$] and end [4.6 (0–29.4) vs. 7.3 (0–29.2), $p = 0.66$] of follow-up period.
**Conclusion:** Our data from a prospective cohort study confirm that biological therapy is able to halt disease progression during a long-term follow up. Moreover, we showed that neither CRP values or HBI as measured at the beginning of biological therapy were able to predict the worsening of bowel damage.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1374 DETECTION OF ANTI-INFLIXIMAB ANTIBODIES IS IMPACTED BY ANTIBODY TITER, INFLIXIMAB LEVEL AND IGG4 ANTIBODIES: A SYSTEMATIC COMPARISON OF THREE DIFFERENT ASSAYS

**Introduction:** There is scant information on the accuracy of different assays used to measure anti-infliximab antibodies (ADAs), especially in the presence of detectable infliximab (IFX).
**Aims & Methods:** We thus aimed to evaluate and compare three different assays for the detection of IFX and ADAs and to clarify the impact of the presence of circulating IFX on the accuracy of the ADA assays. Blood samples from 79 ulcerative colitis (UC) patients treated with IFX were assessed for IFX levels and ADAs using three different assays: an in-house assay and two commercial kits, semi-fluid phase ELISA (SFPE) and Bridging ELISA (BE). Sera samples with ADAs and undetectable levels of IFX were spiked with exogenous IFX and analysed for ADAs.
**Results:** The three assays showed 92–96% agreement for the measured IFX level. However, the in-house assay and SFPE assays detected ADAs in 34 out of 79 samples, whereas BE only detected ADAs in 24 samples. Samples negative for ADAs with BE, but ADA-positive in both the in-house and SFPE assays, were positive for IFX or IgG4 ADAs. In spiking experiments, a low concentration of exogenous IFX (5 µg/mL) hampered ADA detection with BE in sera samples with ADA levels of between 3 µg/mL and 10 µg/mL. In the SFPE assay detection interference was only observed at concentrations of exogenous IFX higher than 30 µg/mL. However, in samples with high levels of ADAs (> 25 µg/mL) interference was only observed at IFX concentrations higher than 100 µg/mL in all three assays. Binary (IFX/ADA) stratification of the results showed that IFX+/ADA- and IFX-/ADA+ were less influenced by the assay results than the double positive (IFX+/ADA+) and double negative (IFX-/ADA-) combination.
**Conclusion:** All three methodologies are equally suitable for measuring IFX levels. However, erroneous therapeutic decisions may occur when patients

show double negative (IFX-/ADAs-) or double positive (IFX+/ADAs+) status, since agreement between assays is significantly lower in these circumstances.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1375 UTILITY OF EMERGENCY DEPARTMENT CT SCANS IN PATIENTS WITH ULCERATIVE COLITIS

**D. Booras**[1], M. Chiorean[2], D. La Selva[2]
[1]*Internal Medicine, Virginia Mason Medical Center, Seattle/United States of America/WA*
[2]*Gastroenterology, Virginia Mason Medical Center, Seattle/United States of America/WA*

**Contact E-mail Address:** dion.booras@virginiamason.org
**Introduction:** Although abdominal CT scans are commonly ordered as part of the emergency department (ED) work-up for patients with ulcerative colitis (UC), their utility in management is unclear.
**Aims & Methods:** Our hypothesis is that most ED CT scans have limited diagnostic and therapeutic impact. The aims of our study were to determine the rate and predictors of ED CT scans among patients with UC. In addition, we also sought to identify variables that can predict significantly abnormal findings on EDCT. Methods: UC patients identified from a single-institution IBD database who were evaluated in the ED from 2009–2015 were retrospectively reviewed. Demographic and clinical data including laboratory and radiological investigations were collected. Patients with recent UC diagnosis ( < 3 months), previous colectomy and those with non-GI-related ED visits were excluded. We determined the proportion of patients with a new major CT finding and evaluated clinical and laboratory predictors of relevant diagnoses. Findings of active colitis on EDCT were censored. We used the X-square test and multivariate regression analysis to test the association of the outcomes with variables of interest.
**Results:** Results: During this interval, 365 UC patients presented to the ED. Of these, 261 were excluded (no GI complaint, no established UC, prior colectomy). The remaining 138 patients (51% male) had a total of 260 ED visits (median 1, range 1–16) of which 38.1% resulted in a CT scan (median 1/patient, range 1–8) and 36 (36.4%) had major new findings (intra and extra-intestinal). In univariate analysis, abdominal pain significantly increased (RR = 1.5; CI 1.2–1.7) and rectal bleeding (RR = 0.38, CI 0.2–0.7) and being on any IBD medications (RR = 0.86, CI 0.75–0.98) significantly decreased the likelihood of ordering a CT scan while a plain abdominal X-ray order had a negative trend. 44% of patients had a CT or MRI in the previous year and this did not affect the chance of getting a new EDCT. In univariate analysis, rectal bleeding (RR = 0.14), diarrhea (RR = 0.33), and an elevated CRP (RR = 0.45) were negative predictors of new significant CT findings while there was no interaction with taking any IBD medications. On multivariate analysis, only diarrhea remained a significant negative predictor (RR = 0.19, CI 0.065–0.58). Overall, 67.3% ED visits resulted in hospitalization, a rate which was not affected by ordering a CT or the presence of significant findings.
**Conclusion:** UC patients presenting to the ED frequently undergo CT scans with relatively modest yield. Diarrhea as the main complaint is the only significant negative predictor for major new findings on the abdominal CT scan. Ordering a CT scan or a new major CT diagnosis did not affect the likelihood of hospitalization. A risk stratification score for improving the yield of EDCT could be developed using simple clinical variables.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** soniamcb@hotmail.com
**Introduction:** Higher tioguanine (6-TGN) levels have been associated with better clinical and endoscopic outcomes in patients with inflammatory bowel disease under thiopurine therapy. Unfortunately dosing of 6-TGN levels is not available in most centers. Previous studies have suggested that an elevated erythrocyte mean corpuscular volume (MCV) can be a valid surrogate of adequate 6-tgn levels.
**Aims & Methods:** This was a retrospective study using a cohort of patients under combination therapy with Infliximab and azathioprine followed in a single center. We evaluated the influence of a ΔMCV in major endpoints including clinical and endoscopic response and remission at the end of the first year of treatment. Clinical response was defined as a decrease of 3 points in Harvey-Bradshaw Index and clinical remission as a Harvey-Bradshaw Index ≤4. Endoscopic response was defined as improvement in endoscopic appearance and endoscopic remission as the absent of ulcers. In a subgroup of patients anti-TNF pharmacokinetics (serum levels and antibodies) were also evaluated.
**Results:** 143 patients with Crohn's Disease (CD) were included, 67 patients (53.1%) male with mean age of 28 ± 11.5 years. MCV at baseline and at week 48 of treatment was 88.2 fL ± 15.8 and 89.7 fL ± 4.7, respectively. At the end of the first year of combination therapy, 13.3% patients achieved clinical response, 74.1% clinical remission, 40.6% endoscopic response and 43.4% endoscopic remission.
Patients with higher variations in MCV were more likely to be in clinical remission (3.16 ± 4.94 vs -0.95 ± 6.44, p < 0.001). There was no statistical significance between ΔMCV and clinical response.
Patients with endoscopic response and remission had higher ΔMCV (2.57 ± 3.70 vs -3.38 ± 7.05, p < 0.001 and 3.17 ± 3.97 vs -0.27 ± 5.74, p = 0.006, respectively). The area under the receiver-operating curve (auroc) for predicting endoscopic remission, endoscopic response and clinical remission according to the ΔMCV was 0.665(95%CI 0.532–0.797, p = 0.025), 0.714 (95%CI 0.545–0.883 p = 0.011) and 0.711 (95%CI 0.616–0.806, p < 0.001), respectively.
For each unit increase in MCV level there was a significant increase in the probability of achieving clinical remission- OR 1.17 (95%CI 1.07–1.27, p = 0.001), endoscopic response- OR 1.29 (95%CI 1.10–1.50, p = 0.001) and endoscopic remission- OR 1.17 (95%CI 1.027–1.326, p = 0.018). There was a negative correlation between C-reactive protein (CRP) levels and ΔMCV (spearman rho -0.254, p = 0.003); patients with a negative CRP at week 48 had higher ΔMCV (5.67 ± 5.37 vs 3.45 ± 4.71, p = 0.012). We found no significant association between ΔMCV and Infliximab through levels and antibodies.
**Conclusion:** Our results suggest that there is an association between ΔMCV and better outcomes in CD patients under combination therapy. Assessment of ΔMCV may be an alternative to 6-TGN dosing where unavailable
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1377 SERUM NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN IN INFLAMMATORY BOWEL DISEASE: A NEW ACTIVITY MARKER

M. Rivero, **M.J. Garcia**, M.T. Garcia-Unzueta, P. Ruiz, S. Alvarez, A. Cimadevilla, B. Castro, J. Crespo
*Gastroenterology, Marqués de Valdecilla Universitary Hospital, Santander/Spain*

**Contact E-mail Address:** digrtm@humv.es
**Introduction:** Neutrophil gelatinase-associated lipocalin (NGAL) is a bacteriostatic protein with pro-inflammatory effect. Furthermore, this protein is overexpressed in patients with inflammatory bowel disease.
**Aims & Methods:** Our aim was determine the relationship between serum NGAL levels, type of inflammatory bowel disease and inflammatory activity. Methods: 17 IBD patients with inflammatory activity and indication of anti-TNF treatment were collected (average age 46 years, 60% women). 3 patients were diagnosed by ulcerative colitis and 14 Crohn's disease. Serum NGAL determination was measured by immunoassays (ELISA) at baseline, post-induction (8 weeks) and 6 months after the initiation of anti-TNF. Regarding the type of anti-TNF treatment, 7 patients received infliximab and 10 adalimumab. Clinical activity index (Harvey-Brandshaw and Mayo Index) and biological markers (RCP, ESR, platelets, leukocytes and hemoglobin) were collected.
**Results:** A decreased of NGAL at 6-month post-treatment was observed in patients who obtained clinical response (n = 10) (20.48 ± 9.33 vs 16.93 ± 4.33 ng/ml; p = ns). However, an increase in NGAL levels was obtained at 6-month treatment in patients without clinical response (n = 7) (21.07 ± 13.36 vs 30.75 ± 19.47 ng/ml; p = 0.043) There was a positive correlation between clinical index and serum NGAL levels at baseline r: 0.52, p = 0.036 and at 6-month after initiation of anti-TNF r: 0.70, p = 0.002. A correlation between serum NGAL levels and biological parameters were observed such as RCP r: 0.61, p = 0.012, platelets r: 0.68, p = 0.004, leukocytes r: 0.72, p = 0.001 and ESR r: 0.56, p = 0.023 at week 8 post-treatment. After 6 months, there was still a positive correlation between NGAL and RCP r:0.70, p = 0.002, platelets r: 0.56, and leukocytes r:0.72, p = 0.001. No correlation was observed between NGAL and hemoglobin.
**Conclusion:** Serum determination of NGAL is useful as biomarker in inflammatory activity in IBD. Serum NGAL is increased in active IBD. A positive correlation is observed between NGAL and other markers of inflammation demonstrating its role in pathophisiology of IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Recently, the Lémann Index (LI) was developed to assess bowel damage (BD) in Crohn's disease (CD). LI should be evaluated by using magnetic resonance (MR) or CT-enterography in association with endoscopy.
**Aims & Methods:** Our aim was to investigate the concordance between ultrasonography-based LI (US-LI) and MR-based LI (MR-LI). We retrospectively evaluated all consecutive CD patients referred to our IBD Unit from February to September 2015. All patients had undergone ileo-colonoscopy, US and MR within 1 month. The US/MR diagnosis of CD and the assessment of extension/complications were performed in accordance with the current literature. US-LI and MR-LI were calculated for each patient by scoring: previous surgery, location, extension, intestinal complications. Furthermore, we evaluated the association between LI and: CD duration (months) and Harvey-Bradshaw index (HBI) and other relevant clinical features. Furthermore, in accordance with recent literature a LI > 4.8 was considered indicative of BD. Statistical analysis included T-student, ANOVA, chi-square, Cohen's k coefficient and Spearman's r test. All differences were considered significant when $p < 0.05$.
**Results:** Finally, 30 CD patients were enrolled. Regarding CD location, 36% showed ileal disease (L1), 10% had an isolated colonic CD (L2) while 64% had an ileo-colonic disease (L3). Moreover, 20% of patients presented a non-complicated behavior (B1); 47% had almost one stricture (B2) while the remaining 33% showed a penetrating CD (B3). Perianal CD was observed in 23% of subjects, while 43% had undergone previous surgery. Mean HBI was 12.7 + 6. When calculating BD, mean US-LI and MR-LI were 6.44 (95%CI 3.6–9.2) and 6.9 (95%CI 4.2–9.7), respectively ($k = 0.90$; $p < 0.001$), with 16 patients (53%) showing a LI indicative of underlying BD. No significant correlation was evident between LI and HBI ($p = 0.9$) while a significant correlation was found between both US-LI and RM-LI and CD duration ($p = 0.01$).
**Conclusion:** US-LI shows high concordance with MR-LI and could be considered a good option for assessing BD in CD by using a high available and relatively inexpensive procedure. Our data confirm the low accuracy of the current clinical activity indices in assessing BD in CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1379 PATIENT-NEAR INFLIXIMAB TROUGH-LEVEL TESTING BY A NOVEL QUANTITATIVE RAPID TEST: THE QUANTUM BLUE INFLIXIMAB ASSAY

I. Lindsjø[1], G. H. Malmstrøm[2], **A. Røseth**[1]

**Contact E-mail Address:** arneroseth@gmail.com
**Introduction:** Therapeutic drug monitoring (TDM) has become standard clinical practice over the last few years. There is overwhelming clinical evidence that optimization of anti-TNF drugs improve clinical outcome partly because this decreases the risk for anti-drug-antibodies (ADA) and improves the efficacy of the drug itself. There is also another aspect for advocating TDM, that is improving the health economic aspect of these very expensive drugs. Approximately 44% of the patients (pts) are correctly dosed, 21% under dosed and 26% had IFX levels above 7, i.e. had unnnecessary high levels. Consequently, nearly half of the pts need a dose optimization. However, this has been hampered by the absence to near patient test which could deliver trough level information within the time frame of a hospital consultation. Currently, tests are mainly ELISA based, performed in a centralized laboratory facility and the test result is usually delayed for several days. This means that when the patients comes for infusion, the trough level is not available for dose adjustment until next infusion time, often weeks away.
**Aims & Methods:** Objective of the study: The study had two aspects; first is to correlate a CE-marked rapid test for IFX trough level, the Quantum Blue Infliximab test (QB-IFX®) (Bühlmann Laboratories, Basel, Switzerland) to an ELISA assay in routine use at the Norwegian Radium Hospital. Secondly, to correlate the performance of such a test done by; A) a nurse and B) a trained laboratory person. Methods and materials: The study comprised 19 pts with IBD receiving IFX treatment (Remicade or Remzina). At the day of infusion, ordinary routine bloodtest (CRP, Hb, LFT etc) and plasma for IFX-trough ELISA was collected in addition to 3 ml serum for QB-IFX rapid test. Part A: A nurse (IS) received one hour of "laboratory" training before running the QB-IFX under supervision of AR. The serum was thawed, vortexed and diluted 10uL in 190 uL assay buffer and again vortexed for 5 sec. 70uL was applied to the rapid test cassette and a 15 min. timer started. A new cassette was loaded every two min. After 15 min, the first cassette was read using the "Q B- IFX®" dedicated electronic reader. Subsequently, a cassette was read every two min thereafter. Part B: The same procedure was followed but this time by a highly experienced lab technician (GHM).
**Results:** The Pearson's r between the QB-IFX and the ELISA was 0.94, $p < 0.0001$. Passing- Bablok analysis resulted in a slope of 1 (0.73–1.17, 95% CI) and a bias (Bland -Altman) of -11%. Furthermore, the Pearson's r between the QB-IFX values done by a nurse and a lab technician was 0.92, $p < 0.0001$.
**Conclusion:** Conclusion: To our knowledge, this is the first study that documents a close correlation between an ELISA test and a 15 min. rapid test for IFX trough level. Furthermore, we have shown that such a test can accurately be performed by a nurse at a point-of-care site, e.g. an infusion centre. The results implies that TDM now can be moved from a distant laboratory to a near pts facility like an infusion centre and ensure correct dosing and instant decision making in IBD as well as in other pts receiving IFX treatment.
**Disclosure of Interest:** A. Røseth: I am affiliated part time with Buhlmann Laboratories as a medical advisor. Otherwise, Im full time employed at Lovisenberg Hospital Oslo

**Contact E-mail Address:** dorit.vedel.ankersen@regionh.dk
**Introduction:** Due to the chronic relapsing nature of Inflammatory bowel disease (IBD) it is of great importance to detect and treat a relapse as soon as possible in order to decrease the total inflammation burden, decrease or postpone the risk of surgery and possibly change of disease course. A validated Fecal Calprotectin (FC) home testing kit and smart phone application (app) has been added to an existing eHealth web app, thereby making it possible for the patients to monitor their disease activity using clinical scores and FC from home. FC levels can be obtained within 18 minutes using the home testing kit and is shown on the smart phone. Results from clinical scores and FC are categorized in a traffic light manner on the eHealth web app for instant recommendation of individualized treatment strategy – treat to target[1].
**Aims & Methods:** Our aim, with this one-year randomized control trail of 120 adult IBD patients, is to determine if an eHealth screening procedure for disease activity should be implemented in clinical practice 'on demand' or 'every 3 months'. Both groups use the web program noh.constant-care.dk to tightly monitor their disease activity either 'on demand' or 'every 3 months'. The web algorithm consists of a short disease questionnaire either Harvey-Bradshaw Index (HBI) for Crohn's disease (CD) or Simple Clinical Colitis Activity Index (SCCAI) for Ulcerative colitis (UC) plus home monitoring of FC, which together gives a total inflammation burden scoring (TIBS). Moreover, but not a part of the TIBS disease activity web algorithm, patients also enter in the web program their fatigue score (FACIT-F), Medication Adherence Report scale (MARS), Quality of Life (s-IBDQ) and Copenhagen IBD Disease Course (CIDC) type. The latter will only be measured at inclusion and at follow up.
**Results:** So far, baseline results of ninety-eight IBD patients are available, 78 with UC and 20 with CD. All of them have fulfilled HBI or SCCAI on the web program at inclusion. Ninety (91.8%) FC results were obtained at baseline and eight (8.2%) were missing. According to the web algorithm, patients were in median in remission in both groups, 'every 3 months' vs. 'on demand', Median (interquartile range): FC in mg/kg 70 (20–560) vs. 88 (20–808), SCCAI: 1 (0–3) vs. 1 (0.5–2.5), HBI 1 (0–2) vs. 3 (1–6) and TIBS 5.5 (0–33) vs. 9 (2–34). Baseline descriptive data for the ninety-eight patients randomized to 'on demand' or 'every 3 months' is listed in table 1 and no significant differences between the two groups were found.
**Conclusion:** Adult IBD patients in remission regarding disease activity were included. Feasibility and usability of the web apps were acceptable and only 8.2% failed home monitoring FC test at inclusion, mostly due to technical problems prior to the app being CE-marked and distributed from App Store and Play Store. Results are awaiting for long-term course.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

| Smoking, number (%) Current Former Never | 4 (8.5) 13 (27.7) 30 (63.8) | 5 (10.6) 15 (31.9) 27 (57.4) | 0.41 |

Imaging (LCI; Fujifilm, Tokyo, Japan) findings of the mucosa and compared these with findings from conventional endoscopy and magnifying chromoendoscopy; furthermore, we compared the extent of mucosal inflammation of biopsied tissues to determine if LCI is suitable to access mucosal healing. LCI is the color enhancement imaging new technology for emphasizing slight color difference on mucosa.

**Aims & Methods:** We performed colonoscopy to assess mucosal healing in UC in clinical remission using the classifications for conventional endoscopy (Mayo endoscopic score 0, 1, 2, and 3) and magnifying chromoendoscopy, followed by LCI. Biopsy samples were obtained from 24 cases and 36 specimens. We focused on acute inflammatory cell infiltration (ACI), chronic inflammatory cell infiltration (CCI), and crypt architectural irregularities (CAI) findings of inflamed tissues, and classified these as 0, 1, 2, or 3 based on severity. LCI was performed with non-magnified observation; those with a clear image of the submucosal vein were classified as LCI-C and those with an unclear image, where the whole image was observed as red, as LCI-U.

**Results:** Mayo endoscopic score 0, 1, and 2 according to the conventional endoscopic classification for LCI-C vs. LCI-U were 79.2%, 20.8%, and 0% vs. 0%, 66.7%, and 25.0%, respectively. Those classified as MR, MI, and MD according to magnifying chromoendoscopy classifications were 58.3%, 41.7%, and 0% vs. 0%, 50%, and 50%, respectively. Compared with biopsied tissue findings, the mean values of ACI, CCI, and CAI were 0.3, 1.2, and 0.8 vs. 0.9, 2.0, and 2.0, respectively. These results indicate that for both endoscopic and histological findings, the extent of inflammation in LCI-C was significantly lower than that in LCI-U.

**Conclusion:** LCI of UC in remission is sufficient to estimate the extent of inflammation in the mucosa, similar to conventional endoscopy and magnifying chromoendoscopy. The estimation of mucosal healing with LCI and magnifying chromoendoscopy is useful to predict the recurrence of UC in remission.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1382 PATENCY CAPSULE RETENTION IN IBD. IS IT ALWAYS DUE TO STRICTURES?

**M. Muscat**[1], J. Gauci[1], P. Ellul[2]

**Introduction:** Capsule retention is one of the complications of Small bowel capsule endoscopy (SBCE). The patency capsule (PC) is a useful tool prior to SBCE as to identify those patients with a higher retention risk. The aim of our study was to determine the patency capsule retention in patients with IBD as compared to non-IBD patients.

**Aims & Methods:** Patients who had a patency capsule (2009–2014) were identified through a database. Their clinical notes were reviewed. Patients were followed for a minimum of 12 months post procedure.

**Results:** 148 patients, mean age being 37.8 years (8–78 years) (76.5% female) were recruited. 23% of patency capsules were retained. 11.8% of these had a repeat patency capsule which was retained as well. The main indication for patency capsule was IBD (38.2%). The rest were performed in the investigation of: anaemia (23.5%), familial polyposis (8.8%), abdominal pain (5.9%), coeliac disease,(5.9%) tufting enteropathy (5.9%), abnormal imaging of the small bowel (5.9%), eosinophilic gastroenteropathy (5.9%). There was no statistically significant difference between IBD and non-IBD patients for PC retention ($p = 0.128$, RR 1.08). As for the retained PC cohort, from the IBD subgroup, 61.5% of patients with normal CT or MR enterography retained the PC. In the non-IBD group, 76.2% with normal CT or MR enterography did not pass the PC. There was no statistically significant difference between the 2 groups ($p = 0.8$).

**Conclusion:** This study demonstrates a high PC retention rate in both groups compared to published data. In patients with IBD, small bowel disease which is not detected on CT or MR imaging may partially account for this. However, a slower transit time may also be responsible in both groups. A careful history together with use of prokinetics and bowel preparation may actually enable the PC to be excreted thus allowing for capsule administration. Furthermore, a PC should always be performed prior to SBCE in patients with IBD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1383 UTILITY OF C-REACTIVE PROTEIN (CRP) IN PREDICTING COMPLICATED DISEASE COURSE IN CROHN'S DISEASE

**I. W. Reilly**[1], Y. Prasad[1], S. Subramanian[2]
[1]*Gastroenterology And Hepatology, Royal Liverpool University Hospital, Liverpool/United Kingdom*
[2]*Royal Liverpool University Hospital, Liverpool/United Kingdom*

**Contact E-mail Address:** i.w.reilly@doctors.org.uk

**Introduction:** Crohn's disease (CD) is a progressive disorder with evolution of disease phenotype from inflammatory to a complicated disease course with stricturing or penetrating behaviour. Early identification of patients likely to develop a complicated disease course will result in better stratification for early, aggressive 'top-down' therapeutic strategy. Currently available clinical predictors (young age, smoking and extensive small bowel disease) have limited sensitivity. Biomarkers such as CRP have long been utilised to monitor both response to treatment and predict need for surgery in isolated ileal CD.(1)

**Aims & Methods:** In this study we sought to identify if CRP at presentation could predict early or late complications in CD. Patients with CD diagnosed at Royal Liverpool University Hospital between 2006 and 2014 were identified from a retrospective database. Those who had CT or MR imaging around time of diagnosis were included in this study. The CRP at diagnosis, smoking status, presence of complications on index and follow up imaging and time to complications were recorded for each case. Continuous variables were summarised as means ± standard deviation (SD) and categorical variables as frequencies. The predictive utility of CRP was examined using a multivariate logistic regression.

**Results:** A total of 81 patients were included in the study, mean age 41 (SD 17.2), of which 28 (35%) were men, 53 (65%) were women and 25 (31%) were smokers. Eighteen (22%) had complications (abscess, stricture) at diagnosis and 22 (35%) had complications at follow up (Median follow up 529 days). Neither smoking (odds ratio (OR) 0.53, 95% CI 0.13–2.18, $P = 0.4$) nor CRP (OR 1.0, 95% CI 0.99–1.01) predicted a complicated disease course at diagnosis. Similarly, smoking (OR 4.3, 95% CI 0.8–21.9, $P = 0.07$) and CRP (OR 1.0, 95% CI 0.99–1.01, $P = 0.36$) did not predict complicated disease course during follow up. However, presence of complications at diagnosis predicted complications at follow up (OR 28.6, 95% CI 4.5–181.2, $P < 0.001$).

**Conclusion:** In a retrospective cohort of CD patients CRP at diagnosis did not predict a complicated disease course in the short or long term. The study was underpowered to confirm that smoking predicts a complicated disease course, but the OR indicates it is likely to be so. Finally, presence of complications at diagnosis was predictive of a complicated disease course at follow up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The timely diagnosis of inflammatory bowel disease (IBD) is still an important challenge and takes several years in the western industrial countries. However, there is no explanation why it takes so long from first symptom to determine the correct diagnosis.
**Aims & Methods:** We evaluated risk factors and circumstances which would lead to a delayed diagnosis of Crohn's disease (CD) or Ulcerative Colitis (UC). 386 adult IBD patients (200 CD = 51.8%, 186 UC = 48.2%, 210 females and 176 males) visiting 3 IBD outpatient clinics of the University hospital Charité and the City Hospital Waldfriede were included in our study. We created a questionnaire to assess patient characteristics like gender, age, residence at diagnosis and we assessed disease dependant symptoms, disease intensity at onset and change of diagnosis. Furthermore we requested intervals from begin of symptoms to first medical contact and determination of diagnosis. Disease characteristics such as disease location, symptom intensity or leading symptoms were assessed. Data analysis was performed using the SPSS 22.0.
**Results:** The mean time from first symptom to diagnosis for all included IBD patients was 8 mo. UC patients were significantly faster diagnosed than CD patients (UC 4 mo. vs.12 mo., $p < 0.0001$). The time interval from first symptom to first physician contact by multivariate data analysis was significantly faster in patients suffering from UC compared to CD (1 mo vs. 2 mo, $p = 0.049$). The diagnosis of UC was mostly diagnosed by gastroenterologist (45.6%) whereas the diagnosis of CD was established during admission to hospital (45%). The faster diagnosis of IBD was made by general practitioners and during hospital admission (each 6 mo). Most frequently the diagnosis was established by colonoscopy (CD:78%, UC:96%). Males were significantly faster diagnosed than females (1.5 mo. vs. 3 mo.; $p = 0.027$). Age at diagnosis or year of diagnosis didn't lead to a diagnostic delay. Severity of symptoms at disease onset significantly influenced the time to diagnosis (UC: $p = 0.002$ and CD: $p = 0.033$). Surprisingly, the time to diagnosis in UC patients with affected family members was significantly longer compared to patients without affected family members (10 mo. vs. 4 mo., $p = 0.0012$). CD patients with affected family members contacted significantly faster a physician (0.5 mo vs. 2.5 mo., $p = 0.003$). Fever lead to a significantly shorter time to diagnosis, whereas the symptom exhaustion lead to a significantly longer time span to diagnosis ($p = 0.038$). Patients with flatulence waited significantly longer to contact a physician (HR 0.27; $p = 0.035$) whereas vomiting and nausea lead to a significantly faster physician contact (HR 1.39; $p = 0.019$). Patients with the leading symptom fistula waited significantly shorter to contact a physician (HR 3.19; $p = 0.013$). Whereas weight loss or skin involvement lead to a faster diagnosis (HR 15.4/6.5; $p = 0.01$ each), joint pain or abdominal pain lead to a delayed diagnosis (HR 0.3/0.7; $p = 0.027$/0.006). There was no correlation between time to diagnosis and residence of the patient. Only 20% of patients had ever heard from IBD. Interestingly, if patients knew about IBD they waited significantly longer to contact a physician compared to patient who never heard about IBD (3 mo vs. 1.4 mo, $p = 0.02$).
**Conclusion:** The delay of diagnosis of IBD is still an underestimated problem leading to a prolonged period of time were patients suffer from symptoms. Surprisingly, patients and physicians share the responsibility for the delay of diagnosis indicating the need for a better information system for physicians but also patients. Especially in context of the worsening of disease course with delay of diagnosis it is extremly necessary to optimize the diagnostic process and to shorten the diagnostic delay.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1385 RELATIONSHIP BETWEEN SERUM INFLIXIMAB TROUGH LEVELS AND LABORATORY PARAMETERS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

**A. Fabian**[1], K. Farkas[1], D. Kanaaneh[1], A. Balint[1], R. Bor[1], M. Rutka[2], A. Milassin[1], T. Ferenci[3], F. Nagy[1], Z.G. Szepes[4], T. Molnar[2]

**Contact E-mail Address:** fabiananna9@gmail.com
**Introduction:** Anti-tumor necrosis factor (TNF)-α, infliximab, is a potent therapeutic option in patients with inflammatory bowel diseases (IBD) of moderate to severe activity. The trough level of anti-TNF-α shows a close relationship with maintained disease activity. Previous studies reported a correlation between serum infliximab trough levels and certain laboratory parameters (C-reactive protein [CRP], albumin) associated with disease activity and suggested a higher elimination rate of the drug by intense inflammation.
**Aims & Methods:** We aimed to investigate the correlation between serum infliximab levels and routine laboratory parameters in patients with inflammatory bowel disease. Blood samples were collected at random intervals from IBD patients before infliximab infusions (originator or biosimilar). Serum infliximab trough levels and antibodies against infliximab were determined with ELISA technique. Various laboratory parameters (including electrolytes, liver, kidney and pancreas function, albumin, CRP, iron, and qualitative blood count) were also measured.
**Results:** A total number of 170 blood samples were collected at random intervals from 64 IBD patients (mean age: 36 years; male/female ratio: 27/37; 25 patients with ulcerative colitis, 39 patients with Crohn's disease). Disease activity was recorded in 93 cases (55%). Dose escalation was necessary in 24 cases (14%). No infusion reaction was reported. Originator product was administered in 35 and biosimilar in 29 patients. The level of antibodies against infliximab was measurable in 30 cases (17.6%). The mean infliximab serum trough level was 6.595 ug/mL. As a result of multivariate analysis, serum infliximab trough levels were significantly lower in case of originator drug administration compared to biosimilar ($p = 0.0019$), in active disease ($p = 0.027$), and in the presence of antibodies against infliximab ($p < 0.0001$). Gender, age and dose escalation did not cause a significant difference in infliximab levels. No correlation was found between the serum levels of infliximab and any of the routine laboratory parameters.
**Conclusion:** As opposed to the literature we were unable to identify a correlation between serum infliximab trough levels and routine laboratory parameters such as CRP or albumin, and therefore no biochemical activity markers can substitute the determination of anti-TNF level.

**Introduction:** Anaemia is an important manifestation of Crohn's disease (CD) and arises, mostly, from iron deficiency or chronic inflammation. It is more common in patients with clinical activity, although it may manifest in sustained clinical remission (CR).
**Aims & Methods:** To determine the factors related to the development of anaemia in a group of patients with CD. One-year cross-sectional single-centre study (2015). Patients with CD followed in an Inflammatory Bowel Disease (IBD) outpatients clinic were evaluated; retrospective review by consulting a national IBD database and medical records. Definitions- anaemia: haemoglobin < 130 g/L in males and < 120 g/L in females; iron deficiency: ferritin < 30 mg/dL; CR: Harvey Bradshaw < 5; endoscopic remission (ER): SES-CD < =2 or Rutgeerts score < i2. Statistical analysis: SPSS V20 (Chi2, Fisher's exact test, Pearson correlation).
**Results:** 127 patients were evaluated, mean age was 47 years (19–85), 58.3% female; Montreal classification: A1/A2/A3: 8/89/30, L1/L2/L3: 44/15/61, L4: 8, B1/B2/B3: 55/31/41, perianal disease: 49; previous abdominal surgery: 52; 26% of the patients had anaemia (n = 33) and 32.3% iron deficiency (n = 41) - ongoing therapy: immunomodulators (IM): 16, anti-tumour necrosis factor (anti-TNF): 6, IM+anti-TNFa: 7, aminosalicylates alone: 4, corticosteroids: 5. Haemoglobin was inversely correlated with C-reactive protein, CRP, ($r = -0.210$, $p = 0.018$). 72.7% of patients with anaemia (n = 24) were in CR and only 5 in ER; MRI or CT enterography was done in 10 patients and 9 had radiographic changes. Factors associated with the development of anaemia were: presentation at diagnosis (anaemia or clinical findings similar to ulcerative colitis were more common, $p = 0.001$), elevated CRP ($p = 0.037$) and endoscopic activity ($p < 0.001$).
**Conclusion:** The development of anaemia in patients with CD, even in clinical remission, should prompt an early assessment of mucosal healing to optimize the therapeutic strategy.

**Introduction:** The absence of specific signs and symptoms in Crohn's disease often cause delay in the diagnosis of inflammatory bowel disease. In this context, it was recently developed the "Red Flags"[1] index, whose purpose is early hospital referral of patients with suspected Crohn's disease.
**Aims & Methods:** Validation of Red Flags index. Retrospective study, considering all patients referred to the query of inflammatory disease, with suspected Crohn's disease between May 2012 to October 2015. "Red Flags" index was calculated, based on the information provided in the first consultation. After diagnostic investigation, crohn's disease was confirmed in some patients and excluded in others. Original cut-off ($\geq 8$) of the red flags index was used.
Statistical analysis (SPSS v20.0): chi-square, t-student, sensitivity, specificity, negative and positive predictive (NPV/PPV) value and area under the curve (AUROC).
**Results:** Considering 91 patients (female: 59.8%, mean age 37 years), Crohn's disease was confirmed in 53.3% ($n = 49$). In 47.3% ($n = 43$), Red Flags index was above 8. The Red Flags index value of $\geq 8$ was associated with the presence of crohn's disease ($p < 0.01$). The original cut off demonstrated a sensitivity, specificity, PPV, NPV for the diagnosis of Crohn's disease of 73.5%, 83.3%, 83.7%, 72.9% (AUROC: 0.80), respectively.
**Conclusion:** The Red Flags Index is associated with the presence of Crohn's disease. The cut off $\geq 8$ showed a good diagnostic capacity.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1388 SOLUBILE TRANSFERRIN RECEPTOR IN DIAGNOSIS OF IRON DEFICIENCY ANEMIA IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**M. Stojkovic Lalosevic**[1], S. Stankovic[2], L. Martinovic[1], M. Vojnovic[1], D. Kojic[3], S. Boskovic[3], M. Stojkovic[3]

**Contact E-mail Address:** drmilicastojkovic@gmail.com
**Introduction:** Soluble transferrin receptor (sTfR) is a dimer protein, and it represents a cleaved extracellular portion of the transferrin receptor 1. Levels of sTfR are related to iron status, and can be used in diagnosis of iron deficiency anemia (IDA), and differentiation from anemia of chronic disease (CDA). Although there are well-known and used markers for differential diagnosis of anemia, such as ferritin, there usage in inflammatory conditions is questionable due to its behavior as acute-phase reactant.
**Aims & Methods:** The aim of our study was therefore to clarify the correlation of sTfR and biochemical, pathohistological and endoscopic findings of patients with inflammatory bowel disease (IBD). A cross-sectional study was preformed among 30 patients with IBD. All patients underwent a total colonoscopy with ileoscopy. Complete blood count was obtained prior to the procedure in addition to inflammatory markers (CRP, erythrocyte sedimentation rate-ESR). Serum iron, TIBC, UIBC were assesed with an electrochemiluminesence immunoassay and sTfR was assessed using an immunoturbidimetric method. Mayo score and CDAI respectively were calculated for each patient.
**Results:** Sixteen patients had ulcerative colitis (UC) and fourteen patients had Crohn's disease. Our results showed that there was no statistically significant difference in all examined parameters (Hemoglobin, MCV, ferritin, CRP, ESR, Iron, TIBC, UIBC, sTfR) between these two groups of patients ($p > 0.05$). There was statistically significant negative correlation between values of Iron, TIBC and sTfR ($p < 0.05$). There was no statistically significant correlation between values of sTfR and disease activity presented by Mayo score, CDAI, endoscopic and pathohistological findings ($p < 0.01$).
**Conclusion:** Our results suggest that sTfR can be a useful parameter for the detection of iron deficiency anemia in IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1389 UPPER ENDOSCOPY IN INFLAMMATORY BOWEL DISEASES (IBD): WHAT CONTRIBUTION?

**F. Er-Rabie**, W. Khannoussi, S.E. Elmahjoubi, A. Elmekkaoui, Z. Ismaili, G. Kharrase
*Gastroenterology, University, Oujda/Morocco*

**Contact E-mail Address:** fadoua.errabie@gmail.com
**Introduction:** IBD mainly affect the colon, the ileus, the jejunum, and the anopérineal area. The systematic search for lesions in the upper digestive tract is still controversial. Nevertheless, it seems that two-thirds of patients who suffer from Crohn's disease and the half of those who have ulcerative colitis may have macroscopic and microscopic abnormalities in their upper gastro intestinal tract. Furthermore, an association between IBD and celiac disease has been described.
**Aims & Methods:** We aim to determine the role of upper gastro intestinal endoscopy in IBD. This is a retrospective descriptive study, including 59 patients who were followed in gastro intestinal department of our University Hospital, and who have had an upper endoscopy. We specified epidemiological, endoscopic and histological features.
**Results:** Among 160 patients who have an IBD, 59 have been included. The mean age was 35 years (range: 17 -68 years). 31 patients (52.5%) had Crohn's disease, 24 patients (40.6%) had ulcerative colitis, and 5 patients (9%) had indeterminate colitis Upper endoscopy was systematically performed in 55 (%) patients, and was indicated for investigation of upper gastro intestinal disorders in 7% (4 patients). It was normal in only 6 patients (10%) and revealed: oesophageal involvement in 5% (3 patients), erythematous antritis in 26 patients (44.4%), congestive fundite in 8 patients (13.5%), ulcerative bulbite in 5 patients (8.4%), atrophic appearance of the duodenal mucosa in 4 patients (6.7%), and aphthoid gastro duodenal ulceration evoking an upper localization of Crohn's disease in 3 patients. Histology allowed the confirmation of Crohn's disease in 12% (4 patients) and highlighted villous atrophy in 5% (3 patients). *H. pylori* was detected in 53% (31 patients). In our study, upper endoscopy was pathological in 89%, it could make the diagnostic of an upper localization of Crohn's disease in 12% among all patients who have Crohn's disease, and an association between Crohn's and celiac disease in 3.3% among all IBD patients.
**Conclusion:** Our study prove that realizing a systematic gastroscopy for all IBD patients is far from being profitable. However, its realizing in symptomatic patients or in case of diagnostic problem (Crohn's Disease, ulcerative colitis?) is much more justified and useful.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1390 SCREENING FOR DYSPLASIA AND COLORECTAL CANCER IN ULCERATIVE COLITIS: AN ALGERIAN STUDY

**Introduction:** Patients with longstanding extensive ulcerative colitis have an increased risk of colorectal cancer.
**Aims & Methods:** The aims of this study were to determine the incidence of dysplasia and colorectal cancer, in patients with longstanding ulcerative colitis. We also evaluated prospectively, the proportion of dysplastic lesions detected by chromoendoscopy from targeted biopsies of macroscopically visible abnormalities, as opposed to random biopsies of colonic mucosa. In this prospective study, consecutive patients with clinically inactive, longstanding UC (8 years) were recruited from 4 centers; colonoscopy with chromoendoscopy using 0.1% methylene blue was performed for each patient. Four mucosal biopsy specimens were taken every 10 cm between the coecum and the rectum, with additional biopsies or removal of any abnormality mucosal. All the endoscopies were performed by a single endoscopist, all the biopsies have been reviewed by a pathologist experienced in gastroenterology.
**Results:** 224 chromoendoscopy were performed in 106 patients. We diagnosed 49 neoplastic lesions in 31 patients; there were 6 adenocarcinomas, 8 high-grade dysplasia, 24 low-grade dysplasia, and 11 lesions indefinite for dysplasia We did 8035 random biopsies witch found 7 dysplastic lesions in 6 patients: 1 high-grade dysplasia, 2 low-grade dysplasia and 4 lesions indefinite for dysplasia.

Random biopsies alone diagnosed dysplasia in 2 patients (1.8%), and had clinical impact only in one patient (0.9%).
**Conclusion:** The risk of colorectal cancer in Algerian ulcerative colitis patients is high. Colonoscopic surveillance is actually the only way to detect colorectal cancer at an early stage in ulcerative colitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1391 NATURAL HISTORY OF NON SEVERE ULCERATIVE COLITIS AT DIAGNOSIS

**W. Dahmani**, W. Ben Mansour, M. h. Loghmari, A. Guedich, L. Safer
*Gastroenterology, Fattouma Bourguiba University Hospital, Monastir/Tunisia*

**Contact E-mail Address:** wafadh115@gmail.com
**Introduction:** The clinical course of ulcerative colitis (UC) may range from a quiescent course with prolonged periods of remission to severe disease requiring intensive medical treatment or surgery. Few data are available for the prevalence and the factors associated with long-term non-severe UC.
**Aims & Methods:** We aimed to assess the natural history of non severe UC at diagnosis and to identify predictive factors of mild evolution over the long term. We conducted a retrospective observational study conducted in a university hospital including patients diagnosed with UC between January 2005 and December 2016. Non severe UC was defined as no requirement for immunosuppressants, anti-TNF and colectomy. Statistical analysis was performed using SPSS v21.0, and a p-value $< 0.05$ was considered statistically significant.
**Results:** Among 105 patients with UC, 78 (74%) had a non severe disease at diagnosis. There were 37 men and 41 women with a mean age of 36.2 years [range: 18–69 years]. The mean follow-up period was of 7.8 years. Nineteen patients (24.4%) had acute severe colitis after a mean period of 40.8 months. Four patients (5.1%) required colectomy. Immunosuppressants were needed in 19 cases (24.4%) and anti-TNF in 2 cases (4.6%). Forty-nine patients (62%) had a non severe disease at the maximum follow-up. Long term non severe UC was significantly associated with the distal location of disease ($p = 0.001$) and the absence of corticosteroid therapy during the first year ($p = 0.002$).
**Conclusion:** In our series, nearly 1/3 of UC with non severe disease at diagnosis became severe with time. Absence of steroid use during the first year and distal location of disease were predictors of a long term non severe outcome.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** tohmori@ige.twmu.ac.jp
**Introduction:** Crohn's disease (CD) patients with no symptoms and negative inflammatory markers still may be at risk of relapse. Capsule endoscopy (CE) allows convenient visualization and scoring of the mucosal condition at sites of small bowel lesions in CD patients. However, in many patients with no symptoms and CE suggesting no activity together with negative inflammatory, indications for starting treatment are unclear. This study was to understand the long-term outcomes in such patients, to determine the indications for initiating treatment for CD based on CE.
**Aims & Methods:** Between July 2012 and December 2015, CE was undertaken in 80 patients with CD after patency was confirmed by a patency capsule. Twenty-five patients who required treatment within 3 months after CE were excluded, and eleven patients who had CDAI $\geq 150$ or CRP $\geq 0.5$ mg/dl were excluded, and 44 were evaluated. At CE, the Capsule Endoscopy Crohn's Desease activity index (CECDAI) was determined and the patients were divided into a CECDAI $\leq 3$ group ($n = 27$) and a CECDAI $\geq 4$ group ($n = 17$). The rationale for classification into two groups was as follows. A CECDAI score of 3.8 is believed to be equivalent to a Lewis score of 135; CECDAI $< 3.8$ and Lewis $< 135$ are considered normal (quiescent disease), while a CECDAI score of 5.8 is equivalent to a Lewis score of 790; CECDAI $\geq 5.8$ and Lewis $\geq 790$ indicate moderate to severe disease. Since the CECDAI score is calculated as an integer, a score of $\leq 3$ is normal in clinical setting.
**Results:** The included patients were 22 male, and 22 female, average age $39.8 \pm 15.9$ years. Likewise, the average duration of CD was $119 \pm 88$ months. In 13 patients, CD lesions were confined to the small intestinal, and 31 patients had small and large intestinal involvement. At CE, the CDAI score was $66 \pm 33$, albumin (Alb) $= 4.3 \pm 0.3$ g/dl, and C-reactive protein (CRP) $0.13 \pm 0.11$ mg/dl. There was no significant difference between the 2 groups with respect to age, disease duration, medications including corticosteroids biologics, immunomodulators, surgical history, haemoglobin, Alb, CRP, or CDAI score. However, the Kaplan-Meier survival analysis showed a significant difference between the CECDAI $\leq 3$ and the CECDAI $\geq 4$ groups ($P = 0.0358$, Wilcoxon test).
**Conclusion:** We found that significantly more patients with the CECDAI $\geq 4$ required treatment intensification, or needed to switch to an alternative treatment over the long-term after CE, even when CDAI or CRP was not high at the time of CE. Based on these observations, we believe that the justification for starting aggressive therapeutic intervention in the clinical practice setting is not clear, if the patient has no symptoms. In contrast, if a patient has a CECDAI score of $\geq 4$, diligent monitoring is warranted to suppress a likely CD flare up.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In the COLLECT study the Toll like receptor (TLR-) 9 agonist cobitolimod (formerly known as DIMS0150, Kappaproct®) was evaluated for its therapeutic efficacy in ulcerative colitis patients refractory to conventional therapy.
**Aims & Methods:** In this post hoc analysis the clinical effects of cobitolimod were analysed in anti-TNF-antibody experienced versus naive patients with active ulcerative colitis. Cobitolimod was studied in a randomized, double blind, placebo-controlled, multicentre, pan-European trial named COLLECT in 131 patients with moderate to severe active ulcerative colitis defined by a CAI score of 9 and more. Patients were on mandatory steroid therapy and could be taking sulphasalazine, aminosalicylates, or thiopurines at stable doses. Patients were randomly assigned to receive two single doses of cobitolimod (30 mg) or placebo (in a 2:1 ratio) topically through the endoscope to the inflamed mucosa at baseline (week 0) and after 4 weeks (week 4). For this post-hoc analysis efficacy was studied using the secondary endpoint symptomatic remission (SR) (absence of blood in stool and mean weekly stools $< 35$) at week 4, 8 and 12. As endoscopic examination was performed at week 4 and 12 symptomatic remission in combination with mucosal healing (MH) defined as endoscopic Mayo score £1 were assessed at week 4 and 12. In the FAS (full analysis set) population 39% of the patients had received anti-TNF-antibody treatment before inclusion, which was discontinued at least 4 weeks before study enrolment, and 61% of the patients were anti-TNF-antibody naive.
**Results:** In the anti-TNF experienced patient population symptomatic remission was achieved in 16/26/29% of the cobitolimod vs. 6/12/18% in placebo treated patients at week 4/8/12, respectively. In the anti-TNF naive patient population symptomatic remission rates were higher with 42/56/52% in the cobitolimod vs. 19/39/42% in placebo treated patients at week 4/8/12, respectively. With respect to the endpoint symptomatic remission plus mucosal healing the anti-TNF experienced patient population showed remission rates of 10/23% for cobitolimod vs. 6/18% for placebo treated patients at week 4/12, respectively. In the anti-TNF naive patient population absolute remission rates for SR plus MH were again higher with 28/38% of the cobitolimod vs. 0/27% in placebo treated patients at week 4/12, respectively.
**Conclusion:** Those post-hoc results of the COLLECT study demonstrate that dual topical administration of the TLR-9 agonist cobitolimod is able to induce clinical remission both in anti-TNF-antibody experienced and naive UC patients. As expected, absolute remission rates in anti-TNF experienced patients are smaller, but with a similar effect-size to anti-TNF naive patients compared to placebo treated patients of the same subgroup. Therefore, the concept of TLR-9 activation is a promising and well-tolerated novel therapeutic option both for anti-TNF-antibody pre-treated and anti-TNF naive ulcerative colitis patients.

**Introduction:** Biosimilar infliximab was authorized by the EU in 2013 for the treatment of active fistulising Crohn's Disease (CD).

**Aims & Methods:** Our aim was to analyze the cost-effectiveness of biosimilar infliximab (by Hospira UK) in Belgium, France, Germany, Hungary, Italy, The Netherlands, Sweden and in the United Kingdom. A Markov model was developed to assess the cost-utility of biosimilar infliximab, as well as of treatment sequences involving three biologicals followed by standard care on a 5-year time horizon from the third party payers' perspective. Input data on effectiveness and health state utilities were obtained from the literature and assumptions were made if disease-specific data were not available. Country-specific costs and discount rates were considered. Uncertainty was assessed by one-way and probabilistic sensitivity analysis.

**Results:** Applying standard care as comparator scenario in all analyses, the incremental cost-utility ratio (ICUR) of biosimilar infliximab varied significantly across countries (from €24.785/QALY in Hungary to €52.235/QALY in Sweden) but was lower in each country compared to the originator drug (the lowest ICUR was calculated for Hungary: €49.286/QALY; and the highest for Germany: €96.494/QALY) and also compared to adalimumab (the lowest in France: €61.799/QALY; the highest in Germany: €136.118/QALY). The ICER of biosimilar infliximab-adalimumab-vedolizumab sequence (€51.506-€84.403/QALY) was lower in all countries than the same sequence with the originator infliximab (€65.612-€107.199/QALY), and was also lower than of adalimumab-biosimilar infliximab-vedolizumab strategy (€53.337-€88.050/QALY). Results of biosimilar infliximab-adalimumab-vedolizumab treatment sequence were the most sensitive to the perspective of the analysis, utility weights and the time horizon. Taking into account productivity loss, ICERs decrease by 4–25% across countries. A 10% increase in utility weights decreases the ICERs by 9% and a 10% decrease increases by 11% in all countries. On a 10-year time horizon ICERs decreases by 6–8%.The change of the assumption for biosimilar infliximab price from 50% of originator infliximab price to 40% and 60% ICERs change by 4–6%.

**Conclusion:** Applying biosimilar infliximab instead of the originator product is a cost-effective alternative that makes biological treatments more affordable and might facilitate access. Given the significant impact of utility weights on the results and the scarcity of available data, preference based quality of life studies focusing specifically on fistulising CD patients are encouraged in order to improve the validity of the analyses.

**Introduction:** Anti-tumour necrosis factor (TNF) s form a major part of therapy in Crohn's disease with a primary non-response rate of 10–30% and a secondary loss of response rate of 5% per patient-year. BMI has been linked to primary non-response in observational cohort studies and may be due to pharmacokinetic effects on drug levels.[1] Myopenia is prevalent in patients with Crohn's disease who are in clinical remission and can be measured using body composition analysis tools.

**Aims & Methods:** The composition of a patient's body mass may demonstrate a more refined method of analysis and can predict for outcomes of anti-TNF primary non-response and secondary loss of response. Between January 2007 to June 2012, 650 anti-TNF-naïve patients underwent anti-TNF therapy for Crohn's disease in a single centre. Demographics including age, sex and BMI were collected. Patient's Montreal classification at diagnosis was identified. Primary non-response was defined as cessation of anti-TNF within 6 months of first administration as deemed by their treating gastroenterologist using global physician assessment. Secondary loss of response was defined as a recurrence of patient's symptoms after a period of improvement with subsequent need for cessation or switch of anti-TNF therapy. CT images were analysed for body composition parameters and used to estimate body fat-free mass. The outcome measures were primary non-response and secondary loss of response. COX-regression analysis was used to predict for outcomes with three-year follow-up data. A hypothetical dose of 5 mg/kg was delivered with estimated tissue levels.

**Results:** Of the 650 patients with anti-TNF therapy, 106 were included. 26 (24.5%) were primary non-responders and 29 (27.4%) had secondary loss of response. 13 patients were obese (BMI $>30$). Sex-specific cut-offs that defined a significant association between low muscle, high visceral fat and myosteatosis with outcomes were ascertained by stratification analysis. There were 26 patients (24.5%) who experienced primary non-response. Of these, 15 (57.7%) were myopenic. There were 6 (25%) patients with nonvisceral obesity and 5(25%) with myosteatosis. On multivariate analysis, myopenia predicted for primary non-response (HR4.74;1.81–12.39, $p=0.002$) to anti-TNF therapy (See Table 1). No other factors (visceral obesity, myosteatosis, age, gender and type of anti-TNF) were associated with LOR or PNR (Table 1). In patients with PNR, 15 (57%) were myopenic. In out cohort, 29 (27.4%) patients had secondary loss of response. The reason for the switch or cessation of anti-TNF therapy was due to recurrence in symptoms. Of the patients that had secondary loss of response, 7 (24.1%) were myopenic, 8 (27.6%) had visceral obesity and 5 (17.3%) had myosteatosis. However, on univariate analysis, there were no significant factors for prediction of secondary loss of response (Table 3). The association between estimated total body fat-free mass and BMI was poor ($r^2=0.15$). A consequence of high fat mass or low fat free mass would be a larger volume of distribution of anti-TNF therapy. A hypothetical dose of anti-TNF at 5 mg/kg of body weight was administered with calculated variations in the resulting anti-TNF per kg estimated fat-free mass. The overall distribution of estimated anti-TNF per kg fat-free mass varied greater than six-times (range 14.36– 97.92 mg anti- TNF per kg). Men were more likely to have a lower fat-free mass in proportion to their BMI than women ($p=0.05$), and thus a larger proportion of men than women were in the highest ranges of anti-TNF per kg fat-free mass.

**Table 1:** The relationship between PNR and clinico-pathological parameters

| | | Univariate Analysis | | Multivariate Analysis | |
|---|---|---|---|---|---|
| | | OR 95% CI | p-value | OR 95% CI | p-value |
| **Gender** | Male | 1 | | | |
| | Female | 1.37 (0.56–3.40) | 0.488 | | |
| **Age** | (b = -0.002) | 0.99 (0.96–1.03) | 0.910 | | |
| **Myopenia** | Absent | 1 | | 1 | |
| | Present | 4.69 (1.83–12.01) | **0.001** | 4.73 (1.81–12.39) | **0.002** |
| **BMI** | BMI < 30 | 1 | | | |
| | BMI > 30 | 0.52 (0.11–2.52) | 0.420 | | |
| **Visceral Obesity** | Absent | 1 | | | |
| | Present | 1.03 (0.36–2.96) | 0.951 | | |
| **Mysoteatosis** | Absent | 1 | | | |
| | Present | 1.13 (0.33–3.17) | 0.923 | | |
| **Myopenic Obesity** | Absent | 1 | | | |
| | Present | 0.52 (0.11–2.53) | 0.420 | | |
| **Anti TNF drug** | Infliximab | 1 | | 1 | |
| | Adalimumab | 0.32 (0.10–0.98) | **0.048** | 0.31 (0.09–1.06) | 0.061 |

**Conclusion:** For patients with CD, certain BC profiles may demonstrate predictive effect on treatment responses. Our study has identified myopenia as a significant predictor of primary non-response of anti-TNF therapy in Crohn's patients. Adjusting dosage and undertaking a holistic management approach with nutrition and muscle-building exercises may improve therapeutic outcomes in patients commencing anti-TNF therapy.

## P1396 PLACENTAL MADCAM1 EXPRESSION – POTENTIAL CONSEQUENCES FOR THE TREATMENT WITH VEDOLIZUMAB DURING PREGNANCY

**Z. Zelinkova**[1], K. Berakova[2], D. Podmanicky[3], B. Kadleckova[4]
[1]*Gastroenterology, St Michael's Hospital, Bratislava/Slovak Republic*

[4]*IBD Center, Assiduo, Bratislava/Slovak Republic*

**Contact E-mail Address:** zelinkova@assiduo.sk
**Introduction:** Inflammatory bowel diseases (IBD) affect patients in reproductive age. Over the past two decades, the experience with the treatment of IBD during pregnancy has been increasing and most of the IBD drugs have been shown to be effective and safe for the use by the mothers-to-be. Vedolizumab, a monoclonal antibody against alpha4beta7 integrin has been shown to be effective in inducing and maintaining remission in IBD. By blocking alpha4beta7, it is preventing the homing of lymphocytes to the gut mucosa through binding to mucosal vascular adressin cell adhesion molecule 1 (MadCAM1) localised on the endothelial cells. As with other biologicals in the past, the question arises on the safety of the use of this novel molecule during pregnancy. Embryonic implantation is a complex process orchestrated by maternal immune response. It is not clear whether MadCAM1 is expressed in human placenta which could have consequences for the local immune response during pregnancy in case of alpha4beta7 blockade. Therefore, the aim of this study was to determine the expression of MadCAM1 in the placental tissue.
**Aims & Methods:** Placental tissue of 15 placenta's from spontaneous abortions occurring during the first trimester and 12 mature placenta's were stained by immunohistochemistry for the expression of MadCAM1. The localization of positive cells was determined based on the comparison with the hematoxylin-eosin staining. Samples from small intestinal wall were used as positive controls.
**Results:** MadCAM1 was expressed invariably by decidual vessels, syntiotrophoblast and cytotrophoblast in all samples from the first trimester. In contrast, there was no expression of MadCAM1 in the samples from mature placenta's.
**Conclusion:** MadCAM1 is expressed in human placenta during the first trimester. Blocking alpha4beta7 integrings may thus interfere with the maternal immune surveillance crucial for the successful course of early stages of the pregnancy.

**Introduction:** Topically acting mesalazine suppositories are the gold standard for the treatment of active proctitis. In some patients, alternative treatment options are needed.
**Aims & Methods:** To compare the efficacy and safety of two different dosages of a novel budesonide suppository vs a mesalazine suppository vs a combination treatment of budesonide/mesalazine suppositories in active ulcerative proctitis (modified UC-DAI 4–10, with endoscopic subscore $\geq$ 1). This was a prospective, double-blind, double-dummy, randomised, multicenter Phase II trial in 337 patients (ITT population) with active proctitis, comparing the following 4 different suppository treatment arms over 8 weeks: budesonide 2 mg (BU2; n = 89 patients), budesonide 4 mg (BU4; n = 79), mesalazine 1000 mg (ME; n = 81); BU2 plus ME (BUME; n = 88). Primary endpoint was the time to resolution of clinical symptoms defined as the first day of 3 consecutive days with a score of 0 for rectal bleeding and stool frequency.
**Results:** Mean time to resolution of symptoms was [days] 35.5 in BU2, 29.8 in BU4, 29.2 in ME and 29.3 in BUME (BU2 vs BUME, p = 0.032; BU2 vs ME, p = 0.046). Clinical remission (modified UC-DAI subscores "rectal bleeding" and "stool frequency" = 0) occurred in 49.4% of patients in BU2, 57.0% in BU4, 66.7% in ME and 58.0 in BUME; BU2 vs ME ($p < 0.05$). Endoscopic remission (modified UC-DAI subscore < 2 AND at least 1 point reduction) was observed in 68.5% with BU2, 75.9% with BU4, 77.8% with ME, and 81.8% with BUME. 45.5% of patients improved histologically in BU2, 51.9% in BU4, 60.5% in ME, and 56.8% in BUME. Physician's and patient's global assessment was at least good in 68.5% and 71.9% with BU2, 81.0% and 84.8% with BU4, 82.7% and 87.6% with ME, and 90.9% and 89.7% with BUME, respectively. Majority of patients assessed administration of both suppositories as easy and did not have any preference. No serious adverse event and no unexpected adverse drug reaction occurred in the study.
**Conclusion:** BU4 was more efficacious than BU2 and similarly efficacious than the standard ME. The combination treatment BUME did not result in major advantages compared to BU or ME monotherapy in this patient population. BU4 appears to be an effective and safe novel treatment option for proctitis.

## P1398 VSL#3 IS NO LONGER VSL#3 IN CONTINENTAL EUROPE: WARNING FOR DOCTORS AND PATIENTS

**C. De Simone**
*University L'Aquila, l'Aquila/Italy*

**Contact E-mail Address:** claudio.desimone@bluewin.ch
**Introduction:** The probiotic mix VSL#3 has built strong scientific evidence over the last 2 decades and is recognized by main Gastroenterology Associations (AGA, ECCO) for the prevention of onset and maintenance of pouchitis as well as for Ulcerative Colitis. Recently, a formulation produced by a different manufacturer (therefore different from the original formulation) has been launched under the same brand VSL#3 in Italy, Holland and sporadically in the UK., causing confusion to healthcare providers and patients regarding safety and efficacy.
**Aims & Methods:** Viability and functional expression of probiotic bacteria are influenced by a variety of external factors, including fermentation conditions (i.e. micronutrients, pH etc.), method of concentration and method of stabilizing the culture, including storage conditions. These changes impact on the numeric recovery of live /dead bacterial cells and their effect on host biomarkers, such as immune cells, anti-inflammatory profile, and biochemical patterns. (1,2,3). The "original VSL#3" formulation endorsed by the Guidelines was therefore compared with the "new VSL#3" formulation. The live/dead status of bacteria was assessed using a mixture of SYTO® 13 green fluorescent nucleic acid stain (live bacteria) and the red fluorescent nucleic acid stain, Propidium Iodide (PI) (dead bacteria). The two formulations were also tested on different cell lines for DNA cycle and cell apoptosis.
**Results:** The "new VSL#3" has 233% more dead bacteria than the "original VSL#3". The percentage of dead bacteria in the single sachet is an important parameter since: (a) it is a good predictor of the quality of the product and its shelf life stability, and (b) "dead bacteria" are biological response modifiers. The two formulations are also different when tested on different cell lines. The "original VSL#3" influences cell cycle profile differently when compared to the "new VSL#3", in particular in its capability to arrest the cells in G0/G1 phase and in inducing the apoptotic death. Consistent with the increased apoptosis, a statistically significant reduced number of cells treated with the "original VSL#3" is observed in the G2 phase when compared to the "new VSL#3" and correlates with a reduced proliferative index of cells treated with "original VSL#3" compared to "new VSL#3". Since this test is the final outcome of a very complex cascade of a number of immunological and biochemical pathways activated by the bacteria present in the formulation, the results are relevant for IBD patients who, because of their chronic inflammatory state, are at high risk of cancer.
**Conclusion:** These preliminary assessments confirm that the "new VSL#3" is different from the "original VSL#3" thus impacting the specific activity, synergy and characteristics of this complex bacterial blend. Doctors and patients must be informed that all previous studies, clinical experiences and recognition by AGA and ECCO cannot translate to the "new VSL#3" and thus imposes the need for proper assessment of the safety and clinical efficacy of the "new VSL#3".
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1399 CALPROTECTIN IS LESS ACCURATE THAN MAYO ENDOSCOPY SCORE TO MONITOR CONTINUOUS CLINICAL RESPONSE IN PATIENTS WITH MODERATE TO SEVERE ULCERATIVE COLITIS

W. Reinisch[1], J. Colombel[2], A. Khalifa[3], R. Yao[4], S. Huyck[4], G. Philip[4], **F. Cornillie**[3]

**Contact E-mail Address:** freddy.cornillie@merck.com

**Introduction:** Continuous clinical response (CCR) is an endpoint applied in the PURSUIT maintenance (M) trial to reflect the performance of patients over time.[1] Calprotectin is a faecal marker highly associated with mucosal inflammation in ulcerative colitis (UC).[2]

**Aims & Methods:** We investigated whether change of calprotectin levels during follow-up of UC patients taking golimumab Q4W can replace endoscopy as an objective measure of disease activity in UC. This is a post-hoc analysis of the PURSUIT-M trial, whose primary endpoint was CCR, defined as sustained clinical response assessed by partial Mayo score Q4W and Mayo score at weeks 30 and 54.[3] We compared the association of CCR with the Mayo endoscopy score (at weeks 30 and 54) to the association of CCR with the change of calprotectin levels from pre-induction baseline to weeks 30 and 54. CCR implies Mayo response, including endoscopic response at weeks 30 and 54; therefore weeks 30 and 54 endoscopic score were used as the reference to test the accuracy of calprotectin change. Comparative evaluation of receiver-operating characteristic curve AUC data was performed using the DeLong method.[4]

**Results:** The Mayo endoscopy score at weeks 30 and 54 was highly associated with CCR through 54 weeks: AUC of 0.83 and 0.90, respectively (**Table**). Compared to the Mayo endoscopy score as the reference, the association (AUC) of change of calprotectin levels from baseline to weeks 30 and 54 was 0.66 and 0.64, respectively. At both weeks 30 and 54, change of calprotectin levels from baseline was significantly less accurate than the Mayo endoscopy score in predicting CCR ($P < 0.0001$ for both weeks 30 and 54).

| Testing for Association with CCR | Change of Calprotectin Levels From Baseline | Mayo Endoscopy Score |
|---|---|---|
| Week 30 (n = 432) | | |
| AUC | 0.6605 | 0.8308 |
| Difference | −0.1703 ($P < 0.0001$) | reference |
| Sensitivity/Specificity | 0.73/0.57 | 0.89/0.73 |
| Week 54 (n = 428) | | |
| AUC | 0.6389 | 0.8979 |
| Difference | −0.2589 ($P < 0.0001$) | reference |
| Sensitivity/Specificity | 0.65/0.58 | 0.91/0.84 |

AUC=area under the curve.

**Conclusion:** Change of calprotectin levels from baseline to weeks 30 and 54 in PURSUIT-M less accurately predicts CCR compared to the Mayo endoscopy score. Although early change in calprotectin levels (from baseline to week 6 of PURSUIT induction) is a predictor of CCR,[5] its accuracy to monitor CCR during maintenance is lower than that of endoscopy. Our data thus support endoscopy as the superior objective assessment of mucosal activity in UC versus calprotectin, which can be considered an adjunctive biomarker as suggested in the STRIDE consensus.[1]

## P1400 THE COMBINED CELL AND ANTICYTOKINE THERAPY PROMOTES DEEP REMISSION OF CROHN'S DISEASE

O. Knyazev, **N. Fadeeva**, A. Parfenov, S. Khomeriki, K. Noskova
*Ibd, Moscow Clinical Research Center, Moscow/Russian Federation*

**Contact E-mail Address:** chueva@mail.ru

**Introduction:** Anticytokine therapy with anti-TNF-a drugs contributes to deep remission of Crohn's disease (CD). At present, for the treatment of CD used mesenchymalstem cells (MSCs). Simultaneously, MSCs, patients receiving concomitant immunosuppressivetherapy. At the present time has not been studied clinical efficacy of combined use of MSCs and anti-TNF-a drugs in the treatment of patients with CD.

**Aims & Methods:** We aimed to examine the efficacy of combination therapy of mesenchymal stem cells (MSCs) of bone marrow, and infliximab (IFX) to achieve immunobiological and histological remission in patients with Crohn's disease. Methods: Sixty-seven patients with CD (colitis and ileocolitis) divided into 3groups. The first group of patients CD (n = 21) received standard anti-inflammatory therapy + MSCs. The second group (n = 30) received therapy anticytokine IFX. A third group of patients with CD (n = 16) received anticytokine therapy IFX + MSCs. Immunobiological effectiveness of the therapy was evaluated by the level of CRP and fecal calprotectin (FCP) and pathomorphological assessmentwas evaluated by index of Geboes. Evaluation of efficacy was performed after 2,12 and 24 months after initiation of therapy. Baseline CRP in acute disease ingroup 1 was 24.0 6 1.9 mg/L in the 2nd—22.5 6 2.1 mg/L ($P = 0.37$) in 3rd—23.06 2.4 mg/L ($P = 0.47$). Baseline FCP in the 1st group was 804.8 6 88.8 mg/g, inthe 2nd—848.3 6 83.9 mg/g ($P = 0.09$), in the 3rd—937.5 6 125.6 mg/g ($P = 0.006$). The index of Geboes in the 1st group was 4.4 6 0.2 points, the 2nd—4.356 0.2 points ($P = 0.11$), in the 3rd—4.6 6 0.3 points ($P = 0.002$).

**Results:** After 2 months, the level of CRP in patients in the 1st group was 9.8 6 1.1 mg/Lin the 2nd—8.4 6 1.3 mg/L ($P = 0.14$) in 3rd—7.9 6 0.9 mg/L ($P = 0.18$). The level ofthe FCP in patients in 1st group was 88.8 6 5.3 mg/g, in the 2nd—90.6 6 6.8 mg/g ($P = 0.001$), in the 3rd—68.8 6 3.3 mg/g ($P < 0.001$). The index of Geboes in the 1st group was 0.7 6 0.1 points ($P < 0.17$), in the 2nd—0.66 6 0.1 points, 3rd—0.5 6 0.06 points ($P < 0.001$). After 12 months, the level of CRP in patients in the 1st group was 7.95 6 0.2 mg/L in the 2nd—8.0 6 0.2 mg/L ($P = 0.39$) in 3rd—8.1 6 0.2 mg/L ($P < 0.11$). The level of the FCP in patients in 1st group was 85 6 5.0 mg/g, in the 2nd—95 6 3.5 mg/g ($P < 0.001$), in the 3rd group—75 6 5.0 mg/g ($P < 0.001$). The index of Geboes in the 1st group was 0.9 6 0.1 points in the 2nd—1.1 6 0.1 points ($P < 0.001$), in the 3rd group—0.8 6 0.1 points ($P < 0.001$). After 24 months the average level of CRP in patients in the1st group was 9.6 6 2.2 mg/L in the 2nd—9.4 6 1.1 mg/L ($P$ ¼ 0.67) 3rd—7.9 6 0.9 mg/L ($P = 0.004$). The level of the FCP in patients in 1st group amounted to 118.0 6 5.2 mg/g, in the 2nd—116.0 6 4.8 mg/g ($P = 0.17$) in the 3rd group—80.0 6 5.0 mg/g ($P < 0.001$). The index of Geboes in the 1st group was 1.1 6 0.2 points, in the 2nd—1.1 6 0.1 points ($P = 1.0$), in the 3rd group—0.8 6 0.1 points ($P < 0.001$).

**Conclusion:** The combined mesenchymal stem cells and anticytokine anti-inflammatory therapy of CD contributes significantly deeper immunobiological and histological remission CD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Strictures are a frequent complication of Crohn's disease (CD) and may occur in different segments along the gastrointestinal (GI) tract. In contrast to ileocecal strictures, endoscopic balloon dilation (EBD) for CD-associated strictures of the upper gastrointestinal (UGI) tract is rarely reported. We therefore performed a combined efficacy and safety analysis based on all published studies of EBD for UGI strictures available in the literature.

**Aims & Methods:** A formal systematic literature review was performed to assess all relevant citations found in Embase, Medline and the Cochrane library regarding EBD in upper GI CD. In addition our own unpublished data was included in this analysis. Upper GI tract was defined as esophagus, stomach and duodenum up to the ligament of Treitz. Available technical and clinical variables were

extracted from all studies available for a descriptive pooled data analysis. Weighted efficacy averages were calculated for sub-groups.
**Results:** 13 publications with a total of 73 CD patients and 127 performed dilation procedures were included. Stricture locations were: duodenum n = 44, stomach n = 16 and esophagus n = 6. Technical success rate was 94.1%, resulting in clinical efficacy in 90.9% of patients. The mean maximum balloon caliber used for dilation was 18.9 mm. Major complications with regard to dilation, defined as perforation, bleeding or dilation-related surgery, occurred in 2.8% of all procedures. During a mean follow-up period of 25.5 months, 49.6% of patients reported symptomatic recurrence, while 54.2% of patients needed to undergo re-dilation and 31.3% required surgical intervention. The mean time to re-dilation was 7.4 months. Currently, there is no study available investigating the impact of concomitant therapeutic approaches such as steroid injection, cutting techniques or stent placement on the outcome of EBD for upper GI strictures in CD patients.
**Conclusion:** EBD for CD-associated strictures of the upper gastrointestinal tract has a high rate of short-term technical and clinical success with robust long-term efficacy and acceptable complication rates. Therefore, EBD should be considered as an alternative to surgery in patients with CD associated UGI strictures. Larger, controlled studies are needed to further evaluate EBD for upper GI strictures in CD patients.

## P1402 SCREENING FAILURE RATES IN A LARGE CLINICAL TRIAL CENTRE FOR INFLAMMATORY BOWEL DISEASES: INCIDENCE, CAUSES AND CONSEQUENCES

**L. Gijbels**[1], S. Coenen[2], M. Noman[2], S. Vermeire[2], G. Van Assche[2], M. Ferrante[2]
[1]*Biomedical Sciences, KU Leuven, Leuven/Belgium*
[2]*Department Of Gastroenterology And Hepatology, University Hospitals Leuven, Leuven/Belgium*

**Contact E-mail Address:** liese.gijbels@gmail.com
**Introduction:** Inflammatory bowel diseases (IBD) are chronic gastrointestinal disorders sometimes requiring introduction of investigational medical therapy in a clinical trial setting. Before enrolling in such a trial, patients must meet strict screening criteria. There is almost no data available on the incidence and causes of screen failure (SF), nor on the consequences of SF for these IBD patients.
**Aims & Methods:** We investigated incidence rates of SF over time in a tertiary IBD centre, identified the different (avoidable) causes, and explored the outcome of these patients. A review of all IBD patients screened for a sponsored double-blind placebo-controlled phase 1, 2 or 3 induction study between Jan 2009 and Dec 2015 was conducted at our tertiary IBD centre. Causes of SF were categorized into 6 groups: disease activity, haematology, chemistry, microbiology, protocol violation and withdrawal of consent. Thereafter, avoidable causes within each category were identified and defined as causes that could have been detected by detailed pre-screening (patient's medical history, previous lab reports, and current clinical disease activity). Finally, patient outcome was categorized into 5 groups: rescreening for the same clinical trial, screening for another trial, (re) introduction of conventional therapy, referral for surgery, or watchful waiting.
**Results:** During the 7-year study period, a total of 535 IBD patients were screened and 77 (14%) SF were identified in 37 different studies (78% female, median age 42 years, 56% Crohn's disease, 44% ulcerative colitis). SF rate clearly increased with time: 15% (9/61) in 2009, 7% (6/81) in 2010, 12% (10/83) in 2011, 8% (5/63) in 2012, 14% (14/98) in 2013, 23% (20/87) in 2014 and 21% (13/62) in 2015 (linear-by-linear p = 0.011). The most prevalent cause of SF was insufficient disease activity scoring (36% overall, 4% clinical and 32% endoscopic activity). Other causes were microbiology (22%), protocol violation (14%), withdrawal of consent (13%), deviation on chemistry (10%) or haematology (4%). Further analysis demonstrated that 23% (18/78) of SF could have been avoided: 4 patients with an inadequate clinical disease activity, 3 not meeting all exclusion criteria regarding previous medical history, 8 with deviations on chemistry and 3 on haematology. After SF, 21% (16/77) of patients could be rescreened and 14 of them were randomized in the same clinical trial, 21% (16/77) patients were screened for another trial, 42% (32/77) patients initiated conventional therapy, 6% (5/77) patients were referred for surgery, and 10% (8/77) patients did not receive further therapy.
**Conclusion:** Although the overall SF rate of 14% is considered acceptable, we observed a clear increase in SF rates in the last years. This increase is probably explained by more rigorous evaluation of endoscopic findings (central reading with strict endoscopic activity scoring). Indeed, while avoidable causes remained stable during the last 7 years, unavoidable causes (including endoscopic findings) increased. Nevertheless, approximately one-fifth of SF in IBD could have been avoided by thoroughly checking medical history, previous lab reports and current clinical activity scoring.

## P1403 TROUGH LEVELS AND ANTIBODIES TO USTEKINUMAB ARE NOT CORRELATED TO RESPONSE TO USTEKINUMAB TREATMENT IN CROHN'S DISEASE PATIENTS

**C. Painchart**[1], S. Brabant[2], N. Duveau[3], M. Nachury[4], P. Desreumaux[1], J. Branche[1], R. Gerard[5], M. Boualit[5], M. Labalette[2], B. Pariente[5]

**Introduction:** Ustekinumab (UST), a monoclonal antibody against the p40 subunit of interleukin 12/13, is effective in Crohn's disease (CD) patients refractory to anti-TNF agents. Trough levels and anti-drug antibodies to anti-TNF have been shown to be correlated to response to anti-TNF treatment. The aim of the present study was to assess the association between UST trough levels and anti-ustekinumab antibodies, and response and remission to induction and maintenance UST treatment in CD patients.
**Aims & Methods:** We performed a prospective study including all CD patients refractory to anti-TNF who received subcutaneous (SC) UST from September 2015 to February 2016 in tertiary referral French center of Claude Huriez hospital in Lille. During induction, patients received 90 mg of SC UST at week 0, 4 and 12. During the maintenance phase, patients received 90 mg of SC UST every 8 weeks, which could be optimized by shortening injection interval to every 4 weeks in case of loss of response. Clinical response was defined by a decreased Harvey Bradshaw Index (HBI) by 3 points, clinical remission by HBI < 5, loss of response by new increase of HBI. UST trough levels and antibodies were dosed at 12 weeks, and at a single time-point for patients who had received more than 3 months of UST. The results of dosage were obtained by enzyme-Linked ImmunoSorbent Assay technique. We evaluated the correlation between clinical and biological response and remission to UST, and UST through levels and antibodies concentration. Differences between independent groups were traced with the use of the Mann–Whitney exact test.
**Results:** Twenty-seven patients with active disease received at least three SC UST injections and were prospectively included. At time of ustekinumab introduction, 60% of patients received concomitant immunosuppressant and 56% received corticosteroids. At the end of the induction phase (week 12), clinical response was observed in 64% patients. There was no significant difference in mean UST trough levels who responded to UST induction (median 1160 ng/ml; IQR: 568–1448) as compared to patients who did not respond (median 1740 ng/ml; IQR: 682–2968, p = 0.61). Sixteen patients (60%) received at least 4 injections of UST, with 5 patients who were optimized at the time of dosages. Clinical response was observed in 12/16 patients (75%). Median UST concentration in clinical responder was 1429 ng/ml (IQR: 649–19745), and 1522 ng/ml in non-responder (IQR: 1168–1759), with no significant difference in mean UST trough levels in two groups of patients (p = 0.95). UST trough levels were similar in patients in deep remission (3/27 patients, median UST concentration of 1252 ng/ml) and in patients who were not in deep remission (median 1429 ng/ml; p = 0.96). UST antibodies were undetectable in 0/27 patients.
**Conclusion:** We confirmed that UST treatment is effective in a majority of CD patients refractory to anti-TNF agents. Median trough levels to UST are not correlated to response and remission to UST induction and maintenance treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1404 HOSPITALISATIONS AND TREATMENT DISCONTINUATION AMONG PATIENTS WITH ULCERATIVE COLITIS AND CROHN'S DISEASE TREATED WITH VEDOLIZUMAB COMPARED WITH INFLIXIMAB

M. Raluy-Callado[1], N. Alam[1], R. Wang[1], **J.M. Khalid**[2]
[1]*Evidera, London/United Kingdom*
[2]*Takeda Development Centre Europe Ltd, London/United Kingdom*

**Contact E-mail Address:** mona.khalid@takeda.com
**Introduction:** There is a dearth of real-world comparative-effectiveness studies of anti-integrins vs. anti-TNFs for the treatment of ulcerative colitis (UC) and Crohn's disease (CD). The objectives of this study were to compare IBD-related hospitalisations and time to discontinuation of 1st-line therapy among biologic-naïve patients with IBD treated with vedolizumab (VDZ) vs. Infliximab (IFX).
**Aims & Methods:** This retrospective study used data from 01/05/2014 to 16/02/2016 in the US Explorys Universe electronic health records database. Patients ≥ 18 years of age, diagnosed with UC (ICD-9 556.xx) or CD (ICD-9 555.xx), who initiated VDZ or IFX were included. Patients had ≥ 12 months of medical history prior to index, ≥ 180 days of follow-up, and were biologic-naïve. Patients initiating concomitant biologic therapies, and those who died were excluded. The date of the 1st infusion was defined as the index date. Patients initiating VDZ were propensity score matched (1:2) with those initiating IFX. Discontinuation was defined as no subsequent infusion of the index drug within 90 days of the previous infusion, treatment switch or add-on of another biologic agent. A Kaplan-Meier analysis was performed to assess the risk of discontinuation. The discontinuation rate difference was estimated using Cox regression analysis adjusted for 1:2 matching. The proportion of patients who experienced an IBD-related hospitalisation during the 180 days following the index date, as well as the overall mean rate of hospitalisations by treatment group (VDZ or IFX) were reported and tested for statistical differences.
**Results:** 91 biologic-naïve VDZ patients were matched to 182 biologic-naïve IFX patients. The average age in both groups was 44 years. 63.7% and 63.4% in VDZ and IFX groups were patients with CD, respectively, and 53.8% and

59.3% in VDZ and IFX groups were female, respectively. In the 6 months following treatment initiation, patients treated with VDZ showed a trend towards a lower risk of discontinuation compared with matched IFX patients (HR: 0.86 [95% confidence interval: 0.63, 1.16])). The proportion of patients with an IBD-related hospitalisation was numerically lower in the VDZ vs. IFX group (7.7% vs. 15.9%, P = 0.058) and the mean number of IBD-related hospitalisations was significantly lower for patients who were treated with VDZ vs. IFX (0.11 vs. 0.29, P = 0.048).
**Conclusion:** In real-world clinical practice among patients with UC and CD receiving 1st-line biologic therapy, those treated with VDZ showed a trend towards lower risk of treatment discontinuation and fewer IBD-related hospitalisations than patients treated with IFX. Further comparative effectiveness studies with larger samples and longer follow-up are required to confirm these findings.

**Introduction:** Corticosteroids are the cornerstone of inducing remission in IBD but are limited in their ability to maintain remission, and associated with significant side effects. This is the first nationwide outpatient study of steroid use in IBD and factors affecting their use.
**Aims & Methods:** We audited consecutive IBD patients attending clinics at 11 centres over 3 months using a web-based assessment tool. Cases meeting criteria for steroid excess (SE) as defined by ECCO guidelines [1, 2] were blind peer reviewed and classified as non-IBD use, unavoidable and inappropriate steroid excess (ISE) according to standardised definitions. Associations between steroid use and patient and institutional factors were analysed.
**Results:** Of 1177 patients [48% CD, 49% UC, 3% IBD-U] 79% were in remission/mild disease, 18.5% had moderate and 2.5% severe disease. In the previous 12 months, 30% had received steroids, 13.8% had SE. Peer review revealed that SE was inappropriate in 51.2% of these (8% non-IBD use; 40.7% unavoidable). Excess steroid exposure was more common in patients with active UC compared to active CD (41.6% vs 26.6%; p = 0.02). In multivariate analysis, disease activity was a significant predictor of SE/ISE. In addition, being established on anti-TNF agents protected against SE and ISE in CD. Exposure to thiopurine (SE + ISE) and starting anti-TNF therapy (ISE) were associated with excess steroid use in UC. CD patients from centres with an IBD MDT were less likely to have SE, similarly CD patients in centres with combined surgical clinics were less likely to experience SE and ISE. Care in centres with dedicated IBD clinics was associated with less SE and ISE in patients with UC. Centres with large numbers of GI trainees showed higher rates of SE in UC and SE and ISE in CD. (All of above independent predictors on multi-variate with significance $p < 0.001$).
**Conclusion:** We identified inappropriate excess steroid use in 7% of UK IBD patients. Risk factors for steroid exposure differed between UC and CD, likely reflecting inter alia, differences in access to biologic drugs. Our study is the first to demonstrate positive effects of service configurations (IBD MDT, dedicated IBD clinics, combined surgical clinics) on treatment outcomes even after correction for differences in disease severity. There was an association between ISE in Crohn's and the number of GI trainees per centre suggesting possible gaps in training. Routine recording of excess steroid exposure is feasible and should be considered as a quality marker for outcomes of IBD services.

**Introduction:** 25% to 61% of patients with Crohn's disease (CD) will require intestinal resection during the first 5 years after diagnosis. Throughout the follow-up, operated patients can develop complications and require hospitalization or new surgeries. The aim of this study was to determine the incidence of hospitalizations and reinterventions in patients with CD undergoing ileocolonic resection with anastomosis.
**Aims & Methods:** PRACTICROHN was a retrospective study, including patients with CD aged ≥18 years-old from 26 centres who underwent ileocolonic or ileorectal resection with ileocolonic (or ileorectal) anastomosis between January 2007 and December 2010. Clinical, endoscopic and treatment data before and up to 5 years after surgery were retrospectively collected from medical records.
**Results:** 314 patients were analysed (mean age 40 years [SD 13], 48% men). Of these, 149 (51%) were smokers at the diagnosis and 115 (77%) at the time of surgery. Only 30 patients (9.5%) quitted smoking at the fifth year. Median time from CD diagnosis to surgery was 6 years (IQR 1–12). Indication for surgery was: 147 (48%) stenosing, 98 (32%) penetrating disease, 46 (15%) stenosing + penetrating and 14 (4%) refractoriness to medical treatment. 208 (68%) of patients received preventive therapy after surgery: 13% aminosalycilates, 9% antibiotics, 46% immunomodulators (IMM) and 1% anti-TNFs. During the follow-up, 56 patients (18%) needed at least one hospitalization during the first year, with median time of stay of 10 days (IQR 6–15). The reasons for hospitalization were: 36 (45%) recurrence or CD activity, 35 (44%) postoperative complications, 1 (1%) CD-related infection and 7 (9%) for other reasons. There was no CD cancer-related hospitalization. After 5 years 94 (30%) patients required hospitalization, most of them due to active disease. 45 (14%) required reintervention after 5 years, most of them (n = 23, 7%) during the first year, and the most frequent reason was postoperative complication (n = 18, 78%). Median time to first reintervention was 288 days (IQR 133–527).

| Hospitalizations, n (%) | 1–12 months n = 314 | 13–24 months n = 314 | 25–36 months n = 314 | 37–60 months n = 314 |
|---|---|---|---|---|
| **Total (accumulated)** | 56 (17.8) | 74 (23.5) | 82 (26.1) | 94 (29.9) |
| Previous surgery complication | 35 (11.1) | 48 (15.2) | 55 (17.5) | 63 (20) |
| Recurrence, CD activity | 36 (11.4) | 56 (17.8) | 72 (22.9) | 100 (31.8) |
| Neoplasia related to CD | 0 (0.0) | 0 (0.0) | 2 (0.6) | 5 (1.5) |
| CD related infection | 1 (0.3) | 2 (0.6) | 4 (1.2) | 8 (2.5) |
| Other | 7 (2.2) | 12 (3.8) | 16 (5.0) | 27 (8.5) |
| Total Reinterventions (accumulated) n (%) | 23 (7.32) | 33 (10.51) | 37 (11.78) | 45 (14.33) |
| Consecuence or complication of previous surgery | 18 (5.7) | 25 (7.9) | 28 (8.9) | 33 (10.5) |
| Related to CD | 10 (3.1) | 15 (4.7) | 17(5.4) | 22 (7.0) |
| Penetrating complication | 9 (2.8) | 13 (4.2) | 15 (4.7) | 19 (6.05) |
| Abscess | 5 (1.5) | 5 (1.5) | 6 (40) | 6 (1.9) |
| Mass | 1 (0.3) | 2 (0.6) | 2 (0.6) | 4 (1.2) |
| Fistulae | 5 (1.5) | 8 (2.5) | 9 (2.8) | 11 (3.5) |
| Perforating | 2 (0.6) | 4 (1.2) | 4 (1.2) | 4 (1.2) |
| Stenosing | 1 (0.3) | 1 (0.3) | 1 (0.3) | 3 (0.9) |
| Resistance to treatment | 1 (0.3) | 3 (0.9) | 3 (0.9) | 6 (1.9) |

**Conclusion:** During the CD-related post-surgery evolution, 1 in 5 patients will require hospitalization for disease recurrence or postoperative complications, and

1 in 14 will require a new reintervention after 5 years. Probably surgery centralization in experienced centres could minimize postoperative complications, and a more exhaustive postoperative prophylaxis could reduce complications for disease activity.

**Introduction:** We assessed the impact of adalimumab (ADA) treatment on the well-being domain from the recently restructured IMPACT III questionnaire in patients (pts) enrolled in the IMAgINE 1 trial. The effect of ADA on emotional and social functioning domains has been reported previously.[1]

**Aims & Methods:** In IMAgINE 1, 6–17 years old pts with moderate to severe CD (baseline [BL] PCDAI >30) who failed or were intolerant to conventional therapy received ADA for 52 weeks (wks).[2] Escalation to blinded weekly (EW) ADA was allowed after wk 12 for pts with disease flare/non-response followed by open-label (OL) EW ADA for continued flare/non-response. Pts ≥10 yr at BL received the IMPACT III questionnaire; each individual question has five Likert response options (0 – 4); scores are then linearly transformed to a range of 0 to 100 for ease of data interpretation, with higher scores representing better HRQoL. Changes from BL in the well-being domain score and in individual IMPACT III questions at wks 12, 26, and 52 were reported. Prior infliximab exposure was used for subgroup analyses. Last observation carried forward (LOCF) was used for missing data (post-BL), pts who discontinued, or who moved to OL EW ADA.

**Results:** A total of 172 pts were analyzed: 55% were males, median PCDAI was 40, median CRP 1.2 mg/dL, and mean IMPACT III well-being score 46 at BL. 75 pts had prior exposure to infliximab. Mean well-being domain scores at BL for infliximab-naive and experienced pts were 49 and 44, respectively. Statistically significant improvements in well-being domain and individual questions scores were observed from week 12 and maintained to week 52 (Table). Overall well-being domain score at wks 12, 26, and 52 was 69, 68, and 68, respectively. Numerically higher changes from BL in well-being domain scores were seen in infliximab-naive pts compared with infliximab-experienced pts at wks 12, 26, and 52 (26, 27, and 25 vs 18, 16, and 16, respectively).

**Conclusion:** ADA treatment was associated with significant improvements in HRQoL in children with CD. Increases in well-being domain scores and individual question scores were maintained up to week 52 regardless of prior infliximab exposure.

**Contact E-mail Address:** farah.bahbah@ferring.com

**Introduction:** The aims of this study, set up in 2011, are to describe the progression and methods of therapeutic management of mild to moderate ulcerative colitis (UC) and to assess the remission rate and duration, as well as to determine the prognostic factors for relapse at 3 years.

**Aims & Methods:** 812 patients experiencing a flare-up of mild to moderate UC were enrolled by 130 gastroenterologists, 64% of whom are in private practice. The patient data are recorded in an electronic CRF during consultations conducted as part of regular follow-up. The finale and descriptive analysis of the data available as of 28 October 2015 is presented below and represents 494 (60.8%) patients who had a visit at least at 3 years.

**Results:** At 1 year, 527 (84%) patients were in remission of the UC flare which motivated inclusion. During the 3 years of follow-up, 417 (51.35%) patients had at least 1 relapse and 55 (7%) had at least 1 hospitalisation related to UC. At enrolment, 583 (72%) patients were receiving treatment for UC; 432 subjects were treated with oral 5-ASA, which was combined with rectal 4- or 5-ASA in 131 patients. At the consultation at 3 years, 379 (80.8%) patients were receiving treatment for UC; 273 patients were treated with oral 5-ASA. The ongoing treatment at each annual visit is presented in the following table. One notes an improvement of adherence as well as stability of the UCCS score over the 3 years of follow-up.

**Conclusion:** In this large prospective cohort of patients with mild to moderate UC, inducing remission and maintenance are mainly based on treatment with 5-ASA. At 3 years of follow-up, 72% of patients are treated with 5-ASA among 81% receiving a treatment for UC. 84% of the patients are in remission according to UCCS score and one notes an improvement in the treatment adherence over the 3 years of follow-up.

## P1409 A PILOT STUDY TO EVALUATE THE BENEFITS OF A RECRUITMENT PLATFORM, CT-SCOUT$^{TM}$ IN INFLAMMATORY BOWEL DISEASES (IBD) CLINICAL TRIALS: LINKING POTENTIAL PATIENTS TO CLINICAL TRIALS

**Y. Bouhnik**[1], A. Amiot[2], A. Nuzzo[1], L. Mansouri[1], D. Soudan[1], C. Stefanescu[1]

**Contact E-mail Address:** yoram.bouhnik@bjn.aphp.fr

**Introduction:** Patient enrollment in clinical trials is the weakest link in the long and expensive clinical development process that brings new molecules to treat IBD and other disabling chronic diseases. It has been estimated that insufficient patient enrollment in clinical trials can double the clinical development time and in certain cases cause the trial to be prematurely terminated (1). The major reasons for poor patient recruitment is lack of study protocol knowledge together with the fear of a time-consuming process. The CT-SCOUT$^{TM}$ platform is a web-based device designed by the executive board of the GETAID - a French academic research group - that makes the clinical trials pre-screening, and inclusion process more efficient.

**Aims & Methods:** We conducted a prospective, single centre, open-label, observational pilot study. The objective was to evaluate the benefits of implementing the CT-SCOUT$^{TM}$ platform for patient enrollment into clinical trials within our tertiary-care, academic IBD centre. All physicians involved in the IBD centre were asked to use the CT-SCOUT$^{TM}$ platform on a daily basis to evaluate whether or not patients were eligible for either academic or industry-sponsored trials. The primary endpoint was the patient randomization rate per month. Characteristics of our IBD centre were noted on a prospective basis. The intervention period (Apr 2014 – Dec 2015) was compared with the previous 21-month reference period (Jul 2012 – Mar 2014) using Wilcoxon's matched-pair signed-rank test. Logistic regression analysis was performed to determine predictors of patient enrollment.

**Results:** After implementing CT-SCOUT$^{TM}$, the inclusion (Informed-consent form signature) and randomization rate increased from $1.7 \pm 1.4$ to $4.7 \pm 3.1$ ($p = 0.001$), and from $1.2 \pm 1.2$ to $3.5 \pm 2.8$ ($p = 0.005$) patients per month, respectively. During the 42-month study period, patient population grew in terms of both consultations and hospitalizations. The number of study coordinators and ongoing trials remained stable. See table.

| Characteristics (n per month, mean ± SD) | Before CT-SCOUT$^{TM}$ (Jul 2012 to Mar 2014) | With CT-SCOUT$^{TM}$ (Apr 2014 to Dec 2015) | P |
|---|---|---|---|
| IBD Consultations | $219 \pm 48$ | $270 \pm 57$ | 0.002 |
| IBD day hospitalization | $139 \pm 25$ | $189 \pm 32$ | 0.001 |
| IBD hospitalization | $15 \pm 6$ | $18 \pm 6$ | 0.13 |
| Physicians | $5.9 \pm 0.4$ | $6.4 \pm 0.7$ | 0.001 |
| Study-Coordinator | $1.6 \pm 0.5$ | $1.4 \pm 0.4$ | 0.09 |
| Academic study | $3.8 \pm 0.4$ | $3.7 \pm 0.5$ | 0.54 |
| Industry-sponsored study | $4.0 \pm 0.0$ | $4.5 \pm 0.7$ | 0.002 |

Using CT-SCOUT$^{TM}$ platform was predictor of a higher patient randomization in clinical trials (OR = 6.4, $CI_{95}$% [1.1–35.7], $p = 0.03$), as well as the increased consultation (20.4, 1.6–250.0, $p = 0.02$) and hospital patient populations (7.9, 1.3–50.0, $p = 0.03$).

**Conclusion:** Regardless of increasing the cohort of IBD patients followed in the centre, introducing CT-SCOUT$^{TM}$ has multiplied the patients recruitment rate in clinical trials by a three-fold factor in both academic and industry-sponsored clinical trials. CT-SCOUT$^{TM}$ appears to be a promising and easy-to-use web-based solution to the global issue of patient enrollment in clinical trials, considerably reducing clinical trial duration, therefore allowing new drug candidates to be registered more quickly and be made available to patients earlier.

## P1410 SWITCHING OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE FROM ORIGINAL INFLIXIMAB (REMICADE®) TO BIOSIMILAR INFLIXIMAB (REMSIMA™) IS EFFECTIVE AND SAFE – ONE-YEAR FOLLOW-UP

**M. Kolar**[1], D. Duricova[1], M. Bortlik[1], V. Hruba[1], N. Machkova[1], K. Mitrova[1], K. Malickova[2], M. Lukas[1], M. Lukas[1]

**Introduction:** Biosimilar infliximab (IFX) seems to have similar efficacy and safety to original preparation in patients with inflammatory bowel diseases (IBD) who are naive to anti-TNF therapy. However, the evidence on switching from original to biosimilar preparation is very sparse.

**Aims & Methods:** Our aim was to evaluate efficacy and safety of switching from original to biosimilar IFX in patients with Crohn's disease (CD) and ulcerative colitis (UC) one year after the switch. Consecutive patients with CD and UC on maintenance IFX treatment in our centre who were switched from original to biosimilar IFX during period from January to March 2015 were included. Patients were followed prospectively in regular intervals coincident with infusion applications. At each visit disease activity was registered using Harvey-Bradshaw index (HBI) for CD and Simple clinical colitis activity index (SCCAI) for UC; blood sample was taken for analysis of blood count, biochemistry and IFX pharmacokinetics (trough levels, TL and anti-drug antibodies, ATI) and stool samples were collected for measurement of fecal calprotectin (FC). Furthermore, adverse events were registered. All patients were evaluated at week 56 (W56) of treatment with biosimilar IFX.

**Results:** Seventy-four patients with IBD, 56 with CD and 18 with UC, were switched to biosimilar IFX after mean time of $3.0 \pm 2.2$ years on original preparation. Almost half of individuals (35, 47.3%) were on concomitant immunosupressants and one patient had systemic corticosteroids. Majority of patients, 52 (72.2%) were at the time of switch (week 0, W0) in clinical remission, 16 (22.2%) had mild to moderate active disease and 4 (5.6%) individuals had severe disease activity. Comparing W0 and W56, no significant difference in C-reactive protein levels ($4.3 \pm 8.0$ mg/L vs. $3.3 \pm 3.8$; $p = 0.89$) and FC ($135 \pm 153$ µg/g vs. $199 \pm 225$; $p = 0.17$) was observed. Likewise, no increase in immunogenicity was found (ATI positivity: 9.5% vs. 6.0%, $p = 0.54$). Furthermore, clinical disease activity was stable until the end of follow-up (remission at W0 vs. W24: 72.2% vs. 77.8%; median difference of both HBI and SCCAI between W0 and W56 was 0). We found statistically significant increase in IFX TL ($3.4 \pm 3.8$ µg/mL vs. $4.7 \pm 4.5$, $p = 0.01$) which was by further ANOVA analysis explained by larger share of patients with intensified therapy at W56 (13.5% vs. 26.9%). Six patients discontinued IFX treatment up to W56 due to loss of response ($n = 2$ UC patients), adverse event ($n = 2$) and gravidity ($n = 2$). No patient experienced infusion reaction and the frequency and type of adverse events were similar to those observed during treatment with original IFX.

**Conclusion:** Based on our results switching of IBD patients from original to biosimilar IFX is effective and safe. Importantly, no increase in immunogenicity was observed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1411 THE EVOLUTION OF INDICATIONS AND OUTCOMES OF SURGERY FOR PATIENTS WITH CROHN'S DISEASE DURING THE BIOLOGICAL AGENT ERA

**C. Attree**[1], D. Ormonde[2], J. Staton[1], C. Platell[3]
[1]*Notre Dame University, Fremantle/Australia*
[2]*Gastroenterology, Saint John of God, Subiaco/Australia*
[3]*Saint John of God, Subiaco/Australia*

**Contact E-mail Address:** janelle.staton@nd.edu.au

**Introduction:** Inflammatory bowel disease is common, affecting 61,000 Australians and costing approximately $2.7 billion per annum. Studies are equivocal on the affects of biological agents on the primary indication of surgery.

**Aims & Methods:** To determine if the introduction of biological agents has changed the indications and outcomes of surgery for patients with Crohn's disease. In accordance with the theorized mechanism of action of biological agents, it was hypothesized that there would be a reduction in penetrating disease with a concomitant rise in stricturing disease as the primary indication of surgery. From 1996 to 2013, sequential surgical procedures performed on patients with Crohn's disease at two large West Australian metropolitan hospitals were recorded. The cohort was divided into pre- biological agent [pre-BA] availability (1996–2006) and post-biological agent [post-BA] availability (2007–2013). The difference in the frequency of indications for surgical procedures and outcomes between the cohorts was determined statistically using chi-square tests.

**Results:** 224 patients underwent 244 surgical procedures (pre-BA, $n = 105$; post-BA, $n = 139$). The mean age was 40.6 years with a larger percentage of females in pre-BA (66.7%) than post-BA (47.5%; $\chi2\ (1) = 8.92$, $p = 0.003$). There was no change in the primary indication for surgery. Rates of emergency surgery decreased from 19% to 8.6% ($\chi2\ (1) = 5.69$, $p = 0.017$). Patients requiring a stoma decreased from 30.5% to 15.8% ($\chi2\ (1) = 7.45$, $p = 0.008$). There was a significant difference in the number and types of anastomoses between groups.

**Conclusion:** There was no clear evidence that the introduction of biological agents changed the indications for surgery in this cohort. The study does demonstrate a reduction in emergency surgeries and stomas, leading to better overall patient outcomes. Further investigation of individual patient response to biological agents is warranted.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Adalimumab (ADA) is a well-documented, effective and safe treatment option for moderate to severe Crohn's disease (CD). The drug is administered and dosed in a standard treatment regimen, but serum drug concentration (SDC) measurements offer the possibility to optimize the treatment strategy. However, an optimal therapeutic SDC range should be established to avoid the risk of adverse effects from too high - or suboptimal effect due to too low SDCs.

**Aims & Methods:** Our aim was to determine the lower cut-off of the therapeutic serum concentration (TSC) in a cohort of CD patients, who had received three or more doses of ADA, using CRP as a marker of inflammation and disease activity. In a subgroup analysis of a cross-sectional study at Stavanger University Hospital on IBD patients treated with anti-TNF-a agents, we identified adult patients with CD who were treated with ADA. Treatment interval and duration, drug dosage, time since onset of disease, CRP, SDC, age and gender were recorded. SDCs were measured using an in-house assay automated on the AutoDELFIA immunoassay platform at Oslo University Hospital, Radiumhospitalet. A CRP above 10 mg/L was chosen as a surrogate marker for significant inflammation and active disease, 10 (9.9%) of the included patients fulfilled this criterion. In total, 103 patients were included, of which 101 (98%) had a valid SDC.

**Results:** Median (range) age was 35 (16–78) years, and 47.5% were men. Median duration of treatment was 32 (2–110) months, with median time since onset of disease 9 (1–36) years. Median ADA dosage was 40 (40–80) mg, and median treatment interval 2 (1–2) weeks. Median SDC was 6.9 (0–24.6) mg/L. Median CRP was 2.8 (1–45) mg/L. Seven (6.9%) of the patients presented with anti-drug antibodies. A receiver operating characteristics (ROC) analysis gave an area under the curve of 0.743 (std. error 0.076, $p = 0.012$, 95% CI 0.595–0.891). An optimal cut-off of TSC in terms of optimizing sensitivity and specificity was found at 5.55 mg/L, with a sensitivity of 70% and a specificity of 69.2%. Thirty-four (33.7%) patients had a SDC below this threshold.

**Conclusion:** A lower therapeutic cut-off concentration of 5.55 mg/L was identified for Crohn's disease patients under established treatment with adalimumab, using CRP as marker for active disease. Identifying this value may help optimize the ADA treatment for CD patients, and avoid insufficient serum concentration levels with subsequent increased inflammatory activity.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1413 ANTI-TNF THERAPY IN REFRACTORY POUCHITIS AND CROHN'S DISEASE-RELATED COMPLICATIONS OF THE POUCH AFTER ILEAL POUCH-ANAL ANASTOMOSIS FOLLOWING COLECTOMY FOR ULCERATIVE COLITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Huguet[1], B. Pereira[2], M. Goutte[1], F. Goutorbe[1], G. Bommelaer[1], **A. Buisson**[3]
[1]*Gastroenterology Department, University Hospital Estaing, Clermont-Ferrand/France*

[3]*M2ish, UMR 1071 Inserm/Université d'Auvergne; USC-INRA 2018M2iSH, Clermont-Ferrand/France*

**Contact E-mail Address:** a_buisson@hotmail.fr

**Introduction:** Pouchitis is the most common complication after ileal pouch-anal anastomosis following colectomy for ulcerative colitis. Approximately 15% of the patients experienced chronic pouchitis refractory to antibiotics. In the last decade, it has been well established, that a secondary Crohn's disease–associated pouch complication could also occur in these patients. Data about the effectiveness of anti-TNF agents in refractory pouchitis or Crohn's disease–associated pouch complications remains sparse and the definitions of these two entities often overlap in the available articles.

**Aims & Methods:** We aimed to perform a systematic review and meta-analysis to evaluate the efficacy of anti-TNF therapy in differentiating patients with

chronic refractory pouchitis and CD-related complications. To identify relevant articles and abstracts, a systematic literature search was performed using both medical subject headings (MESH) and keywords (restricted to English language) and was performed in MEDLINE (1966 to December 2015). Abstracts of international congresses (DDW, UEGW, ECCO) were inspected by a manual search. The search process, selection of the manuscripts, and data extraction were performed independently by two physicians, and discrepancies between them were resolved by a third physician. Our work was performed according to the PRISMA statement. Statistical analysis was conducted using Comprehensive Meta-analysis software and Stata software. Prevalence and 95% confidence interval were estimated using random-effects models assuming between and within study variability. Statistical heterogeneity between results was assessed by examining forest plots, confidence intervals and using $I^2$. A sensitivity analysis was conducted to assess the influence on the global prevalence of the inclusion and exclusion of studies. CD-related complications of the pouch were defined as the presence of non-anastomotic fistula and/or non-anastomotic stenosis and/or prepouch ileitis. Chronic refractory pouchitis was defined as inflammation limited to the pouch. Inflammatory complications of the pouch included the two former entities.

**Results:** We identified a total of 21 articles and 3 abstracts, most of these retrospective case series, including a total of 313 patients treated either with infliximab (n = 232) or adalimumab (n = 81) (Table 1).

Main characteristics of the 24 studies included in the meta-analysis

| Huang et al. 2003 | 2 | IFX | 100% | 100% | 100% | 3 |
| Arnott et al. 2001 | 2 | IFX | 0% | 0% | 0% | 3 |
| Ricart et al. 1999 | 7 | IFX | 85.7% | 85.7% | 71.4% | 2+ |

The short-term and the long-term responses were evaluated at 8 weeks 95%CI [5–10] and 12 months 95%CI [12–18.5], respectively. Overall, the rate of complete response after anti-TNF induction therapy for inflammatory complications of the pouch was 0.51 (95%CI [0.39–0.64]; $I^2 = 0.56$). The rate of short-term complete response was 0.57 (95%CI [0.38–0.75]; $I^2 = 0.36$) for infliximab-treated patients compared to 0.38 (95%CI [0.08–0.72]; $I^2 = 0.50$) for adalimumab-treated patients (p = 0.20). The long-term rate of complete response in patients treated with anti-TNF therapy was 0.52 (95%CI [0.39–0.65]; $I^2 = 0.59$), with 0.59 (95%CI [0.45–0.72]; $I^2 = 0.30$) for infliximab-treated patients compared to 0.30 (95%CI [0.15–0.46]; $I^2 = 0.00$) for adalimumab-treated patients (p = 0.19). Considering only the patients for those data are sufficient to differentiate refractory pouchitis from Crohn's disease-related complications of the pouch (n = 210), the rate of complete response after anti-TNF induction therapy for inflammatory complications of the pouch was 0.52 (95%CI [0.36–0.68]; $I^2 = 0.56$). The rate of complete response after anti-TNF induction therapy seemed to be higher for Crohn's disease-related complications of the pouch 0.64 (95%CI [0.5–0.77]; $I^2 = 0.18$), compared to refractory pouchitis 0.10 (95%CI [0.08–0.35]; $I^2 = 0.00$) (p = 0.06). The rate of long-term complete response in patients treated with anti-TNF was 0.57 (95%CI [0.43–0.71]; $I^2 = 0.32$) for Crohn's disease-related complications of the pouch compared to refractory pouchitis 0.37 (95%CI [0.14–0.62]; $I^2 = 0.47$) (p = 0.57).

**Conclusion:** Despite wide heterogeneity of the data, anti-TNF agents have a clear trend to have higher and faster efficacy in Crohn's disease-related complications of the pouch compared to refractory pouchitis, highlighting the need to differentiate these two entities in clinical practice.

**Introduction:** Crohn's disease is a chronic condition requiring maintenance therapy to prevent relapse and further complications. Adherence to therapy and compliance with treatment is associated with improved outcomes.

**Aims & Methods:** We aimed to identify psycho-social and other risk factors associated with noncompliance to chronic drug treatment in Crohn's disease. Methods: A total of 128 outpatients attending the gastroenterology clinics in Soroka Medical Center and diagnosed with Crohn's disease, on maintenance treatment for a period of one year (6 month before and after study enrollment), were eligible for this study. Patients completed questionnaires including demographics, disease activity using the Harvey Bradshaw Index (HBI), psychological data including the Brief Symptom Inventory (BSI) and COPE questioners and the SF-36 & SIBDQ questionnaires regarding Health Related Quality of Life (HRQoL). For each patient, drug refill information for the study period was obtained from computerized pharmacy records. Compliance was defined as at least 80% acquisition of prescribed medication. Univariate analysis and regression models were used to identify significant associations for compliance as a continuous or a dichotomic variable.

**Results:** Of 128 patients 78 (61%) were noncompliant with maintenance treatment. Noncompliant patients were more likely to be unemployed (47.4% vs. 28.6%, p = 0.035), associated with "poor" economic status (30.3% vs. 8.5%, p = 0.004), with active Crohn's disease (54.2% vs. 27.9%, p = 0.006), lower SIBDQ score (median 44(IQR 9,68) vs. 52.5(20.70), p = 0.004), higher psychologic distress GSI score (0.42(0,2.39) vs. 0.23(0,1.68), p = 0.009), and lower SF 36 - Physical Functioning sub-scale (44.14(14.09,65.91) vs. 46.74(25.73,60.13), p = 0.03). Coping strategies were not related to compliance. We performed a quantile regression model, to better understand the differential effect of the variables along different quantiles of compliance. We found that disease duration (B = -0.026, p < 0.001, 95% CI -0.031–0.02), and higher number of Crohn's medications (B = -0.217, p = 0.004, 95% CI -0.365–0.07) were consistent predictors for low compliance in the lower quantiles (0–40% compliance), and "poor" economic status (B = -0.148, p = 0.004, 95% CI -0.248–0.048) as a predictor in the higher quantile (80% compliance).

**Conclusion:** Noncompliance is associated with unemployment, "poor" economic status, low quality of life score, high psychological distress, and lower SF 36 - Physical Functioning sub-scale. In multivariate regression analysis the strongest effect on noncompliance is derived from increasing medication number. These patient characteristics may be helpful in targeting those patients with higher risk for noncompliance.

**Introduction:** An increasing number of inflammatory bowel disease (IBD) patients receive treatment with adalimumab. Patterns of adalimumab use and associated costs have never been described in a large real-life cohort. The aim of this study was to investigate patterns of adalimumab use and drug survival in a large real-life cohort of IBD patients.

**Aims & Methods:** We analyzed health insurance claims data of Achmea, the largest health insurance provider in the Netherlands, with a population of approximately 4 million insured persons. Data on healthcare use of adult IBD patients and prescription drugs were collected from 2008 to 2014. Drug survival was evaluated using Kaplan-Meier analysis in patients starting with adalimumab treatment who were insured by Achmea during the entire observation period.

**Results:** In this cohort, the number of patients who received IBD-related care ranged from 8695 in 2008 to 11065 in 2014. Cohort characteristics are provided in table 1. A total of 1496 IBD patients were treated with adalimumab during the

observed period. The annual proportion of IBD patients that received at least one prescription of ADA increased from 2.8% in 2008 to 8.1% 2014. When only drug costs are considered, annual costs of ADA treatment increased from €3,155,702 in 2008 to €13,006,126 in 2014. Since 2008, 1401 patients started with adalimumab. Drug survival was evaluated in 875 patients (77% Crohn's disease). Median drug survival of all patients was 648 days (95% CI 550–746). Crohn's disease patients were treated significantly longer than ulcerative colitis patients with a median drug survival of 727 and 390 days respectively ($p = 0.011$). No association was found between drug survival and gender ($p = 0.08$). Respectively 6 months, 1 year and 2 years after the initiation of treatment, 65%, 48% and 30% of patients were still receiving adalimumab.

**Table 1:** Cohort characteristics.

| Patients receiving IBD care | 2008<br>8695 | 2014<br>11065 |
|---|---|---|
| - Crohn's disease (n,%) | 3926 (45%) | 5070 (46%) |
| - male gender (n,%) | 3953 (45%) | 4926 (45%) |
| IBD patients receiving adalimumab | 246 | 892 |
| - Crohn's disease (n,%) | 221 (90%) | 716 (80%) |
| - male gender (n,%) | 83 (34%) | 382 (43%) |
| - combination treatment (n,%) | 74 (30%) | 270 (30%) |
| Adalimumab costs | €3,155,702 | €13,006,126 |

**Conclusion:** Adalimumab use and associated costs increased from €3,155,702 in 2008 to €13,006,126 in 2014. The majority of adalimumab discontinuation occurs within 1 year after initiation. Crohn's disease patients are treated significantly longer with adalimumab than ulcerative colitis patients.

**Introduction:** Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are chronic inflammatory disorders that can be treated with biologic therapies. While the development of such therapies has led to key improvements in the treatment of IBD for the last decade, a loss of efficacy over time is often observed with biologic therapies, with immunogenicity a leading contributor to this loss of response.

**Aims & Methods:** The objective of this analysis was to evaluate evidence on the formation of anti-drug antibodies (ADAbs) to biologics used to treat IBD. A systematic literature review was conducted focusing on adalimumab (ADM), certolizumab pegol (CZP), golimumab (GLM), infliximab (IFX), ustekinumab (UST) and vedolizumab (VDM). Online searches included MEDLINE®, Embase® and the Cochrane Central Trials Register for the period from January 2009 to August 2015. Key congresses and references in selected articles were hand-searched. Eligible studies involved patients with CD or UC, and were randomised controlled trials (RCTs), non-RCTs or observational studies. Case reports/series/studies, systematic/literature reviews, letters, commentaries and editorials were excluded. Abstracts identified were screened for eligibility by one reviewer, with a second reviewer checking 10% of screened abstracts. Articles considered eligible were subject to full-text review. Study quality was assessed using recognised quality assessment tools (including the Jadad scoring system) and studies with a high risk of bias were excluded.

**Results:** A total of 22,334 abstracts were screened; 938 articles were retrieved for full-text review and 114 studies from 122 publications assessed. Of these, 5 studies were excluded due to high risk of bias. Over 90% of studies reported on IFX and ADM, reflecting the time these agents have been on the market (Table 1). Few studies were available for the more recently approved agents CZP ($n = 4$), GLM ($n = 2$), UST ($n = 1$) and VDM ($n = 4$). IFX was the most immunogenic agent (based on 10 RCTs and 63 non-RCTs or observational studies) and UST the least (based on 1 RCT) (Table). Immunogenicity was measured at differing time points dependent on dosing intervals and local protocols. ADAbs were detected as early as 10–14 days post-dosing but can take months to develop. An association was found between reduced efficacy of ADM and IFX therapy and the presence of ADAbs. For ADM, the presence of ADAbs did not correlate with safety, but more ADAb-positive patients receiving IFX reported AEs than ADAb-negative patients. For ADM, CZP and IFX, ADAb-positive patients had lower serum levels of the biologic than ADAb-negative patients. One study reported monitoring ADAbs to IFX in CD was more cost effective than dose escalation without drug monitoring and immunogenicity assessment.

**Table:** Range of rates of ADAbs formation to biologics in patients with CD or UCab

| Biologic agent | All studies | CD (n) | UC (n) | CD or UC (n) |
|---|---|---|---|---|
| Adalimumab | 0.3–38% (22) | 0.3–35% (11) | 2.9–5.3% (3) | 14–38% (8) |
| Certolizumab pegol | 3.3–25.3% (4) | 3.3–25.3% (4) | - | - |
| Golimumab | 0.4–2.9% (2) | - | 0.4–2.9% (2) | - |
| Infliximab[c] | 0–65.3% (73) | 2.9–60.8% (22) | 6.1–41% (8) | 0–65.3% (43) |
| Ustekinumab | 0.7% (1) | 0.7% (1) | - | - |
| Vedolizumab | 1–4.1% (4) | 1–4.1% (2) | 3.7% (1) | 4% (1) |

[a]Only studies reporting rates of ADAbs were included (8 studies did not report specific proportions of patients developing ADAbs).[b]Immunogenicity analyses are product- and assay-specific.[c]Selected studies excluded from analysis due to small sample size ($n = 28$) and high rates of immunogenicity.- Indicates no publications available.ADAbs, anti-drug antibodies; CD, Crohn's disease; UC, ulcerative colitis.

**Conclusion:** The potential clinical implication of lower biologic serum concentrations in the presence of immunogenicity is a concern for effective treatment and requires further study. In particular, more studies are required to assess the immunogenic potential of the more recently approved biologics. Diversity of study designs, patient populations, disease severity, concomitant therapies, assay methods and timing limits comparisons across studies. However, this analysis suggests that agents eliciting the lowest rate of immunogenicity may be preferential for treating CD and UC.

## P1417 TREATMENT OF BONE MARROW MESENCHYMAL STROMAL CELLS REDUCES THE ACTIVITY ANKYLOSING SPONDYLITIS ASSOCIATED WITH CROHN'S DISEASE

O. Knyazev[1], **N. Fadeeva**[1], A. Parfenov[1], A. Konoplyannikov[2], A. Lishchinskaya[1], N. Orlova[1]
[1]*IBD, Moscow Clinical Research Center, Moscow/Russian Federation*
[2]*Cells Therapy, Medical Radiological Research Cente, Obninsk/Russian Federation*

**Contact E-mail Address:** chueva@mail.ru

**Introduction:** Patients with ankylosing spondylitis (AS) and Crohn's disease (CD) should be administered early aggressive therapy, how effective in inflammatory bowel disease (IBD) and articular manifestations. Nonsteroidal anti-inflammatory drugs (NSAID) effective for the treatment of rheumatic manifestations, but their use is associated with an exacerbation of IBD. For the treatment of CD are also using mesenchymal stromal cells (MSCs). Also conduct safety studies and efficacy of MSCs for the treatment of AS. Objective: To compare the efficacy of therapy mesenchymal stromal cells (MSCs), bone marrow, and the standard anti-inflammatory therapy in the extra-intestinal manifestations (sacroiliitis and ankylosing spondylitis) in patients with Crohn's disease (CD).

**Aims & Methods:** 34 CD patients with extraintestinal manifestations (ankylosing spondylitis and sacroiliitis, are not related to the activity of Crohn's disease) were divided into two groups. The first group of patients aged 18 to 58 years (Me-34) ($n = 16$) received MSCs culture scheme (0–1–2–3, then every 26 weeks). The second group of patients with CD ($n = 18$) aged 20 to 60 years old (Me-28) received standard anti-inflammatory therapy with glucocorticosteroids (GCS) and immunosuppressive (IS). Evaluation of efficacy was conducted on the level of activity of inflammation (CRP, thrombocytosis) and ankylosing spondylitis activity index (BASDAI) were performed at 12, 25 and 52 weeks of therapy.

**Results:** Among the patients in 1-st group reduction in the activity of the AS after 12 weeks of observation occurred in 4/16 patients (25.9%). In 2-nd group, a decrease in activity of the AS occurred in 5/18 (27.7%) ($p = 0.83$). After 26 weeks in patients (group 1) receiving MSCs, reducing the activity of the AS occurred in 10/16 (62.5%). In 2 group, a decrease in activity of the AS occurred in 5/18 (27.7%) ($p = 0.044$). After 52 weeks in 1 group patients the minimal activity of the AU persisted in 10/16 (62.5%) patients with CD. In 2 group, there was increased activity of the AS in one patient 4/18 (22.2%) ($p = 0.042$).

**Conclusion:** MSCs transplantation can reduce the activity of the AS associated with Crohn's disease compared to standard anti-inflammatory GCS/IS therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1418 BIOLOGICAL THERAPY AND PREGNANCY IN INFLAMATORY BOWEL DISEASE: THE LONG-TERM SAFETY OF IN UTERO EXPOSURE IN A TERCIARY CENTER

**E. Soares**, M. Gravito-Soares, S. Mendes, M. Ferreira, F. Portela, C. Sofia
*Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** es18497@gmail.com

**Introduction:** Inflammatory Bowel Disease (IBD) is often diagnosed in the reproductive age group. FDA classify the anti-TNF drugs as presumably safe in IBD, although the literature is scarce and focus mainly on the short-term effects.
**Aims & Methods:** We aimed to evaluate the long-term safety of in utero exposure to the anti-TNF drugs in IBD. Methods: Case-control retrospective study of all pregnancies in IBD, in a tertiary center between 1994–2015. It was compared 2 groups: with exposure (cases) and without exposure (controls) to the anti-TNF drugs up to 3 preconception months. The exclusion criteria include pregnancies with no sufficient data, scheduled abortion or pregnancies that occurred previously to IBD diagnosis. It was evaluated obstetric complications and fetal prognosis, including birth defects, serious infections (infections requiring hospitalization), allergies and tumors.
**Results:** It was included 59 pregnancies, corresponding to 35 IBD women with an average of $2.4 \pm 1.4$pregnancies. The average age of conception was $32.0 \pm 4.6$years. Most pregnant women had Crohn's disease (67.8%;n = 40). The anti-TNF exposure in pregnancy occurred in 11(18.6%) IBD women, of which 5(45.4%) in monotherapy. The proportion of complications during pregnancy (18.2%vs22.9%;p = 0.733), including the number of abortions (9.1%vs16.7%;p = 0.528), during delivery (30.0%vs37.5%;p = 0.659) and in newborn (20.0%vs20.0%;p = 1.000) were similar in both groups. For an average follow-up in post-delivery of $6.7 \pm 4.8$years ($2.5 \pm 2.0$vs$7.7 \pm 4.7$years;p = 0.001), there was a higher proportion of serious infections in newborns of anti-TNF-exposed mothers (40.0%vs7.5%;OR8.222;p = 0.008), without differences in length of stay ($2.2 \pm 0.5$vs$4.3 \pm 4.9$days;p = 0.425) or diagnosis age of infection ($1.0 \pm 0.6$vs$1.2 \pm 1.4$years;p = 0.816). None of infections required intensive care or resulted in sequelae. There were no significant differences in the development of allergies (0.0%vs15.0%;p = 0.192) or neoplasia (0.0%vs2.5%;p = 0.614). After multivariate analysis, the only factor associated with the occurrence of serious infections was intrauterine exposure to anti-TNF (OR9.867;p = 0.011).
**Conclusion:** Intrauterine exposure to anti-TNF seems to be associated with increased risk of serious infections, especially in the first post-delivery year, although with no long-term complications. Further large-scale investigations are necessary in order to evaluate the real impact of these drugs in the infectious risk.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1419 INFLAMMATORY CYTOKINES AND THEIR REGULATION OF 11 BETA HYDROXYSTEROID DEHYDROGENASE TYPE 2 IN IBD PATIENTS

**M. Hussey**[1], G. Holleran[2], S. Smith[2], M. Sherlock[3], D. Mcnamara[2]
[1]*Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin, Ireland, Dublin/Ireland*
[2]*Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland*
[3]*Endocrinology, Adelaide and Meath Hospital, Dublin/Ireland*

**Contact E-mail Address:** mhussey@tcd.ie

**Introduction:** Endogenous Glucocorticoid metabolism may represent a key regulatory pathway in IBD. 11-beta hydroxysteroid dehydrogenase type 2 (11BHSD-2) is a key isoenzyme which dehydrogenase, converting the active GC cortisol (corticosterone in rodents) to inactive cortisone. We have previously shown that decreased levels of 11 BHSD2 are found in IBD patients and are independent of the glucocorticoid receptor and other cofactors. Recognised regulators of 11BHSD2 include pro inflammatory cytokines often associated with inflammation. Their effect on 11BHSD 2 expression in IBD patients is unknown.
**Aims & Methods:** We aimed to determine the association between key pro inflammatory cytokines (IL-6, TNF$\alpha$, IL-1 Beta and Rela (subunit for NFKB)) and 11BHSD2 expression in an IBD cohort. **Method:** Following informed consent, patients with known IBD aged 18–80yrs were prospectively recruited; exclusion criteria: (1) Steroid $\leq$ 6weeks (2) Coagulopathy, (3) Pregnancy, (4) Cushing/Conns Syndrome. Disease activity was assessed using biochemical (CRP), clinical (Harvey-Bradshaw Index/Mayo Score), endoscopic & histological parameters. Controls with a normal colonoscopy without a history of IBD were also recruited. Biopsies were obtained from inflamed tissue from IBD patients and a single colonic biopsy was obtained from controls. Biopsies were stored in RNA later & analyzed in batch, using Quantitative real time RT-PCR (TaqMan) & commercially available Probes & Primers. Relative transcript levels were determined using 18 S as a reference gene. Relative expression of 11BHSD2, IL-6, TNF$\alpha$, IL-1Beta and Rela (NFKB) were calculated as a mean and compared among groups using a student t test and subjects were controlled for for disease activity based on clinical, biochemical, histological and endoscopic parameters. A p value of $\leq 0.05$ was considered significant.
**Results:** To date 24 IBD patients (17 Ulcerative Colitis (UC) & 7 Crohn's Disease (CD)) and 12 controls have been recruited. IBD and control cohorts were demographically similar with 63% vs 58% being male with a mean age of 45yrs (range 20–67yrs) and 53yrs (range 25–83) respectively. Amongst the IBD cohort, 33% (n = 8) had severe, 46% (n = 11) moderate and 21% (n = 5) mild disease histologically. The mean HBI score and mayo was 7 (range 0–12 and 0–21 respectively) and the mean CRP was 35.4 mg/l (range 1–184.3 mg/l).Overall there was a significant downregulation of 11BHSD2 amongst IBD patients compared with controls, 11.06 au vs. 153 au, $p \leq 0.01$ 95%CI 30.9–252.9. Expectantly, levels of IL-1Beta, IL-6, TNF $\alpha$ and Rela were all significantly higher amongst IBD patients vs. controls as outlined in Table 1. They were also statistically upregulated in patients with more active disease as outlined in Table 1. This was accompanied by a downregulation of 11BHSD2, (active 4.8 vs inactive 12.1 au, $p \leq 0.1$), although it did not quite reach statistical significance.

**Table 1:** Relative expression of 11BHSD2 and cytokines overall & according to disease activity.

| Mean Relative Expression (au) | IBD Patients N = 24 | Controls N = 12 | P value | Active patients N = 14 | Inactive patients N = 10 | P value |
|---|---|---|---|---|---|---|
| **11BHSD 2** | 11.06 | 153 | $\leq$0.01 | 4.8 | 12.1 | NS |
| **IL-6** | 18.2 | 0.6 | $\leq$0.02 | 25.5 | 5.2 | $\leq$0.03 |
| **TNF $\alpha$** | 6.0 | 1.3 | $\leq$0.02 | 7.9 | 2.6 | $\leq$0.04 |
| **IL-1Beta** | 13.1 | 0.2 | $\leq$0.02 | 17.9 | 5.3 | $\leq$0.04 |
| **Rela (NFKB)** | 3.1 | 1.0 | $\leq$0.03 | 4.0 | 1.6 | $\leq$0.05 |

**Conclusion:** Levels of 11BHSD 2 significantly lower in IBD patients in response to increased levels of key inflammatory cytokines during active inflammation. Dysregulation in this pathway could potentially explain exogenous GCS resistance and further work is warranted.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1420 A CLINICAL TRIAL OF THE EFFECTS OF VAGUS NERVE STIMULATION IN BIOLOGIC-REFRACTORY CROHN'S DISEASE

**Introduction:** The autonomic nervous system regulates innate and adaptive immunity (Andersson, *J Exp Med* 2012; 209:1057). Activation of its efferent arm, the Cholinergic Anti-inflammatory Pathway (CAP) by electrical vagus nerve stimulation (VNS) reduces inflammation and ameliorates disease in animal models of colitis (Matteoli, *Gut* 2013; 62:1214). VNS has been studied in a biologic-naïve Crohn's disease (CD) population showing significant benefit (Bonaz, *Neurogastoenterology*, 2016; doi:10.1111).
**Aims & Methods:** We studied the efficacy of VNS in biologic–refractory CD patients in a clinical trial. This is an open label study of patients with active CD (CDAI 220–450, stool calprotectin 200 µg/g, and SES-CD ulcer score $\geq$ 2 in at least 1 segment with centrally blinded endoscopy reading). Patients refractory to biologic agents (TNF antagonists and/or vedolizumab) entered an 8 week wash out. A VNS stimulation device was implanted, consisting of a pulse generator and an electrical lead tunneled into the carotid sheath and affixed to the vagus nerve. Two weeks following implantation stimulation was initiated (pulse width 250 microseconds, 10 Hz frequency, output current incremented by tolerability to a max of 2.0 mA, for 60 seconds). From 4 to 6 weeks the output current was increased and stimulation was increased to 5 minutes. At 8 weeks, stimulations were increased from QD to QID if CDAI remission was not achieved. The stimulation remained at this level from 8 to 16 weeks, the time point of repeat endoscopy and primary endpoint (PE).
**Results:** So far, 5/8 patients reached the PE (6 males, 38 years [range 21–65]). The median (IQR) CDAI decreased from 300 (271–388) to 171 (127–395), fecal calprotectin from 4708 (1996–9390) to 1153 (509–3861) µg/g, the hs-CRP from 5.95 (2.64–8.10) to 2.78 (1.45–7.13) mg/dL and the SES-CD from 24.5 (17.1–29.0) to 19.0 (13.5–28.5). There were 3/5 patients with CDAI-100 response, 2/5 with CDAI remission, and 4/5 with reduced SES-CD. There were 9 Serious Adverse Events occurring in 5/8 patients, all of which were CD-related except for 1 (device-related postoperative infection).
**Conclusion:** VNS induced clinical and endoscopic improvement in a significant proportion of highly refractory CD patients. The trial is ongoing and additional patients will be studied.

## P1421 PREDICTORS OF THE RESPONSE TO CORTICOSTEROIDS TREATMENT IN THE ULCERATIVE COLITIS

**E. Barreiro Alonso**[1], C. Saro Gismera[1], M. Sánchez[2]
[1]*Aparato Digestivo, Hospital DE Cabueñes, Gijon/Spain*
[2]*Medicine, Farmacología, Universidad de Oviedo, Oviedo/Spain*

**Contact E-mail Address:** evabarreiroalonso@yahoo.es

**Introduction:** Ulcerative colitis (UC) may require corticosteroid treatment [1], without a reliable predictable index of response [2], except in patients with severe UC by means of Ho risk score [3], to facilitate second-line treatment or surgery [1].

**Aims & Methods:** The aims of the study were: - To assess whether the predictive value of Ho index might be applied to identify no responding patients to corticosteroid treatment in all cases of UC, independently of the severity of the disease. - To search for predictors of corticosteroids efficiency in patients with UC based on clinical characteristics and biological markers of the patients. For these, an observational retrospective study of 14 years, including 136 patients of both sexes, analyzing epidemiological and sociodemographic characteristic and clinical parameters regarding their response to corticosteroids in different phases was performed.

**Results:** UC debuts at any age, although in our sample there are three peaks: at 31, 47 and 69 years, without gender differences [4]. The 20.59% of the patients were never treated with corticosteroids, which mostly correspond to A3 and / or E1 and / or S0–1 of Montreal Classification [1]. The patients treated with corticosteroids, depending on their response, were divided in: no responding (33.09%), corticosteroid dependent (24.26%) or corticosteroid refractory (8.82%), and good responding UC (46.32%) (4). In the good responding patients the efficacy to corticosteroids decreased linearly after successive treatments (X), fitting to an equation: $Y_{\text{Percent responding}} = -13.53 + 92.38 * X$, with 98.9% of predictive response. Ho index, validated in severe UC [3], might only have a predictive value in cases with low score (0–1 points) and in the first administration of corticosteroids. But not for the remaining cases of UC. The binary logistic regression analysis gave a predictive model of response (in 75.7% of cases) to the first corticosteroid treatment, taking into account the age of the patients at diagnosis (years), the days delayed before initiation of treatment after the diagnosis of UC, and the C-Reactive Protein (CRP) (mg/l). The equation was: $Y_{\text{Responding (yes/no)}} = -1.5717 + \text{age} * 0.045 + \text{days delayed initiation treatment} * 0.0007 - \text{CRP} * 0.0105$.

**Conclusion:** - In patients responding to corticosteroids treatment in the first administration the percentage of response successive treatments is linearly predicted. - Ho score risk lack of predictive value when applied to all cases of UC. - The analysis of binary logistic regression gave a predictive equation of response to corticosteroids based on the age of diagnosis of UC, number of days until the start of corticoid treatment and the value of CRP. This should be validated in a new sample of patients.

**Introduction:** The incidence of thiopurine-induced leukopenia is higher in Asians than in individuals of European descent, but the predictability based on TPMT genotype is limited, especially in Asian patients. NUDT15 R139C was firstly found to be associated with thiopurine-induced leukopenia in a Korean inflammatory bowel disease (IBD) cohort, which is not clear in Chinese population.

**Aims & Methods:** The aim of this study was to confirm the role ofNUDT15R139C genotypeson thiopurine-induced leukopenia in Chinese IBD patients and investigate the relevant factors. A multi-center study was conducted in four tertiary hospitals in different areas of China. IBD patients onstandard dose ofthiopurine-were recruited. Clinical and epidemiological characteristics were collected from IBD databases of each included center. NUDT15 R139C genotypeswere determined with PCR-RFLP and sequencing. The interactions between gene variant and leukopenia (white blood cell $< 3000\,mm^{-3}$) were analyzed. Logistic analysis was conducted to find the risk factors for leukopenia.

**Results:** A total of 758 patients were included. Among them, 107 (14.1%) patients developed leukopenia. There was significant association of NUDT15 R139C variant and thiopurine-induced leukopenia ($P = 7.24*10^{-21}$). All of the 11 homozygous variant carriers developed early leukopenia (<8 weeks), 31.7% (52/164) heterozygous carriers developed leukopenia, while only 7.9% (44/557) wild type carriers developed leukopenia. Compared with the wide type homozygotes (CC), patients carrying variant allele T (CT+TT) have much higher risk for leukopenia ($P = 7.63*10^{-7}$, OR = 4.97, 95%CI 2.63~9.39).The sensitivity, specificity, PPV and NPV of T allele for leukopenia were 43.5%,90.5%,39.7% and 91.7%. Significant higher risks for leukopenia were found in different stages (<8Ws, 8–24Ws and >24Ws) with different OR values. Multi-factor analysis found that female and NUDT15 R139C variant were independent risk factors for thiopurine-induced leukopenia. For heterozygous carriers, the available dosage was lower than the wild type ($P < 0.001$). The results were consistant in the included centers.

**Conclusion:** NUDT15 R139C could be a promising biomarker for thiopurine-induced leukopenia in Chinese patients with IBD and be helpful for individualized therapy.

## P1423 EFFECTS OF HIGH- AND LOW-FAT MEALS ON THE PHARMACOKINETICS OF OZANIMOD, A NOVEL SPHINGOSINE 1-PHOSPHATE RECEPTOR MODULATOR

**J. Q. Tran**, J. P. Hartung, C. Tompkins, P. A. Frohna
*Celgene, Summit/United States of America*

**Contact E-mail Address:** jtran@celgene.com

**Introduction:** Ozanimod (RPC1063) is an oral, selective sphingosine 1-phosphate (S1P) 1 and 5 receptor modulator in clinical development for the treatment of relapsing multiple sclerosis and inflammatory bowel disease. Since food has the potential to significantly influence the rate and extent of drug absorption, we designed and conducted a food-effect study with ozanimod.

**Aims & Methods:** The objective of this study was to characterize the effects of high-fat and low-fat meals on the pharmacokinetics (PK) of a single oral dose of ozanimod in healthy adult subjects. This was a randomized, open-label, 3-period, 6-sequence, crossover study. Twenty-four healthy adult subjects were enrolled to receive a single 1-mg oral dose of ozanimod under 3 different conditions separated by washout periods of 7 days: fasted (treatment A), with a standard FDA high-fat meal (treatment B), and with a low-fat meal (treatment C). PK parameters for ozanimod and its two active metabolites (RP101988 [major] and RP101075 [minor]) were calculated. Point estimates and 90% confidence intervals (CIs) about the geometric mean ratio between treatments for maximum concentration ($C_{max}$) and overall exposure ($AUC_{0\text{-inf}}$ or $AUC_{0\text{-last}}$) were determined using linear mixed-effects models.

**Results:** Twenty subjects completed both treatments A and B and 23 subjects completed both treatments A and C and provided PK data for the pair-wise comparison of fed vs fasted. The 90% CIs between fed (high-fat or low-fat) and fasted treatments for the $C_{max}$ and $AUC_{0\text{-inf}}$ of ozanimod and RP101988 were all within the no-effect boundary of 0.80 to 1.25. For the minor metabolite RP101075, the 90% CIs between high-fat and fasted for $AUC_{0\text{-last}}$ and the 90% CIs between low-fat and fasted for $C_{max}$ and $AUC_{0\text{-last}}$ were within the no-effect boundary. While the 90% CI between high-fat and fasted treatments for RP101075 $C_{max}$ (0.76 to 0.88) fell outside the lower bound of the no-effect boundary, this decrease was not considered to be clinically meaningful. Median time to reach $C_{max}$ ($T_{max}$) for ozanimod was delayed following a high-fat meal (12 hours) compared to fasted and low-fat meal conditions (8 hours), but the range (6 to 12 hours) was the same. Mean elimination half-life ($t_{1/2}$) values for ozanimod and its active metabolites ranged from 17–21 hours and were similar across all 3 treatments. Overall, single oral doses of 1 mg ozanimod were considered generally well tolerated.

**Conclusion:** Ozanimod may be taken with or without food.

## P1424 INFLIXIMAB DOSE DOUBLING IS EFFECTIVE FOR OPTIMIZING TROUGH CONCENTRATIONS AND REGAINING CLINICAL RESPONSE IN PATIENTS WITH CROHN'S DISEASE

**E. Dreesen**[1], V. Ballet[2], G. Compernolle[1], G. Van Assche[2], M. Ferrante[2], S. Vermeire[2], A. Gils[1]

**Introduction:** Loss of response to infliximab (IFX) in patients with Crohn's disease can be managed by treatment intensification. Dose escalation could be preferred over interval shortening because of convenience for the patient.

However, evidence supporting dose doubling in Crohn's disease is sparse and controversial.
**Aims & Methods:** The aim of this study was to retrospectively review the effect of IFX dose doubling (from 5 mg/kg to 10 mg/kg body weight) on clinical response (based on physician global assessment and evaluated at the time of the next infusion) in a cohort of 70 patients with Crohn's disease following a loss of clinical response during maintenance treatment. IFX was measured in four consecutive trough samples before (T-1 and T0) and after (T + 1 and T + 2) dose doubling, using an in-house developed ELISA. Trough concentrations (TC) and CRP are shown as median [IQR].
**Results:** Dose doubling was clinically successful in 81% (n = 57) of the patients. Seventy percent (n = 49) of the patients received double dose IFX following an unsuccessful infusion interval shortening, resulting in an 84% (n = 41) response rate. The success rate of dose doubling as a first treatment intensification strategy was similar (76%, n = 16). The overall TC just before the infusion of 10 mg/kg IFX (T0) was 1.7 μg/mL [0.3 – 4.3] and was significantly higher in responders, 2.0 μg/mL [0.9 – 4.3], compared to non-responders, 0.3 μg/mL, [0.3 – 1.3] (p = .04). Dose doubling significantly increased TC to 5.2 μg/mL [1.7 – 10.1] at T+1 (p < .0001). Clinical response was associated with significantly higher TC after dose doubling at T+1, 5.5 μg/mL [3.0 – 10.4], compared to non-responders, 0.5 μg/mL [0.3 – 1.3] (p = .004). ROC analysis indicated that a target T + 1 IFX TC of 1.5 μg/mL is already associated with clinical response (88% specificity, 77% sensitivity, AUROC 0.75, p < .01). IFX TC increased between T0 and T + 1 in 73% (n = 51) of patients and was associated with a response rate of 90% (n = 46). In 27% (n = 19) of the patients no increase in TC was observed, which was associated with a significantly lower response rate of 58% (n = 11) (p = .004). An IFX TC increase > 1 μg/mL predicts clinical response (73% specificity, 85% sensitivity, AUROC 0.76, p < .01). Clinical response to dose doubling was also reflected in a significant decrease and normalization of CRP from 7.9 mg/L [1.7 – 22.4] at T0 to 4.4 mg/L [1.8 – 12.0] at T + 1 (p = .002), which did not occur in case of non-response (from 10.5 mg/L [3.9 – 62.5] to 5.1 mg/L [3.0 – 41.7]) (p = .5). CRP at T0 was not associated with response. Eight out of 13 non-responders received a second IFX infusion at 10 mg/kg at T + 1 which resulted in higher TC before the next infusion at T + 2 (6.0 μg/mL versus 0.7 μg/mL) but clinical response was never regained.
**Conclusion:** Dose doubling of IFX successfully restored the clinical response even when earlier infusion interval shortening attempts failed. During loss of response, IFX TC were sub-therapeutic (< 3 μg/mL), despite earlier infusion interval shortening attempts to regain response. Dose doubling was effective for restoring therapeutic IFX TC. Clinical response to IFX dose doubling is associated with higher pre- and post-escalation TC and with a normalization of CRP.

**Introduction:** We performed a systematic review and meta-analysis to assess efficacy and safety of interventions used as adjunct to standard treatment in patients with active mild to moderate ulcerative colitis (UC).
**Aims & Methods:** Medline, Embase, Cochrane Central Register of Controlled Trials and reference lists of relevant reviews were systematically searched up to September 2015. We included randomised controlled trials of therapies added to current treatment with 5-aminosalicylic acid, immunosuppressants or steroids in patients with active UC. We synthesised results regarding remission, response, mucosal healing, and incidence of any adverse event. We quantified heterogeneity with the $I^2$ statistic.
**Results:** Seventeen studies (1338 patients) assessed efficacy of 6 adjunctive interventions. All studies were placebo controlled, except for one that compared beclomethasone propionate (BDP) with prednisone. Budesonide multimatrix (MMX), BDP, per os LMWH (Low Molecular Weight Heparin), transdermal nicotine and phosphatidylcholine all led to higher remission compared to placebo. Nevertheless, only per os (LMWH), transdermal nicotine, phosphatidylcholine and probiotics led to response, whereas mucosal healing was observed only following treatment with budesonide MMX or probiotics. Finally, all interventions but nicotine were associated with similar risk for any adverse event compared to placebo (table 1).
**Conclusion:** Budesonide MMX, BDP, phosphatidylcholine, probiotics and per os LMWH seem to be a safe option for adjunctive treatment of active mild to moderate UC. However, these conclusions are based on limited evidence, hence there is need for additional large trials.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1426 EFFICACY OF INFLIXIMAB BIOSIMILAR CT-P13 INDUCTION THERAPY ON MUCOSAL HEALING IN ULCERATIVE COLITIS

**Introduction:** CT-P13 is the first biosimilar to infliximab that was approved for the same indications as its originator infliximab. No data is available on the effect of infliximab biosimilar on mucosal healing.
**Aims & Methods:** The aim of this study was to evaluate the efficacy of CT-P13 induction therapy on mucosal healing in patients with ulcerative colitis (UC). UC patients, who received CT-P13 therapy from its local introduction at three Hungarian and one Czech IBD centres, were prospectively enrolled. Sigmoidoscopy was performed after the end of the induction therapy at week 14. Mucosal healing was defined as Mayo endoscopic subscore 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore 0. Trough level of CT-P13 was measured at week 14.
**Results:** Sixty-three UC patients who underwent CT-P13 induction therapy were enrolled in the study. Indication of the therapy was acute, severe flare up and chronic, refractory activity in 24 and 39 patients. Cumulative clinical response and steroid-free remission at week 14 were achieved in 82.5% and 47.6% of the patients. Sigmoidoscopy revealed steroid-free mucosal healing in 47.6% of the patients, complete mucosal healing was present in 27%. Mayo endoscopic subscore decreased significantly at week 14 compared to baseline. Trough levels of infliximab correlated with mucosal healing.
**Conclusion:** This was the first study examining the efficacy of CT-P13 induction therapy on mucosal healing in UC. Our results indicate that mucosal healing is achieved in two thirds of UC patients by the end of the induction treatment with CT-P13.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1427 SUBTHERAPEUTIC LEVELS OF INFLIXIMAB AND ADALIMUMAB ARE ASSOCIATED WITH INCREASED DISEASE ACTIVITY IN PATIENTS WITH CROHN'S DISEASE

**Introduction:** Anti-TNF-$\alpha$ agents have a central role in the treatment of moderate to severe inflammatory bowel disease (IBD), but low serum drug concentrations (SDC) may result in lack of response. Measuring SDC offers the possibility of individualized and optimized treatment.
**Aims & Methods:** Our aim was to determine the prevalence of subtherapeutic SDC in a cohort of IBD patients, who had received at least three doses of infliximab (IFX) or adalimumab (ADA). We also wanted to investigate whether SDC below our defined therapeutic ranges were associated with increased levels of disease activity markers. In a cross-sectional study at Stavanger University Hospital we included patients with ulcerative colitis (UC) or Crohn's disease (CD), aged 16 years and above. Demographic data, Partial Mayo Score (PMS) or Harvey Bradshaw Index (HBI), CRP, fecal calprotectin and type of anti-TNF-a agent were recorded. SDC were measured using automated in-house methods at Oslo University Hospital. Therapeutic serum concentrations were defined as 3–8 mg/L for IFX and 5–12 mg/L for ADA.
**Results:** In total, 210 patients were included, of which 73 (34.8%) had UC and 137 (65.2%) CD. Median (range) age was 37 (16–78) years and 57.6% were men. Median duration of treatment was 25 (2–98) months for UC, and 38 (2–164) for CD. Twenty-four (33%) patients with UC and 103 (72.5%) with CD received ADA, 49 (67%) UC- and 39 (27.5%) CD patients received IFX. In the ADA group, subtherapeutic SDC were present in 16.7% (UC) and 27.7% (CD). In the group receiving IFX, subtherapeutic SDC were present in 23% (UC) and 30.3% (CD). CD patients treated with ADA with SDC $<5$ mg/L had a significantly higher median fecal calprotectin- and CRP-levels compared to those with SDC $\geq 5$ mg/L ($p=0.005$ and $p=0.003$, respectively). CD patients treated with IFX with SDC $<3$ mg/L had higher CRP compared to patients with SDC $\geq 3$ mg/L ($p=0.003$). Fecal calprotectin levels were not significantly different. CRP and fecal calprotectin levels were not different in UC patients with subtherapeutic versus therapeutic SDC. We found no differences in disease activity indexes (HBI, PMS) between therapeutic and subtherapeutic SDC in either of the disease groups. In ADA treated patients, anti-drug antibodies were detected in 6.3% (CD) and 0% (UC) of the samples, whereas 3% (CD) and 14.6% (UC) of IFX treated patients presented with anti-drug antibodies.
**Conclusion:** In patients with CD subtherapeutic serum drug concentrations were associated with a significantly higher disease activity for both anti-TNF agents. These findings were not observed in the UC cohort.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1428 TUBERCULOSIS INFECTION IN AN INFLAMMATORY BOWEL DISEASE COHORT OF PATIENTS RECEIVING ANTI-TNF THERAPY IN A MODERATE TO HIGH TUBERCULOSIS INCIDENCE AREA IN EUROPE

**R. Barosa**[1], M. Patita[1], L. Roque Ramos[2], G. Nunes[3], P. Figueiredo[3], A. Carmo Vieira[1], V.M.F. Pereira Fernandes[4], J. Freitas[5]
[1]Dept. Of Gastroenterology, Hospital Garcia de Orta, Almada/Portugal
[2]Gastroenterology, Hospital Garcia de Orta, Almada/Portugal
[3]Hospital Garcia de Orta, Almada/Portugal
[4]Hospital Gracia de Orta, Almada/Portugal
[5]Hospital Garcia Da Orta - Almada, Hospital Garcia de Orta, Almada/Portugal

**Contact E-mail Address:** a.rita.b@gmail.com
**Introduction:** Portugal has been considered a high incidence area for tuberculosis (TB) until 2000 and since then TB has been declining from 44.1 to 22.9 cases per 100 000 inhabitants, which is still higher than the average incidence in Europe. The incidence in urban centres, as is the case of our hospital, is also higher. Inflammatory bowel disease (IBD) patients receiving anti-tumor necrosis factor $\alpha$ (anti-TNF$\alpha$) are at increased risk for active TB.
**Aims & Methods:** We aimed to study the prevalence of latent (LTBI) and active TB in an IBD cohort under anti-TNF living in an intermediate to high TB incidence area. Retrospective cohort study of IBD patients receiving anti-TNF$\alpha$ from May 2001 to September 2015. Demographic, clinical, laboratorial and radiological data were collected from patients' medical records. LTBI was diagnosed when there was a positive tuberculin cutaneous test (TCT) or Booster (induration $\geq 5$ mm) or, since 2005, interferon gamma releasing assay (IGRA), and no radiological or clinical evidence of active TB.
**Results:** 101 patients were included with a mean age of 40.6±13.8 years, 58.4% were female. 78.2% had Crohn's disease, 19.8% had ulcerative colitis and 2.0% inflammatory bowel disease unclassified, with a median duration of disease of 10,5 years (IQR 6.3–15.9). 74.2% were on immunosuppressors when anti-TNF$\alpha$ was started. TCT was positive in 12.9% with TCT booster and IGRA diagnosing LTBI in further 1.0% of the patients each. Isoniazid was used in all 14.9% LTBI patients. Active TB was diagnosed in 3.0% ($n=3$), but the incidence of active TB in patients starting anti-TNF$\alpha$ after 2005 was only 1.2%. The mean age at diagnosis of TB was $44.0 \pm 7.9$ years. Two patients were anti-TNF$\alpha$ naives; two patients were under infliximab and one under adalimumab with a mean duration of anti-TNF therapy of $53.7 \pm 8.6$ months. TCT was negative in all 3 patients and IGRA was not available at the time of starting anti-TNF$\alpha$ in 2 (2001–2002). Two patients presented extrapulmonary TB (miliar and pleural). None of the patients died and one restarted anti-TNF one year after TB diagnosis.
**Conclusion:** Active tuberculosis in IBD patients receiving anti-TNF$\alpha$ in an intermediate-high incidence area was 3.0% and the infection was most frequently extra-pulmonary. Excluding and treating LTBI before anti-TNF$\alpha$ as recommended failed to eliminate the risk of active TB.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1429 CUMULATIVE EXPOSURE TO ANTI-TNF ALPHA AND RISK OF CANCER

**L. Maia**[1], P. Lago[1], Â. Rodrigues[1], M. Santos[2], C. Caetano[1], M. Salgado[1], I. Pedroto[1]
[1]Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal
[2]Cardiology, Centro Hospitalar do Porto, Porto/Portugal

**Contact E-mail Address:** luismaia.gastro@gmail.com
**Introduction:** Although current evidence suggests no excess risk of cancer in patients with inflammatory bowel disease (IBD) treated with anti-tumour necrosis factor alpha (anti-TNF) agents, little is known about how the risk changes during time of exposure.
**Aims & Methods:** In this study we aimed to analyse the impact of the cumulative exposure to anti-TNF agents on cancer development in patients with IBD. Retrospective cohort study with 210 patients with IBD submitted to any duration of anti-TNF agents between 2003 and 2014. Demographic, clinical and medication data were collected. The primary outcome was the diagnosis of any cancer after initiation of an anti-TNF agent.
**Results:** Of the 210 patients 56.2% were women and the age at the end of follow-up was 43.24 + /- 13.98 years. Median follow-up time was 10.0 years, for 2442,3 persons-year. One hundred and ninety patients were diagnosed with Crohn's disease, 17 with Ulcerous Colitis and 3 with IBD unclassified. 94.8% were treated with azathioprine (average 1505.7 days) and 26.7% with methotrexate (average 1101.5 days) – total time of exposure to immunomodulators of 840,3 persons-year. One hundred and sixty three patients were treated with infliximab (average 1286.5 days) and 82 with adalimumab (average 1018.4 days): 788.7 years of exposure overall. Combination therapy with azathioprine was used in 132 (62.9%) patients (average 842.7 days) and with methotrexate in 44 (21.0%, average 686.5 days). Five patients had a personal history of cancer, and none of them recurred. Fourteen patients developed cancer during follow-up (6.7%; 5.7/1000 persons-year of follow-up and 17.8/1000 persons-year of anti-TNF therapy exposure): 1 colorectal, 2 fistula-related and 11 extra-intestinal cancers. Half of them were under azathioprine on diagnosis. Three (21.4%)

were diagnosed with less than 12 months of anti-TNF therapy and 8 (57.1%) with less than 24 months. The duration of exposure to anti-TNF, in days, was not associated with excess risk of cancer (OR 1.0; p = 0.196; 95% CI = 0.999–1.000), even after adjustment for age, smoking, time from diagnosis and exposure to azathioprine.
**Conclusion:** In patients with IBD, duration of exposure to anti-TNF therapy was not associated with excess risk of cancer. The potential increase in the risk of cancer with this therapy does not seem to be associated with its duration.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Anemia represents the most common systemic complication of inflammatory bowel disease (IBD) and results from a combination of complex mechanisms, though iron deficiency and inflammation play major roles.
**Aims & Methods:** We aimed to analyze the prevalence and severity of anemia in a cohort of IBD patients and to determine the impact of anti-tumor necrosis factor (TNF) therapy on hemoglobin (Hb) levels. Retrospective study of an adult IBD cohort assigned to start anti-TNF therapy. Demographic, clinical and laboratorial (prior starting anti-TNF and after six months of therapy) data were collected from patients medical records. Anemia was defined as an Hb level lower than 12 g/dL in women and 13 g/dL in men; it was classified as mild (Hb $\geq$ 10 g/dL), moderate (Hb between 8–10 g/dL) or severe (Hb $\leq$ 8 g/dL).
**Results:** 85 patients were included, 57.6% female, with a mean age 35.5 ± 13.9 of years. 76.5% of patients had Crohn's disease (27.1% with fistulising phenotype) and 23.5% Ulcerative Colitis. At baseline, 87% of patients were under immunomodulators, 72.9% started Infliximab and 27.1% started Adalimumab. The prevalence of anemia was 58.8%. Anemia was considered mild in the majority of cases (42.4%) and severe in 11.8%. 8% of patients were under iron supplementation. At baseline, Hb levels correlated inversely with C-reactive protein levels (Spearman's rho -0.345, $p < 0.005$) and sedimentation rate (Spearman's rho -0.467, $p < 0.005$). We found a statistically significant difference in Hb levels before and after 6 months of being under anti-TNF therapy (11.7 g/dL Vs. 12.7, $p < 0.005$), with a significant decrease on the prevalence of anemia (58.8% Vs. 35.2%, $p < 0.005$). Fistulizing Crohn's disease (CD) was associated with anemia ($p = 0.04$). In contrast, gender, IBD type, CD location, UC extension or previous immunosuppression were not associated with anemia prevalence at baseline.
**Conclusion:** Anemia is a prevalent condition in the IBD population, irrespective of IBD type. A CD penetrating behavior is associated to the presence of anemia. High levels of inflammation are related to lower Hb levels. Anti-TNF therapy successfully improves Hb levels and is associated to a decrease in the prevalence of anemia.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1431 INFLIXIMAB BIOSIMILAR CT-P13 THERAPY IS EFFECTIVE IN MAINTAINING CLINICAL AND ENDOSCOPIC REMISSION IN CROHN'S DISEASE AND ULCERATIVE COLITIS – EXPERIENCES FROM A SINGLE CENTER

**K. Farkas**[1], M. Rutka[1], T. Ferenci[2], F. Nagy[1], A. Balint[1], R. Bor[1], Á. Milassin[1], A. Fabian[1], Z.G. Szepes[3], T. Molnar[4]

**Introduction:** CT-P13, the first biosimilar monoclonal antibody to infliximab (IFX) has previously been confirmed to be efficacious in inducing remission in inflammatory bowel disease (IBD) patients.
**Aims & Methods:** The aim of this study was to assess the efficacy and safety of maintenance CT-P13 therapy in Crohn's disease (CD) and ulcerative colitis (UC). Patients diagnosed with CD and UC, who were administered CT-P13, were prospectively enrolled. Clinical outcome was estimated at fixed appointments throughout the 54-week treatment period. In UC, control sigmoideoscopy was performed at week 14 and week 54 to assess mucosal healing. In CD, control endoscopy was performed at week 54. Predictive factors, like CT-P13 trough levels at week 2, 6 and 14, antibody positivity at week 2, 6 and 14, C-reactive protein (CRP) level, concomitant steroid and azathioprine therapy, previous use of anti TNF, need of dose intensification and endoscopic remission for disease outcome at week 54 were statistically evaluated.
**Results:** Twenty-eight CD and 29 UC patients were included in the study of which 27 CD and 25 UC patients completed the induction therapy and 25 CD and 21 UC patients completed the 54-week treatment period. In CD, clinical response was achieved in 96.4% of the patients at week 14 and in 80% at week 54. Loss of response developed in 20% of the patients at week 54. In UC, clinical response was achieved in 82.8% of the patients at week 14 and in 62% at week 54. Rate of loss of response was 38% at week 54. Mucosal healing was shown in 74% of the patients at week 14 and in 68.8% at week 54. Overall, infusion reaction occurred in 14.3% of CD and 17.2% of UC patients. Bowel resection had to be performed in 2 CD patients and colectomy was needed in 3 UC patients throughout the treatment period. One UC patient died after the 2nd infusion because of azathioprine-induced myelosuppression. Dose intensification was the only factor associated with lower response rate in UC. None of the examined parameters were predictive to worse outcome in CD.
**Conclusion:** Our results confirm that CT-P13 is safe and effective in maintaining both clinical and endoscopic remission. Dose intensification was the single parameter that influenced disease outcome in UC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1432 CLINICAL EXPERIENCE WITH VEDOLIZUMAB IN ANTI-TNF REFRACTORY IBD PATIENTS

**Introduction:** Idiopathic inflammatory bowel disease (IBD), including Crohn's disease (CD), ulcerative colits (UC) and indeterminate colitis, are chronic inflammatory disorders defined by distinctive clinical, pathological, endoscopic and radiological features[1]. Treatment options for IBD include glucocorticoids for induction and treatment to induce recovery in relapse phase, immunosuppresive agents (i.e. azathioprine, mercaptopurine or methotrexate) and tumour necrosis factor antagonists (Anti-TNF). At times, we encounter patients in our clinical practice who had primary loss of response or secondary loss of response on treatment with Anti-TNF. Further investigations looking into this would include endoscopic and radiologial evaluation, as well as the use of therapeutic drug monitoring and check for antibody assay. The approval of Vedolizumab (VDZ) in 2014 for the treatment of moderate to severe Inflammatory Bowel Diease offers gastroenterologists a gut-specific biologic alternative to anti-TNF therapy in patients with refractory disease. Gut selective blockade of lymphocyte trafficking by VDZ, an $\alpha 4\beta 7$ integrin antibody, has been shown in clinical trials to offer effective induction and maintenance therapy in both ulcerative colitis and Crohn's disease [2,3] and a potential role as a rescue therapy post anti-TNF therapy [4,5].
**Aims & Methods:** We evaluated the efficacy of VDZ in a cohort of anti-TNF refractory IBD patients attending three teaching hospitals affiliated with Royal College of Surgeons in Ireland (RCSI). VDZ was administered intravenously at weeks 0,2,6 and 8 at a dose of 300 mg. Patients' characteristics and disease severity at first VDZ infusion and clinical response at week 12 post treatment were assessed. Clinical response among CD patients was assessed using the Harvey Bradshaw Index (HBI) and the Mayo score was used for UC patients. The data was obtained from the patients' charts and from patients when they attended the outpatient's review clinic pre and post commencement of VDZ infusions.
**Results:** Between November 2014 and March 2016, 19 patients (13 CD and 6 UC, 12 females and 7 males) received a total of 88 VDZ infusions. The mean age for our VDZ cohort was 36 years (range 20 – 55). There were two patients who were started on VDZ recently and have not reached week 12 of treatment yet. All 19 patients had undergone prior anti-TNF treatment, including 15 patients (79%) who had undergone both infusion and subcutaneous anti-TNF therapies. Thirteen patients were on concomitant immunomodulators (68%), while 8 patients (42%) had prior colonic resections. The mean pre-VDZ baseline HBI was 8 and Mayo score was 9. At week 12,10 of our 11 (91%) CD patients showed $\geq$ 3 point reduction in their HBI and 5 of our 6 (83%) UC patients had $\geq$3 point reduction in their Mayo scores. 15 out of 17 patients (88%) had shown clinical response. There were no reported infusion reactions or adverse events among our VDZ cohort.
**Conclusion:** Vedolizumab is safe, well tolerated and effective in our refractory IBD cohort all of whom had failed or lost response to prior anti-TNF therapy. Despite clinical trials suggesting superior efficacy among anti-TNF naive IBD patients, in clinical practice VDZ remains second-line therapy to anti-TNF.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1433 PERCEPTION FROM PATIENTS WITH ULCERATIVE COLITIS OR CROHN'S DISEASE TOWARDS THE PERFORMANCE OF BIOSIMILARS VERSUS BIO-ORIGINATORS

X. Hu[1], E. Sullivan[2], J. Piercy[2], J. Waller[2], **C. Black**[1], S. Kachroo[1]

[2]*Adelphi Real World, Bollington/United Kingdom*

**Contact E-mail Address:** christopher.black2@merck.com

**Introduction:** While the clinical impact of biosimilar substitution on patients with ulcerative colitis (UC) and Crohn's disease (CD) is being investigated by several clinical trials, evidence on how patients perceive biosimilars as treatment options and their satisfaction on the effectiveness is sparse.

**Aims & Methods:** We aimed to assess and compare the satisfaction of patients receiving a biosimilar and patients receiving a bio-originator. The Adelphi Biosimilars Therapy Insight Programme uses a well-established methodology, similar to that used in over 100 separate projects, and contains real-world, cross-sectional survey data from 25 German gastroenterologists who currently prescribe biosimilars, collected in Q4 2015 - Q1 2016. Gastroenterologists completed patient record forms (PRFs) about their UC and CD patients who were either receiving a bio-originator or a biosimilar of the same molecule. The PRF contained detailed questions on diagnosis, severity of condition and symptoms. Patients were then invited to complete a patient self-completion form containing questions on demographics and level of satisfaction with their current treatment.

**Results:** A total of 136 patients with UC or CD were included in this analysis, with 70 (51%) receiving a biosimilar and 66 (49%) receiving a bio-originator at time of survey. Demographically, patients on a biosimilar or a bio-originator did not differ significantly in terms of age, gender, ethnicity, and BMI. They also had similar symptom duration and current disease severity. Patients were asked to consider all aspects of the current treatment (effectiveness, safety, and quality) and almost all patients on bio-originators (91%, $n = 60$) felt satisfied they were receiving the best treatment compared to 79% of patients on a biosimilar ($p = 0.0486$). When asked about their perception of their current drug's performance on controlling their symptoms, 26% of those on a bio-originator responded that they were ''Very satisfied'', compared to 13% of patients on a biosimilar, but the difference is not significant ($p = 0.0580$). Nonetheless, this is consistent with the physicians' impression where satisfaction with bio-originators' control of patients' symptoms was higher (''Very satisfied'': 30% vs 16%, $p = 0.0446$).

**Conclusion:** A significantly larger proportion of patients who were receiving a bio-originator felt satisfied about the safety, clinical effectiveness and manufacturing quality of the drug than did the patients receiving a biosimilar. Biosimilars have only recently been approved for treating UC and CD. There isn't a lot of experience using them yet. Patients' preferences should be considered in treatment decisions. The benefit of cost-saving of biosimilars should not be achieved at the price of compromised patient satisfaction.

## P1434 WEIGHT DISTRIBUTION IN EUROPEAN PATIENTS WITH CROHN'S DISEASE IN ADELPHI 2015 DSP

**D. Naessens**[1], B. Hoskin[2], J. Lucas[2]
[1]*Janssen-Cilag, Beerse/Belgium*
[2]*Adelphi Real World, Bollington/United Kingdom*

**Contact E-mail Address:** dnaessen@its.jnj.com

**Introduction:** While it is generally acknowledged that active Crohn's disease results in weight loss, there is a paucity of information on the weight distribution of Crohn's patients at the time of initiation of therapy with biologics and the difference between Crohn's patients whose disease is under control versus those patients whose disease is not under control. This research aims to describe the weight distribution in European countries in patients recently started on biologic therapy, to describe patients weights in patients whose disease is under control versus not under control and comparing these results with results obtained for the general population according the Special Eurobarometer Health and Food (Wave 64.3), a large, representative, survey conducted across the EU for the European Commission.

**Aims & Methods:** The Adelphi DSP is a retrospective, cross-sectional analysis of survey data of patients with Crohn's disease, conducted between December 2014 and March 2015. Gastroenterologists from the US, Italy, France, Spain, Germany and the UK completed Patient Record Forms (PRFs) for the next 8 presenting Crohn's patients; questions included: specific demographics, physician subjective levels of severity (mild, moderate, severe), remission status and current treatment received. Respondents were incentivized for survey completion. Average weights were calculated for Italy, Spain, France, Germany and the UK (EU-5). Since weight distribution in Italy, Spain and France are more similar according to the Special Eurobarometer, results for these countries were also pooled in order to improve the reliability of the estimate for these countries. Patients not in control of their disease were defined as having a physician subjectively defined disease severity of moderate to severe and documented as not currently being in remission in the patient record form (PRF). Patients in control of disease were defined as mild disease and being in remission in the PRF.

**Results:** There are 2350 CD patients in total within the Adelphi Real World CD DSP in Europe, of which 996 patients were receiving a biologic at the time of data collection.

**Table 1:** Average weight in kg (SD; N)

| | EU – 5 | | France – Italy - Spain | |
|---|---|---|---|---|
| | Male | Female | Male | Female |
| Patients on a biologic < 3 months | 71.2(12.84;76) | 58.8(11.79;77) | 69.7(12;51) | 58.6(13.12;42) |
| | 65 (13.08; 153) | 64.7 (13.63; 93) | | |
| Patients on biologic not in control | 71.7 (15.09; 167) | 60.8 (15.54; 155) | 70.9 (13.55; 94) | 61.1 (18.26; 87) |
| | 66.4 (16.23; 322) | 66.2 (16.67; 181) | | |
| Patients regardless of treatment not in control | 72.8 (17.38; 325) | 61.5 (17.38; 317) | 73.3 (19.01; 185) | 60 (14.87; 173) |
| | 67.2 (17.82; 642) | 66.8 (18.36; 358) | | |
| Patients regardless of treatment in control | 77.1 (18.59; 589) | 64 (17.45; 547) | 75.8 (17.1; 355) | 62.9 (16.89; 328) |
| | 70.8 (19.18; 1136) | 69.6 (18.17; 683) | | |
| Eurobarometer * | 71.48 | 69.7 | | |

*unweighted average

**Conclusion:** These results provide an accurate estimate of the average weight observed of Crohn's patients in the EU in the real-world setting, substantiate the fact that uncontrolled patients' average weight is lower than those of the average population, and substantiate the weight differential between patients in remission and patients with active moderate-severe disease. This study contributes to the scant literature in this area, informing our understanding of the disease in real-world settings of clinical care.

## P1435 MYCOPHENOLATE MOFETIL IS A VALID OPTION IN HARD-TO-TREAT PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**F.S. Macaluso**[1], M. Maida[2], S. Renna[1], E. Orlando[1], M. Affronti[1], C. Sapienza[1], M. Dimarco[1], G. Rizzuto[1], R. Orlando[1], M. Cottone[1], A. Orlando[1]
[1]*Di.bi.m.i.s., Division Of Internal Medicine, ''villa Sofia-cervello'' Hospital, University of Palermo, Palermo/Italy*
[2]*Gastroenterology, Cervello Hospital, Palermo/Italy*

**Contact E-mail Address:** fsmacaluso@gmail.com

**Introduction:** Few studies evaluated the role of mycophenolate mofetil (MMF) in inflammatory bowel disease (IBD). In addition, they were mostly performed on patients with failure to thiopurines only, and none specifically focused on subjects with previous multiple intolerances and/or nonresponses to immunosuppressants (IM) and biologics.

**Aims & Methods:** The aim of this study was to evaluate efficacy and tolerability profile of MMF in patients with IBD and limited medical treatment options. This study was conducted at the Division of Internal Medicine of ''Villa Sofia-Cervello Hospital'', Palermo, a tertiary referral centre for IBD. All consecutive patients who started an off-label treatment with MMF from January 2014 to March 2016 were entered in a prospectively maintained database. All adverse events and clinical outcomes were reported. We defined as ''complete response'' the steroid-free clinical remission, and as ''partial response'' a clinical improvement with concomitant reduction or discontinuation of steroids. All clinical variables were assessed at univariate analysis in order to identify predictive factors of treatment success.

**Results:** Baseline features of the study population ($n = 24$) are summarized in table 1. All patients had at least one previous nonresponse to IM or biologics. In particular, 15 (62.5%) were non responders to at least one IM, and 22 (91.7%) to at least one biologic agent; 12 (50.0%) were not responder to at least one IM plus at least one biologic. In addition, 20 (83.3%) had a previous intolerance to at least one IM, and 13 (54.2%) to at least one biologic. At the time of initiation of MMF, 22 patients had a moderate to severe active disease (91.7%), two had clinically inactive disease but were steroid-dependent, and 21 (87.5%) were concurrently taking oral corticosteroids with a median dose of 15 mg/day of prednisone (range 5–37.5 mg). The median duration of total follow-up was 32 weeks (range 12–124). Four weeks after initiation of MMF therapy, a complete response was achieved in 4 patients (16.7%), while a partial response in 13 (54.1%). At the end of follow- up 12 patients (50.0%) remained on MMF. Six achieved and maintained steroid-free remission throughout the study period (25.0% of total), and a further 6 patients (25.0%) achieved a partial response with complete discontinuation of steroids. Twelve patients (50.0%) were considered as treatment failure, and five of them underwent surgery. Drug side-effects were experienced by 7 out of 24 of patients (29.2%), leading to MMF discontinuation in five of them. No factor was identified as predictive for treatment success with MMF at univariate analysis. There was a trend towards a

higher efficacy in patients with ulcerative colitis compared with Crohn's disease (63.6% vs. 38.5%), but this was not significant (p = 0.20).

| Variable | N = 253 |
|---|---|
| **Age (years). mean ± S.D.** | 41.4 ± 12.5 |
| **Male gender, n (%)** | 10 (41.7%) |
| **Smokers, n (%)** Never Current Ex | 18 (75.0%) 2 (8.3%) 4 (16.7%) |
| **Type of Disease, n (%)** Crohn's Disease Ulcerative Colitis | 13 (54.2%) 11 (45.8%) |
| **Localization of the disease, n (%) Crohn's Disease** Ileal Ileocolic Colic Upper gastrointestinal tract Perianal Disease **Ulcerative Colitis** Proctitis Left-sided Extensive | 2 (15.4%) 9 (69.2%) 1 (7.7%) 1 (7.7%) 5 (41.7%) 0 (0.0%) 7 (63.6%) 4 (36.4%) |
| **Behavior (Crohn's Disease), n (%)** Inflammatory Stricturing Fistulizing | 3 (21.3%) 5 (38.3%) 5 (38.3%) |
| **Previous resections (Crohn's Disease), n (%)** | 10 (76.9%) |
| **Extraintestinal manifestations, n (%)** | 8 (33.3%) |
| **Concurrent IBD medications at baseline, n (%)** Prednisone 5-Aminosalycilates Biologics (combination therapy) | 21 (87.5%) 9 (37.5%) 4 (16.7%) |
| **Previous Intolerances/Nonresponses, n (%)** Nonresponse to at least one IM or one biologic Nonresponse to at least one IM Nonresponse to at least one biologic Nonresponse to at least one IM plus at least one biologic Intolerance to at least one IM Intolerance to at least one biologic | 24 (100%) 15 (62.5%) 22 (91.7%) 12 (50.0%) 20 (83.3%) 13 (54.2%) |

**Conclusion:** In our prospective mid-term experience, MMF was successful and well tolerated in half of the patients with IBD and multiple previous failures to other IM and/or biologics.

## P1436 RISK FACTORS FOR COLECTOMY IN ULCERATIVE COLITIS PATIENTS WITH SEVERE FLARE-UP

**W. Dahmani**, W. Ben Mansour, A. Guedich, M. h. Loghmari, L. Safer
*Gastroenterology, Fattouma Bourguiba University Hospital, Monastir/Tunisia*

**Contact E-mail Address:** wafadh115@gmail.com
**Introduction:** Surgery continues to play an important role in acute severe ulcerative colitis (ASUC). Determining risk factors predisposing to colectomy could help the clinicians to indicate surgical intervention at the appropriate time in patients with ulcerative colitis (UC).
**Aims & Methods:** Aim: to investigate different factors which may predispose to colectomy in ASUC. Methods: In this retrospective study, we evaluated every hospital admissions due to acute exacerbation of UC and requiring intravenous corticosteroid treatment between 2000 and 2015. Two groups of patients were individualized: those who underwent colectomy (Gl) and those who avoided surgery (G2). Different parameters were compared and statistically analyzed between the two groups. $P < 0.05$ was considered statistically significant.
**Results:** Of the 105 UC patients hospitalized during the study period, 43 (41%) met the criteria of severe ulcerative colitis (44% male and 56% female; median age: 37 years). The median disease duration was 48 months. Twenty-four patients (55.4%) had pancolitis, 15 (34.8%) had left-sided colitis and 4 (9.3%) had proctitis. Overall 30.2% of the patients underwent colectomy. Patients of G1 were characterized by the following features when compared to those of G2: younger age at UC diagnosis (median age 30 years vs. 44 years, p = 0.02), more frequently pancolitis at diagnosis (44% vs. 26%, p = 0.026), with lower albumin level at admission (24.2 g/l vs. 35 g/l, p = 0.01). No difference was found between the two groups when analyzing disease duration, body mass index, extra-intestinal manifestations presence and inflammatory laboratory parameters.
**Conclusion:** Our results suggest that severe UC patients with younger age at diagnosis, pancolitis and hypoalbuminemia have a higher likelihood of requiring colectomy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1437 THE PROGNOSTIC FACTORS AND OUTCOMES OF RE-OPERATION WITHIN 6 MONTHS IN PATIENTS WITH INTESTINAL BEHCET'S DISEASE

**Y.E. Park**, J.H. Cheon, W.H. Kim, T.I. Kim, S.J. Park, H.J. Lee
*Intestinal Medicine, Severance hospital, Seoul/Korea, Republic of*

**Contact E-mail Address:** ready200@yuhs.ac
**Introduction:** Patients with intestinal Behcet's disease (BD) who received surgical treatment often require reoperation. However, there have been no studies on the prognostic factors and outcomes of reoperation timing in the patients with intestinal BD.
**Aims & Methods:** We evaluated 53 patients who received colorectal reoperation with intestinal BD between 2006 and 2016. We sought to compare between those requiring early surgical resection within 6 months and those over 6months after the initial bowel surgery and to determine the prognostic factor for early reoperation.
**Results:** Seventeen patients (32.1%) received reoperation within 6 months, and 36 patients (67.9%) received reoperation after 6 months. The early reoperation group with intestinal BD had significantly higher perioperative ESR and C-reactive protein (CRP) levels than the late reoperation group (P = 0.010; 74.7 ± 34.2 vs 46.9 ± 35.5, P = 0.001; 71.9 ± 17.4 vs 37.7 ± 6.4). Variables including male gender, emergency surgery at first operation status, and high ESR and CRP levels were significant prognostic factors in univariate analysis; however, after the multivariate analysis, high CRP level was the only independent factor for early reoperation (P = 0.024; adjusted HR, 1.017; 95% CI, 1.002–1.033). The mortality rate between the 2 groups was not significantly different using log-rank test. (P = 0.122)
**Conclusion:** Perioperative high CRP level was the prognostic factor of early reoperation (within 6 months) for patients with intestinal BD after bowel respective surgery.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: The majority of patients with Crohńs disease require intestinal resections during the course of their disease. It is still unclear whether disease behavior and/or the type of treatment impact on the reoperation rate.
Aims & Methods: Methods: We retrospectively reviewed the charts of all 341 Crohńs disease patients who had resective surgery at our center from 2000 to 2014. Kaplan-Meier analysis was performed over this 14 year period. For the statistics SPSS version 20.0 was used.
Results: Results: The male/female ratio was 165/176 (48.4/51.6%). The median age at diagnosis was 24 years and at index operation it was 37 years. One-hundred patients exhibited stenosing and 241 penetrating behavior. Perianal disease was reported in 93 cases (27.3%). Prior to surgery, treatment included biological agents (anti-TNF), azathioprine (AZA) and corticosteroids in 17.6%, 45.7% and 53%, respectively. Smoking habits were reported in 28.4%. The distribution of surgical procedures at the index operation was ileocecal resection (n = 154), resection of small bowel (n = 40) or colon (n = 122) and combined (n = 24). Overall, 97 patients required at least one more operation (uncensored) whereas 188 had no reoperation (censored) at the date of their last follow-up. In 56 cases (16.4%) no follow-up data were available. Of the 97 operations 71 were resective and 26 cases with non-resective surgery (mostly anal fistula) were excluded from the Kaplan-Meier analysis. Forty-six experienced one re-resection, 21 had two, 3 had three and 1 had 7 re-resections. Cumulative resective surgery-free survival tended to be superior in stenosing versus penetrating course of disease (p = 0.07). The Kaplan-Meier analysis showed comparable re-resection rates following small bowel and ileocecal resections but colonic resections had the highest re-resection rates (p = 0.0000053). Also, the preoperative use of steroids and AZA before index operation had no impact on re-resection rates (p-value = 0.97 and 0.74 respectively). In contrast, in the cohort that had required anti-TNF agents preoperatively, there was a trend to higher reoperation rates (p = 0.055), whereas the presence of granulomata and active smoking had no significant impact (p = 0.11 and 0.39 respectively). However, postoperative azathioprine and anti-TNF appeared to delay resective surgery (p = 0.13 and 0.12, resp.).
**Conclusion:** Penetrating disease, colonic resection and requirement of preoperative anti-TNF are indicators of poor prognosis with repetitive resection (s).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1439 PILOT STUDY ORAL ADMINISTRATION OF LACTOBACILLUS CASEI DG FOR 8 WEEKS AFTER ILEOSTOMY CLOSURE TEND TO DECREASE THE ACTIVATION LEVELS OF MACROPHAGES AND DENDRITIC CELLS IN ILEAL POUCH MUCOSA

**Introduction:** An imbalance in gut microbiota seems to contribute to the development of ulcerative colitis (UC) and, after the restorative proctocolectomy to chronic pouchitis. Although it has been suggested that probiotic supplementation is an effective approach to colitis, its effects on activation of dendritic cells, macrophage and T cells in the ileal pouch mucosa have never been explored
**Aims & Methods:** To evaluate the effect of *Lactobacillus casei* (*L. casei*) DG, a probiotic strain, supplementation on activation state of dendritic cells, macrophage and T cells in the ileal pouch mucosa.
Twelve UC patients who had restorative proctolectomy accepted to be enrolled in this prospective pilot study. They received a daily oral supplementation of *L. casei* DG (24x109 CFU) for 8 weeks from the ileostomy closure to a pouch endoscopy after 8 weeks. Biopsies were collected from the pouch mucosa to assess activation of dendritic cells, macrophage (CD40 and CD80 expression) and T cells (CD69 expression) by dual staining flow cytofluorimentry. Wilkoxon match paired rank test was used to compare the results at the two time points
**Results:** No patients showed any sign of clinically active pouchits the two time points. Following 8 weeks of oral *L. casei* DG administration the expression of the costimulatory molecules CD40 and CD80 on the surface of CD163 + cells (macrophages) tended to be lower (62 [IQR: 56–149] vs 51 [IQR: 29–85], $p = 0.07$ and 69 [IQR: 52–135] vs 45 [IQR: 25–93], $p = 0.07$, respectively). Similarly CD40 tended to be less expressed on the surface of CD1a + cells (dendritic cells) (91 [IQR: 44–195] vs 37 [IQR: 31–90], $p = 0.07$). No significant variation was observed in CD4 + and CD8 + T cells activation
**Conclusion:** Supplementation of *L. casei* DG seems to decrease the activation of and mucosal-associate innate immune cells in ileal pouch mucosa. The results of this pilot study encourage the design of a randomized controlled trial aimed to decrease the risk of chronic pouchitis
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Many studies have investigated the gut microbiota composition in irritable bowel syndrome (IBS), mostly using 16 S sequencing. However, knowledge about gut microbiota metabolic capacities and the association with diet in IBS is limited. We previously reported an association between IBS symptom severity and gut microbiota composition (Tap UEGW 2015). We aimed to assess the genetic content of this microbiota signature for IBS severity using a whole metagenomics sequencing approach
**Aims & Methods:** 144 subjects (106 IBS patients and 38 healthy subjects) were included in this study. Exhaled $H_2$ and $CH_4$, oro-anal transit time, psychological and gastrointestinal symptom severity were determined. FODMAPs intake was calculated based on 4-days food diaries from a subset of 75 subjects (65 IBS and 10 healthy). Metagenomic analysis of fecal microbiota was generated using the SOLiD technology. Metagenomic reads were mapped to the MetaHIT database in order to quantify metagenomic species (MGS) and their associated genes. MGS gene content was also used to assess a specific genomic lineage for each subject. In addition to classical numerical ecology and multivariate statistics, co-inertia analysis between MGS lineages and individual FODMAPs (fructose, fructans, Galacto-Oligo-Saccharides (GOS), Lactose) was performed.
**Results:** A total of 55 MGS were identified to be associated with the microbiota signature for IBS symptom severity. Based on their genetic content, 20 MGS could be further divided into 40 genomic lineages. Within some MGS, we found that two different genomic lineages (equivalent to subspecies) could be oppositely associated with symptoms severity. Although FODMAPs intake was not directly associated with health status in our study, co-inertia analysis showed that MGS associated with IBS severity could be linked with intake of GOS and fructans, but not lactose. The strongest association was found between one specific genomic lineage of Roseburia intestinalis associated with IBS severity and GOS intake.
**Conclusion:** Whole metagenomics sequencing allowed us to better characterize the gut microbiota signature associated to IBS symptom severity. Specific genomic lineages derived from MGS and their association with intake of FODMAPs deserve further functional exploration. This study supports the relevance of analyzing microbiota at lower taxonomic level than species and opens opportunities for personalized nutritional recommendations.

### P1441 ESCHERICHIA COLI NISSLE 1917 REINFORCES INTESTINAL EPITHELIAL BARRIER AND PREVENTS PERMEABILITY ALTERATIONS INDUCED BY CYTOKINES AND PAR-2 ACTIVATION: AN IN VITRO STUDY

M.R. Barbaro, **C. Cremon**, P. Dino, M. Carapelle, D. Fuschi, L. Bellacosa, E. Capelli, V. Stanghellini, G. Barbara
*University Of Bologna, St.Orsola-Malpighi Hospital, Bologna/Italy*

**Contact E-mail Address:** cesare.cremon@aosp.bo.it
**Introduction:** The integrity of intestinal epithelial barrier is key to avoid the entrance of pathogens and antigens in the deeper mucosal layers. The "leaky gut" plays a crucial role in the pathogenesis of inflammatory bowel diseases (IBD) and potentially also in the pathophysiology of irritable bowel syndrome (IBS). Probiotics are live microorganisms widely used in clinical practice, although their mechanism of action remains unclear. Escherichia coli Nissle 1917 (EcN) is a probiotic with demonstrated efficacy in the maintenance of remission of ulcerative colitis, although its mechanism of action is incompletely known.
**Aims & Methods:** The aim of the present study was to characterize the mechanism of action of EcN in the prevention of increased intestinal permeability caused by known inflammatory stimuli. We used an in vitro model of intestinal permeability using CaCo-2 cells. Two concentrations of EcN ($10^8$ and $10^6$) were applied to CaCo-2 to evaluate their effect on paracellular permeability. The ability of EcN in the prevention of increased epithelial monolayer permeability induced by SLIGRL (a protease-activated receptor-2 activating peptide), tumor necrosis factor (TNF)-a and interferon (IFN)-g was investigated. Paracellular permeability was evaluated using sulfonic-acid-conjugated to fluorescein (FITC). mRNA expression of tight junction proteins, zonula occludens-1 (ZO-1), occludin, claudin-1, claudin-2 and junctional adhesion molecule-A (JAM-A) was assessed by qPCR
**Results:** EcN induced a dose-dependent reinforcement of CaCo-2 monolayer of 52% ($10^8$) and 32% ($10^6$) compared to untreated CaCo-2 (CTR). SLIGRL 200 uM induced a 7-fold increase in CaCo-2 permeability compared to CTR; the co-incubation of SLIGRL and EcN induce a recovery of epithelial integrity of 77% for $10^8$and 63% for $10^6$ compared to SLIGRL alone. SLIGRL 50 uM increased epithelial permeability (83%) compared to CTR and this effect was reverted by the co-incubation with EcN. TNF-a and IFN-g induced an increase in CaCo-2 permeability compared to CTR (4- and 1-fold respectively) reverted by EcN but not in a dose-dependent way qPCR analysis showed EcN induced a significant increase in occludin, JAM-A and claudin-1 compared to CTR ($P < 0.05$), while a borderline effect was observed on ZO-1 expression. No effect was observed on claudin-2 expression. The co-incubation of EcN with TNF-a induced a significant recovery in ZO-1 and occludin expression compared to TNF-a alone ($P < 0.05$). Co-incubation of EcN and SLIGRL induced a borderline increase of JAM-A and decrease of MLCK expression compared to SLIGRL alone.
**Conclusion:** EcN reinforces epithelial integrity acting on different tight junction proteins. In the presence of inflammatory stimuli, which increase epithelial monolayer permeability, EcN exerts a marked protective role. Future studies should extend these observations to exploit EcN therapeutic potentials in IBS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1442 A PERIANAL SWAB-BASED PCR ASSAY FOR DIAGNOSING COLONIZATION BY PATHOGENIC C.DIFFICILE

**N. M. Joshi**, E. Taylor, R. Murphy, A. Whiley, M. Wilks, D. S. Rampton
*Barts And The London School Of Medicine And Dentistry, Cente for Immunobiology, Blizard Institute, London/United Kingdom*

**Contact E-mail Address:** n.m.joshi@qmul.ac.uk

**Introduction:** C.difficile is a Gram-positive anaerobe that can cause life-threatening diarrhoea. There is no current method with which to identify pathogenic C.difficile colonisation (PCDC) quickly. In order to be pathogenic, C.difficile must have the ability to make toxin B.

**Aims & Methods:** We have designed and validated an rtPCR assay targeting the toxin B with which to diagnose PCDC quickly using a perianal swab. Perianal swabs were taken prospectively from 99 patients with proven stool culture-positive C.difficile infection (CDI) within 24 hours of diagnosis. DNA from swab tips was extracted using the automated QIAsymphony platform. Half of the DNA extracts from patients with CDI along with control C.difficile DNA were used to optimise an rtPCR assay using primers targeting the C.difficile toxin B gene. PCRs were run as 10$\mu$L reactions on 96 well plates in duplicate and the volume of extract per reaction was varied (1–3$\mu$L). PCR positive was defined as: amplification curve crossing the threshold at $<40$ cycles, $<0.5$ CT difference between duplicates, melting points to be $\pm$ 1.25OC of that of C.difficile DNA and no amplification in negative controls. PCR positivity was compared to culture result as the gold standard. Once optimised, the assay was validated using the remaining 48 DNA extracts from CDI patients and extracts from swabs taken from 11 control patients with C.difficile-negative diarrhoea.

**Results:** In optimisation, assay sensitivity increased as more DNA extract was added (40%, 62% and 78% for 1$\mu$L, 2$\mu$L and 3$\mu$L respectively, $p = 0.0042$). The 3$\mu$L assay showed 92% efficiency and linearity of 0.997 was selected for the validation study. For validation using perianal swabs from 48 patients with proven CDI and 11 C.difficile stool culture- negative patients, assay sensitivity was 69%, specificity 93%, positive predictive value (PPV) 97% and negative predictive value (NPV) 48%.

**Conclusion:** We designed an rtPCR assay to identify C.difficile toxin B in DNA extracted from perianal swabs taken from patients with diarrhoea. Although the sensitivity in the validation experiments was low (69%), the high specificity and PPV mean that the assay may have clinical applicability. As almost all patients testing positive with the PCR swab test will be colonised with pathogenic C.difficile, they could be isolated on hospital admission to reduce the chance of nosocomial spread. Patients testing positive could also be prospectively followed to see if colonization with pathogenic C.difficile on admission is a risk factor for subsequent C.difficile-induced diarrhoea (CDI), poorer outcome if diagnosed with CDI, or relapsing disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1443 METAGENOMIC CHARACTERISATION OF GUT MICROBIOTA IN IBS PATIENTS

**Introduction:** Irritable Bowel Syndrome (IBS) is a gastrointestinal (GI) disorder that exhibits different GI and neurological symptoms such as abdominal pain, diarrhoea, constipation and mood disorders. The gut microbiota play an important role in modulating the communication between the Central Nervous System (CNS) and the GI tract, the so-called microbiota-gut-brain axis. In this context, IBS is a clear example of the alteration of the fine equilibrium between the gut microbiota and the CNS. Furthermore it has been observed that probiotic treatments of IBS results in the relief of GI and neurological symptoms, thus we could hypothesize the direct impact of the gut microbiota on IBS physiopathology. Since the IBS bacterial gut microbiota has been extensively studied we focused our attention also on the fungal counterpart of the gut microbiota, "the mycobiota".

**Aims & Methods:** The aim of the present work was to evaluate biodiversity in bacterial and fungal microbiota of a cohort of 20 IBS subject and 21 healthy subject (HS) through culture-based and metagenomics approaches. The bacterial diversity that relies on DNA polymorphism has been performed by means of cluster analysis of ARDRA profiles. Moreover the absolute abundances of bifidobacteria and enterobacteria has been evaluated by qPCR. For IBS gut mycobiota characterization, fungal strains from IBS stool samples were isolated and identified by mean of ITS1–4 sequencing. Furthermore, isolates were phenotypically characterized to evaluate their resistance to GI tract stresses (temperature, low pH and oxbile resistance), while Candida isolates were further clustered by means of their RAPD profiles.

**Results:** The cluster analysis of ARDRA profiles showed that IBS bacterial microbiota clusters apart from HS microbiota. In addition we observed a 2.8-fold increase in the absolute abundance of enterobacteria in IBS subjects vs HS. The analysis of the gut mycobiota revealed significant differences in fungal isolates abundance in IBS subjects vs HS even if we did not find any significant difference in species richness. In particular, results showed an abundance of fungi (61.8% C. albicans), with a higher number of colony count 4.7 $\log_{10}$ CFU/g faeces in IBS subjects respect to HS faecal samples with 1.9 $\log_{10}$ CFU/g (48.75% C. albicans).

RAPD prolfile analysis of C. albicans and C. parapsilosis showed that IBS isolates clustered apart from HS isolates, suggesting their different genotypical background. Finally, we observed that IBS fungal isolates showed different phenotypical features with an increased ability to growth to high temperatures and low pH respect to isolates from HS.

**Conclusion:** Our results showed the presence of alterations in the microbial community structure of IBS subjects, both at bacterial and fungal level, respect to HS. The absolute abundance of enterobacteria in IBS subjects suggests their connection with putative inflammatory phenomena as previously observed in IBS and other pathologies (Lee and Park, 2014). The phenotypical characterization of IBS fungal isolates revealed that such isolates showed a different response in respect to GI-like stresses. Moreover we observed that C. albicans and C. parapsilosis isolates from IBS are both phenotypically and genotypically different from HS Candida isolates suggesting their putative different ecological distribution. Finally we could hypotesize that dysbiosis of the gut microbiota in IBS could be one of the driving factor in IBS pathophysiology that could be responsible of intestinal fungal population overgrowth.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Rifaximin is a non-absorbable antibiotic active against Gram + and Gram - bacteria which is also able to produce a favorable modulation of the gut microbiota[1,2,3,4,5]. However, it is still not clear if this beneficial effect could be associated with clinical improvement.

**Aims & Methods:** The aim of this study was to explore the correlation between gut microbiota modulation and symptoms improvement in patients undergoing rifaximin treatment. Rifaximin 1200 mg/daily was administered for 10 days to patients with ulcerative colitis (UC), Crohn's disease (CD), irritable bowel syndrome (IBS), diverticular disease (DD) and cirrhotics with hepatic encephalopathy (HE). Inclusion criteria: no exposure to antibiotics, pre-/pro-biotics and bowel colonoscopy preparation for at least one month, and omnivore normocaloric diet for at least one year. Fecal samples were collected and symptoms were assessed at baseline and at the end of treatment. Clinical improvement was evaluated by Mayo score for UC, CDAI for CD, IBS-SSS for IBS, GSS for DD, and West Haven classification for HE. Fecal microbiota composition was assessed by a metagenomic gene-targeted approach (16 S rRNA) using the Roche 454 GS Junior ad Qiime pipeline. Biostatistical analysis was performed using R-statistics packages.

**Results:** Twenty-five patients were included in the study. Clinical improvement was observed in 10 (40%) patients after rifaximin treatment. Nonmetric multidimensional scaling (NMDS) ordination on Bray Curtis distance highlighted a significant clustering of patients who experienced clinical improvement compared to those who did not ($p = 0.047$; PERMANOVA). Differential abundance analysis revealed an increased abundance of Faecalibacterium prausnitzii in case of symptoms amelioration after rifaximin treatment (improved post vs pre: $\log FC = 1.96$; $p = 0.05$; not improved post vs pre: $\log FC = -0.37$; $p = 0.810$). The post-treatment between-groups comparison confirmed a significantly higher abundance of Faecalibacterium prausnitzii in those patients whose symptoms improved after rifaximin ($\log FC = 4$; $p < 0.0001$). Clinical improvement was also paralleled by a significant increase in bacterial alpha-diversity ($p = 0.024$).

**Conclusion:** In patients with gastrointestinal and liver diseases clinical improvement consequent to rifaximin treatment is associated with the increase in Faecalibacterium prausnitzii abundance. The increase in beneficial bacteria may mediate rifaximin effects in different pathologic settings.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** as703@ic.ac.uk

**Introduction:** Fusobacterium nucleatum is a gram-negative, obligate anaerobe that is a typical resident of the oral microbiome. More recently, F. nucleatum has been associated with malignant and pre-malignant colorectal neoplasia in several metagenomic studies and plausible mechanisms of tumourigenesis have been proposed[1,2]. However, actual isolation of Fusobacterium from colorectal neoplasia has been extremely limited and no attempt has been made to isolate Fusobacterium from the oral and colorectal microbiomes in the same individual.

**Aims & Methods:** We prospectively recruited adult patients undergoing elective resection of colorectal neoplasia. An oral periodontal swab was taken pre-procedure and tissue biopsies were obtained from adenomas / carcinomas and adjacent macroscopically normal tissue following resection. Tumours were swabbed if insufficient tissue was available for biopsy. Oral swabs and tissue biopsies (or swabs) were inoculated onto Fusobacterium-selective culture plates and incubated in a strictly anaerobic environment before distinct colonies were isolated. Fusobacteria were initially identified by Matrix-Assisted Laser Desorption/Ionization-Time of Flight (MALDI-TOF) mass spectrometry which was subsequently confirmed by 16s rRNA sequence analysis. Furthermore, DNA was extracted from available tissue samples and 16 s rRNA genes were sequenced using the Ilumina MiSeq platform.

**Results:** Between January 2014 and April 2015 samples were obtained from 36 patients undergoing resection of colorectal neoplasia (33 carcinomas, 3 adenomas). Tumour locations were 19 rectum, 11 ascending/caecum and 6 sigmoid colon. Oral swabs were obtained in 25 patients (72%), of which 15 (60%) yielded Fusobacterium isolates. Fusobacterium isolates (8 nucleatum, 2 gonidoformans) were also cultured from neoplastic tissue/swabs in 6 patients (17%) and normal mucosa in 4 patients (11%). In 2 (8%) patients, paired Fusobacterium isolates were obtained from both mouth and tumour. Metagenomic analysis revealed that Fusobacterium species were found in 8/23 tumour biopsies compared to 2/25 normal mucosal samples (35% vs. 8%, $p = 0.09$). However, of the 10 DNA positive biopsy samples, only 2 yielded Fusobacterium isolates on culture.

**Conclusion:** This is the first investigation to culture a significant number of Fusobacterium isolates from both the oral and tumour microbiomes of patients with colorectal cancer. Although metagenomic analysis demonstrated a trend towards overexpression of Fusobacterium on tumour tissue compared to healthy mucosa, the low rates of isolation from DNA positive tissue highlights the difficulty in culturing these fastidious organisms from clinical samples. Isolation from the oral microbiome was more successful and it will be interesting to make genetic comparisons between isolates from the oral and colorectal microbiomes where pairs were available.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Many countries use fecal immunochemical testing (FIT) to screen for colorectal cancer (CRC). However, FIT has a low sensitivity for precancerous adenomas and serrated lesions. There is increasing evidence that fecal microbiota play a crucial role in CRC carcinogenesis. Therefore, we assessed if the fecal microbiome can be used as additional biomarker in FIT for CRC screening.

**Aims & Methods:** Positive FIT samples ($n = 200$) of a CRC screening cohort, involving average risk subjects aged 50–74 years, were analyzed for universal 16 S, and bacteria previously associated with CRC, Escherichia coli, Fusobacterium nucleatum, Bacteroides and Faecalibacterium prausnitzii, by qPCR. Stability of microbial content over time was analyzed, both in stool samples of a healthy volunteer, as well as in FIT-positive samples. The qPCR results were compared to findings at colonoscopy. Advanced neoplasia was defined as an adenoma with a diameter $\geq$10 mm, and/or with a $\geq$25% villous component, high-grade dysplasia and/or CRC.

**Results:** Of the FIT-positive samples, 20 had to be discarded for various reasons resulting in 180 samples. Colonoscopy outcomes are described in table 1. Fecal microbiome was stably measured with no significant decrease in fecal microbiota up to 6 days for *E. coli* ($p = 0.53$), F. nucleatum ($p = 0.30$), Bacteroides ($p = 0.05$) and F. prausnitzii ($p = 0.62$). No significant differences in fecal microbiome in FIT were found between screenees with and without advanced neoplasia ($p = 0.23$). Total bacterial load (i.e. 16 S) was significant higher in patients with CRC and high-grade dysplasia ($p = 0.006$). For other bacteria, relative to 16 S, no association was found with colonic lesions. Table 1. Most advanced lesion at colonoscopy of FIT positive screenees.

| Finding at colonoscopy | n (%) |
|---|---|
| Normal | 41 (22.4) |
| Serrated polyps | 25 (13.7) |
| Tubular adenoma < 10 mm | 59 (32.2) |
| Tubular adenoma >=10 mm | 33 (18.0) |
| (tubulo) villous adenoma | 14 (7.7) |
| High-grade dysplasia | 3 (1.6) |
| Colorectal carcinoma | 5 (3.3) |
| **Total** | **180 (100*)** |

*numbers do not add up exactly to 100% due to rounding

**Conclusion:** To the best of our knowledge we are the first to describe the use of measuring the gut microbiome in FIT for CRC screening. Our results show that the fecal microbiome can be measured in FIT-samples and remains stable for 6 days. Total bacterial load was higher in CRC and high-grade dysplasia. Our results show that different microbial content may be associated with different stages of disease. These results pave the way for further research to determine the role of microbiota in FIT, to increase FIT sensitivity.

## P1447 THE INCIDENCE AND TREND OF CLOSTRIDIUM DIFFICILE INFECTION AT A JAPANESE UNIVERSITY HOSPITAL FROM 2005 TO 2014

**I. Yoshikawa**, S. Kumei, T. Watanabe, K. Kume, M. Harada
*Environmental Health, University of Occupational and, KItakyushu/Japan*

**Contact E-mail Address:** ichiro@med.uoeh-u.ac.jp

**Introduction:** Although the incidence of Clostridium difficile infection (CDI) is increasing worldwide, the incidence and trend of CDI in Japan remains uncertain. This retrospective cohort study evaluates the incidence and trend of CDI from 2005 to 2014 at a 678-bed university hospital in Japan.

**Aims & Methods:** Data on Clostridium difficile toxin assay results and the number of admission and discharge were collected from hospital databases. Annual hospital-onset, hospital-associated (HO-HA) CDI incidence and seasonal variation were evaluated. HO-HA CDI cases were defined as patients with symptom onset more than 48 hours after admission to the hospital.

**Results:** 126,396 patients were admitted with 2,130,436 patient-days at our hospital during the 10-year study period. Overall, there were 307 HO-HA CDI cases, a rate of 1.44 cases per 10,000 patient-days. Table shows annual incidence of HO-HA CDI. The incidence rate of HO-HA CDI was 1.29 in spring, 1.42 in summer, 1.56 in fall, and 1.48 in winter per 10,000 patient-days.

**Table:** CDI cases per 10,000 patient-days from 2005 to 2014.

| 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 |
|---|---|---|---|---|---|---|---|---|---|
| 1.83 | 1.46 | 1.98 | 1.41 | 1.01 | 1.19 | 1.18 | 1.44 | 2.13 | 0.72 |

**Conclusion:** The incidence of CDI was lower than that reported from hospitals in most Western countries. CDI incidence was not increased from 2005 to 2014, and did not significantly differ between seasons at a Japanese university hospital.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1448 METAGENOMICS ANALYSIS THE FUNCTION AND MOLECULAR MECHANISMS OF THE VARIABLE BACTERIA IN IBS-D AND DEPRESSION

**L. Zhang**[1], S. W. Zhu[1], X. Q. Wang[2], Z. Wang[2], Y. X. Liu[1], K. Wang[1], H. Q. Zhu[2], L. Duan[1]
[1]*Gastroenterology, Peking University Third Hospital, Beijing/China*
[2]*Biomedical Engineering, College of Engineering, Peking University, Beijing/China*

**Contact E-mail Address:** zhanglu@bjmu.edu.cn
**Introduction:** Alteration of gut microbiota is related to Irritable Bowel Syndrome (IBS) and depression. Actually, depression often comorbid with IBS. In our previous study, we found that diarrhea-predominate IBS (IBS-D) and depression had the similar gut microbiota structure. However, whether the function of gut microbiota of IBS-D and depression is similar remains unclear.
**Aims & Methods:** To explore the difference of functional variation of gut microbiota between IBS-D and depression using metagenomics.IBS-D patients, depression patients and health controls were enrolled. Subjects with organic intestinal diseases, diabetes, obesity, cancer, history of abdominal operation and other psychological disorders and those who had taken probiotics, antibiotics or antidepressants in the 4 weeks before enrollment were excluded. Metagenome DNA were extracted from fecal samples and sequenced through Illumina HiSeq 2000. Genes were predicted using MetaGUN and further annotated using BLAST against the eggNOG database and the KEGG Orthology database. To calculate coefficient of correlation in the co-occurence network, SparCC was applied.
**Results:** Fecal samples were collected form 31 subjects (11 IBS-D, 10 depression and 10 health controls). The differential abundance of 54 gut microbiome genes in IBS-D group and 111 in depression group were identified. These genes are primarily associated with the metabolism of carbohydrate, amino acid, cofactors and vitamins, nucleotide, energy and membrane transport. The genes associated with pentose phosphate pathway (eda, hxlA), porphyrin and chlorophyll metabolism (cobU, cobP, cysG, chlD, chlI), mineral absorption (ATOX1) and base excision repair (tag) decreased in IBS-D only, whereas genes associated with metabolism of ascorbate and aldarate metabolism (garL, ulaA, ulaC, ulaB), galactose metabolism (gatA, gatB, gatC), bacteria secretion system (gspC, vasD, hcp, impK), folate biosynthesis (pabA, moaC, MOCS1), nitrogen metabolism (nrfC, narI, narJ, nifH), two component system (fliC, phoR, motA, narL, tsr, crp, desK, hydH) increased in depression only. In the network, the most intensive interaction was between the protein associated with carbohydrate transport and metabolism in health controls, while it was between the proteins associated with inorganic ion transport and metabolism, cell wall/membrane/envelope biogenesis and signal transduction mechanisms in IBS-D and depression, which can enhance bacteria virulence when overexpressed. The interaction between the proteins associated with defense mechanisms increased in depression but decreased in IBS-D.
**Conclusion:** The function of gut microbiota of IBS-D and depression differs from that of health controls, but the variation is different between IBS-D and depression in genes associated with metabolism functions, bacteria secretion and signal transduction together with co-occurrence network. It might be related to the different clinical features of IBS-D and depression.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1449 UNDISSOCIATED GELATINE TANNATE AND XYLOGLUCAN PREVENT GUT LEAKINESS AND MUCOSAL INFLAMMATION INDUCED BY LPS: INSIGHTS IN THE MECHANISM OF ACTION

**H. Eutamene**
*Toxalim, University of Toulouse, INRA, INP-Purpan, Neuro-Gastroenterology and Nutrition Group, Toulouse/France*

**Contact E-mail Address:** heutamen@toulouse.inra.fr
**Introduction:** Gelatine tannate (GT) and xylogucan (XG) are commercially available in several countries for the oral treatment of diarrhea in children and adults. However, the mechanism of action remains poorly understood.
**Aims & Methods:** Therefore, we aimed to investigate the effects of GT and XG treatment and the mechanisms of action involved in LPS treated rats, an animal model characterized by two common gastroenteritis features, namely the intestinal epithelial barrier impairment and mucosal inflammation. The parameters evaluated were 1) the severity of intestinal mucosal inflammation, 2) gut paracellular permeability, 3) tight junction proteins expression and 4) spatial localization of the commensal bacteria load in ileal and colonic sections. Male Wistar rats were orally treated with GT (250 mg/kg) or XG (12.5 mg/kg) or vehicle (water plus $Na_2CO_3$, p.o) 2 h before IP injection of LPS from *E. coli* (1 mg/kg). Jejunal tissue strips were collected to evaluate 1) mucosal inflammation by MPO activity measurement 2) paracellular intestinal permeability to FITC-dextran 4 KDa in Ussing chambers and 3) occudin and Jam-A protein expression levels by western blotting. The commensal bacterial load was determined by FISH technique in ileal and colonic samples.
**Results:** Compared with control, LPS administration promotes a significant increase ($p < 0.05$) of intestinal paracellular permeability associated with a decreased expression of occludin and JAM-A and a subsequent jejunal mucosal inflammation. LPS also induced mucus barrier impairment reflected by the close apposition of commensal bacteria to ileal and colonic epithelium. Both GT and XG significantly ($p < 0.05$) reduce the severity of LPS induced mucosal inflammation and jejunal hyperpermeability. However, both treatments did not prevent the LPS-induced occludin and JAM-A down regulation. Further, GT and XG treatments result to a containment of the commensal bacterial load at the external face of the mucus layer limiting the bacterial mucus layer invasion and contact between bacteria and intestinal epithelium.
**Conclusion:** In this study we show that GT and XG treatments prevent LPS-induced gut leakiness and subsequent intestinal inflammation. These beneficial effects result from a mechanical protection of the gut epithelium through a "coat"-forming ability which avoids the upload of adverse luminal factors through the intestinal epithelium and subsequent adverse consequences.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1450 PREDICTING TREATMENT FAILURE IN C.DIFFICILE INFECTION: A PROSPECTIVE OBSERVATIONAL COHORT STUDY

**N.M. Joshi**, J. Goodhand, W. Alazawi, S. Das, M. Wilks, D. S. Rampton
*Barts And The London School Of Medicine And Dentistry, Cente for Immunobiology, Blizard Institute, London/United Kingdom*

**Contact E-mail Address:** n.m.joshi@qmul.ac.uk
**Introduction:** C.difficile-induced diarrhea is often refractory to treatment and can be life-threatening. As yet, there is no prospectively derived tool with which to predict treatment failure (TF) in C.difficile infection (CDI).
**Aims & Methods:** We performed a fully powered, pragmatic, prospective observational study to create such a tool. Patients with confirmed CDI were consented to enter the study within 24 hours of testing positive.
Demographic data (including age, antibiotic and PPI use, smoking, ward type), clinical variables (pulse, PB, temperature) and blood test results (FBC, urea, creatinine, CRP, albumin) and faecal calprotectin on the day of diagnosis were collected. TF was defined as occurrence of any of: death while admitted, colectomy, ongoing diarrhoea at day 7, recurrent diarrhoea at < 30 days after initial CDI diagnosis. Case level re-structuring was used to account for missing data and forward stepwise binary regression to derive a predictive model. The model was internally validated by bootstrapping and assessed by Receiver Operated Characteristic (ROC) analysis.
**Results:** 122 patients were recruited and primarily treated by their routine clinical team with metronidazole (n = 89) or vancomycin (n = 29). 63 patients (52%) failed treatment: 28 died during their admission, 43 had continuing diarrhea at day 7, 16 had recurrent diarrhea within 30 days and 1 had a colectomy (some patients had TF on > 1 criteria). TF rate was the same whether metronidazole or vancomycin was primary therapy. Of the variables measured, only age and serum albumin predicted TF (age, $p = 0.029$; albumin, $p = 0.0001$). An equation with which to predict individual patients' risk of TF was then derived: for ease of clinical application, a simple read off table was derived allowing prediction of outcome using the patient's age and serum albumin. The model correctly predicted TF in 79% of cases. By ROC analysis, the model initially had an Area Under the Curve (AUC) of 0.76; in the internal validation assessment the AUC was 0.75.
**Conclusion:** A prospectively and internally validated tool with which to predict treatment failure in CDI has been derived. The tool consists of 2 variables (age and serum albumin) on the day of diagnosis of CDI. The predictive tool could be used to highlight those who might benefit from more intensive treatment, for example using fidaxomicin or faecal microbial transplant as primary CDI therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1451 A STABLE AND CLINICAL REPRESENTATIVE MOUSE MODEL OF CLOSTRIDIUM DIFFICILE–ASSOCIATED DISEASE

Y. Chen[1], **L. Qianyun**[2], F. Jiaxi[2]
[1]*Guangdong Provincial Key Laboratory of Gastroenterology, Department of Gastroenterology, Nanfang Hospital, Southern Medical University, State Key Laboratory of Organ Failure Research, Guangzhou/China*
[2]*Department Of Gastroenterology, Nanfang Hospital, Southern Medical University, Guangzhou/China*

**Contact E-mail Address:** 273736028@qq.com
**Introduction:** *Clostridium difficile* (*C.difficile*), a toxin-producing bacillus responsible for life-threatening diarrhea that leads to significant morbidity and mortality worldwide, has caused considerable social and economic burden.[1,2]*C.difficile*–associated disease (CDAD) has been studied in a number of animal species, including hamsters, guinea pigs, rabbits, germ-free mice and rats. Hamsters historically have been most widely used to investigate disease pathogenesis and treatment, but are not ideal models because they develop fulminant disease which can't well mimic clinical course of disease in human beings.[3,4]In recent years, the most frequently used model is conventional C57BL/6 mice, in which CDAD can be initiated by a mixture of antibiotics, and colonization may follow clindamycin and *C.difficile* challenge. But our previous study found that the range of severity of C57BL/6 mice couldn't be induced by different concentration of *C.difficile* bacterial suspension. In most cases, infection caused only mild diarrhoea or no symptoms at all. This disadvantage may limit the application of C57BL/6 mice in the study of refractory or recurrent C. difficile infection. In order to evaluate efficacy and safety of new treatments

before they are given to humans, research into CDAD pathophysiology, and elucidate mechanisms of protective immunity, there is an urgent need to establish a better model of CDAD with clinical representation and good stability.
**Aims & Methods: Aims:** The aim of this study was to construct a *C.difficile*–associated disease model with clinical representation and good stability, provide a promising research tool for the infection of *C.difficile*. **Methods:** We choose 3 different commonly used strains of mice (C57BL/6, BABL/c and KM) in this research, all were exposed to multiple antibiotics (kanamycin 0.04 mg/g, gentamicin 0.0035 mg/g, polymyxin, 0.0042 mg/g) metronidazole 0.0215 mg/g, and vancomycin 0.0045 mg/g) for 9 days. One day later, they were given single intraperitoneal injection of clindamycin (10 mg/kg) and then challenged 1 day later with different doses ($10^8$CFU/ml~$10^{10}$CFU/ml) of the most common clinical isolates by gavage, and then the duration and severity of diarrhea, general state of health and pathological changes of colonic tissues were observed. All results were repeated for three times separately.
**Results:** All of the dealed mice developed symptoms of infection, but severity of diarrhea and weight lose differ among the breeds. Typical histologic features of CDAD, including inflammatory reaction, hyperemia and edema were evident in BALB/c mice, and disease severity varied from mild to severe in accordance with the challenge dose, the mortality of the high dose group is 16.7% (n = 12). While various dose of C difficile didn't result in corresponding change in C57BL/6 and KM mice, C57BL/6 mice all developed mild self-limited diarrhea or no diarrhea at all, no deaths occurred; KM mice's symptom severity has a great individual difference between inter-groups.
**Conclusion:** By comparing the symptoms and pathological manifestations of all experimental groups, we found the symptoms of BALB/c mice are more easily managed by changing the challenge dose. Compared with C57BL/6 and KM mice, BALB/c mice can better represent the usual course and spectrum of CDAD in human beings.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1452 A HOSPITAL-BASED STUDY ON RISK FACTORS OF RECURRENT CLOSTRIDIUM DIFFICILE ASSOCIATED DISEASE IN HONG KONG

**K. Tsang**, K.-. Ng, W.-. Luk, Y.-. Chan, C.-. Ho
*Department Of Medicine And Geriatrics, Princess Margaret Hospital, Hong Kong/Hong Kong PRC*

**Contact E-mail Address:** tkfpatrick@yahoo.com.hk

**Introduction:** The incidence and severity of *Clostridium difficile* associated disease (CDAD) is increasing worldwide. Up to 35% of patients are complicated by recurrence of CDAD. This increases morbidity and mortality and the disease burden in hospital. Many studies have identified risk factors for the first episode of CDAD. However, risk factors of recurrent CDAD are not well established. Local data are limited.
**Aims & Methods:** Aims The objective of this study is to determine the recurrence rate and identify risk factors associated with recurrence of CDAD. Methods A 30-month multi-centre retrospective cohort study was conducted by recruiting patients diagnosed to have CDAD (both recurrent and non-recurrent) across three hospitals in Hong Kong. Five hundred and seventy five patients suffering from CDAD were recruited. They were then divided into the recurrent group and non-recurrent group.
**Results:** Of 575 patients recruited, sixty five patients developed recurrent CDAD. The recurrence rate was 11.3%. Multivariate logistic regression analysis was performed. Patients taking proton pump inhibitor (PPI) significantly increased the risk of CDAD recurrence (adjusted OR 2.006, 95% CI 1.135 – 3.546, P = 0.017). Taking PPI more than the WHO defined daily dose[1] further increased the risk (adjusted OR 3.573, 95% CI 1.107 – 11.533, P = 0.033). As PPI dosage increased, the adjusted odds of developing recurrent CDAD also increased, from an odds ratio of 1 (reference) to 2.006 for PPI therapy less than or equal to the WHO defined daily dose, and to 3.573 for PPI therapy more than the WHO defined daily dose. Patients who were fed via a NG tube had a significantly higher risk of recurrent CDAD (adjusted OR 2.177, 95% CI 1.237 – 3.834, P = 0.007). Two-fold increase in the risk of recurrence was found in patients with serum albumin level less than 25 g/L (adjusted OR 2.037, 95% CI 1.118 – 3.711, P = 0.020).
**Conclusion:** This study showed that the recurrence rate of CDAD was 11.3%. Several independent risk factors of recurrent CDAD were identified, which included the use of PPI, NG tube feeding and serum albumin level less than 25 g/L. Moreover, PPI use more than the WHO defined daily dose further increased the risk. The incidence and severity of CDAD recurrence is increasing worldwide. Therefore, it is important to identify these risk factors to help us evaluate and improve our current clinical practice. Judicious use of PPI and regular review of the need of NG tube feeding are important measures to prevent recurrence of CDAD. Morbidity, mortality and thus burden on the health-care system might then be reduced.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Disruption of the gut microbiota has been demonstrated as a risk factor for C. difficile infection (CDI). Novel therapies aim to restore the gut microbiota to its pre-disease state as a protective factor against recurrence. Findings from recent controlled studies of faecal microbiota transplant have raised questions about a placebo response. We explored the potential of 16 s rRNA analysis as a predictive biomarker.
**Aims & Methods:** The objective of this analysis was to determine whether 16 s rRNA analysis could be used as a predictive biomarker in the assessment of the placebo response to a microbiome-based drug targeted at recurrent CDI. PUNCH CD 2 was a randomised placebo controlled study of RBX2660, a microbiota-based drug manufactured from live human-derived microbes and targeted at the prevention of recurrent CDI. Of the 133 patients in the study, a total of 44 patients were randomised to receive 2 doses of placebo. Longitudinal 16 s rRNA analysis was performed on patient stool after the second dose using the Illumina MiSeq platform. The variable region V4 was targeted to identify the operational taxonomic units (OTUs) in each sample. We report the results of the first 20 consecutive patients in the placebo arm.
**Results:** Of the 20 sequenced patients (55% female; mean age: 59.2 years), 8 experienced recurrent CDI symptoms prior to 56 days; 12 patients did not. At baseline, the microbiome profiles of the 20 patients were similar. At 7 and 30 days, OTU analysis showed increased divergence between patients who went on to further recurrence and those who did not. Clostridiales and Enterobacteriales predominated at all time points. Overall OTU analysis demonstrated a slight but non-significant variation between the two groups.
**Conclusion:** In this randomised controlled study of RBX2660 for recurrent CDI, 16 s rRNA analysis was not predictive of which patients receiving placebo had a further recurrence of CDI symptoms and which did not. Further analysis of the entire cohort is needed to determine the possibility of a predictive analytical method.

**Introduction:** Diarrhea is the most common side effect of broad-spectrum antibiotic's treatment, which occurs in 5 to 62% cases. Most cases of antibiotic-associated diarrhea (AAD) can be classified in two categories: 1) *Clostridium difficile*- induced diarrhea; 2) idiopathic diarrhea - no infection agent is recognized. The mechanism of idiopathic AAD is not clear.
**Aims & Methods:** The present study was designed to test the hypothesize whether the disturbance in microflora composition after 5 or 14 days ceftriaxone treatment alters colonic water/electrolyte transport and whether this effect is dependent on changes in expression pattern of CFTR, AQP8, ENaC and NHE3 transporters and levels of mucus secretion. Male Wistar rats were treated daily with ceftriaxone (50 mg/kg, i.m.) for 5 or 14 days. Net water and ion transport (Na+, K+, Cl-) were evaluated on the 6th or 15th day by isolated colonic loop perfusion technique in vivo; mRNA expression - by RT-PCR; level of surface colonic mucus layer - by periodic acid/Schiff (PAS) staining; the fecal microflora composition - by bacteriological culture methods; C. difficile toxins A and B - by immunochromatographic assay.

**Results:** We showed that after 5 and 14 days of ceftriaxone administration diarrhea developed in 13% and 6% animals, respectively. While, there were none C. difficile toxins A and B positive rats after 5 days of ceftriaxone administration, but 25% (1 of the 4) animals were positive after 14 days. We have observed pro-secretory changes in colon after 5 days of ceftriaxone treatment. It was associated with downregulation of ENaC expression which are responsible for active sodium absorption and increase CFTR expression which are responsible for active Cl secretion. Moreover, expression of AQP8 was also decreased. After 14 days of ceftriaxone treatment, we have still observed pro-secretory changes in colonic epithelium but less profound than after 5 days of treatment. It has been mainly driven by $Cl^-$ secretion. Expression of CFTR channels was also increased. Surprisingly, that along with net $Cl^-$ secretion, net $Na^+$ absorption was increased as well as expression of electroneutral $Na^+/H+$ exchanger (NHE3) and electrogenic ENaC. Ceftriaxone treatment for 5 days was associated with 3.1-fold ($p < 0.01$) decrease in colonic mucus secretion. After 14 days of ceftriaxone treatment, we observed 3-fold increase in colonic mucus secretion ($p < 0.05$ vs. water treated-rats). These changes were accompanied by increased number of conditionally pathogenic microflora after 5 days treatment and returned to control value after 14 days treatment.
**Conclusion:** The present study demonstrated for the first time that parenteral treatment with cephalosporin antibiotic ceftriaxone had induced diarrhea which was associated with changes in colonic net water and ion transport; allowed us to speculate that clinically observed transitory diarrhea during antibiotic therapy might be physiological defense response driven by shift in normal microflora composition.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1455 ENDOSCOPIC BAND LIGATION (EBL) METHOD USING SMALL-CALIBER COLONOSCOPE FOR COLONIC DIVERTICULAR BLEEDING

**Y. Sato**, H. Yasuda, S. Nakatsu, S. Ozawa, M. Yamashita, Y. Matsuo, H. Yamamoto, F. Itoh
*Gastroenterology And Hepatology, St. Marianna University Hospital, Kawasaki/Japan*

**Contact E-mail Address:** y2satou@marianna-u.ac.jp
**Introduction:** Incidence of colonic diverticular bleeding has increased in recent years. In colonic diverticular bleeding, the source of bleeding is often difficult to identify. Our hospital had reported that the use of enhanced computed tomography can help improve the bleeding source identification rate1). In recent years, it has been reported that, of hemostasis methods, endoscopic band ligation (EBL) results in a lower rate of re-bleeding than the clipping method2). As of 2015, EBL has been used as the first choice for hemostasis as much as possible at our hospital. A possible disadvantage of EBL is the fact that it requires re-intubation of a scope. At our hospital, when re-intubation the scope after identifying the source of bleeding, we switch from the initial scope to the PCF-PQ260L (Olympus corporation), which offers a superior insertability with its small caliber and passive bending system.
**Aims & Methods:** We examined the usefulness of EBL using the small-caliber colonoscope. Subjects were comprised of 548 patients who underwent emergency lower gastrointestinal endoscopy for colonic diverticular bleeding at St. Marianna University Hospital between January 2005 and March 2016. For all of the patients who underwent EBL, the source of bleeding was identified, after which the initial scope used was changed to the small-caliber colonoscope, and this was re-intubation to perform hemostasis treatment.Patients were divided into two groups according to the method of hemostasis, i.e. the EBL group and the clipping group. We retrospectively analyzed the treatment outcomes for each groups. In the EBL group, the time required to reach the bleeding source upon re-intubation was also examined.
**Results:** Of the 548 patients, the source of bleeding was identified in 233 patients (42.5%). The EBL group had 40 patients, including 25 male and 15 female patients with an average age of $77 \pm 10$ years. The clipping group had 193 patients, including 143 male and 50 female patients with an average age of $69 \pm 12$ years. Oral antithrombotic agents were administered to significantly more ($P < 0.01$) patients in the EBL group (23 patients; 57%) than the clipping group (68 patients; 35%). The most common source of bleeding was the ascending colon in both groups (EBL group: 23 patients; 57%, clipping group: 124 patients; 64%), and no significant difference was observed. Re-bleeding rate was significantly lower ($P = 0.01$) patients in the EBL group (2 patients; 5%) than in the clipping group (44 patients; 23%). Of the patients who experienced re-bleeding, transcatheter arterial embolization was performed on three patients, and emergency surgery was performed on one patient. Following treatment, there were no perforations observed in either group. The mean procedure time for hemostasis treatment was significantly shorter ($P < 0.01$) in the EBL group ($47 \pm 18$ min) than in the clipping group ($66 \pm 33$ min). In the 23 patients in whom the source of bleeding was in the ascending colon, the average cecal intubation time at the the initial insertion was $12 \pm 5$ min, then the mean time to reach the source of bleeding upon re-intubation of the scope was $6 \pm 3$ mins. Thus, the time of re-intubation was significantly shorter that the initial intubation time ($P < 0.01$).
**Conclusion:** Compared to the clipping method, the EBL method resulted in a significantly lower rate of re-bleeding and better hemostasis outcomes. Furthermore, no adverse events occurred. The small-caliber colonoscope gives it superior insertability and allows for shorter re-intubation than the initial intubation time. Furthermore, even with the addition of re-intubation time, the duration of time to achieve hemostasis was significantly shorter with the EBL method than the clipping method. Therefore, these results demonstrated the usefulness of the EBL method with the small-caliber colonoscope.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction: Introduction:** The incidence of *Clostridium difficile* infection (CDI) assumes epidemic proportions, constituting the leading cause of antibiotic-associated diarrhea.[1–3] Recurrence after the first-line treatment with antibiotics is high.[2] Despite its application in humans being described for about 50 years, fecal microbiota transplantation (FMT) has gained recent popularity as it appears to be a safe and highly effective approach for refractory and recurrent CDI.[1,3]
**Aims & Methods: Objective:** This case series aimed to evaluate the efficacy and safety of FMT in the treatment of refractory and recurrent CDI. **Methods:** Between June/2014-February/2015, a prospectively recorded single-centre case series of patients with refractory or recurrent CDI treated with FMT was collected. Primary and secondary outcomes were defined as resolution of diarrhea without recurrence of CDI within 2 months after one or more FMT, respectively.
**Results: Results:** 18 FMT were performed in 14 patients, 64.3 (n = 9) were women with a median age of 72 years. The indications for FMT were refractory CDI in 9 procedures and recurrent CDI in 9. FMT was performed via upper endoscopy in 14(77.8%) procedures and colonoscopy in 4(22.2%). One upper FMT was excluded due to recurrence of CDI after antibiotic exposure for a respiratory infection. The overall cure rate of FMT was 84.6% (11/13) via the upper route and 100% (4/4) via the lower route, with 2 of these lower FMT corresponding to the 2 patients where the upper FMT failed. Primary and secondary cure rates were achieved in 94.1% (16/17) and 100% (17/17) of patients, respectively. No complications were reported during follow-up.
**Conclusion:** FMT appears to constitute a safe and effective approach in the management of refractory and recurrent CDI.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Fecal microbiota transplantation (FMT) is a safe and effective approach in the management for refractory and recurrent Clostridum difficile infection (R-CDI). Administration of fecal samples can be performed via lower gastrointestinal (GI) route as colonoscopy or enema or via upper GI route, including nasogastric tube and gastroduodenoscopy. The retention enema is an excellent option but is may be difficult for some patients to retain the transplanted stool and more infusions may be required.
**Aims & Methods:** The aim of the study was to determine the efficacy of FMT via enema with an alternative procedure. Fecal transplant protocol: We included patients who were at least 18 years of age with a R-CDI. Exclusion criteria were prolonged compromised immunity because of recent chemotherapy, the presence of human immunodeficiency virus (HIV) infection, or prolonged use of prednisolone at a dose of at least 60 mg per day; pregnancy; use of antibiotics other than for treatment of C. difficile infection at baseline. Patients received an abbreviated regimen of vancomycin (500 mg orally four times per day for 4 or 5 days); polyethylene glycol-based colonoscopy preparation on the day prior to FMT, loperamide, 2 or 3 hours prior the infusion, for the retention of transplanted material. Donors and fecal samples preparation Fecal samples were

collected by five volunteers donors ( < 30 years of age). The feces were screened for parasites, *C.difficile*, and enteropathogenic bacteria. Blood was screened for antibodies to HIV; hepatitis A, B, and C; cytomegalovirus; Epstein–Barr virus; Treponema pallidum; Strongyloides stercoralis; and Entamoeba histolytica. Donor fecal samples (50 g) were mixed with 250 or 500 ml of sterile saline buffer, mixed into slurry and filtered once with surgical gauze for large particles and twice with a coffee filter. If the transplant was not performed the same day of sample collection, the solution was frozen in 10% (vol/vol) glycerol and stored at −80°C, according to standard procedure. Patients were randomly allocated to receive frozen or fresh FMT via enema. The fecal solution was administreted using a suction catheter (16 fr). Before the infusion, a rectal balloon (has been used a standard Foley catheter, 20 fr) was inflated with sterile saline solution up to 20–30 mL volume distension. This procedure allowed to avoid significant loss of fecal samples during infusion.

**Results:** Eleven procedure were perfomed in eight patients. The average patient age was 69 years (range, 42–83 years). Follow-up ranged from 10 days to 1 years. The patients received a 250-ml suspension on 75% of cases (range 250–500 mL). The time of infusion was average 30 minutes. Heighty-seven percent of patients experienced resolution (7/8) after a single treatment. Only one patient was treated with 3 infusion without response. The resolution of diarrhea occurred in 5/7 patients within 24 hours and in 2 patients after 72 hours from transplantation. No major adverse events correlated to FMT was registered.

**Conclusion:** Our preliminary results confirmed the efficacy of FMT by enema using a retention rectal balloon. The procedure has been well accepted and tolerated by patients without any complications. The healing has been immediate in the majority of patients with short recovery time.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1458 FECAL MICROBIOTA TRANSPLANTATION VIA ENEMA FOR RECURRENT CLOSTRIDIUM DIFFICILE INFECTION MODULATES THE INFLAMMATORY HOST RESPONSE AND RESTORE INTESTINAL DYSBIOSIS

C. Cicerone[1], G. Bruno[1], D. Alessandra[2], A. Oliva[2], G. Antonella[2], T. Valentina[2], V. Iebba[2], F. Pantanella[2], M. a. Zingaropoli[2], L. Lamonaca[3], V. Vullo[2], M. Trancassini[2], S. Schippa[2], **E.S. Corazziari**[3]

**Introduction:** Fecal microbiota transplantation (FMT) is able to restore resistance to *C.difficile* (CD) colonizationby re-establishing a healthy microbial ecosystem in the gut of patients with high cure rates. Inaddition to A/B toxins effect, recent study showed that the host immune response and microbiotacomposition play a role in the pathogenesis of CD infection.

**Aims & Methods:** The aim of the study was to determinethe efficacy of FMT via enema in recurrent CD infection (R-CDI) and to evaluate the FMT impacton the host immune response and the gut microbiota composition. Methods. Fecal transplant protocol. The study recruited patients with R-CDI admitted at the Policlinico Umberto I Hospital, (Rome).Patients received 4–5 days oral vancomycin (500 mg every 6 hours) and the day prior to FMT, polyethylene glycol-based oral lavage of the colon. Loperamide was given 3 hours prior to the infusion in order to facilitate the retention of transplanted material. Fecal material was collected from 5 healthy donors (<30 years old). Patients were randomly allocated to receive frozen or freshFMT via enema. Microbiota characterization. Fecal microbiota composition was evaluated before and after the FMT in patients and healthy donors. To this purpose, 16 S rDNA sequencing (MiSeq) was used for fecal microbiota characterization. The real Time PCR was employed for a quick evaluation of the fecal ecosystem by analyzing the relative abundance of the bacterial phylum *Bacteroitedes* and *Firmicutes*, and of the bacterial species Escherichia coli and Fecalibacterium prausntizii, whose ratio was used as a dysbiosis index. T cells phenotype Lymphocyte surface phenotypes were evaluated in 4 patients by flow cytometry using freshperipheral blood before (T0) and after (T1) FMT. For the activation analysis of T cells CD4+ andCD8+, the following fluorochrome-labeled antibodies were used: Pacific Blue-CD3, PerCp/Cy5.5- HLA DR, Pe/Cy7-CD8, CD38-APC, APC/Cy7-CD4. Immune activation was defined as co- expression of HLADR +CD38 + on CD 4 and CD8 T cells.

**Results:** A total of 11 FMT procedures were performed in eight patients. The median patients age was 69 years (range 42–83 years). Seven patients (87%) experienced resolution; among them, 6/7 (85.7%) were cured after a single treatment. No major adverse events were observed. Microbiota characterization. Before FMT, the phylum of *Proteobacteria* was highly prevalent in all patients, in particular the gamma *Proteobacteria* class and the Enterobacteriaceae family. After the FMT, a rapid decrease of the *Proteobacteria* was observed, with a parallel increase of the phyla *Firmicutes* and Bacteroitedes, which reached 80% of the total microbiota.Immuneractivation. At T0, high levels of CD4 + and CD8 + HLADR + CD38 + T lymphocytes were found. The levels of immuneractivation of T lymphocytes were decreased after FMT, but this variation was not statistically significant.

**Conclusion:** FMT via enema was effective, safe and induced a rapid recovery of the microbiota balance with a reduction of the inflammatory response.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** gianluca.ianiro@hotmail.it

**Introduction:** Fecal microbiota transplantation (FMT) from healthy donors is highly effective for the management of recurrent *Clostridium difficile* infection (rCDI). Although with minor evidence, FMT appears to be a reliable treatment of severe CDI. C-difficile associated pseudomembranous colitis (PMC) is an endoscopic sign of severe disease, potentially life-threatening. In our recently published randomized controlled trial,[1] we observed that repeat FMT by colonoscopy was able to cure PMC associated to rCDI.

**Aims & Methods:** Our aim was to describe a prospective series of patients with rCDI-associated PMC treated with repeat FMT by colonoscopy at our Centre. We identified prospectively all patients with rCDI and endoscopic appearance of PMC treated with FMT by colonoscopy. We excluded the first two patients from the analysis, as the treatment protocol had still not defined when we treated them Demographic and clinical data of included patients, together with their endoscopic and FMT-related characteristics, were collected. At first infusion, patients underwent the following protocol, previously described[1]: a short regimen of vancomycin (125 mg by mouth four times a day for 3 days), followed by bowel cleaning with 4 L of macrogol preparation (SELG ESSE) on the last 1 or 2 days (according to the clinical condition of the patients) of antibiotic treatment, followed by FMT from healthy donor by colonoscopy the next day. Patients received further infusions after being restricted to a light diet and prepared for colonoscopy by taking only 2 L of bowel prep before the colonoscopy, until the resolution of colitis.

**Results:** Overall, we included for the analysis 10 patients with rCDI-associated PMC treated with repeat FMT; of them, 8 were inpatients (80%). Mean age was 73 years old (range: 60–89). Female patients were 7 (70%). The mean number or CDI recurrences was 3. In all treated patients, we observed the progressive disappearance of pseudomembranes as we repeated the infusions. On average, patients received 3 fecal infusions (range: 2–4). Infusions were delivered between 3 and 6 days after the first FMT. At first colonoscopy, pseudomembranes were identified in the whole colon in 5 patients (50%), and in the left/distal colon in the other 5 (50%), respectively, although in two patients we delivered the fecal material in the left colon, without completing the colonoscopic exam, because of severe inflammation, which disappeared after further infusions. Overall, both fresh and frozen material, as well as both external and related donors, were used for FMT. Repeat FMT cured rCDI-associated PMC in all patients (100%). No serious adverse events related to the procedure were observed.

**Conclusion:** Repeat FMT achieved a 100% resolution rate of rCDI-associated PMC in our small prospective series. As PMC is a sign of severe, potentially life-threatening disease, its endoscopic recognition is of paramount importance, and its treatment through colonoscopic FMT appears to be highly effective. Therefore, both further research and dissemination of this technique are warranted for a better management of patients with rCDI-associated PMC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** *Clostridium difficile* infection (CDI) is an increasingly important nosocomial problem complicating up to 1.0% of all hospital admissions and associated with considerable health burden

**Aims & Methods:** To determine the incidence, risk factors and outcomes of nosocomial CDI in a major University Medical Center in Lebanon. In this

two-year ongoing prospective study, nosocomial CDI attack rates were measured, and relevant patient information was collected including baseline characteristics, antibiotic and PPI use, length of stay, morbidity and mortality. Patients were followed for 8 weeks after discharge for relapsing CDI identified by recurrent symptoms ± positive toxin or nucleic acid testing. Stool samples were collected for ribotyping and genotyping of C. difficile strains.
**Results:** Over the study period, 177 patients were diagnosed with nosocomial CDI for an incidence of 0.20% (177 of 86,564 hospital admissions). Of those, 163 patients (mean age 62.2 ± 19.1 years) gave informed consent and constitute the study population for this interim analysis. Mean hospital stay was 23.8 ± 30.1 days (range 0–278). Infection was diagnosed within 7 days of admission (range 0–95 days) in 103 patients (63.6%). Patients had no history of prior CDI but 110 of the 163 (67.5%) were hospitalized within 12 weeks of the index admission. 38 (23.3%) had received prior antibiotics (mostly fluoroquinolones) within 8 weeks before hospitalization. 23.9% of inpatients who developed CDI did not receive antibiotics during their current hospital stay prior to diagnosis. The study cohort had considerable comorbidities evidenced by a Charleston Comorbidity Index (CCI) ≥ 8 in 30.1% of patients. Carbapenems (50.1%) and piperacillin-tazobactam (41.1%) were the most commonly used in-hospital antibiotics. PPI use was frequent, both at home (52.1%) and during hospitalization (86.5%). CDI relapse occurred in 36 patients (22.1%). There was a significant association between prior hospitalization and CDI recurrence within 60 days of discharge ($p = 0.02$). No significant associations were found between relapse and age, PPI use, CKD, immune compromised status, or CCI (< or ≥8). Mortality occurred in 14.7% of patients. On logistic regression, only a CCI ≥8 was significantly associated with mortality [OR 4.392 (1.363–14.149); $p = 0.013$]. Bacterial ribotyping and genotyping studies are in progress.
**Conclusion:** Antibiotic exposure, comorbidities, and prior hospitalization constitute the major risk factors for nosocomial CDI. Relapse is relatively common and is associated with repeat hospitalization. High baseline comorbidity score was the only predictor of increased mortality.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1461 OBESITY, DIABETES MELLITUS, HEAVY ALCOHOL CONSUMPTION, SMOKING AND RISK FOR COLORECTAL POLYPS AND CANCER IN A FIT-POSITIVE SCREENING POPULATION

**M. Fabbri**, R.M. Zagari, D. Colussi, F. Bazzoli, L. Ricciardiello
*Department Of Medical And Surgical Sciences, University of Bologna, Bologna/Italy*

**Contact E-mail Address:** margheritafabbri@virgilio.it
**Introduction:** Colorectal cancer (CRC) is one of the leading causes of cancer incidence and death worldwide. Epidemiological studies obtained from several world areas have shown that obesity and type 2 diabetes increase the risk for the disease. Obesity is the fastest growing risk factor, and its incidence has increased by 1% every year, including Southern Europe. Thus, it could represent an important risk factor also in this area.
**Aims & Methods:** To evaluate the association between comorbidities and lifestyle factors including obesity, diabetes mellitus, alcohol use, smoking and risk for colorectal cancer and adenoma/serrated polyps (excluding hyperplastic polyps) in the population aged 50–75 years who were part of a FIT-based colorectal cancer screening program in Northern Italy. Between March 2005 and December 2013 a total of 3906 FIT + subjects underwent total colonoscopy. We compared subjects without lesions with those with polyps (adenomas and/or serrated), and also with colorectal cancers. Heavy drinkers were considered those with alcohol consumption of > 35 gr/daily. Smokers were considered those who either claimed to have smoked throughout their life at least 100 cigarettes and to be a smoker at the time of interview, or to have quit less than 10 years prior to undergoing screening. Obese subjects were considered those with a BMI ≥ 30 $Kg/m^2$. A multivariate logistic regression analysis was used to estimate odds ratios.
**Results:** Of the patients undergoing colonoscopy, 1903 subjects had a diagnosis of at least one adenoma or serrated polyp. Two hundred and fifty-two subjects (6.5%) were diagnosed with colorectal cancer (195 colon and 56 rectum). Obesity, heavy drinking and smoking were significantly associated with an increased risk of adenomatous/serrated polyps, and colorectal cancer. For adenomatous/serrated polyps odds ratios were 1.40 (95% CI, 1.15–1.69) for obese individuals, 1.05 (95% CI, 0.67–1.65) for heavy alcohol drinkers and 1.44 (95% CI, 1.25–1.67) for smokers, respectively. For patients with colorectal cancer, odds ratios were 1.20 (95% CI, 0.83–1.75) for obese subjects, 3.05 (1.63–5.72) for heavy drinkers, 1.30 (95% CI, 0.97–1.75) for smokers, 1.38 (95% CI, 0.88–2.17) for individuals with type 2 diabetes, respectively. When considering colon cancer alone, odds ratios were 1.52 (95% CI, 1.01–2.29) for obese subjects, 3.54 (95% CI, 1.83–6.85) for drinkers, 1.26 (95% CI, 0.90–1.76) for smokers, 1.42 (95% CI, 0.87–2.32) for subjects with type 2 diabetes, respectively.
**Conclusion:** In our FIT+ population, obesity, heavy alcohol consumption and smoking are significant risk factors for adenomas/serrated polyps and colorectal cancers. Diabetes mellitus has an independent relationship with CRC that is more significant for cancer of the colon than the rectum. In the future, early screening strategies should be targeted to high-risk individuals, in particular to those with obesity and type II diabetes.

**Introduction:** According to the WHO definition, Serrated Polyposis Syndrome (SPS) is a disease characterized by either 1) the presence of at least five serrated polyps proximal to the sigmoid colon with two ≥10 mm in size, 2) more than 20 serrated polyps throughout the colon, or 3) any number of serrated polyps proximal to the sigmoid colon in an individual who has a first-degree relative with SPS. While SPS demonstrates hallmarks of a genetic disease, the exact risk for colorectal cancer (CRC) is unknown, although a cumulative 7% risk of CRC at 5 years in patients under surveillance was reported[1]. No data on SPS are available among the Italian population. Thus, the aim of our study was to assess the prevalence of SPS in a FIT-based CRC screening population in Italy, and possible associations with comorbidities and lifestyle factors.
**Aims & Methods:** We retrospectively reviewed records of 3906 FIT-positive patients aged 50–75 participating to a CRC screening program in North Italy between March 2005 and December 2013. For each patient we extracted endoscopic and pathological reports, age at the time of colonoscopy, gender, BMI, comorbidities and lifestyle information including cigarette smoking, alcohol consumption, and compared them with subjects with negative colonoscopies. Mann-Whitney and Fisher's exact tests were used to test quantitative variables and proportions, respectively.
**Results:** Of the 3906 patients reviewed, 12 (0.31%) met the WHO criteria for SPS. Of them, 75% (9/12) were diagnosed at first colonoscopy. 83% (10/12) of patients fulfilled WHO criterion number 1, and 16.7% (2/12) patients fulfilled WHO criterion number 2. Mean age at diagnosis was 60.5 years. 41.6% (5/12) of patients presented synchronous adenomatous polyps, and in 4/5 patients the adenomas had advanced features. When comparing SPS patients to those with a negative colonoscopy, we found a strong correlation with smoking (66% vs 25%, $p = 0.004$) and a borderline association with BMI ≥ 25 (83% vs. 57%, $p = 0.058$).
**Conclusion:** Our data are in line with those obtained from other European cohorts[2], indicating that SPS is more common than previously thought. SPS was strongly associated with smoking, and a borderline association was found with being at least overweight. Our data suggest that lifestyle factors might be important contributors to the onset of SPS.

**Introduction:** The incidence of colorectal cancer in Korea is increasing. The age-standardized mortality rates of colorectal cancer continue to increase, unlike those of other common cancers whose mortality rates have decreased in recent years.[1] As the prevalence of advanced adenoma and the incidence of colorectal cancer increases with age, advanced adenoma, which has been implicated in the etiology of colon cancer, is a significant concern for the average-risk individual.
**Aims & Methods:** This study aimed to estimate the cumulative incidence of recurrent advanced colonic neoplasia after polypectomy on surveillance follow-up colonoscopy, and compare the differences according to risk groups and age groups. We reviewed 9,102 subjects who underwent screening colonoscopy, and we retrospectively analyzed 1,974 subjects who underwent follow-up surveillance colonoscopy after polypectomy. We estimated the cumulative incidence for recurrent advanced colonic neoplasia (advanced adenoma or adenocarcinoma) according to baseline risk groups: high-risk group (advanced adenoma or ≥3

adenomas), low-risk group (1–2 adenomas < 1 cm in size), and normal group. The rate of recurrent advanced colonic neoplasia was compared among age groups (50 s, 60 s, and more than 70 years). The relative risk was computed by the hazard ratio using Cox proportional regression after multivariate (age group, sex, family history of colorectal cancer, smoking status, BMI > 25 kg/m$^2$, FOBT (fecal occult blood test) positivity, 3 or more adenomas, colonic adenoma ≥1 cm in size, villous component, and risk groups) adjustments.
**Results:** At screening colonoscopy, subjects' mean age was 55.9 years (55.7%, men). Among 9,102 subjects, 3,431 (37.7%) had a colonic adenoma. 464 subjects (5.1%) had advanced adenoma. Forty-five subjects had an adenocarcinoma on screening colonoscopy (0.49%). After polypectomy, 1,974 subjects (men 72.1%) underwent follow-up surveillance colonoscopy. The mean follow-up period was 41.8 months. 111 advanced neoplastic tumors were newly diagnosed during follow-up surveillance colonoscopy. Among the 111 advanced neoplasia, 58 subjects (52.3%) had three or more adenomas, 96 (86.5%) had a colonic neoplasia ≥1 cm in size, and 23 (20.7%) had a villous histology. No significant difference was observed in the location of recurrent advanced neoplasia between the right-sided colon (62.2%) and left-sided colon (37.8%) (P = 0.219). Six adenocarcinomas from 6 subjects were newly diagnosed during follow-up surveillance colonoscopy. The 5-year cumulative incidence rates of advanced neoplasia by risk groups were 20.5% in the high-risk group (95% CI 0.73 to 0.86), 7.8% in the low-risk group (95% CI 0.90 to 0.95), and 2.2% in the normal group (95% CI 0.96 to 0.99) (P < 0.001). The 3-year cumulative incidence rates of advanced neoplasia were 9.3% in the high-risk group (95% CI 0.87 to 0.94), 3.1% in the low-risk group (95% CI 0.96 to 0.98), and 0.6% in the normal group (95% CI 0.99 to 1.0) (P < 0.001). The 5-year cumulative incidence rates of advanced neoplasia by age groups were 6.8% for 50 s (95% CI 0.91 to 0.96), 10.1% for 60 s (95% CI 0.86 to 0.94), and 20.0% for aged ≥70 years (95% CI 0.69 to 0.92) (P < 0.001). The 3-year cumulative incidence rates of advanced neoplasia were 2.9% for those 50 s (95% CI 0.96 to 0.98), 4.7% for 60 s (95% CI 0.93 to 0.98), and 10.1% for aged ≥70 years (95% CI 0.83 to 0.97) (P = 0.001). In multivariate analysis (adjusted for age group, sex, family history of CRC, smoking status, BMI > 25 kg/m$^2$, FOBT positivity, 3 or more adenomas, colonic adenoma ≥1 cm in size, villous component, and risk groups), the high-risk group (vs. low-risk group, HR = 7.5, 95% CI 2.0 to 27.8) (P = 0.003) and age ≥ 70 years (vs. 50 s, HR = 4.1, 95% CI 1.7 to 9.8) (P = 0.002) were significant risk factors for recurrent advanced neoplasia after polypectomy.
**Conclusion:** The high-risk group and age older than 70 years were significant risk factors for advanced neoplasia recurrence on surveillance colonoscopy after polypectomy or adenoma removal in average-risk individuals.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The role of multigene panels for hereditary cancer risk assessment is yet to be established. We aimed at describing the prevalence of cancer predisposition gene mutations identified by a multigene panel in individuals with suspected Lynch syndrome (LS).
**Aims & Methods:** We performed germline analysis with a next-generation sequencing 25-gene-panel (Myriad myRisk™ Hereditary Cancer) using DNA from 95 patients with suspected LS (endometrial cancer < 50 y-o and/or fulfillment of revised Bethesda criteria) from Nov-2014 through March-2015 within the FAMOSA study. We classified all identified germline variants for pathogenicity and calculated the prevalence of pathogenic mutations and variants of uncertain clinical significance (VUS). We analyzed data on patients' personal and family history of cancer.
**Results:** We included 95 patients [female:46(48.5%), mean age:48.6+12]: 8(8.5%) with endometrial cancer and 87(91.5%) with colorectal cancer. Multigene panel testing identified 20(21%) patients with LS syndrome mutations (8MLH1, 7MSH2, 4MSH6, 1PMS2) and 1(1%) with a mutation in BRCA2 in a 35 y-o woman without personal/familial history of breast/ovarian cancer. In patients diagnosed with mutations in the MMR genes and prior molecular screening (n = 9), two displayed MMR proficiency and 5 patients had a negative prior genetic result by conventional techniques.
**Conclusion:** In individuals with suspected Lynch syndrome, multigene panel testing identified unexpected high-penetrance mutations in 1% of cases. Parallel sequencing also detected a meaningful number of cases with previous false negative results
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1465 NEGATIVE TEST RESULTS OF FECAL IMMUNOCHEMICAL TEST IN PRE-TESTED COLORECTAL CANCER PATIENTS

**Introduction:** **B**urgenland **PRE**vention trial of colorectal cancer **D**isease with **I**mmunologi**C**al **T**esting (B-PREDICT) aims to reduce colorectal cancer (CRC) incidence. All inhabitants of Burgenland aged between 40 and 80 years are included in annual fecal immunochemical test (FIT)-based screening. FIT positive tested individuals were subjected to colonoscopy. Recently, test results of 12 years screening were evaluated. We evaluated the difference between annually and biannually FIT testing.
**Aims & Methods:** B-PREDICT, initiated in 2003 was expanded to the whole province Burgenland in 2006. Annually, more than 150,000 individuals aged between 40 and 80 years are invited to participate in FIT screening. In total, 1,400,000 stool sample containers were delivered to the target group and 547,672 used sample containers were returned to general practitioners, reflecting a participation rate of 39.1%. A qualitative assay was used until 2009, that was replaced by a quantitative system (OC-Sensor, Mast Diagnostica, Germany, cut-off 50 ng Hb/mL) by beginning of 2010. In total, 2,160 patients with initial diagnosis (ID) of CRC were recorded during the period of observation. 1,301 colonoscopies, performed within 30 days before ID were analyzed in regard of indication for colonoscopy. FIT results within the same year, one year and two years prior to ID of CRC were analyzed in pre-tested patients comparing different test systems.
**Results:** In total, 22% of all test results within the year of ID were false negative, 55% within one year and 72% within two years prior to ID. False negative results of the qualitative quick test were 20% in the same year, 59% for 1 year and 73% for 2 years before ID, respectively. For quantitative OC-Sensor, 23% of test results were false negative in the year of ID, 46% within 1 year and 65% within 2 years before ID. The distributions of negative test results of different test systems showed no significant differences.
**Conclusion:** Efficacies of different test systems are comparable. However, rates of false negative results evaluated in pre-tested CRC patients are still high. Thus, annually stool testing may be beneficial.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Accurate determination of tumour spectrum in Lynch syndrome (LS) patients and estimation of its relative risk (RR) is essential for counselling and establishing appropriate surveillance programs.
**Aims & Methods:** We aimed to characterize tumours presented in a Portuguese population with LS and to estimate the RR of each tumour comparing with the general population. We included LS families followed in a specialized centre between 1996–2014. We collected demographic data, tumour type and gene mutations. To calculate tumour RR we used a reference cohort from the Portuguese Oncologic National Registry. Statistical analysis: SPSS v22.
**Results:** Of 112 LS families (MSH2 gene mutations - 61% / MLH1–32% / MSH6–6% / PMS2–0.8%) we identified 377 mutation carriers (MC) with

57% female. Overall there were 344 tumours recorded in 54% of MC: 58% colorectal cancer (CRC) and 42% extracolonic tumours (ECT). Men had more CRC ($p = 0.038$), whereas women had more ECT ($p = 0.001$). Mean age at diagnosis was lower for CRC ($p < 0.001$). MLH1 mutation carriers had a higher frequency of CRC ($p = 0.034$); MSH2 MC had a higher frequency of urothelial cancer ($p = 0.038$) and a tendency for prostate cancer ($p = 0.054$); and in MSH6 MC there was a tendency to higher frequency of ovarian cancer ($p = 0.066$). ECT considered part of LS spectrum: endometrial cancer (12%), ovarian (5%), stomach (4%), urothelial (4%), small bowel (3%), pancreas (0.6%), cholangiocarcinoma (0.3%) and sebaceous tumours / keratoacanthomas (3%). Non-LS spectrum tumours: other skin cancers (3%), prostate (2%), breast (1%) and others (3%). In our population, we found an increased RR for skin tumours (RR 73.17; 95% CI 47.02–109) and cancers of the small bowel (RR 45.44; 95% CI 25.27–75.75), renal pelvis/ureter (RR 41.34; 95% CI 20.16–75.87), endometrium (RR 17.4; 95% CI 12.65–23.37), ovary (RR 15.64; 95% CI 9.26–24.86), colon/rectum (RR 13.58; 95% CI 11.78–15.57) and stomach (RR 2.598; 95% CI 1.51–4.19).

**Conclusion:** To the best of our knowledge, this is the first report of the tumours presented and their RR in a significant number of Portuguese families with LS. We confirmed the presence of an elevated risk for LS-spectrum cancers, as previously described in the literature.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1467 EVALUATING 12 YEARS OF FECAL IMMUNOCHEMICAL TEST-BASED COLORECTAL CANCER SCREENING IN BURGENLAND

**Introduction:** **B**urgenland **PRE**vention trial of colorectal cancer **D**isease with **I**mmunologi**C**al **T**esting (B-PREDICT) aims to reduce colorectal cancer (CRC) incidence. All inhabitants of Burgenland aged between 40 and 80 years are included in annual fecal immunochemical test (FIT)-based screening. FIT positive tested individuals were subjected to colonoscopy. Recently, test results of 12 years screening were evaluated.

**Aims & Methods:** B-PREDICT, initiated in 2003 was expanded to the whole province Burgenland in 2006. Annually, more than 150,000 individuals aged between 40 and 80 years are invited to participate in FIT screening. In total, 1,400,000 stool sample containers were delivered to the target group and 547,672 used sample containers were returned reflecting a participation rate of 39.1%. A qualitative assay was used until 2009, that was replaced by a quantitative system (OC-Sensor, Mast Diagnostica, Germany, cut-off 50 ng hemoglobin/mL) in 2010.

**Results:** Age-standardized CRC incidence in Burgenland was 43.4/100.000 (1998/2000, Statistik Austria) and thereby heading the Austrian cancer statistics. Since implementation of B-PREDICT, incidence rates were continuously reduced to 25.7/100.000 (average 2009/2011). In total, 2,160 patients with initial diagnosis (ID) of CRC were recorded during the observation period. 1,301 colonoscopies, performed within 30 days before ID were analyzed in regard of indication for colonoscopy yielding the following distribution: hematochezia 256, FIT (B-PREDICT) 196, anemia 168, suspected malignancy 127, guaiac test 117, follow-up care after CRC 58 or after polypectomy 54, loss of weight 42, screening colonoscopy 41, obstipation 36, diarrhea 34, abnormal defecation 29, planned polypectomy 14, and others 129. The total number of recorded colonoscopies is 107,796 including 13,590 screening colonoscopies and 21,257 FIT-triggered colonoscopies. CRC detection rates for screening colonoscopy were 0.3% and 0.9% for FIT-triggered colonoscopies.

**Conclusion:** Compared to screnning colonoscopy the CRC detection rate was three times higher when the target group was pre-tested using FIT.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1468 FAMILIAL COLORECTAL CANCER AND GENETIC SUSCEPTIBILITY: A SCREENING OF 99 COLORECTAL RISK GENE VARIANTS IN FIRST DEGREE RELATIVES OF PATIENTS WITH COLORECTAL CANCER

**Introduction:** Epidemiological studies have reported a 2- to 3-fold increased risk of colorectal cancer (CRC) in first-degree relatives (FDR) of patients with CRC compared with the overall population. Since FDR share 50% of genes with CRC cases, it is likely that susceptibility to CRC in these individuals results from common variants in low-penetrance genes associated with CRC risk. However, very little is known about the prevalence of these CRC risk variants in FDR of patients with CRC.

**Aims & Methods: Aim:** To evaluate potential differences in the distribution of genotypes and allele frequencies of certain single nucleotide polymorphisms (SNPs) associated with CRC risk in FDR of patients with CRC and individuals with no family history of CRC. **Methods:** We carried out a case-control study comprising 750 FDR of patients with non-syndromic CRC (cases), and 750 sex-aged- and histological lesion- matched individuals with no family history of CRC (controls). Cases and controls were selected from the Spanish CRC screening registries in Aragon and The Canary Islands. All subjects underwent at least one colonoscopy and diagnosis was confirmed by histological study. Both, cases and controls, were classified according to histological findings in the following 3 groups: a) individuals with no colorectal lesions, b) subjects with non-advanced adenomas (NAA), and c) subjects with advanced adenomas (AA). Genomic DNA from cases and controls was genotyped for a panel of 99 SNPs previously associated with CRC risk by the MassArray™ (Sequenom) platform. Genetic analysis was performed using the SNPassoc package implemented in R. To address the issue of adjustment for multiple testing, the false discovery rate method and Bonferroni's correction were applied.

**Results:** Average age of participants was $54.5 \pm 9.4$ years with a slight predominance of women (51.7%). In 57% of patients, no preneoplastic lesions were found. By contrast, 288 patients (144 cases and 144 controls) showed NAA, and 354 patients (177 cases and 177 controls) had AA. Concerning gene analysis, and after applying the false discovery rate method, allele A of the rs17094983 intergenic SNP (DACT1-RPL31P4) was found to be significantly less frequent in FDR of patients with CRC than in controls (13.6% vs 17.8%; log-additive model, OR:0.72, 95% CI:0.58–0.89). Moreover, stratified analysis by histological lesions showed additional differences in genotype distribution between cases and controls. Thus, rs647161C variant located in the C5orf66 gene was significantly less frequent in cases than in controls (30.4% vs 37.8%; log-additive model, OR:0.73, 95% CI:0.59–0.89) among patients without preneoplastic lesions. In addition, individuals carrying the rare allele A of the rs11255841 variant in the lncRNA gene LINC00709 were significantly more frequent in the group of cases than in controls (54.3% vs 37.1%; dominant model, OR:2.04, 95% CI:1.19–3.51) among patients with NAA.

**Conclusion:** The specific variants associated with CRC risk rs17094983, rs647161 in C5orf6, and rs11255841 in LINC00709 genes show significant differences in genotype distribution between FDR of patients with CRC and individuals with no family history of CRC. Our results suggest the involvement of these variants in the genetic susceptibility to familiar CRC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Early-onset (≤50 years) colorectal cancer (CRC) is suggestive of a hereditary predisposition that may have important consequences for the index case and their relatives. Lynch syndrome, which is caused by germline mutations in DNA mismatch repair (MMR) genes, is thought to account for up to 20% of early-onset CRC. Thus, the majority of early-onset CRC has proficient MMR genes and a yet unidentified genetic predisposition. Population-based studies have suggested that MUTYH mutations can fill the molecular diagnostic gap in this group of patients.

**Aims & Methods:** The objective of our study was to evaluate the contribution of germline MUTYH gene mutations in patients with early-onset CRC. We evaluated patients with early-onset CRC referred to a Specialized Consultation and recorded clinical and demographic data. Both microsatellite instability (IMS), MS-S: stable; MS-L: low; MS-H: high), and immunohistochemistry analysis were performed in tumours. Mutational analysis in MUTYH gene was performed by NGS/MLPA and variants were confirmed by Sanger sequence.

**Results:** So far, a total of 38 patients (male $n = 16$) were analyzed, mean age of 40 years (23–50), with CRC in the right colon ($n = 10$), left colon ($n = 14$), rectum ($n = 14$) in stage in I ($n = 4$), II ($n = 8$), III ($n = 19$) and IV ($n = 7$); 34% with synchronous or metachronous adenomas, being serrated lesions in 4; 13% and 24% had family history of CRC or adenomas, respectively, and 18% had family history of extra-colonic cancers. IMS: IMS-S $n = 27$, IMS-H $n = 4$, IMS-L $n = 2$, not available $n = 5$. In IMS-H tumours there was loss of expression of MLH1/PMS2, however, it was not documented any pathogenic germline mutation in MMR genes. We did not find biallelic MUTYH mutations in none of the 38 patients. However, we found monoallelic mutations in 2 (5%) patients, in the hotspot G396D. These 2 patients had an IMS-S CRC diagnosed at 37 and 39 years, the first one with personal and family history of adenomas.

**Conclusion:** These results, although preliminary, suggest that biallelic mutations are not responsible for a significant percentage of early-onset CRC. However, the high prevalence of monoallelic mutations in this population may justify an increased risk for adenomas / CRC.

**Introduction:** It is known that the expression of beta-tubulin isotypes is changed in cancer but there is still not enough data about such alterations in colorectal cancer (CRC) and their impact on prognosis and chemosensitivity.

**Aims & Methods:** The objective of this study was to reveal influence of changes in the level of betaI- and betaIII- isotypes of tubulin on CRC outcome. The study was performed on surgical histological material of 125 colorectal adenocarcinomas from 124 patients. Double immunofluorescence with anti-cytokeratin antibody and anti-betaI- or anti-betaIII-tubulin was performed. The level of the betaI-tubulin expression was analyzed by image analyses software: epithelial regions were automatically selected by cytokeratin channel; acquired regions of interest have been used as a mask of selection on tubulin channel; integrated density and area of regions of interest were measured. Expression value was calculated as ratio of integrated density to epithelial region's area and then normalized according to positive and negative controls.

**Results:** The expression of betaI-tubulin was significantly elevated in CRC (median 36.6 in normal mucosa vs. 78.8 in CRC, $p = 0.000$). Moreover, normalized value of betaI-tubulin expression in CRC less then 85.1 and 71.5 was associated with lower disease-free ($p = 0.008$) and cancer-specific survival ($p = 0.015$) respectively. BetaIII-tubulin was almost absent in normal mucosa, but was present in CRC cells (median 1.6 in normal epithelium vs. 12.0 in CRC, $p = 0.000$). Elevated normalized value of betaI-tubulin in CRC more then 12.7 and 9.7 was associated with lower disease-free ($p = 0.002$) and cancer-specific survival ($p = 0.022$) respectively. Moreover, increased level of betaIII-isotype in tumor budding was associated with lower disease-free survival in patients on 5-FU chemotherapy ($p = 0.010$).

**Conclusion:** These results demonstrate for the first time that betaI–tubulin expression is increased in CRC, but lower levels of this isotype are associated with worse survival. Expression of betaIII–tubulin is also increased in CRC, but higher levels of this molecule are associated with worse survival. Moreover, upregulation of betaIII–tubulin in the tumor budding in the invasive front could be important for determination of 5-FU resistant patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1472 COMPREHENSIVE METHYLATION ANALYSIS OF IMPRINTING-ASSOCIATED DIFFERENTIALLY METHYLATED REGIONS IN COLORECTAL CANCER

**Introduction:** The expression of imprinted genes depends on the methylation status of differentially methylated regions (DMRs). The disruption of imprinting causes various congenital malformation syndromes, such as imprinting disorders, and is deeply involved in the development and progression of cancer. In colorectal cancer (CRC), aberrant methylation of DMRs within the IGF2/H19 imprinting domain has been reported. However, there have been no comprehensive analyses of methylation of DMRs in CRC.

**Aims & Methods:** We analyzed the methylation status of 38 DMRs in 106 CRC tissues and corresponding normal tissues. Cases with metastasis, preoperative chemotherapy, and inflammatory bowel diseases were not subjected to this study. We also investigated CpG island methylator phenotype (CIMP) using classical CIMP markers (hMLH1, MINT1, MINT2, MINT31, p16), and methylation status of long interspersed nucleotide element 1 (LINE1). These methylation statuses were quantitatively analyzed with bisulfite-pyrosequencing. Then we performed statistical analyses to clarify the relationships between the epigenetic conditions and clinicopathological factors of CRC.

**Results:** Among four DMRs in the IGF2/H19 domain, H19-DMR plays an important role for the expression of the imprinted genes, IGF2 and H19. We found that 44% of the cases showed hypomethylation at IGF2-DMR2 and 66% at IGF2-DMR0, whereas only 2% of the cases showed hypermethylation of H19-DMR and H19-promoter. The result indicated that hypomethylation of IGF2-DMRs was more frequent in IGF2/H19 imprinting domain in CRC. The comprehensive methylation analysis of 38 imprinted DMRs revealed that on average, $9.2 \pm 6.1$ DMRs per case were hypermethylated and $2.9 \pm 2.3$ DMRs were hypomethylated, indicating a frequent occurrence of hypermethylation. We found 6 particular DMRs to be aberrantly methylated in 50% or more of the CRC samples, i.e. high frequency aberrantly methylated DMRs (HF-DMRs). Of these, five DMRs (PEG1, TRAPPC9, NDN, NESP55, GNASXL) showed hypermethylation and the IGF2-DMR0 showed hypomethylation. Additionally, nine DMRs were aberrantly methylated in less than 10% of cases, i.e. DMRs resistant to aberrant methylation (RE-DMRs). Statistical analyses did not show any relationships between the aberrant methylation of imprinted DMRs and clinicopathological factors. We identified that 25% of cases showed a positive status of CIMP. However, there was no association between CIMP status and aberrant methylation of imprinted DMRs, including the hypermethylation of HF-DMRs and the hypomethylation of IGF2-DMR0. As for methylation status of LINE1, hypomethylation of LINE1 was associated with aberrant methylation of imprinted DMRs.

**Conclusion:** Our results revealed that in CRC, imprinted DMRs are likely to be hypermethylated. In the IGF2/H19 domain, however, IGF2-DMR0/2 hypomethylation is more frequent than H19DMR hypermethylation. We found that certain DMRs are susceptible to aberrant methylation, while another subset is resistant. Aberrant methylation of imprinted DMRs was not associated with clinicopathological factors. No association between hypermethylation of imprinted DMRs and CIMP positive suggested different causal mechanisms. However, global hypomethylation was associated with aberrant methylation of imprinted DMRs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1473 IS THE ASSOCIATION BETWEEN PHYSICAL ACTIVITY AND COLORECTAL ADENOMA MEDIATED BY MUSCLE-DERIVED MYOKINES?

**Introduction:** Exercise reduces the risk of colorectal cancer and adenoma but the mechanisms are not known. Exercise-induced muscle contraction releases multiple muscle-derived proteins (myokines) that exert effects on peripheral organs. These may mediate the beneficial effects of exercise including cancer prevention. Irisin is a myokine that increases thermogenesis and energy expenditure[1]. It is implicated in metabolic conditions (eg, diabetes mellitus) and has been shown to induce apoptosis in breast cancer cell lines but to date, has not been studied in colorectal cancer or adenoma.

**Aims & Methods:** We seek to determine whether the association between physical activity and colorectal adenoma is related to serum irisin levels. A case-control study was performed. Eligible subjects, aged 45–70 years, scheduled for ambulatory colonoscopy, were prospectively recruited. Baseline assessment was performed. Self-reported physical activity data was collected using the validated IPAQ Long questionnaire. Physical activity levels were characterized both as continuous and categorical variables. Venous specimens were drawn before colonoscopy.

All colonoscopies were performed by gastroenterologists from a single tertiary hospital. All polyp histology was reported by a pathologist blinded to anthropometric and physical activity data. Any uncertainty was reconciled by a second GI pathologist.

Consecutive cases with adenoma and matched controls with normal colonoscopy underwent body composition analysis by dual energy X-ray absorptiometry (DEXA). Skeletal muscle mass was quantified by skeletal muscle mass index, SMI ($kg/m^2$). Irisin levels (Biovendor Human Irisin Elisa Kit) were assayed. Logistic regression was used to evaluate associations.

**Results:**

| Variable (data presented as proportion or median and IQR) | Controls | Cases |
|---|---|---|
| Age (years) | 58(10) | 60.5(9) |
| Male gender, n (%) | 24(60) | 16(61.5) |
| Chinese race, n (%) | 39 (97.5) | 26(100) |
| Obese, n (%) | 4 (10) | 7 (26.9) |
| Charlson comorbid index category 0, n (%) | 35(87.5) | 23 (88.5) |
| Current smoker, n (%) | 2 (5) | 6 (23.1) |
| High physical activity, n (%) | 22(55) | 11(42.3) |
| Total body percentage fat | 32.1 (11.2) | 32.7 (9.4) |
| Skeletal muscle mass index ($kg/m^2$) | 6.2(2.1) | 6.5 (0.9) |
| Serum Irisin (ug/ml) | 2.8 (1.3) | 2.1 (2.4) |

66 patients were studied (see Table above). Irisin levels were significantly associated with the presence of adenoma (Odds ratio 0.61 [0.38–0.98], $p = 0.040$) even after adjusting for known confounders.

**Conclusion:** Higher irisin levels are associated with a lower likelihood of colorectal adenoma even after correcting for confounders including physical activity and direct measures of adiposity and muscle mass. This is in keeping with a protective role for irisin. This relationship should be explored in colorectal cancer patients and mechanistic insight should be sought.

**Introduction:** MicroRNA has been found to play critical role in colorectal adenoma-carcinoma sequence. Recently, miRNA specific high throughput arrays became available to detect promising microRNA expression alterations even in colorectal cancer (CRC). While miRNA expression markers are well characterized in tissue, less is known about miRNA expression profiles in plasma samples.
**Aims & Methods:** The purpose of this study was to identify miRNA expression patterns between normal colonic (N), tubular adenoma (ADT), tubulovillous adenoma (ADTV) and colorectal cancer (CRC) plasma samples.Furthermore, our aim was to analyze the expression level of miRNA in matched tissue samples. Sixteen peripheral plasma samples and matched tissue biopsy samples (normal [N] n = 4tubular adenoma [ADT]n = 4; tubulovillous adenoma [ADTV] n = 4;colorectal cancer [CRC]n = 4) were also selectedand total RNA included miRNA was isolated.Matched MiRNA microarray experiments were conducted by GeneChip® miRNA 3.0 Array (Affymetrix). RT-qPCR (microRNA Ready-to-use PCR Human Panel I + II; Exiqon) was used for validation.
**Results:** Out of the 1733, the detectable number of miRNA, which could be found in each group was; N = 306, AD = 334, CRC = 321. Four miRNA (miR-4315, -519 e, -4257, -4253) showed altered expression between normal CRC groups in plasma. Expression of miR-4257 and miR-4253 are downregulated in CRC tissue samples moreover concentration of these miRNAs show upregulation in CRC compared to normal plasma pairs. MiR-4315 and miR-519 e are downregulated in both sample types in case of CRC, though higher expression was observed in normal plasma pairs. MiR-1972 was also selected and upregulation (FC = 0.5) in CRC was confirmed by RT-PCR in plasma furthermore positive correlation was observed in tissue. MiR-2116 and miR-548 p were upregulated only in tubulovillous adenoma compared to normal and tubular adenoma in plasma in contrast to tissue with a low concentration. Four miRNA were upregulated, three miRNA were downregulated in neoplastic lesions compared to normal in plasma, downregulated candidates showed upregulation in tissue pairs.
**Conclusion:** miRNAs were also found in peripheral blood system in a lower concentration compared to tissues. Systematic changes could observed in different stages. Circulating miRNAs of plasma could have a clinical significance in detection of neoplastic alterations.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1475 A SEVEN-GENE SIGNATURE PREDICTS OVERALL SURVIVAL OF PATIENTS WITH COLORECTAL CANCER

H. Chen[1], **Y. Qian**[2], W. Ge[1], S. Zheng[1]

**Contact E-mail Address:** qianqianonline@gmail.com
**Introduction:** Colorectal cancer (CRC) is a major cause of global cancer mortality. Gene expression profiles can help predict prognosis of colorectal cancer, although with no firm conclusions. For most of studies, disease recurrence was used as the survival endpoint for analysis. In this paper, we aim to build a robust genes signature for prediction of overall survival (OS) in patients with CRC.
**Aims & Methods:** Fresh frozen CRC tissues from 67 patients were analyzed using Affymetrix HG-U133plus 2.0 gene arrays. Univariate survival analysis was used to screen genes associated with the overall survival of patients. A likelihood-based survival modelling approach was further adopted to unearth the optimal genes signature. The survival risk score system was built by BRB-ArrayTools, and validated in two external data sets of different platforms using receiver operating characteristic (ROC) curves.
**Results:** By performing univariate survival analysis, 6487 genes were found to be associated with the overall survival in patients with CRC from our cohort. KEGG analysis revealed that these genes were mainly involved in pathways such as endocytosis, axon guidance, spliceosome, Wnt signalling and ubiquitin mediated proteolysis. A linear prognostic model of seven-gene signature (NHLRC3, ZDHHC21, PRR14L, CCBL1, PTPRB, PNPO, and PPIP5K2) was constructed and weighted by regression coefficient, which divided patients into high- and low-risk groups. The OS for patients of high-risk group was significantly poorer compared with patients of low-risk group (hazard ratio [HR] = 25.79, $P < 0.001$). Interestingly, all seven genes were found to be significantly altered in CRC tissues as compared with adjacent normal tissues, indicating their potential role in CRC development. Importantly, this seven-gene signature was further validated as an independent prognostic marker for OS prediction in patients with CRC in other two cohorts (n = 55 for cohort I, area under the respective ROC Curves (AUC) = 0.715, P = 0.011; n = 272 for cohort II, AUC = 0.599, P = 0.027).
**Conclusion:** We developed a robust seven-gene signature that can predict the overall survival of patients with CRC, independently of the pathological staging. The gene signature may have important implications in clinical practice, especially for identifying CRC patients who are at high risk of mortality.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1476 FOUR ROUNDS OF TWO-SAMPLE FECAL IMMUNOCHEMICAL OCCULT BLOOD TEST SCREENING FOR COLORECTAL CANCER

**Introduction:** Screening for colorectal cancer (CRC) using fecal immunochemical testing (FIT) requires successive rounds. Using two FITs (2-FIT) per screening round increases sensitivity and could maximize the yield of screening. However, limited data exists on 2-FIT screening over multiple rounds and the number of interval CRC (iCRC) found.
**Aims & Methods:** In this study we assessed the participation rate, diagnostic yield and iCRC of 2-FIT screening over 4 biennial successive rounds. From 2008 to 2015 average-risk subjects aged 50–74 years were invited for 4 rounds (R1-R4) of biennial 2-FIT screening. Per round, participants received two identical quantitative FITs (OC Sensor Micro, Eiken Japan) to sample from two consecutive bowel movements. FIT was considered positive if the hemoglobin (Hb) concentration was ≥10 μg Hb/g feces in at least one FIT. For each round, we excluded individuals with a history of CRC or IBD, colon imaging ≤2 years, a life expectancy <5 years, as well as those who died, moved away or had a positive FIT in previous rounds. Participation rate, positivity rate (PR), diagnostic yield, detection rate (DR) and positive predictive value (PPV) for advanced neoplasia (AN) and CRC were calculated. Diagnostic yield was defined as screenees with AN relative to all invitees. DR was defined as all screenees with AN or CRC relative to all participants. AN compromised CRC and advanced adenoma (>10 mm, or >25% villous component and/or high-grade dysplasia). iCRCs were identified through record linkage with the Dutch Comprehensive Cancer Centre.
**Results:** In total 3,131 were eligible at least once during the four screening rounds. Out of these, 1,882 (60%) were eligible to be invited in R4 (mean age 66 ± 5.3 years; 48% males). In R4, 64% (95%CI 61–66) participated (Table 1), 5.3% participated for the first time (62/1.172). The PR was 10.8% which was not significantly different from PR in R3 (p = 0.367). Although the numbers were too small to reach statistical significance, noteworthy is the increase in DR and PPV in R4 compared to R3 (p = 0.201, p = 0.175 respectively) (Table 1). In total, 72% (2.269/3.131) of all eligible subjects participated at least once. Of those attending at least once, cumulative PR was 28% (638/2.269, 95%CI; 26–30), cumulative DR of AN was 6.3% (144/2.269). After 4 rounds cumulative yield was 4.6% (144/3.131, 95%CI; 4–5) for AN and 0.8% (25/3131) for CRC. Two CRCs were detected in the fourth round, both pT1N0. In total, 25 screen detected CRCs, and only two iCRCs <2 years after a negative FIT were found.

**Table 1:** Overview results two-sample FIT screening in multiple rounds

| Round | Eligible invitees | Participation | Positivity rate | Detection rate AN | PPV AN CRC | |
|---|---|---|---|---|---|---|
| | N | N (%) | N (%) | N (%) | N (%) | % (95% CI) |
| **1** | 3057 | 1875 (61.3) | 239 (12.8) | 77 (4.1) | 13 (0.7) | 34% (28 – 41) |
| **2** | 2579 | 1582 (61.3) | 132 (8.3) | 27 (1.7) | 4 (0.3) | 21% (15 – 29) |
| **3** | 2287 | 1473 (64.4) | 141 (9.6) | 18 (1.2) | 6 (0.4) | 13% (8 – 20) |
| **4** | 1846 | 1172 (63.5) | 126 (10.8) | 22 (1.9) | 2 (0.2) | 20% (13 – 28) |
| | | P = 0.056 | P < 0.001 | P < 0.001 | P = 0.109 | P < 0.001 |

AN; advanced neoplasia, CRC; colorectal cancer, PPV; positive predictive value, CI; Confidence Interval.
**Conclusion:** Participation in 2-FIT screening is high and stable over at least 4 screening rounds. Detection rate and PPV dropped significantly over multiple rounds yet seem to increase in R4. Future research comparing these results with four rounds of 1-sample FIT screening is needed to confirm usability of 2-FIT screening and to evaluate if in a 2-FIT screening program decreases the incidence of interval cancers.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1477 ROLE OF FAECAL BIOMARKERS IN DETECTING COLORECTAL CANCER AND ADENOMA IN SYMPTOMATIC PATIENTS

[4]*Colorectal Surgery, Leicester General Hospital, Leicester/United Kingdom*

**Contact E-mail Address:** monikawidlak@yahoo.co.uk
**Introduction:** Colorectal cancer (CRC) is the third most common malignancy in the world. The diagnosis can be difficult as symptoms of CRC are variable and have poor specificity. Most patients with symptoms have benign pathology but in an effort not to miss CRC, almost all patients undergo invasive colonic investigations. In the UK, the prevalence of CRC in this patient group ranges from 6–8%. Thus there is a quest for simple, non-invasive testing that can help streamline those with significant colonic pathology.
Guaiac faecal occult blood test (gFOBT), which is currently utilised in the bowel cancer screening programme, has relatively poor specificity for colorectal cancer and will be replaced with immuno-chemical testing (FIT) which has improved sensitivity and specificity. Conversely faecal calprotectin (FC) has good evidence for detecting inflammatory bowel disease (IBD) but its value in colorectal cancer is less well studied.
**Aims & Methods:** To prospectively analyse the role of faecal biomarkers (FIT and FC) to detect colorectal cancer and adenomas in patients presenting with lower gastrointestinal (GI) symptoms. 799 consecutive patients (median age 67 (29–93) years; 50.7% women) with lower GI symptoms referred for investigations from the primary care (as per national referral pathway) were recruited prospectively from colorectal and gastrointestinal clinics. After applying a strict exclusion criteria, 434 patients were included who had complete colonic investigations. FIT and FC were measured in all patients and final outcomes recorded. All analysis was carried out using Matlab R2011b. Groups were compared using the Mann-Whitney U test. Results were considered significant if $p < 0.05$.
**Results:** FIT returned a sensitivity of 92% and specificity of 87% for detection of colorectal cancer; AUC of 0.96 (CI 0.90–1.00). FC had sensitivity of 68% and specificity of 84% for detecting colorectal cancer; AUC of 0.83 (CI 0.73–0.93). The combination of both FIT and FC had minimal improvement over FIT alone; sensitivity 92% although specificity improved to 94% with AUC of 0.96 (CI 0.90–1.00). For adenoma detection, FIT was superior with a sensitivity of 69.0% and specificity of 70.3%; AUC 0.71 (CI 0.63–0.79) with FCP showing no benefit compared to not testing. For detection of both cancer and adenomas, FIT again was superior with a sensitivity of 76% and specificity of 70%; AUC of 0.77 (CI 0.71–0.83) and FCP showing no benefit compared to not testing.
**Conclusion:** FIT is a good biomarker for detection of colorectal cancer in symptomatic patients. The combination of both FIT and FC improves specificity but not sensitivity.
**Disclosure of Interest:** R. Arasaradnam: R Arasaradnam has provided educational lectures on behalf of ThermoFisher ltd. Which provide FC analysis

**Introduction:** It is generally accepted that carcinomas arising from adenomas in familial adenomatous polyposis (FAP) patients. On the other hand, a few cases of carcinoma with depressed type without adenoma has been reported. The closer examination of morphology of carcinomas in FAP patients has not been reported.
**Aims & Methods:** [Aim] To clarify the morphology of carcinomas in FAP patients.
[Material and Method] From 2000 to 2012, 170 patients of FAP with carcinomas were operated in 23 institutes participated in Study Group for FAP in JSCCR. In the study, 373 lesions of carcinoma were investigated. To clarify the morphology according to the development of carcinomas, 238 lesions of superficial type of carcinoma were evaluated in comparison with the data of 4019 lesions of early colorectal carcinoma* as non FAP Japanese patients.
**Results:** In 170 patients, 238 lesions were superficial type of carcinoma and 135 lesions were advanced carcinoma (type1 :19, type2 :100, type3 :10, type4 :0, type5 :6). In 238 lesions of superficial type of carcinoma, 10 lesions of depressed type were diagnosed (4.20%) in 9 patients. The other 228 lesions were categorized as protruded type or flat type (95.8%). As a localization, depressed type of carcinoma were 6.49% (5/77) in the right side colon. 2.56% (3/117) in the left side colon, 4.55% (2/44) in the rectum. In FAP patients, the lesion of depressed type of carcinoma was significantly less than non FAP patients (4.20%, 10/238 vs 16.7%, 670/4019, $p < 0.001$).
**Conclusion:** In FAP patients, carcinoma was widely accepted arising in the numerous adenomas as polyps. A few cases of depressed type of carcinoma in FAP patients were reported. But the frequency was unclear. This study reported the analysis of morphology of carcinomas in FAP patients compare with non FAP patients. Depressed type of carcinoma were present and diagnosed in plural institutes. In FAP patients, depressed type of carcinoma is present but less than non FAP patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** costinstreba@gmail.com
**Introduction:** Colorectal cancer (CRC) currently ranks as one of the most common cancers worldwide, being the fourth leading cause of cancer death. Accurate diagnosis and staging requires histology and determines therapeutic approach.
**Aims & Methods:** Our aim was to investigate colorectal cancer histologically and immunohistochemically, identifying and quantifying morphometric elements through fractal analysis and using an automatic system based on artificial intelligence for diagnosis and classification. We have obtained ethical clearance from the local committee and all included patients provided informed consent for participating in our study. We have prospectively selected patients between September 2014 and October 2015 that underwent surgery for previously diagnosed CRCs. Biopsy material was obtained for diagnostic through biopsy during colonoscopy or postoperatively after surgery with curative intention. Patients were followed post-intervention and the tissue was processed by techniques of classic histology (hematoxylin-eosin staining and trichromic staining with green light by Goldner-Szeckelly method) and immunohistochemistry (anti-p53, anti-Ki67, PCNA and Anti-VEGF-C). We observed histological and immunohistochemical changes, subjecting a median of 50 images per patient to computer analysis with an in-house tool for obtaining fractal dimension, as well as ImageJ for GLCM (histogram of co-occurring greyscale values). Neural networks were applied for diagnosing and classification of tumor types, as well as for staging. We calculated the sensitivity, specificity, positive and predictive predictive values of the system.
**Results:** We included in the study 96 consecutive patients (58 men) - 38 sigmoid tumors, 27 tumors of the descending colon, 12 tumors of the transverse colon, 10 on the ascending colon and 9 of the caecum. Fractal analysis of the nuclear chromatin layout identified major differences between well differentiated tumors compared to other tumor types. We also found significant differences between adenocarcinomas and other histological types; however, we have not encountered significant differences between colloid tumors and signet ring cell tumors. Fractal analysis of immunohistochemical images showed significant differences ($p < 0.0001$) between the anti-Ki67, anti-p53, anti-VEGF and PCNA and normal mucosa; the analysis also showed significant differences between early stages (good and very well differentiated) and advanced ones. Artificial intelligence could distinguish tumor tissue from normal mucosa in 98.7% of cases, classifying tumors with an accuracy of 87.2%, sensitivity

88.4%, specificity 83.2%, positive predictive value 83.11% and negative predictive value of 86.8%.
**Conclusion:** Computerized processing and feature extraction from histological and immunolabeled images can provide additional data for diagnosis, classification and staging of malignant tumors of the large intestine. Neural networks are a suitable tool for automatic interpretation of these data, which may serve as a diagnostic and decision support for colorectal cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1480 ADENOMA DETECTION WITH ENDOCUFF-ASSISTED COLONOSCOPY

**Y. Bensuleiman**, N. Ikezawa, K. Sasaki, S. Yoshida, S. Myoujou, T. Nakajima, S. Yoshida
*Gastroenterology , Akashi Medical Center, Akashi shi Hyogo/Japan*

**Contact E-mail Address:** sato_yahaya@hotmail.com
**Introduction:** Colonoscopy is considered the gold standard method for detecting colonic neoplasia worldwide. However, polyps are still missed substantially in screening colonoscopy, especially those less than 10 mm in size, which are located in the sigmoid and flexures, as well as behind multiple folds and haustrae. Several techniques, such as cap-assisted colonoscopy (CAC), were developed to improve the rate of polyp detection, and some studies reported that CAC promoted polyp detection. A new device, Endocuff (EC), was also developed with the hope of improving the adenoma detection rate (ADR). Recently, several studies have shown that EC-assisted colonoscopies (EACs) improved polyp detection rate compared to standard colonoscopies. The aim of this study was to compare the ADR of EAC with that of CAC in screening.
**Aims & Methods:** Among all the patients who underwent screening colonoscopy at the Akashi Medical Center, Hyogo, Japan, over a period of 3 months between January to May 2016, those who passed the exclusion criteria (those with partial colonic resection, known colonic obstruction, colonic adenoma or cancer, suspected or proven lower GI bleeding, and inflammatory bowel disease) and provided informed consent were randomly assigned to the EAC or CAC group. All examinations were performed by three endoscopists. Prospectively, we could collect data on cecal and ileal intubation rates, insertion time, withdrawal time, colon cleanliness, ADR, clinicopathological characteristics of polyps, and complications. Cecal intubation was confirmed by the documentation of the appendiceal orifice or cecal valve. Withdrawal time was measured from the cecum to the anus, without counting the time spent on suctioning of fluid or polypectomy. We also assessed the difference in polyps according to size, location, and morphology by using EAC and CAC. The data were statistically analyzed.
**Results:** A total of 159 patients were enrolled in this study; EAC and CAC were performed on 84 and 75 patients, respectively. Patient characteristics and colon cleanliness were not significantly difference between the groups. The cecal intubation rate was comparable between the two group (98% vs. 99%, $p = 0.63$).The insertion and withdrawal times were also not significantly different ($8.25 \pm 5.98$ min, $7.95 \pm 1.44$ min with EAC vs $7.91 \pm 5.51$ min, $8.35 \pm 1.98$ mm with CAC; $p = 0.71$ and 0.14, respectively). On the other hand, the ileal intubation rate was significantly lower in EAC than in CAC (35% vs. 83%, $p < 0.01$). A total of 162 adenomas were detected in this study. The ADR in EAC was not significantly different compared with that in CAC (53% vs. 59%, $p = 0.43$). EAC also detected a similar number of adenomas per patient compared to CAC (1.03 vs. 1.00, $p = 0.88$). The location of adenomas was also did not differ between the groups (cecum, 3(3%)/5(7%); ascending colon, 19(22%)/14(19%); transverse colon, 16(18%)/19(25%); descending colon, 9(10%)/5(7%); sigmoid colon, 32(37%)/25(33%); and rectum, 8(9%)/7(9%) in EAC/CAC, respectively). The number of adenomas according to size and morphology of the polyps also did not differ significantly between the groups ($p = 0.64$). Minimal mucosal lacerations were observed in 17 patients (EAC: 16 vs. CAC: 1; $p < 0.01$). Major complications were not observed.
**Conclusion:** This study showed similar maneuverability and ability of polyp detection with EAC and CAC. However, the ADR (53% and 59%) in both groups was higher compared with that of standard colonoscopy, which has been reported. One of the possible reasons for the similarity in ADR between the groups was considered to be the same type of equipment used to flatten large mucosal folds during withdrawal of the instrument. Cecal intubation rate was similar in the two groups, but the ileal intubation rate was significantly lower in EAC than in CAC. However this result will not affect the clinical outcome of ADR because lesions that extend into the cecal valve are very rare. In conclusion, EAC was as safe and efficacious as CAC in screening.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Approximately, 15% of colorectal cancers occur before the age of 50, mostly related to inflammatory bowel diseases, Lynch syndrome (LS), and polyposis syndromes. However, up to 7% of colorectal cancers occur in patients with less than 50 years of age (Early Onset Colorectal cancers - EOCRC) with no evidence of familial predisposition or belonging to hereditary syndromes.
**Aims & Methods:** AIM: To study a large population of EOCRC with no predisposing genetic risk factors in order to define the clinicopathological features and the stage at presentation. We also aimed to evaluate the correlation between histological and molecular patterns, clinicopathological features and oncological outcomes. METHODS: All cases of EOCRC were identified between 2006 and 2014 from a the prospectively maintained databases of the two oncological surgeries. Patients who had LS, inflammatory bowel disease, polyposis syndrome, or a known family history for these conditions were excluded. Medical records from all included patients were reviewed and data was extracted on patient demographics, clinical features, oncological treatment and postoperative follow-up. Tumours histological features and molecular data, including KRAS genotype, MLH1 and MSH2 protein levels, as well as Ki-67, p53 and thymidylate synthase (TS) protein levels were also collected.
**Results:** Ninety-four cases (54% males) were identified. The mean age at surgery was 43 years. The most common site of primary tumour was the rectum (40%), followed by left colon (32%) and right colon (27%). 83% of patients were symptomatic at the time of diagnosis: the most common presenting symptoms were abdominal pain, haematochezia, rectal bleeding. Half of EOCRCs showed an advanced stage with either stage III (34%) or stage IV (16%) at presentation. Histologically, 10% of the cancers were well differentiated, 70% were moderately differentiated, and 20% were poorly differentiated. Mucinous and signet-ring cell histology was seen in 20 (21%) and 2 (2%) cases, respectively. Seventeen patients (22%) had a first- or second-degree relative with CRC outside of a defined syndrome (FAP or HNPCC), and 43% with any type of cancer, regardless of location. Smoking rate in the EOCRC group was 36%, whereas 21% of patients consumed alcohol daily. The majority of patients showed a normal weight, with a mean BMI of 23.4. Regarding the molecular features, 7.2% and 0% lacked of MLH1 and MSH2 expression, respectively, and37% harbored KRAS mutation; 36% and 21% revealed low p53 and high TS levels, respectively. The median follow-up after surgery was 35 months. The overall the 1-year survival was 91%, while at 5 years it dropped to 57%.
**Conclusion:** EOCRCs appear frequently as aggressive cancers located in the sigmoid colon and rectum, are DNA mismatch repair proficient and most patients are symptomatic at the time of presentation. Since screening programs do not include patients under 50 years of age, overall prognosis of EOCRCs is poor related to the advanced stage of disease at the time of diagnosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colorectal cancer is the 3rd most commonly diagnosed cancer in South Korea. The standard method for evaluating the colon is the colonoscopy procedure. Proper bowel preparation is essential for successful examination. A sub-optimal bowel preparation can lead to compromised exams with missed polyps, an increase in procedure time, and aborted exams. Few studies have evaluated the use of smartphone applications as a means of educating and improving the quality of bowel preparation. Therefore, we created a smartphone

application for patients to use as a preparation guide before undergoing a colonoscopy.
**Aims & Methods:** A total of 142 patients (M:F = 84:58, mean age 43.5 ± 9.3 years-old) who were scheduled to undergo a screening colonoscopy in a health examination center were enrolled in this study. The study was conducted as a prospective endoscopist-blinded, controlled design. Participants were divided into two groups, one group was asked to use a new smartphone application that we had newly developed that educates the user on colonoscopy preparation (Smart group, N = 71), the other group received the existing verbal and written instructions (Control group, N = 71).
**Results:** The quality of bowel preparation, assessed using The Boston Bowel Preparation Scale (BBPS) was significantly higher in the smart group than control group (7.70 ± 1.1 vs. 7.24 ± 0.8; p = 0.007 by t-test). Although no significant differences were found between the two groups in cecal insertion time, withdrawal time was significantly higher in the smart group than control group. In addition, the number of patients with polyps between two groups has no significant difference (23/71in smart group vs. 15/71 in control; p = 0.129).
**Conclusion:** Our study is showing that the bowel preparation by smartphone application was significantly better bowel preparation quality as assessed by the BBPS. Smartphone application might replace the written paper instruction, soon. More studies are needed to show the exact impact of bowel preparation with smartphone application.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1483 THE PREDICTIVE VALUE OF FERRITIN IN OLDER PATIENTS IN THE DIAGNOSIS OF COLON CANCER

**F. Karakaya**[1], Ç. Kalkan[1], D. Turan[1], M. Karakaya[1], A. Ç. Kartal[1], I. Soykan[2]
[1]*Gastroenterology, Ankara University Faculty of Medicine, Ankara/Turkey*

**Contact E-mail Address:** mfkarakaya@yahoo.com

**Introduction:** Ferritin is an indicator of iron deficiency. However, it may produce false results in the presence of acute/chronic inflammation. In older patients, colon cancer is an important cause of morbidity and mortality.
**Aims & Methods:** The aim of this study was to determine the predictive value of ferritin and ferritin-transferrin saturation combination for predicting the presence of colon cancer in older patients. 600 patients aged >65 year-old were included into the study. Along with gastroscopic and colonoscopic findings, serum iron profile and C-reactive protein were also recorded. Patients were stratified into three groups according to their iron profiles: group 1: ferritin < 50 μg/L; group 2, Ferritin < 100 μg/L; group 3, Ferritin < 50 μg/L were the indicators for iron deficiency. If ferritin value was higher than 50 μg/L and transferrin saturation is below 16%, iron deficiency diagnosis was made.
**Results:** 528 patients had no upper and lower endoscopic findings that can result iron deficiency and 72 patients had colon cancer with normal gastroscopic findings. C-reactive protein values were found to be significantly high in the colon cancer group (p < 0.001). Ferritin value was found to be similar in the colon cancer and normal colonoscopy groups. In the colon cancer group, by means of showing the presence of iron deficiency; group 1 had 63% sensitivity and 53% specifity, group 2 had 79% sensitivity and 20% specifity, group 3 had 91% sensitivity and 49% specifity. In the ROC analysis, the AUROC value was found to be 0.704 for group 3. The patients in group 3 had significantly higher C-reactive protein values than the ones in group 1 and 3.
**Conclusion:** In older patients, normal ferritin values is not enough to disregard iron deficiency diagnosis. In this situation by using the transferin saturation, a possible presence of iron deficiency should be investigated. Patients with transferin saturation lower than 16% should undergo endoscopic examination with the diagnosis of iron deficiency.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1484 COLORECTAL CANCER SCREENING FROM THE VIEWPOINT OF ITS TARGET POPULATION – RESULTS OF SURVEY

R. Kroupa, **M. Ondrackova**, M. Dastych, A. Hep
*Department Of Internal Medicine And Gastroenterology, University Hospital and Faculty of Medicine, Masaryks University Brno, Brno/Czech Republic*

**Contact E-mail Address:** mondrackova@fnbrno.cz

**Introduction:** Result of colorectal cancer (CRC) screening programs are often presented from the viewpoint of stakeholders, care providers and endoscopists. Studies describing the viewpoint of clients – the target population are rare. Interview/questionaire with direct care provider (general practitioner, endoscopist) may be skewed. Level of participation in CRC screening program in the Czech Republic is about 30%.
**Aims & Methods:** This study aims to acquire independent opinion from the viewpoint of CRC screening target population regarding the CRC screening information sources, reasons for and against participation in the screening. We want to discover the troublesome points in the screening from the practical view of the clients.
Anonymous questionnaires were distributed to relatives of pre-gradual university students, to students of The University of the Third Age Masaryk University Brno (aged over 50) and to patients of gastroenterology department I two periods in years 2013 and 2015. Following issues were found out: demography and CRC in family, sources of CRC program information, reasons for non-participation in the screening, practical troubles with screening tests realization and circumstances that can stimulate the participation.
**Results:** Completed questionnaire was acquired from 404 persons:34% male (139), average age 65.0 ± 8.2 years. We got information from 116 relatives of students (response rate 31%), 215 adult students and 73 patients coming for screening colonoscopy (both with response rate over 90%). CRC in family history was recorded in 15.6% of respondents. Only 17 persons (4.2%) never heard about CRC screening. General practitioner was the main information source of screening (up to 75%), following classical media: TV, radio – 35%, friend or family member advice – 25%, internet – 14%, personalized invitation – 13% and from publicity stunt– 4%. More than 16% of responders did not participate in the screening, their main reasons were: lack of time– 40%, lack of interest in preventive examination 25%, fear of endoscopy– 35% and fear of positive result– 30%. Majority of respondents (78%) had personal experience with FOBT, (in 27% followed by colonoscopy) and they reported inhibitions to manipulate with stool and inappropriate toilet bowl for stool collection as main troubles. Fear of colonoscopy and fear of bowel preparation was reported in 70% (35%). Fear of cancer on endoscopy was mentioned in 53%. According to respondents view, participation rate might improve due to better explanation of screening principles and due to arrangement of painless colonoscopy.
**Conclusion:** One half of clients experience the screening tests with no troubles. Fear of colonoscopy and fear of positive result on test were the main referred problems for participation in regular screening. One quarter of responders feel technical problems with stool catch. Support of CRC screening might be focused on decrease the fear of examination and tools for easy stool catch. Preference of primary colonoscopy with analgosedation could be useful.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1485 EARLY ONSET COLORECTAL CANCERS VS SPORADIC COLORECTAL CANCERS: A CLINICOPATHOLOGICAL AND MOLECULAR EVALUATION

**Contact E-mail Address:** leonardo.eusebi@unibo.it

**Introduction:** Colorectal cancers (CRCs) developing before the age of 50, with no evidence of familial predisposition or belonging to hereditary syndromes are defined as Early Onset Colorectal cancers (EOCRCs). Case series of EOCRCs have been studied, however, little is known about their predisposing factors and the molecular pathways that promote the early onset of these tumours.
**Aims & Methods:** AIM: to evaluate if EOCRCs may be defined as a distinct entity by comparing their clinicopathological, histological and molecular features to a consecutive series of sporadic CRCs developed in patients over 50 years of age. METHODS: A series of 94 EOCRC identified from a prospectively maintained database of the two oncological surgeries was compared to a consecutive series of 192 sporadic CRCs from patients older than 50 years (from the same hospital) that had been analysed and reported in a previous study by our research group. Medical records from all included patients were reviewed and data was extracted on patients demographics, clinical features, and tumours histological and molecular data, including MLH1 and MSH2 protein levels, as well as p53 and Thymidylate synthase (TS) protein levels.

**Results:**

| | EOCRCs (n = 94) | Sporadic CRCs (n = 192) |
|---|---|---|
| Age, years (Average ± SD) | 43.2 ± 3.9 | 67.3 ± 12.1 |
| Sex Male Female | 51 (54%) 43 (46%) | 107 (56%) 85 (44%) |
| Location Right colon Left colon | 30 (32%) 64 (68%) | 83 (43%) 109 (57%) |
| TNM staging 0-II III-IV | 50% 50% | 47% 53% |
| Missmatch repair genes status<br>MLH1 deficiency<br>MSH2 deficiency | 7.2% 0% | 9.9% 4.7% |
| p53 levels (low) | 36% | 36% |
| Thymidylate synthase levels (high) | 21% | 21% |

The mean age at surgery of EOCRCs and controls was 43 and 67 years, respectively. Regarding cancer location, 57% of the control CRCs were located in the left colon, whereas the most common site of EOCRCs was the rectum (p = 0.16). Stage II lesions were the most frequent in the controls (47% of the cases - no stage 0 or stage I cancers were present in this group) whereas the advanced stages III and IV were present in 40% and 13% of the cases, respectively. Similarly, in the EOCRCs group stage III and IV lesions represented 50% of patients, although stage IV cancers seem to occur more often (16%). Histologically, EOCRCs showed a tendency of higher incidence of poorly differentiated tumours compared to control CRCs (20% vs. 15%) (p = 0.29). Mucinous histology and signet-ring cell tumours were present in 15% and 0% of controls compared to 21% and 2% in the EOCRC cohort. Regarding the molecular features, 7.2% and 0% in the EOCRC and 9.9% and 4.7% lacked MLH1 and MSH2 expression, respectively. In both groups, immunohistochemistry analysis showed similar low p53 levels in 36% of cases and high TS levels (21% in both groups).

**Conclusion:** The genetic basis in the majority of early onset colorectal carcinomas remains unknown, However, most EOCRCs appear to arise through the same pathways as sporadic CRCs, such as the classical adenoma-carcinoma sequence. EOCRCs appear more frequently as aggressive cancers, related to the advanced stage of disease and the delayed diagnosis since patients with less than 50 years of age are not included in screening programs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** Ivanakaj@seznam.cz

**Introduction:** First-degree relatives (FDR) were considered to have higher risk of colorectal cancer compared with general population. Some recent studies showed that the risk of FDR is not as high as previously expected and curret guidelines (ESGE, European guidelines) doŕt recommend different surveillance for them. The aim of our study was to compare the detection of neoplastic lesions during screening colonoscopy in FDR and average risk population.

**Aims & Methods:** The data from all screening colonoscopies performed in one non-university gastroenterology center from january 2012 to december 2015 were recorded to database in MS Excel. The main parts of the database comprise of epidemiologic data about the patient including family history of colorectal cancer, data about examination, histologic results and complications. The results of colonoscopies in FDR and average risk patients were compared, the chi-square and Student t test were used to compare dichotomous and continous variables considering level od significance of .05.

**Results:** 1677 screening colonoscopies were performed in total, of them 191 in FDR and 1486 in average risk individuals. Because of nonhomogenous gender distribution in both groups (p = 0.007), men and women were compared separately. FDR in both groups were significantly younger. The number of examinations after positive FOBT and primary colonoscopies were not significantly different between the groups. The detection of neoplastic lesions represented by PDR, ADR, advanced ADR, number of carcinomas and APCR was not higher among FDR. See the table.

| | Men FDR (81) | Men (784) | p | Women FDR (110) | Women (702) | p |
|---|---|---|---|---|---|---|
| **Age** | **60.4** | **62.9** | **0.005** | **61.6** | **63.7** | **0.013** |
| FOBT/primary c. | 38/43 | 396/415 | 0.742 | 50/60 | 389/313 | 0.051 |
| PDR | 58 (71.6%) | 615 (78.4%) | 0.15 | 65 (59.1% | 414 (59.0% | 0324 |
| ADR | 42 (51.9%) | 451 (57.5%) | 0.326 | 44 (40.0%) | 259 (36.9%) | 0.531 |
| Advanced ADR | 16 (19.6%) | 167 (21.3%) | 0.745 | 11 (10.0%) | 80 (11.4%) | 0.666 |
| Carcinoma | 1 (1.2%) | 17 (2.2%) | 0.575 | 2 (1.8%) | 7 (1%) | 0.350 |
| APCR | 0.938 | 1.247 | 0.089 | 0.700 | 0.581 | 0.255 |

**Conclusion:** There were no differences in detection of neoplastic lesions between FDR and average risk population, but FDR were significantly younger at the time of screening colonoscopy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1487 A PILOT STUDY TO ASSESS THE EFFICACY OF PROPHYLACTIC ADMINISTRATION OF ANTIBIOTIC FOR ENDOSCOPIC SUBMUCOSAL DISSECTION IN COLORECTUM

**Introduction:** Endoscopic submucosal dissection (ESD) is accepted as one of the treatments for en bloc resection of large superficial colorectal lesions. However, the risk of perforation is high compared to conventional endoscopic mucosal resection (EMR)[1]. Peritonitis caused by the perforation in colorectum requires surgical treatments. Therefore, prophylactic administration of antibiotic in colorectal ESD is considered necessary for all cases, as it might avoid peritonitis from perforation, it is very difficult to predict about occurrence of delayed[2]. But some studies suggested few bacteremia and low risk on infectious complication after colorectal ESD[3,4].

**Aims & Methods:** The aim of our study is to assess the efficacy of prophylactic administration of antibiotics for endoscopic submucosal dissection in the colorectum. A total of 257 consecutive patients that were not administered with Prophylactic antibiotic treatment before and after ESD were enrolled in this study. Another 252 consecutive patients who have previously received colorectal ESDs with Prophylactic antibiotic treatment were included as a historical control. Treatment outcomes, body temperature, abdominal symptom and inflammatory reaction of the blood investigation (White blood cell [WBC] and °C reactive protein [CRP]) were compared between non-antibiotic and antibiotic groups. In the non-antibiotic group, we administered antibiotics to the particular cases in which temperature of the body was over 38.0°C and peritoneal irritation sign was encountered after ESD. Second generation of Cephalosporins were used for antibiotic group. All of ESD procedures were conducted under CO2 insufflation.

**Results:** Between non-antibiotic and antibiotic groups, there was no significant difference in the mean age (66.8 ± 10.9 vs. 67.8 ± 10.0), the mean tumor size (33.7 ± 20.4 mm vs. 35.2 ± 20.1 mm), ratio of muscular injury or perforation (13.2% vs. 10.7%), the mean amount of rise in temperature (0.41 ± 0.47°C vs. 0.42 ± 0.47°C) and CRP (0.43 ± 0.81 vs. 0.44 ± 0.82) on the next day of ESD procedure. The mean operation times, the number of twofold increase in WBC and abdominal tenderness were 77.2(± 57.6)/97.2(± 72.6) minutes, 6/17 cases and 9/17 cases, respectively ($P < 0.05$). Among the cases with muscular injury/perforation, there was no significant difference in all of the treatment outcome between non-antibiotic group and antibiotic group. Antibiotic treatments were required to 5 cases in non-antibiotic group because of physical symptoms (a high fever over 38°C and muscular defense) on the next day of ESD procedure associated with perforation. But no surgical treatment was needed. One delayed perforation occurred in non-antibiotic group, but it was treated only with a course of antibiotics. In summary, prophylactic administration of antibiotics wasn't necessary if adverse events didn't occur during and after ESD. Even if adverse event like perforation was encountered, it is enough to manage conservative treatment by administration of antibiotics after adverse event occurred.

**Conclusion:** There is no efficacy of prophylactic administration of antibiotics pre- and post-ESD in this study.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Approximately 30% of colorectal cancers present with colonic obstruction. Self-expanding metal stents (SEMS) can be placed endoscopically as a bridge to surgery, allowing relief of the obstruction and time to improve the patient's physical condition prior to curative resection. A systematic review has suggested that this approach is associated with lower rates of stoma formation, shorter lengths of stay, lower complication rates and a higher rate of primary anastomosis when compared to surgery to relieve the episode of obstruction. However, there is a lack of randomised controlled trial data directly comparing the two approaches.

**Aims & Methods:** Hospital Episode Statistics (HES) is an administrative database of data on all elective and emergency care episodes in hospitals in England. Patients admitted with colonic obstruction due to colorectal cancer were identified in HES. Patients were subdivided into two cohorts: SEMS insertion prior to surgery and surgery only. Patients with metastatic disease at the time of presentation were excluded. Mortality, emergency readmission within 30 days, postoperative complications and patient demographic factors were examined using univariate and multivariate regression analysis. Propensity score matching was then used to compare outcomes between the SEMS and control cohorts.

**Results:** Between January 2006 and December 2015, 4,849 patients (mean age 71 (IQR 63–80) years and 51.9% male) who underwent surgery only and 409 patients who had a SEMS as a bridge to surgery (mean age 69.7 (IQR 62–79) years and 56.7% male) were identified. On univariate analysis, SEMS insertion became more common over the study period with only 2.7% of the total procedures being carried out in 2006 compared to 14.7% in 2013 ($p < 0.001$). Death within 30 days of resection was significantly lower in the SEMS cohort (2.0% vs. 9.7% respectively, $p < 0.001$), as was the risk of emergency readmission within 30 days (8.8% vs.15.0%, $p = 0.001$) and the rate of major complications (5.38% vs. 18.36%, $p < 0.001$). Those undergoing a SEMS insertion had lower rates of post-operative anastomotic complications (0.24% vs. 1.53%, $p = 0.035$), sepsis (1.71% vs. 5.74%, $p = 0.001$), thrombosis (0.24% vs. 2.03%, $p = 0.011$) and acute cardiovascular events (2.2% vs. 7.88%, $p < 0.001$) when compared to surgery alone.

Multivariate analysis revealed that those undergoing a SEMS were less likely to be female (OR 0.80 (95% CI 0.65–0.99), $p = 0.036$), live in the East (0.15 (0.07–0.32), $p < 0.001$) or West Midlands (0.20 (0.11–0.35), $p < 0.001$) and were less likely to have major comorbidities (Charlson score of 5 or more 0.60 (0.44–0.81), $p = 0.001$). Following propensity matching, there was a small but not significant difference in survival between the SEMS and control cohorts at 30 days (98.0% vs. 96.2% respectively, $p = 0.1426$) and at 12 months (89.3% vs. 86.5% respectively, $p = 0.2127$). However, patients undergoing a SEMS procedure prior to surgery continued to have a significantly lower rate of emergency readmission within 30 days of resection when compared to those undergoing surgery only (8.7% vs. 20.4% respectively, $p < 0.001$).

**Conclusion:** In this retrospective, matched cohort study of patients with obstructing colorectal cancer undergoing either surgery alone or a SEMS as a bridge to curative surgery, we have demonstrated a significantly lower risk of emergency readmission within 30 days in the SEMS cohort. Patients undergoing a SEMS also appear to have a much lower risk of post-operative complications.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1489 IDENTIFICATION OF THE IRINOTECAN TOXICITY RELATED VARIANTS BY WHOLE EXOME SEQUENCING ANALYSIS

**Introduction:** Concurrent irinotecan and fluorinated-pyrimidine is a common first-line therapy for metastatic colorectal cancer (mCRC). Although prolonged survival is associated with regimens involving irinotecan, severe neutropenia occurs in 20–35% of mCRC cases treated with irinotecan regimens.

**Aims & Methods:** To predict the risk of irinotecan toxicity for individual patients precisely, it is important that determining new biomarkers in addition to known markers; *UGT1A1*28* and *UGT1A1*6* is important, because patients without *UGT1A1*28* or **6* do experience severe irinotecan toxicity. Therefore, we identified the genetic variants associated with the toxicity by whole exome analysis. A case-control study was performed with patients bearing no *UGT1A* variations (loci of *UGT1A1*6*, **27*, **28*, **60*, *UGT1A7* (387 T, 622 T), *UGT1A9*1b*) who exhibited hematologic toxicity in entire course of irinotecan therapy ($n = 5$) and patients bearing one of *UGT1A* variations and exhibited sever toxicity in the first course treatment ($n = 5$) as case group and patients with no *UGT1A* variations and no sever toxicity were used as control group ($n = 5$). Whole exome sequencing (WES) was performed with genomic DNAs extracted from white blood cells and next generation sequencer; NextSeq 500, and then mapping and variant calling were done by BWA and GATK software, respectively. The annotation of each variations were performed by SnpEff software with dbNSFP database to evaluate the impact of variations on protein level. Validation genotyping with specific hydrolysis probes and primers was done by real-time PCR ($n = 75$). The Cochran-Armitage trend test was used to examine the linearity of the relationship between genotypes and irinotecan toxicity.

**Results:** Among numerous variations obtained by WES, single nucleotide polymorphisms (SNPs) were ranked by standardized difference based on the frequencies of each allele between the case and control and the *P* value of the trend test. As a result, top 5 variations were further analyzed to validate. In 75 patients, linkage disequilibrium analysis showed no correlation between the 5 variations and *UGT1A* polymorphisms, and the Hardy-Weinberg equilibrium *P* value for each locus examined in this study was higher than 0.05. The linearity of the relationship with irinotecan toxicity were observed in the SNPs in *APCDD1L*, *R3HCC1*,*MKKS*, *EDEM3* ($P < 0.05$) and a SNP in *OR51I2* ($P = 0.052$) in a sub-population ($n = 68$) excluding known high risk patients with homozygous of the *UGT1A1*28*, **6*, and these compound heterozygous. Interestingly, the homozygous of *R3HCC1* variation showed no hematologic toxicity in both FOLFIRI and FOLFOX treatments ($N = 117$).

**Conclusion:** The irinotecan toxicity related genetic variants identified in this study would be useful for prediction of irinotecan toxicity in addition to *UGT1A1* polymorphisms.

## P1490 GOOD BOWEL PREPARATION INCREASED THE NUMBER OF ENDOSCOPICALLY DETECTED POLYPS WHICH WAS WELL CORRELATED WITH DETECTION OF ADVANCED NEOPLASIA

**T. Amano**[1], T. Nishida[1], H. Shimakoshi[1], A. Shimoda[1], A. Sugimoto[1], K. Takahashi[1], K. Mukai[2], T. Matsubara[1], M. Yamamoto[1], S. Hayashi[1], S. Nakajima[1], K. Fukui[1], M. Inada[1]

**Contact E-mail Address:** jstarwars@mac.com

**Introduction:** Detecting colorectal adenoma, especially advanced neoplasia (AN), is effective in reducing colorectal cancer incidence and mortality. Therefore, improving bowel cleanliness would be important to increase adenoma detection rates (ADR) or polyp detection rates (PDR). Recent studies, however, reported that PDR or ADR appeared to be slightly lower, rather than higher, for excellent preparations compared with good.

**Aims & Methods:** The aim of this study was to evaluate PDR, the number of endoscopically detected polyps and AN detection rate (ANDR) stratified by the Boston Bowel Preparation Scale (BBPS). This study was a retrospective single center cohort study of consecutive patients who underwent colonoscopy from January 2015 to November 2015 at Toyonaka Municipal Hospital. We evaluated the association between bowel preparation quality by using the BBPS and PDR, the number of endoscopically detected polyps, and ANDR among colonoscopies. We defined a case with more than the BBPS of 5 as good preparation.

**Results:** A total of 3480 cases (60% male, mean age 66 years, 22% with positive fecal occult blood test, 52% for surveillance or screening, 26% for the other reasons) underwent colonoscopy. Among them, 84 patients with advanced colorectal cancer and 489 patients with the other reasons were excluded. Finally, a total of 2907 patients were enrolled in this study. PDR is 68% (1994/2907). Average BBPS was $7.1 \pm 1.5$ and good preparation was achieved in 94% of patients who showed significantly higher PDR than poor preparation (69.3% vs 58.1%, $p = 0.0042$) and more number of polyps ($2.0 \pm 0.04$ vs $1.2 \pm 0.2$, $p < 0.001$). However, PDRs seemed to reach the plateau more than the BBPS of 6. We divided into three groups based on the number of polyps (Group A: 1 to 2, Group B: 3 to 5, Group C: more than 6). ANDR of Group A, B and C were 18.4%, 37.9% and 69.8%, respectively. There was significantly increased ANDR with the number of polyps (Odds ratio: Group A:B:C = 1 :2.7 :10.2).

**Conclusion:** Excellent bowel preparation (BBSP > 7) may not be necessary to increase the PDR but good bowel preparation significantly increases the number of endoscopically detected polyps that contributed to higher ANDR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1491 THE OUTCOMES OF COLD POLYPECTOMY ARE NOT INFERIOR EVEN WHEN IT WAS PERFORMED BY LESS EXPERIENCED ENDOSCOPISTS: A PROPENSITY SCORE MATCHED CASE CONTROL STUDY OF 1,000 POLYPS

**Y. Takada**, M. Kato, Y. Kubosawa, Y. Sunata, Y. Hirai, K. Abe, T. Hirata, Y. Takatori, S. Banno, M. Wada, S. Kinoshita, H. Mori, K. Takabayashi, M. Kikuchi, M. Kikuchi, T. Uraoka
*Gastroenterology, National Hospital Organization Tokyo Medical Center, Meguro-ku, Tokyo/Japan*

**Contact E-mail Address:** y.tkd.y53@gmail.com

**Introduction:** Cold polypectomy (CP) is a widely accepted technique used to remove diminutive and small colorectal polyps, because of its safety and convenience. However, the difference of outcomes of CP by endoscopists' experiences remains unclear.

**Aims & Methods:** The aim of this study was to assess safety and efficacy of CP that performed by less experienced endoscopists. A total of 451 consecutive patients who underwent colonoscopy from April 2014 to May 2015 had CP for 1,000 polyps. We retrospectively divided objectives into two groups according to endoscopists' experience; experienced group (Group E) with more than 2,000 cases of colonoscopy and less experienced group (Group LE) with less than 1,000 cases. All endoscopists participated in an intensive training program on endoscopic diagnosis of colorectal polyp including Sano NBI classification by an expert endoscopist before starting to perform CP. CP was applied for polyps less than 10 mm diagnosed as an adenoma endoscopically. We applied cold snare polypectomy (CSP) for small (6–9 mm) polyps, and cold forceps polypectomy (CFP) for diminutive (1–5 mm) polyps, respectively. Clipping was carried out only in case of continuous arterial bleeding after CP. We compared base-line characteristics (sex, number of polyps per patients and polyp size), type of cold polypectomy procedure (CFP or CSP) and outcome measurements including adverse events (immediately/delayed perforation, delayed bleeding required endoscopic intervention), polyp histology and technical success (En-bloc resection rate, lateral resection margin) between two groups. Multivariate analysis was performed to identify risk factors for unclear lateral resection margin using logistic regression model, and cases and propensity score-matched control was chosen on a one-to-one basis by adjusting risk factors revealing independence for unclear lateral resection margin other than endoscopists' experience.

**Results:** In Group E, there were significantly more female (34% vs 28%, $P = 0.003$), more polyps per patient (5.4 vs. 3.5, $P < 0.01$) and larger polyp (4.8 mm vs. 4.0 mm, $P < 0.01$) than Group LE. CSP was more frequently performed in Group E (60% vs. 32%, $P < 0.01$). Perforation and delayed bleeding did not occur at all. The proportion of lesion pathologically diagnosed as high grade dysplasia was 0.15% and 0.20% in Group E and LE, respectively ($P = 0.26$). En-bloc resection rate was accomplished in 96% of patients in both groups. Although unclear lateral resection margin was significantly lower in Group E (49% vs 57%, $P = 0.019$), there was no significant difference of rate of unclear margin (48% vs 51%, $P = 0.18$) after adjustment of size of polyp, number of polyps per patients and type of cold polypectomy procedure between both groups.

**Conclusion:** This large-scale retrospective study demonstrated that clinical outcomes of CP performed by less experienced endoscopists were as good as that by experienced endoscopists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1492 A NOVEL ANTI-CD24 MONOCLONAL ANTIBODY, HUMANIZED AND AFFINITY MATURATED, FORTARGETING GASTROINTESTINAL CANCERS

S. Shapira[1], D. Kazanov[1], V. Padler Karavani[2], I. Benhar[3], **N. Arber**[1]

[2]*Department Of Cell Research And Immunology, Tel-Aviv University, Tel Aviv/Israel*
[3]*Department Of Molecular Microbiology And Biotechnology, The George S. Wise Faculty Of Life Sciences, Tel Aviv University, Tel Aviv/Israel*

**Contact E-mail Address:** nadira@tlvmc.gov.il

**Introduction:** CD24 is a cell-surface heavily glycosylated GPI-anchored protein. We had previously shown that CD24in an important player in the multistep process of GI carcinogenesis (Gastro 2006, Clin Can Res 2007, Can Res 2008). The creation of chimeric, humanized or fully human antibodies was a major breakthrough and led to a wave of USFDA-approved antibodies

**Aims & Methods:** Aim: To further improve the efficacy of the humanized anti-CD24 mAb by increasing its binding strength and therebygenerating a novel therapy tool for GI malignancy Methods: From murine to humanized, unarmed and conjugated, small derivatives and full IgG antibodies wererecombinantly engineered. The antibody genes were recovered, amplified and cloned into appropriate vectors. Thenthe vectors were introduced into a host (mammalian and *E. coli*) and adequate amounts of functional antibody wereachieved. Sequence analysis of the CDR loops was the base for library designing. Affinity maturation was performedin two-steps selection (CDR walking) and by using phage display technique. The binding of the different derivativeswere evaluated on full Glycan array in which more than 70 sugar moieties were printed.

**Results:** In vivo antibody targeting and accumulation within a CD24 positive tumor and its excess clearance wasclearly demonstrated using live imaging device (Maestro Cri device). High-affinity antibodies were selectedand created from combinatorial phage-displayed antibody libraries that contain varying degrees of diversity atrandomized positions. A chosen matured clone was isolated and showed higher binding strength (1.8x10–8), compared to the parental murine and humanized Abs. The matured antibody showed selective recognition andbinding to the CD24 antigen which proves that the genetic manipulations carried out did not affect its properties. Itsstability was enhanced following the maturation process, as well as its pharmacokinetics parameters which showed along serum half-life.The matured antibody mediates ADCC (antibody-dependent cell cytotoxicity), 75% oftarget cell lysis was demonstrated. Combined treatment with standard chemotherapy and natural products, such as monoterpenes (terpinen-4-ol), showed significant reduction in cell viability (90% cell death). Binding of anti-CD24 Ab to glycan microarray could not be detected while high binding intensities were observed where the whole CD24 protein was printed, indicating that the antibodies bind to the core peptide and not to its sugar residues.

**Conclusion:** Targeting CD24 may be a promising treatment for GI malignancies in combination with chemotherapy and natural agents. The resulted matured humanized anti-CD24 mAb proved to be more effective than the murine parental Ab. The long serum half-life is desirable as it would decrease the need for repetitive injections.

## P1493 MONOTERPENES: A NOVEL AND PROMISING THERAPEUTIC AGENT, FOUND IN ESSENTIAL OILS, FOR HUMAN COLORECTAL CANCER

S. Shapira, D. Kazanov, **N. Arber**
*The Integrated Cancer Prevention Center, Tel Aviv Sourasky Medical Center, Tel Aviv/Israel*

**Contact E-mail Address:** nadira@tlvmc.gov.il

**Introduction:** Monoterpenes are major secondary metabolites present in plants, and known to beassociated with the plant defense mechanisms. Many anticancer drugs that are currently in clinical use have beenisolated from plant species. Monoterpenes are such promising agents. Sobrerol was discovered as an oxidationproduct of terpenes while Carveol was isolated from spearmint oil. They exhibit anti-parasitic, neuromodulatory, andanticancer activities. It was demonstrated that carveol and sobrerol have chemopreventive activity against mammarycancer when fed during the initiation phase. We have shown that terpinen-4-ol, an additional monterpene, has animpressive synergistic inhibitory effect, in vitro and in vivo, when combined with commonly used chemotherapeuticagents and biological tools.

**Aims & Methods:** Aim: To study the antitumor effects of monoterpenes, such as carveol and sobrerol, and their mechanism of action invarious types of GI malignancies, alone and in combination with several chemotherapeutic and biological agents. Methods: Carveol and sobrerol were administrated alone or combined with standard anti-CRC agents including, oxaliplatin, fluorouracil (5-FU), cetuximab and bevacizumab. Killing effects were measured qualitatively by lightmicroscopy and quantitatively using the MTT assay. Subcutaneous tumors were produced by injection of 5x106 ofCRC cell lines into nude mice. When the tumors reached a dimension of 5 mm treatment was initiated.

**Results:** Carveol and sobrerol induce a significant growth inhibition of CRC cell lines, including HCT116, HT29 andSW480, in a dose-dependent manner. The synergistic growth inhibitory effects on cancer cell proliferation were impressive.

**Conclusion:** The use of plant-derived anticancer substances alone and in combination with chemotherapeutic orbiological agents for treating various types of cancer is promising, with a synergetic efficacy that allow a lowerconcentration of chemotherapy and biological agents that can not only increase efficacy but can minimize toxicity aswell. Clinically important the Monoterpenes restore the activity and efficacy of cetuximab in ras mutated tumors.

## P1494 THE VALIDITY OF COLORECTAL ESD FOR LARGE COLORECTAL TUMORS IN A GENERAL HOSPITAL

**K. Ashikari**[1], H. Chiba[2], J. Tachikawa[2], M. Nishimura[2], D. Kurihara[2], T. Suto[2], N. Kawano[2], M. Kaai[2], S. Seki[2], T. Ida[2], T. Morohashi[2], T. Goto[2]
[1]*Dr., Omori Red Cross Hospital, Tokyo/Japan*
[2]*Dept. Of Gastroenterology, Omori Red Cross Hospital Dept. of Gastroenterology, Tokyo/Japan*

**Contact E-mail Address:** kei-pushi-1@hotmail.co.jp

**Introduction:** Colorectal ESD has still not been widely performed for large colorectal tumors, because of the high frequency of complications such as postoperative bleeding and perforation.

**Aims & Methods:** To evaluate the validity of ESD for large colorectal tumors, 245 patients who underwent colorectal ESD in Omori Red Cross Hospital from 2012 April to 2016 March were retrospectively analyzed. We divided the patients into Group A (12–49 mm) and Group B (≧50 mm). The two groups were compared with respect to their clinical backgrounds, tumor characteristics and complications.

**Results:** For the 245 cases, 227 cases (92.7%) were assigned to group A ($69.0 \pm 10.7$ years old), and 18 cases (7.3%) were assigned to Group B ($69.6 \pm 15.2$ years old). The tumor location was C32/A48/T50/D25/S31/R41 in Group A and C1/A1/T2/D1/S3/R10 in Group B. The lesion size and procedure time were $25.5 \pm 8.2$ mm and $37.8 \pm 33.5$ min in Group A, and they were $71.4 \pm 23.3$ mm and $126.0 \pm 60.4$ min ($p < 0.01$) in Group B. Fibrosis during ESD (non/mild/severe) was 187/36/4 in Group A and 10/6/2 in Group B ($p = 0.0055$). En bloc resection rates were 100% and 17/18 (94.4%) ($p = 0.073$).

Complication rates were 2/227(0.9%) and 0%. These two cases in Group A were perforation (one of these cases required emergency surgery). Histology was adenoma121/Tis88/T1a9/T1b9/others0 in Group A and adenoma2/Tis12/T1a0/T1b3/others1 in Group B. Curative resection rates were 96.0% in Group A and 88.9% in Group B ($p = 0.189$). With respect to the postoperative course, there were also no differences in WBC, a number of having a high fever (≧38°C), and taking a painkiller between two groups.
**Conclusion:** Despite of higher fibrosis rates or longer procedure time, the benefits of ESD for large colorectal tumors (Group B) are almost similar to Group A.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1495 SAFETY, EFFICACY AND PROBLEMS OF COLD SNARE POLYPECTOMY FOR SMALL COLORECTAL NEOPLASMS

**N. Ikezawa**, M. Hanafusa, Y. Bensuleiman, K. Sasaki, S. Yoshida, T. Nakajima, S. Myojyo, S. Yoshida

**Contact E-mail Address:** nobuikezawa@gmail.com
**Introduction:** Cold snare polypectomy (CSP) has been performed worldwide as a safe endoscopic treatment for colorectal neoplasms compared with hot snare polypectomy (HSP). However, it is considerably difficult to evaluate pathological examination, post-cold polypectomy because of failed polyp retrieval and unclear cut margin. Incomplete resection is one of the most common causes that results in local recurrence after endoscopic treatment for colorectal neoplasms. The aim of this study is to assess the safety, efficacy and problems of CSP compared with HSP for small colorectal neoplasms.
**Aims & Methods:** We retrospectively analyzed a total of 1,239 lesions in consecutive 702 consecutive patients who underwent CSP or HSP for non-pedunculated polyps up to 10 mm in size at the Akashi Medical Center, Hyogo, Japan, from May 2013 to February 2016. When lesions were found, we used chromoendoscopy and narrow band imaging (NBI) in all cases and included a magnifying examination if magnifying endoscopy was possible to use. Endocrip was performed when the oozing did not decline even after one minute of observation in CSP, on the other hand in HSP it depended on operator's decision. We retrieved the transected polyps for histopathological evaluation. We aimed to evaluate patient characteristics, clinicopathological features of the polyps, complications, polyps retrieval, and pathological complete resection rates for neoplasm lesions in both groups. Furthermore, we assessed the influence of snare type (traditional snare or dedicated snare for CSP) on the effectiveness in the CSP group. The data were statistically analyzed.
**Results:** CSP was performed on 817 lesions in 458 patients while HSP was performed on 442 lesions in 244 patients. Patient characteristics and clinicopathological features of the polyps did not show significant differences in both groups. Polyp size was significantly smaller in CSP group compared with the HSP group ($3.63 \pm 1.31$ vs $5.06 \pm 2.23$ mm, $p < 0.01$). The retrieval rate for polyps was significantly lower in the CSP group compared with HSP group at 91% and 96%, respectively, $p = 0.0007$. In addition, pathological complete resection rate of the neoplasm lesions was also significantly lower in CSP compared with HSP at 67% and 74%, respectively, $p = 0.0217$). Delayed bleeding requiring endoscopic hemostasis was seen in one case in each groups. The rate of using endoclip was significantly lower in CSP compared with HSP at 3% and 19%, respectively, $p < 0.01$. In the CSP group, snare type had no influence on the pathological complete resection rate at 66% and 67%, respectively, $p = 0.960$.
**Conclusion:** CSP tended to conduct for significantly smaller lesions compared with HSP in this study. Although there was under such a situation, as the rate of using endoclip was significantly lower in CSP than in HSP, delayed bleeding with endoscopic hemostasis was seen in only one case and perforation was not observed. Thus, CSP could be a safer and more convenient method for small colonic neoplasia compared with HSP. On the other hand, polyp retrieval and pathological complete resection rates were significantly lower compared with HSP. Consequently, these findings highlight the importance of meticulous inspection of the remnant tumor via endoscopy after CSP to avoid unnecessary future local recurrence.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1496 DO FUNCTIONAL GASTROINTESTINAL DISORDERS ORIGINATE IN THE GUT RATHER THAN THE BRAIN? EVIDENCE FROM A 12 YEAR PROSPECTIVE POPULATION-BASED STUDY OF A PREDOMINANT GUT-BRAIN PATHWAY IN OVER 50%

**Introduction:** Mood disorders are present in most patients with functional gastrointestinal disorders (FGIDs) including irritable bowel syndrome (IBS) and functional dyspepsia (FD) leading them to be conceptualized as brain gut syndromes. In contrast, recent evidence suggests gut dysfunction (and gut symptoms) may occur first in a subset and only later do mood disorders follow, implying a predominant gut-brain syndrome. [1] In others, mood disorders may occur first followed by gut dysfunction (a brain-gut syndrome).[1]
**Aims & Methods:** We aimed to re-analyse data from a prospective 12 year cohort study [2] in order to calculate the proportion of people with IBS and / or FD who have a brain-gut and a gut-brain syndrome as this was not estimated in the published paper. Participants ($n = 1775$) were a random population sample from Penrith, Australia who responded to a valid survey on functional gastrointestinal symptoms, psychological factors and quality of life via the SF-12 in 1997 and agreed to be contacted for future research. Of these $n = 1002$ completed the 12-year follow-up survey (response rate = 64%). Among those followed, $n = 44$ met Rome II criteria for new onset IBS and $n = 23$ for new onset FD, respectively. Controls ($n = 626$) did not meet Rome II criteria for any functional gastrointestinal disorder (FGID). Clinically elevated levels of psychological distress (anxiety and depression) were defined as a score of ≥4 out of 12 on the valid Delusions Symptom States Inventory (DSSI). A brain gut syndrome was defined as those people who were free of a FGID at baseline but who had clinically elevated levels of anxiety and/or depression at baseline and who then met criteria for a new onset FGID 12 years later. A gut-brain syndrome was defined as those people meeting criteria for a FGID at baseline who later reported clinically elevated levels of anxiety and/or depression at the 12 year follow up.
**Results:** Among the sample ($n = 1002$), we found a subgroup of 143 people who had either functional gut problems or psychological problems (but not both) at baseline. Of these 67 (47%) recorded psychological distress before a FGID diagnosis, implicating a brain-gut syndrome. In contrast we found 76 (53%) recorded a FGID before psychological distress suggesting a gut-brain pathway. People classified as having a brain-gut syndrome were significantly more likely to be younger and have signficantly higher baseline scores on neuroticism, anxiety, depression but a significantly lower baseline score on the mental but not physical functioning subscale of the SF-12 (Table 1). There was a trend for more females in the brain-gut versus gut-brain group (67.7%, $n = 42$ vs. 50%, $n = 38$, $P = 0.1$) but this was not significant.

Univariate discriminators of brain-gut and gut-brain syndromes

| | Brain- Gut Group (Mean, Std Dev) | Gut-Brain Group (Mean, Std Dev) | P Value |
|---|---|---|---|
| Age | 42.4 (12.9) | 45.8 (11.8) | 0.03 |
| Neuroticism | 6.3 (3.1) | 4.5 (3.1) | 0.002 |
| Extroversion | 5.9 (2.9) | 5.5 (2.8) | 0.3 |
| Anxiety | 5.6 (2.5) | 1.7 (1.1) | <0.0001 |
| Depression | 3.3 (2.7) | 0.7 (0.9) | <0.0001 |
| Physical QoL | 48.6 (10.2) | 49.6 (9.3) | 0.6 |
| Mental QoL | 42.4 (12.9) | 45.8 (11.8) | 0.03 |

**Conclusion:** These data further support the bidirectional nature of the brain-gut pathway in FGIDs and confirms an earlier study that there is a major subset of people (>50%) with FGIDs who have their disorder begin in the gut. We conclude the gut can probably drive psychological alterations in the FGIDs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Visceral hypersensitivity is a core characteristic of irritable bowel syndrome (IBS), likely related to altered processing of sensory stimuli along the brain-gut axis. In particular, interoception (i.e. the process responsible for monitoring and processing visceral sensations and internal stimuli and likely associated with pain and visceromotor control) might play a pathogenic role in IBS. Neuroimaging studies in IBS patients demonstrated structural and functional alteration of brain areas involved in bodily representation. Only a few studies investigated brain functional connectivity through resting-state functional magnetic resonance imaging (rs-fMRI), with inconsistent results.
Aims & Methods:
**Aims:** 1) To investigate functional connectivity within the network involved in self-bodily consciousness; 2) To explore possible relationships between changes in functional connectivity and clinical and psychological measures, including measures of mood and anxiety.
**Methods**: We studied 19 patients aged 22 to 76 years (13 F, 6 M, mean age $39.6 \pm 13.5$ years) with diagnosis of IBS according to Rome III criteria, and 26 healthy controls (16 F, 10 M, mean age $40.1 \pm 15.3$ years). All subjects underwent rs-fMRI, carried out at 3 Tesla (Trio, Siemens Medical Systems, Erlangen, Germany). All patients completed a battery of questionnaires assessing gastrointestinal symptoms, interoceptive awareness (Self-Awareness Questionnaire), attitudes associated with hypochondriasis (Illness Anxiety Scale and Hypochondriac Yale-Brown Obsessive Compulsive Disorder- Modified), anxiety (State Trait Anxiety Inventory) and depression symptoms (Beck Depression Inventory- II). Patients underwent also a neuropsychological examination.
**Results:** 1) We observed two opposite patterns of functional connectivity. First, we found a cluster of significant inverse correlation between hypocondriasis score and rs-fMRI-determined connectivity between posterior cingulate cortex and left supramarginal gyrus, extending into the adjacent superior temporal gyrus; 2) We found a significant and positive correlation between interoception score and rs-fMRI-determined connectivity between left anterior ventral insula and two clusters located in supramarginal gyrus bilaterally; 3) Behavioural data showed that IBS patients had both depression and anxiety symptoms, but also underlined the correlation between depressive symptoms and levels of interoceptive awareness.
**Conclusions:** 1) The psychological and behavioural characterization of our IBS patients demonstrated a definite hypochondriac aspect with high interoceptive awareness; 2) In IBS patients functional connectivity data highlighted an "abnormal network synchrony" (i.e., a functional alteration in specific brain areas involved in interoceptive awareness) in the absence of structural and micro-structural changes; 3) The results of this study might shed new light on the complex pathophysiology of IBS and provide novel targets for efficient treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1498 VISCERAL HYPERSENSITIVITY REMAINS STABLE OVER TIME IN PATIENTS WITH IBS, BUT WITH INDIVIDUAL FLUCTUATIONS

**Introduction:** Visceral hypersensitivity in IBS, measured with a rectal barostat, has been suggested to be a phenomenon that is abolished due to habituation at repeated investigations (Naliboff 2006).
**Aims & Methods:** We aimed to investigate the stability of rectal sensitivity in patients with IBS who had undergone a previous rectal barostat study (index investigation) and also assess variations in symptom pattern and severity in relation to rectal sensory function. IBS patients, who had previously been investigated with a rectal barostat, were included. All patients underwent a second rectal barostat study using the same protocol as the index investigation (isobaric phasic distensions; 30 s duration, 30 s rest; 5 mmHg increments). Thresholds for first sensation, urge to defecate, discomfort, and pain were determined during the distensions. Visceral hypersensitivity was defined as a pain threshold < 31 mmHg (5th percentile healthy controls). Symptoms were characterized by use of questionnaires; GI Symptom Rating Scale-IBS (GSRS-IBS), Hospital anxiety and depression scale, Visceral sensitivity index (VSI), and Symptom Checklist-90-Revised.
**Results:** In all, 27 subjects (17 Female) were included, mean age at index investigation 41, mean 10 yrs difference the new investigation (range 8–12 yrs). Pressure sensory thresholds were unchanged comparing the index study with the new one; perception (7.3 (new) vs 9.9 (old) mmHg $p = 0.09$), urge to defecate (13.5 vs 15.9 mmHg $p = 0.1$), discomfort (22.7 vs 24.9 mmHg $p = 0.4$), and pain (36.9 vs 37.9 mmHg $p = 0.7$). At the index, 8/27 patients had visceral hypersensitivity of which 4 were now reclassified normosensitive, and 7 from normo- to hypersensitive at the new investigation, meaning that 11/27 patients were hypersensitive at follow-up. Nine patients had increased pain thresholds (3–28 mmHg) at the new investigation, and 17 had decreased (1–17 mmHg). Total GSRS-IBS score and the individual symptoms remained unchanged, and no association between change in GI symptom severity and change in perception thresholds were seen ($p > 0.05$). There was no difference in anxiety or depression (HAD scale, $p > 0.05$ for both), no difference in the total IBS-QoL score (53 vs 47.5 $p > 0.05$), and no difference in somatization (SCL-90 R, 1.1 vs 0.4, $p > 0.05$). We also analysed the difference in sensory thresholds and correlated with the difference in symptoms, however no statistical correlation was found ($p > 0.05$ for all).

Differences in GSRS-IBS score, Data presented as mean (SD)

| Domain | New investigation | Index investigation |
|---|---|---|
| Total GSRS-IBS score | 2.3 (1.1) | 2.1 (0.8) |
| Pain GSRS-IBS score | 3.1 (1.5) | 3.3(1.5) |
| Bloating GSRS-IBS score | 3.1 (1.6) | 3.5 (1.4) |
| Constipation GSRS-IBS score | 2.2 (1.7) | 2.6 (1.5) |
| Diarreha GSRS-IBS score | 2.7 (1.4) | 3.0 (1.5) |
| Satiety GSRS-IBS score | 1.4 (1.2) | 1.7 (1.0) |

**Conclusion:** Visceral hypersensitivity and GI symptoms were stable at the group-level over 8–12 years in this cohort of IBS patients, even though individual fluctuations were noted. Our findings contradict previous findings that have indicated that visceral hypersensitivity is an unstable trait in IBS patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1499 IRRITABLE BOWEL SYNDROME WITH POSTPRANDIAL SYMPTOM OCCURRENCE IS ASSOCIATED WITH A POSTPRANDIAL WORSENING OF VISCERAL HYPERSENSITIVITY

M. Di Stefano, **M. Bergonzi**, B. Valvo, I. Benedetti, M. Bresciani, E. Pagani, E. Miceli, G.R. Corazza

**Introduction:** Irritable bowel syndrome (IBS) is characterized by recurrent abdominal discomfort or pain associated with an alteration of bowel habits. Other symptoms, not included in the diagnostic criteria, but similarly bothersome are frequently present (1). The occurrence of symptoms in IBS during the day is variable (2), but meal ingestion may cause their worsening in more than 60% of patients (3). The occurence of postprandial symptoms in IBS raises a great deal of speculative interest on pathophysiological grounds.
**Aims & Methods:** The aim of our study was to evaluate visceral sensitivity in fasting condition and after the ingestion of a meal in a subgroup of IBS patients with postprandial symptoms in comparison with healthy volunteers (HV). 85 patients with IBS (mean age $34 \pm 6$ yrs), diagnosed according to Rome III criteria (IBS-C = 55; IBS-D = 28; IBS-M = 12) and a group of 20 HV comparable for age and gender were enrolled. Postprandial exacerbation of symptoms was present in 40 IBS. After an overnight fast, all the subjects underwent the recto-sigmoid barostat test. Basal and post prandial (200 Kcal, 200 ml liquid meal) recto-sigmoid sensitivity thresholds were determined by sequential ramp distensions with patients reporting their sensation on a 0–6 scale (4). The presence and severity of abdominal symptoms (abdominal pain or discomfort, abdominal distention, bloating, flatulence, nausea, belching, postprandial fullness, satiety, epigastric burning) were evaluated by VAL while fasting and every ten minutes for sixty minutes postprandially.
**Results:** Both mean fasting and postprandial perception threshold in IBS with postprandial symptoms and without postprandial symptoms were significantly lower than HV (fasting: $4.9 \pm 3.0$, $5.3 \pm 3.8$ and $9.8 \pm 3.5$ mmHg; postprandial: $4.5 \pm 3.8$, $4.4 \pm 4.7$, $9.6 \pm 3.9$ mmHg, respectively, ANOVA $p < 0.001$). Postprandial values were not significantly different than fasting values in all

the groups. As expected, in both IBS groups, mean fasting discomfort threshold was significantly lower than in HV (IBS with postprandial symptoms $12.8 \pm 5.2$ mmHg, IBS without postprandial symptoms $13.1 \pm 3.8$ mmHg; HV $20.2 \pm 5.8$ mmHg, ANOVA $p < 0.001$). Between the two subgroups of IBS, this parameter did not show a significant difference. On the contrary, only in IBS patients with postprandial symptoms was the postprandial discomfort threshold significantly lower than fasting values (IBS with postprandial symptoms $9.1 \pm 5.6$ mmHg; $p < 0.001$ vs fasting; IBS without postprandial symptoms $12.1 \pm 5.6$ mmHg; NS vs fasting; HV $19.5 \pm 4.3$ mmHg, NS vs fasting). Finally, only in IBS patients with postprandial symptoms was there a significant increase of postprandial abdominal discomfort and bloating ($2.88 \pm 1.87$ and $4.33 \pm 2.19$, respectively). None of the patients suffered from dyspeptic symptoms.

**Conclusion:** In a subgroup of IBS patients, the postprandial worsening of visceral hypersensitivity may cause postprandial symptom occurrence. Further studies are needed to clarify the neural pathway responsible for this alteration.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Increased visceral sensitivity plays a key role in the pathophysiology of Irritable Bowel Syndrome (IBS) as a disorder of the brain-gut axis. Previous brain imaging studies revealed altered neural responses to expected or delivered visceral stimuli in hypersensitive compared to normosensitive IBS patients. At the same time, evidence supporting a role of fear and arousal in altered pain processing in IBS is accumulating with amygdala as a key region. Resting state imaging allows the investigation of task-independent connectivity between regions that may be involved in altered modulation of visceral afferent signals. While changes in functional connectivity within networks involved in sensory and affective processing have previously been reported in IBS, the possible contribution of visceral sensitivity to altered amygdala resting-state connectivity in IBS has not yet been studied.

**Aims & Methods:** Our aim was to address differences in resting-state connectivity in IBS patients with visceral hypersensitivity compared to normosensitive IBS and healthy controls (HC) with a focus on the amygdala as a key structure involved in emotion and fear processing. Forty-one women with IBS and 20 female HC were included. Rectal sensory thresholds were determined with a barostat and patients were subdivided into a group with increased (hypersensitive IBS, $N = 21$) and a group with normal sensitivity (normosensitive IBS, $N = 20$) based on HC thresholds. Resting state fMRI data was acquired using a 1.5T MRI scanner with a single-shot gradient-echo EPI sequence ($TR = 3s$) to effectively cover the whole brain. Group independent component analysis (ICA) was used within the full sample and sensorimotor, executive control, salience and default mode networks were derived using spatial regression. Within these networks, amygdala was most strongly related the default mode network (DMN). Between-group differences in functional connectivity between amygdala and DMN were carried out using region-of-interest analyses and the mean connectivity within the amygdala was extracted for each participant and correlated with visceral sensitivity.

**Results:** Hyper- and normosensitive IBS differed significantly in rectal thresholds for maximum tolerable distension ($47 \pm 1$ mmHg vs. $30 \pm 2$ mmHg, $p < .001$). Two-sample t-tests revealed enhanced positive connectivity of the amygdala with DMN in hypersensitive compared to normosensitive IBS ($t = 5.06$, $p < .001$). The strength of amygdala connectivity correlated significantly with rectal pain thresholds ($r = -.58$, $p < .001$). DMN-amygdala connectivity did not differ between IBS as a whole and HC or in comparisons of either patient subgroup with HC.

**Conclusion:** Our findings support enhanced connectivity between amygdala and DMN at rest in IBS patients with visceral hypersensitivity. These findings provide a possible link between visceral hypersensitivity and central mechanisms involved in emotional arousal and call for more work on the central fear network in IBS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1501 CHOICE OF RECTAL BAROSTAT PROTOCOL AFFECTS CLASSIFICATION OF SENSORY FUNCTION AND PREDICTION OF SYMPTOM SEVERITY IN IBS

**A. Josefsson**[1], P. Jerlstad[2], G. Näslin[1], H. Törnblom[2], M. Simrén[2]

[2]*Institute Of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg/Sweden*

**Contact E-mail Address:** axel.josefsson@vgregion.se
**Introduction:** Rectal barostat studies are widely used to assess visceral sensory function in patients with irritable bowel syndrome (IBS). However there are no studies comparing the optimal protocol to distinguish visceral hypersensitivity from normal bowel sensitivity. This study compares two protocols and their ability to distinguish between patients and healthy controls, and if the sensitivity measures associate differently with GI symptom severity.
**Aims & Methods:** We retrospectively included patients with irritable bowel syndrome (diagnosed according to Rome II criteria) that previously underwent rectal balloon distention at our center as a component their evaluation. Cohort 1 included 369 patients with IBS (38.5 ± 12.5 (mean ± SD) years; 279 females) and 35 healthy controls (36 ± 11 years; 27 females), cohort 2 included 153 patients with IBS (34.5 ± 12 years; 105 females) and 66 healthy controls (31.5 ± 9 years; 41 females). IBS symptoms were characterized by use of IBS-SSS and GSRS-IBS questionnaires. Cohort 1 underwent a rectal barostat study with isobaric phasic distensions (30 s duration, 30 s rest; 5 mmHg increments, maximum 70 mmHg) (Posserud 2007). Sensory thresholds and the perceived intensity of unpleasantness and pain were determined during the last 10 seconds of each distension. Cohort 2 underwent a rectal barostat study with ramp inflation for sensory thresholds (4 mmHg steps, 1 min/step) followed by random phasic distensions (12, 24, 36, 48 mmHg) for intensity of gas, urge, discomfort and pain (Cremonini 2005). The fifth percentile for pain thresholds in healthy controls was used as cutoff for defining hypersensitivity in both cohorts.
**Results:** There was a significant difference between the cohorts in age (cohort 1 presented first) 38.5 (SD 12.5) vs 34.5 years (SD 12, $p < 0.05$). No difference was seen in sex, body composition, psychiatric illness, oro-anal transit time, or IBS subtype ($p > 0.05$ for all). IBS patients in cohort 1 had lower thresholds for first sensation and pain ($p < 0.001$ for both) compared with cohort 2. However, the perceived intensity of pain was higher at the closest comparable pressure levels in cohort 2 ($p < 0.001$ for all) and differed from their controls ($p < 0.05$). There was also a significant difference in the proportion of patients classified as having hypersensitivity in cohort 1 vs 2; for pain 43% vs 7%, urge to defecate 23.5% vs 7.5%, discomfort 47.5% vs 15%, and altered rectal perception for at least one sensory threshold 60% vs 19% ($p < 0.001$ for all). Overall, the protocol used in cohort 1 showed a better correlation with perceived IBS symptoms. Patients with hypersensitivity for at least one sensory threshold in cohort 1 were more likely to have more severe diarrhea, bloating, pain, and early satiety (GSRS-IBS scores $p < 0.05$ for all) and to have a GSRS-IBS score $> 3$ ($p < 0.05$) compared with patients in cohort 2.
**Conclusion:** IBS patients evaluated with a rectal barostat test using isobaric phasic distensions perceived less pain at comparable pressures than patients where ramp inflation and a random phasic distension protocol was used. The isobaric phasic distension protocol was also better at predicting GI symptom severity.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Visceral pain is a diffuse and stabbing sensation which may be associated with functional gastrointestinal disorders such as Irritable Bowel Syndrome (IBS). This complaint is a crucial feature because of its significant impact on patients' quality of life and lack of efficient therapies. Recent studies revealed dysbiosis associated to IBS suggesting a long term impact of the intestinal microbiota on inflammation, but also on colonic hypersensitivity (CHS). In addition, such patients also suffered from stress-related psychiatric disorders including anxiety and depression. In this context, the aim of this work was to determine the impact of a neonatal maternal separation (NMS) paradigm on intestinal microbiota and to correlate dysbiosis to stress-induced CHS.
**Aims & Methods:** Stress-induced CHS was obtained by NMS: after birth, wild-type C57Bl/6J pups were isolated from their mother from P2 to P14 and CHS was assessed using a non-invasive technique based on a colorectal distension (CRD) coupled to intraluminal colonic pressure recording on 8- and 12-weeks old mice. Fecal pellets were collected directly from mice at week 3 (just before weaning), week 4, 6, 8 and 12. Next generation sequencing (NGS) of 16S genes were performed by Illumina on fecal samples of NMS mice compared to control non-handled (NH) mice.
**Results:** NMS induced a significant CHS at week 8 and week 12 in some mice (NMS sensitized: NMS-S) while some littermates did not shown an increased sensitivity to CRD test (NMS non-sensitized: NMS-NS). Interestingly, CHS was associated with a marked intestinal dysbiosis in NMS-S mice compared to NH and NMS-NS littermate mice from week 3 to week 12. This modification of fecal microbiota composition was characterized by a decreased relative abundance of some bacterial species with a beneficial effect on CHS such as *Bifidobacterium longum* or *Faecalibacterium prausnitzii*.
**Conclusion:** These results shown a direct involvement of intestinal microbiota in stress-induced CHS suggesting that targeting intestinal microbiota could be a new therapeutic approach to modulate CHS and associated abdominal pain in patients.

**Introduction:** Anxiety can contribute to altered brain processing of visceral signals in Irritable Bowel Syndromes (IBS) as a disorder of brain-gut communication.[1] The rostral anterior cingulate cortex (rACC) has been associated with both anxiety and pain perception and has been recently proposed to be a key region in mediating anxiety-related enhancement of pain.[2] The objective of the present study was to identify changes in resting state functional connectivity in rACC as a measure of synchronicity among brain regions in IBS patients and to assess its relation to anxiety.
**Aims & Methods:** Resting state FMRI data were acquired on 22 healthy females and 41 female IBS patients using a 3T MRI scanner. A single-shot gradient-echo EPI sequence was used to effectively cover the whole brain with a TR of 2 s. Data were preprocessed using standard procedures in SPM8. Group independent component analysis was used to identify a resting state network that spatially correlated to the rACC. The mean functional connectivity within the rACC was extracted for each subject. The IBS patients were sub-divided based on Hospital Anxiety and Depression Scale (HADS) into patients with ($IBS^+$, $n = 22$) and without ($IBS^-$, $n = 19$) clinically relevant anxiety, and a one-way ANOVA was used to assess overall group differences in rACC functional connectivity among the controls, $IBS^+$and $IBS^-$.
**Results:** A trend-level between-group difference in functional connectivity was noted within the rACC and between rACC and mid- and posterior cingulate cortex (MCC/PCC) ($F_{(2,61)} = 2.85$, $p < 0.065$). Post-hoc tests indicated that the controls had higher functional connectivity than the $IBS^+$ patients ($p < 0.025$). Similarly, the $IBS^-$ patients were also observed to have higher functional connectivity than the $IBS^+$ patients ($p < 0.09$). No difference was noted between the healthy controls and the $IBS^-$ patients ($p > 0.6$).
**Conclusion:** Anxiety, as a common comorbidity in IBS, contributes to dysfunctional communication between brain regions involved in affective pain control.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** To evaluate the symptomatic response of peroral endoscopic myotomy (POEM) for achalasia subtypes segregated by high-resolution manometry (HRM).
**Aims & Methods:** Treatment-naive subjects with achalasia referred for POEM were followed in this observational study. Chicago criteria designated achalasia subtypes (subtype I: no esophageal pressurization; subtype II: panesophageal pressurization in more than 20% swallows; subtype III: premature contractions in more than 20% swallows). Symptom questionnaires assessed symptom burden before and after POEM on five-point Likert scales as well as Eckcardt score were recorded. Data were analyzed to determine predictors of symptom response.

**Results:** 45 achalasia patients (44.1 ± 14.0years, 46.7% female) fulfilled inclusion criteria, 6 patients with subtype I, 34 patients with subtype II, and 5 patients with subtype III achalasia. Upon follow-up 1.5 years after POEM, Eckcardt score declined from 8.0 (7.0) 9.0) to 1.5 (1.0 3.0) (P = 0.000); these were similar across achalasia subtypes. There was no statistical difference between the incidence of symptom for dysphagia, both solid and liquid, and regurgitation and chest pain. While solid dysphagia was the main symptom in each achalasia subtypes. Post-POEM symptom scores for dysphagia, both solid and liquid, regurgitation and chest pain were significantly lower than pre-operation in type II patients [solid dysphagia:16.0(12.0,16.0) vs 2.0(1.0,8.3)(P = 0.000), liquid dysphagia: 2.0(0.0,5.0) vs 0.0(0.0,0.0)(P = 0.001), regurgitation:9.0(7.0,10.5) vs 0.0(0.0) 1.0)(P = 0.000), chest pain: 2.0(0.0,9.0) vs 0.0(0.0,1.8)(P = 0.005)]. Post-POEM symptom scores for solid dysphagia, and regurgitation were significantly lower than pre-operation in both type I and III patients [type I: solid dysphagia :16.0(12.0) 16.0) vs 1.0(1.0) 5.3)(P = 0.027), regurgitation:10.5(8.3) 12.0) vs 0.0(0.0) 1.5)(P = 0.038); type III: solid dysphagia:16.0(14.0) 16.0) vs 0.0(0.0) 5.0)(P = 0.042), regurgitation: 9.0(7.5) 12.0) vs 0.0(0.0) 0.0)(P = 0.041)]. On multivariate analysis, female gender was positively correlated with symptom scores for solid dysphagia, regurgitation and chest pain, drinking history was positively correlated with symptom scores for Eckcardt score, liquid dysphagia and chest pain, while 4sIRP in solid swallow was negatively correlated with symptom scores for liquid dysphagia and 4sIRP in liquid swallow was positively correlated with symptom scores for both solid and liquid dysphagia.
**Conclusion:** When a uniform approach is utilized, symptomatic outcome are different across achalasia subtypes. Female, drinking history, low 4sIRP in solid swallow and high 4sIRP liquid swallow may predict worse POEM outcome.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1505 PROTEIN DISULFIDE ISOMERASE A3 MEDIATED IMMUNE DYSFUNCTION OF DENDRITIC CELLS IN THE COLON OF RATS WITH VISCERAL HYPERSENSITIVITY

**M. Li**[1], B. Lv[2], T. X. Wang[2], Y. Hu[2]

**Introduction:** The molecular mechanisms of visceral hypersensitivity are still poorly understood. We had already proved that antigen presenting dendritic cells (DCs) mediated abnormal immune response play a cardinal role in the formation of visceral hypersensitivity in rats. Protein disulfide isomerase A3 (PDIA3) is involved in the process of antigen presentation by loaded onto major histocompatibility complex I (MHC I) proteins. Our previous work found that stress can significantly induce high level of protein disulfide isomerase A3 (PDIA3) in the colonic mucosa in IBS rat model. Therefore, in the present study, we established a stress related model with visceral hypersensitivity and try to identified the relationship between PDIA3 and dentritic cells.
**Aims & Methods:** Twenty male rats were chosen to established a stress related IBS model by intraperitoneally infused with corticotropin releasing factor (CRF). All rats underwent abdominal withdrawal reflex (AWR) to evaluate visceral sensitivity. Western blotting was used to determine the protein expression of PDIA3 in colonic mucosa, DCs from mesenteric lymph nodes were numbered by double labeling immunofluorescent staining of either CD11c (marker of dendritic cells in rats) and PDIA3. The rat mesenteric lymph nodes dendritic cells (MLNDCs) were obtained by the technique of magnetic bead sorting. The expression of MHCI was tested by the technique of flow cytometry and western blot. Splenic CD8+Tcells were isolated and purified by magnetic label-based technique. The capacity to stimulate CD8 + T cells was evaluated by mixed lymphocyte reaction (MLR).
**Results:** In comparison to controls, all rats in the model group manifested higher visceral sensitivity ($p < 0.05$). Western blotting showed that protein expression of PDIA3 was up-regulated in colonic mucosa in IBS rats ($P < 0.05$), both CD11c-positive dendritic cells and PDIA3-positive cells observed under fluorescence microscopy were significantly increased in the IBS group compared with the control group ($P < 0.05$), in addition, the number of CD11c/PDIA3-positive cells in the IBS group was statistically more than in the control group in mesenteric lymph nodes ($P < 0.05$). Compared with control group, MLNDC from model group expressed high level of MHCI, and had the ability to attract and stimulate CD8+ T cell proliferation.
**Conclusion:** High level of protein disulfide isomerase A3 observed in dendritic cells could enhance the antigen presentation by up regulating the expression of MHCI on the surface of MLNDC, which may lead to the immune activation of CD8 + T cell and the generation of visceral hypersensitivity of IBS.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1506 INTERACTIONS BETWEEN THE ENDOGENOUS OPIOID AND CANNABINOID SYSTEMS IN THE GASTROINTESTINAL TRACT ARE CRUCIAL IN THE DEVELOPMENT OF TOLERANCE TO OPIOIDS

**Introduction:** Peripherally restricted opioids were proposed as promising therapeutics in diarrhea-predominant irritable bowel syndrome (IBS), as they eliminate diarrhea and alleviate abdominal pain. The development of tolerance to opioids is an important limitation of prolonged opioid administration. Previous studies have shown that tolerance to morphine develops in the ileum, but not in the colon. Moreover, it was reported that the co-activation of opioid (OR) and cannabinoid (CB) receptors reduced the development of tolerance related to the analgesic effect of opioids.
**Aims & Methods:** The aim of our study was to validate a new research tool that could be employed to study the development of tolerance to opioids in the GI tract and to characterize the interactions between OR and CB receptors in this process. To assess the development of tolerance to opioids, an in vitro opioid-induced withdrawal response (WR) protocol was used. Isolated segments of mouse ileum were mounted in organ baths and challenged with naloxone ($10^{-6}$M) to induce WR. WR was expressed as a change of smooth muscle tension prior to and immediately after exposure to naloxone. To validate this in vitro method, selective OR and CB agonists (both $10^{-6}$M): morphine and WIN 55,212–2, respectively, were used.
The involvement of OR and CB receptors interaction in tolerance development was evaluated using, as pharmacological tools, mixed agonists: salvinorin A (SA) and its derivative PR-38, which is devoid of action in the central nervous system (both at $10^{-6}$M). To determine the involvement of CB receptors, AM251, a CB1 receptor antagonist was used. The effect of PR-38 on upper GI tract motility, the geometric center of GI tract and gastric emptying in vivo, was characterized in mice pretreated chronically with PR-38 (5 mg/kg, i.p., injected every other day for 14 days) and compared with animals treated acutely with PR-38 (5 mg/kg, i.p.).
**Results:** In the ileum exposed to morphine, naloxone induced a significant WR; in the tissue exposed to WIN 55,212–2 WR was not observed. There was no WR in the ileum exposed to SA or PR-38; however, the CB1 antagonist AM251 evoked a significant naloxone-induced WR in the ileum exposed to SA or PR-38. Acute and chronic administration of PR-38 produced a significant slowing effect on upper GI transit, reduced gastric emptying and lowered geometric center of GI tract in comparison to control.
**Conclusion:** The dual activation of OR and CB receptors using PR-38 significantly reduced tolerance to opioids in the GI tract. These results indicate that mixed OR/CB receptors agonists may be effective agents in prolonged therapy of GI disorders and that further research is warranted.

[2]*Department Of Biology And Biochemistry, Center for Nuclear Receptor and Cell Signaling, University of Houston, Houston/United States of America/TX*

**Contact E-mail Address:** francescaderrico@hotmail.it
**Introduction:** Increased consumption of High Fat Diet (HFD) can induce several gastrointestinal motility disorders due to enteric neurons loss and reduction in neurotransmitter's synthesis; the most affected neurotransmitters seems to be vasoactive intestinal peptide (VIP), acetylcholine and nitric oxide. It is well known that estrogen can have protection on neurons via estrogen receptor Beta (ER$\beta$). The aim of our study was to investigate the role of LY3201, a selective ER$\beta$ agonist, on HFD induced colonic neuropathy and myopathy.
**Aims & Methods:** Nine male mice were fed a HFD (60% kcal from fat) for three months. Five of them were treated with pellet containing LY3201 and the other 4 with a vehicle pellet for 7 days. Colons were subjected to histological processing and immunohistochemistry was performed to evaluate myenteric neuron's expression of Er$\beta$, VIP, neuronal nitric oxide synthases (nNOS) and choline acetyltransferase (ChAT). The data were compared between the groups using non parametric t-test.
**Results:** Er$\beta$ is expressed in the neurons of the myenteric plexus. The thickness of muscle layer in LY3201-treated group was greater than in vehicle (mean 144.48 ± 20.92 vs 88.53 ± 18.13). The density (cell number/colon length) of colonic myenteric neurons (Neun-positive) in treated group was increased compared to the vehicle (respectively mean 29.85 ± 9.82; 6.93 ± 3.42; $p < 0.004$). In LY3201-treated group, the density of Sox2-positive cells (a subset of neural progenitor cells) was higher (mean 34.76 ± 9.53 treated; 8.94 ± 1.53 vehicle; $p < 0.0017$). Moreover the drug increased Chat (mean 14.8 ± 2.6 treated; 1.9 ± 0.9 vehicle; $p < 0.003$)and nNOS (mean 11.6 ± 2.1 treated; 2.3 ± 0.8 vehicle; $p < 0.0065$) expression while didn't affect VIP significantly.

**Conclusion:** LY3201 increased thickness of the smooth muscle layer and the number of neurons and Sox2-positive cells in the myenteric plexus. Probably it can promote Sox2+ progenitor cells differentiating into neurons. Moreover LY3201 restored neuron's ability to produce neurotransmitters (nNOS/Chat) damaged by HFD. Thus LY3201, a selective ER$\beta$ agonist, can ameliorate HFD induced colonic neuropathy and myopathy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1508 CLINICAL FEATURES OF ESOPHAGEAL ULCERS IN HIV-POSITIVE PATIENTS

**K. Nakagawa**, T. Yamada, S. Kao, A. Shoji, R. Kiyota, K. Shinkai, T. Tashiro, T. Iwasaki, A. Ishihara, K. Nishio, H. Hasegawa, Y. Sakakibara, S. Nakazuru, H. Ishida, E. Mita
*Gastroenterology And Hepatology, Osaka National Hospital, National Hospital Organization, Osaka|Japan*

**Contact E-mail Address:** kentaro0829@gmail.com
**Introduction:** Japan has an increasing population of people with human immunodeficiency virus-1 (HIV) infection. Esophageal ulceration is one of the most common complaints among HIV-positive patients, although esophageal ulceration can also be caused by Candida species, cytomegalovirus (CMV), and herpes simplex virus (HSV). Thus, idiopathic esophageal ulcers can be re-classified as being related to HIV infection after excluding the possibility of infections with pathogens that are also common among HIV-positive patients.
**Aims & Methods:** We retrospectively evaluated the clinical characteristics and endoscopic features of 40 HIV-positive patients with esophageal ulceration who underwent upper gastrointestinal endoscopy between September 1997 and March 2016 at the Department of Gastroenterology and Hepatology, Osaka National Hospital.
**Results:** The median age of the 40 patients (39 men) was 41 years (range, 23–70 years). The average HIV-RNA titers were 1,120,000 copies/mL and the average CD4+ cell count was 58/$\mu$L. The most common presentations of the esophageal ulcers were odynophagia (n = 14, 35%), epigastric or chest pain (n = 13, 32.5%), anorexia (n = 3, 7.5%), anemia (n = 2, 5%), and hematemesis or melena. Among the 40 patients, 34 patients (85%) had ulcers that were oblong with a sharply demarcated ''punched-out'' appearance, 7 patients (17.5%) had ''geographic ulcers'' resembling the islands of an archipelago and 30 patients (75%) had multiple ulcers. The most common sites were the middle and lower thoracic esophagus (n = 15, 37.5%), the lower thoracic esophagus (n = 11, 27.5%), the middle thoracic esophagus (n = 6, 15%), and the upper thoracic esophagus (n = 2, 5%). Moreover, 24 patients had CMV-related ulcers, 2 patients had HSV-related ulcers, 1 patient had a CMV- and HSV-related ulcer, and 9 patients had idiopathic esophageal ulcers (the causes were unclear in 2 patients, because of insufficient investigation). Before antiretroviral therapy (ART), patients with Candida esophagitis received antifungal therapies, and patients with CMV or HSV infection received antiviral therapy (valganciclovir, ganciclovir, or foscarnet). Patients with idiopathic esophageal ulcers were only treated using ART. All cases of idiopathic esophageal ulcers exhibited symptom improvement, and endoscopy after the start of ART revealed reductions in the size and depth of the ulcers (or disappearance). Interestingly, we identified HIV infection in 6 patients after the endoscopy.
**Conclusion:** Esophageal ulceration can help diagnose HIV infection, and it is important to detect the infectious agent(s) that caused the esophageal ulcers. However, clinicians should also be aware of the possibility of idiopathic esophageal ulcers. Our results indicate that ART was effective for treating idiopathic esophageal ulcers, and that endoscopy helped diagnose HIV infection.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1509 IMPAIRMENT IN ACTIVITY OF DAILY LIVING IS A RISK FACTOR FOR HIGH MEDICAL CARE COST IN PATIENTS WITH NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING

**Contact E-mail Address:** y_high_28@yahoo.co.jp
**Introduction:** Despite recent progress of health care standard, non-variceal upper gastrointestinal bleeding (NVUGIB) is still a common and life-threatening disease. It sometimes requires intensive care, thus it would have a big impact on medical care cost. However, little is known about risk factors for increased medical care cost in NVUGIB patients.
**Aims & Methods:** The aim of this study is to clarify characteristics of NVUGIB patients requiring high medical care cost. This was a retrospective study from a tertiary care hospital. Patients who underwent endoscopic hemostasis due to NVUGIB were included in this study. Patients with low risk for re-bleeding (Forrest classification IIb or III) based on retrospective review of recorded endoscopic images were excluded. Medical care cost was calculated in reference to the ''Diagnosis Procedure Combination'' which is diagnosis-dominant case-mix system in Japan. We defined the cutoff value of high medical care cost as its first quartile. Univariate logistic regression model was used to determine an association between high medical care cost and various clinical factors [age, gender, usage of antiplatelet/anticoagulant drug, Glasgow-Blatchford score, activity of daily livings (ADL) before admission]. ADL was assessed according to Katz-6 score (Katz, et al, *Gerontologist* 1970). It is calculated considering whether the patients were possible six basic performances in daily life (bathing, dressing, toileting, sitting and standing, necessity of incontinence products, and eating). If patients couldn't perform these items by themselves, each items scored 1. Scores of each item were summed up and total score ranges 0 (fully maintained) to 6 (completely impaired). We divided the eligible patients into maintained ADL (Katz-6 score: 0) and impaired ADL (Katz-6 score more than 1) groups. Multivariate logistic regression analysis was performed among factors indicated p-value less than 0.20 in univariate analysis. The exchange rate from Japanese Yen to USD was 120.
**Results:** A total of 128 consecutive patients admitted due to NVUGIB between April 2012 and March 2015. Mean age was 68.6 ± 15.4 years old and male-to-female ratio was 2: 1. Median medical care cost was 5,323 USD [IQR 3.661 – 8.172 USD]. There were 13 patients (10%) in impaired ADL group. In univariate analysis, age and impaired ADL before admission revealed significant association with high cost. Of these, impaired ADL was an only independent risk factor [Odds Ratio 15.3 (95% C.I. 2.49 – 183)] in multivariate analysis. Katz-6 score positively also correlated with medical cost ($r = 0.23$, $p < 0.01$).
**Conclusion:** Impairment in ADL before admission was an independent predictor for high medical care cost with NVUGIB patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1510 EFFICACY AND SAFETY OF FERRIC CARBOXYMALTOSE IN THE MANAGEMENT OF IRON-DEFICIENCY ANEMIA IN PATIENTS WITH GASTROINTESTINAL AND LIVER DISEASE

**M. Mendolaro**[1], M. Cappello[2], A. Viola[1], M.G. Cilluffo[1], P.L. Almasio[1]
[1]*Di.bi.mis University Of Palermo, Gastroenterology Section, Palermo|Italy*
[2]*Gastroenterology And Hepatology Unit, AOU, Palermo|Italy*

**Contact E-mail Address:** m.mendolaro@gmail.com
**Introduction:** Iron deficiency anemia (IDA) is common in gastrointestinal and liver disease. Oral iron is often ineffective and poorly tolerated while conventional intravenous (IV) iron is effective but requires repeated infusions. Ferric carboxymaltose (FCM) is a novel intravenous iron preparation that can be administered in single doses. In this retrospective study we aimed to evaluate efficacy and safety of FCM in a cohort of patients with IDA related to gastro-intestinal disease.
**Aims & Methods:** We analyzed 63 consecutive patients admitted to our day-care unit because of IDA from January 2014 to September 2015. Anemia (defined as Hb < 13 g/dl in men, Hb < 12 g/ dl in non-pregnant women) was classified as IDA if ferritin value was < 30 ng/ml. There were 27 (43%) patients with Inflammatory Bowel Disease, 17 (27%) with liver cirrhosis, 4 (6%) with celiac disease, 15 (24%) with other G-I disease. Clinical-demographic characteristics were registered on a dedicated database. We evaluated Hb, serum iron and ferritin values at baseline, after 2 and 8 weeks. FCM was administered by intravenous infusion of 500 mg in 15 minutes. We also evaluated the need for a second infusion of FCM and number of blood transfusions at baseline and after iron therapy. Safety was also assessed.
**Results:** By a single infusion of FCM, we obtained a mean increase of 1.3 g/dl in Hb values (Hb levels at baseline 9.5 ± 1.2 g/dl, 10.8 ± 1.5 g/dl at week 2) ($p < 0.001$). Significant increases in mean levels of serum iron (31 ± 23 at baseline, 60 ± 33 $\mu$g/dL at 2 weeks, D 27 µg/ dl; $p < 0.001$) and ferritin (21.6 ± 47 at baseline, 126 ± 85 ng/mL at 2 weeks, D 105 ng/ml; $p < 0.001$) were also observed. A second infusion of FCM was necessary in 30% of patients. 11 patients (17%) had required at least one tranfusion before FCM treatment while only 5 patients (8%) needed transfusions after FCM. Only one adverse event was observed (skin rash). FCM was well tolerated also in 4 patients with a previous history of anaphylactoid reaction to iv iron.
**Conclusion:** A single infusion of FCM effectively improves Hb and iron status in patients with IDA due to GI disease regardless of etiology. Safety profile was excellent even in patients with liver disease and those with a previous history of allergic reaction to ev iron sucrose. The use of FCM reduces the impact of treatment on everyday life and work productivity and allows a more efficient utilization of hospital resources. Safety in patients with liver disease should be confirmed in larger series for the potential risk of iron overload.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1511 PEPTIC ULCER BLEEDING - DOES ETIOLOGY INFLUENCE CLINICAL OUTCOME?

**A.G. G. Antunes**[1], A. Vaz[1], P. Queirós[2], T. Gago[1], J. Roseira[1], B.M. Santos Peixe[1], H. Guerreiro[1]

[2]*Gastroenterology, Centro Hospitalar do Algarve, Faro|Portugal*

**Contact E-mail Address:** sergiogiao@hotmail.com
**Introduction:** With the declining prevalence of *Helicobacter pylori* (Hp) infection, polymedication and the increase in the average life expectancy, the epidemiology of peptic ulcer (PUD) has changed. Recent epidemiological studies report an increase in idiopathic PUD (I-PUD) incidence. The clinical impact (rebleeding and 30 day mortality) of this data is not fully understood. [1–2]
**Aims & Methods:** In patients with upper gastrointestinal bleeding (UGIB) secondary to PUD, we performed a comparison between the characteristics and clinical outcomes of the different etiologies of PUD, with the main focus on I-PUD. Retrospective analysis of all admissions secondary to PUD bleeding in a

tertiary center, between 2009 and 2014. We divided patients into 4 groups according to etiology: PUD associated to Hp (Hp-PUD); drug induced PUD (D-PUD: non-steroidal anti-inflammatory drugs, antiplatelet, anticoagulants); combined PUD (C-PUD: Hp and drug-induced PUD) and I-PUD (without Hp or drug history). Our main endpoint was rebleeding, defined as: 1) objective evidence of UGIB, with hemodynamic instability and Hb decrease $\geq$ 2g/dL; 2) or a requirement for more than 3 units of blood transfusion for more than 3 days.
**Results:** We identified 381 patients with a mean age of 71 years and with a mean length of hospitalization of 7 days. The PUD was classified as: D-PUD: 41.2%; Hp-PUD: 24.1%; C-PUD:19.7% and I-PUD 15%. Rebleeding happened in 20%, surgery for hemostatic control in 8% and in hospital mortality was 7%. There was a statistically significant difference according to the etiology of PUD for age ($p = 0.019$), Age Adjusted Charlson Comorbidity Index (ACCI; $p < 0.000$), Alcoholism ($p = 0.010$), length of hospitalization ($p < 0.000$) and rebleeding ($p = 0.001$). No statistically significant difference was identified between the groups ($p > 0.05$) for the variables: hemodynamic instability, location (gastric or duodenal), high-risk location (small gastric curvature or posterior wall of the bulb), size of PUD, Forrest classification, number of red blood cell (RBC) units transfused, need for surgery and in hospital mortality. In multivariate analysis besides Forrest $\geq$ 2B ($p < 0.000$; OR = 10.137), I-PUD ($p = 0.049$; OR = 1.972), duodenal location ($p = 0.014$; OR = 2.280), high-risk location ($p = 0.009$; OR = 3.017) and ACCA $\geq$ 6 ($p = 0.000$; 3.011) were independent risk factors for rebleeding.

| | I-PUD N = 57 | Hp-PUD N = 92 | D-PUD N = 157 | C-PUD N = 75 | P value |
|---|---|---|---|---|---|
| Age (years) | 68 (16.66) | 67 (18.69) | 73 (13.69) | 71 (15.5) | **0.019** |
| Gender (m/f) | 43/14 | 68/24 | 114/43 | 53/22 | 0.934 |
| ACCI | 5 (3.06) | 4 (2.26) | 6 (3.14) | 6 (3.20) | **0.000** |
| Past PUD | 13 | 19 | 29 | 7 | 0.158 |
| Smoking | 15 | 15 | 28 | 14 | 0.463 |
| Alcoholism | 10 | 11 | 10 | 2 | **0.010** |
| Hemodynamic instability | 21 | 26 | 33 | 24 | 0.085 |
| Location (Gastric/Duodenal) | 26/31 | 35/57 | 73/84 | 28/47 | 0.420 |
| High-risk location | 9 | 10 | 15 | 8 | 0.642 |
| Forrest $\geq$ 2B | 43 | 53 | 103 | 55 | 0.074 |
| Estimated PUD size (mm) | 12.9 (7.1) | 13.6 (8.3) | 11.5 (6.6) | 11.4 (6.5) | 0.092 |
| Hb (g/dL) at admission | 8.9 (2.54) | 8.1 (2.65) | 8.4 (2.68) | 8.1 (2.29) | 0.209 |
| Number of RBC units | 2 (2.38) | 2 (1.55) | 2 (1.48) | 2 (1.30) | 0.078 |
| Length of hospitalization | 9 (8.32) | 4 (2.70) | 8 (7.20) | 6 (3.69) | **0.000** |
| Rebleeding | 18 | 6 | 37 | 16 | **0.001** |
| Mortality | 7 | 4 | 13 | 4 | 0.272 |

**Conclusion:** In our sample we identified a high prevalence of I-PUD (15%). Different PUD etiologies presented distinct characteristics and clinical outcomes. In our sample I-PUD was an independent risk factor for rebleeding.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1512 RISK OF PEPTIC ULCER BLEEDING ASSOCIATED WITH HELICOBACTER PYLORI INFECTION, NONSTEROIDAL ANTI-INFLAMMATORY DRUGS, LOW-DOSE ASPIRIN IN PEPTIC ULCER DISEASE: A CASE-CONTROL STUDY

**H. Kim**, S.I. Seo, H.S. Kim, W.G. Shin, M.K. Jang, J.H. Lee
*Dept. Of Gastroenterology, Hallym University Kangdong Sacred Heart Hospital, Seoul/Korea, Republic of*

**Contact E-mail Address:** bacter@hallym.or.kr

**Introduction:** The association of *Helicobacter pylori* (*H. pylori*) infection, non-steroidal anti-inflammatory drugs (NSAIDs) and low-dose aspirin in the risk of peptic ulcer bleeding (PUB) has not yet been established. Also, it remains unclear whether aspirin and NSAIDs increase the risk of bleeding from gastroduodenal ulcers.
**Aims & Methods:** This study aimed to determine the risk of PUB associated with *H. pylori* infection, NSAIDs and low-dose aspirin in peptic ulcer disease (PUD). This case-control study included 300 hospitalized patients with PUB and age, sex-matched 300 patients with PUD diagnosed endoscopically at our institution from 2012 to 2015. Adjusted odds ratio (AOR) for the risk of PUB were calculated by logistic regression analysis.
**Results:** The study included 300 cases of PUB and 300 controls of PUD. 57.7% of cases and 52.3% of controls had *H. pylori* infection ($P = 0.18$). In multivariate analysis, low-dose aspirin (AOR, 5.96; $P = 0.0001$), NSAID (AOR, 4.6; $P = 0.0001$), smoking (AOR, 1.98; $P = 0.006$) and alcohol intake (AOR, 1.85; $P = 0.012$) increased risk of PUB compared to PUD. No significant interactions were observed between *H. pylori* infection and NSAIDs or low-dose aspirin use in logistic regression analysis.
**Conclusion:** Both NSAIDs and aspirin are independent risk factors for bleeding in patients with PUD, however, there were no additive effects between low-dose aspirin or NSAID use and *H. pylori* infection. Therefore, preventive strategies for bleeding are warranted in patients with PUD taking low-dose aspirin and NSAIDs continuously.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1513 MEDICAL VERSUS COMBINED THERAPY OF PEPTIC ULCERS WITH ADHERENT CLOTS

**J. P. Rodrigues**, C. Fernandes, T. Freitas, J. Silva, A. Ponte, M. Sousa, J. Carvalho
*Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia/Portugal*

**Contact E-mail Address:** jaimepereirarodrigues@gmail.com

**Introduction:** The optimal therapeutic approach of peptic ulcers with adherent clots, Forrest IIb Classification, is not consensual. The results of the studies so far performed are somewhat contradictory and both isolated medical treatment and medical treatment combined with endoscopic treatment are considered on the European Society of Gastrointestinal Endoscopy guidelines[1].
**Aims & Methods:** We aimed to compare evolution and prognosis of patients with Forrest IIb ulcers approached with isolated medical treatment versus combined treatment (medical and endoscopic). All patients with Forrest IIb gastric or duodenal ulcer, diagnosed between January 2010 and December 2015 were admitted. A clot was considered adherent when resistant to endoscopic aspiration and/or irrigation, with no signs of active bleeding. All patients that underwent any method of endoscopic haemostasis (injection, thermal and/or mechanic) were included in the endoscopic treatment group.
**Results:** We selected 58 patients (69.0% male; mean age 67.0 ± 13.9 years), 43.1% ($n = 25$) in the isolated medical treatment and 56.9% ($n = 33$) in the combined treatment group. Demographic and clinical features were identical between both groups ($p > 0.05$). The recurrence rate was 9.1% ($n = 3$) in the combined treatment group Vs. 28.0% ($n = 7$) in the medical treatment group; $p = 0.059$. Patients of the combined treatment group had shorter duration of hospitalization (5.9 ± 3.2 Vs. 7.8 ± 3.8 days; $p = 0.042$) and required less transfusion (1.2 ± 2.4 Vs. 2.7 ± 2.8 units of blood; $p = 0.031$). The surgery requirement (6.1% Vs. 20.0%; $p = 0.221$), bleeding-related mortality (3.0% Vs 4.0%; $p = 0.841$) and all-cause mortality (12.1% Vs. 24.0%; $p = 0.302$) did not reach statistical difference between both groups. There was an association between syncope at admission, Blatchford score and ulcer size and the recurrence rate ($p < 0.05$).
**Conclusion:** Combined treatment, medical and endoscopic, of Forrest IIb ulcers is associated with shorter hospitalization, less transfusion requirement and a tendency towards recurrence rate reduction.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastrointestinal bleeding represents the main indication for emergency endoscopy and, albeit a plethora of potential interventions, yields a mortality rate of up to 10%. Lately several hemostatic powders, such as "Hemospray", have been released in order to increase the success rates during emergency endoscopy.
**Aims & Methods:** During a study period of 15 months, all emergency endoscopies were evaluated, in whom Hemospray application was performed to achieve hemostasis. The aim of this study was to report short- and long-term hemostasis rates, outcome and adverse events after Hemospray application.
**Results:** In 488 emergency endoscopies, Hemospray was applied during 35 examinations (7.17%) in 27 patients (19 males). Hemospray was used after previous endoscopic treatment in 21 examinations (60%) and in 14 (40%) as salvage therapy.
Short-term success was reached in 34 of 35 applications (97.1%), while long-term success was documented after 23 applications (65.7%).

Recurrence of bleeding was found particularly in malignancy and ulcerative lesions involving larger arteries. But even in these patients, short-term hemostasis enabled hemodynamic stabilization and planning of further definitive interventions.
One major adverse event (2.8%) occurred with gastric perforation immediately after Hemospray application, requiring surgery.
**Conclusion:** Hemospray achieved a short-term hemostasis in virtually all cases. Intermittent hemostasis gives further essential time to improve intensive care treatment. The long-term effect is mainly determined by the type of bleeding source, involvement of larger arteries, and in combination with a hampered coagulation system. But, even in these cases, patients benefit from a hemodynamic stabilization and consecutive interventions optimized conditions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1515 APPRAISING AND IMPROVING JUNIOR DOCTORS MANAGEMENT OF ACUTE VARICEAL UPPER GI BLEEDS: A QUALITY IMPROVEMENT PROJECT

**A. Elzubeir**
*University Hospital Leicester, Leicester/United Kingdom*

**Contact E-mail Address:** amera.elzubeir@doctors.net.uk
**Introduction:** Acute gastrointestinal bleeding is a medical emergency. Some 44% of bleeds are caused by peptic ulcer disease but the most severe haemorrhage and highest mortality is seen amongst those with bleeding oesophageal or gastric varices[1]. Competent triage and assessment are cornerstones of its initial management, with emphasis on identifying sick patients with life-threatening hemodynamic compromise, and then initiating appropriate and timely resuscitation being of paramount importance in the patient's outcome. In a national audit, variceal bleeding accounted for just over 10% of all UK admissions, with approximately two-thirds having a previous history of variceal bleeding and just fewer than 50% presenting outside normal working hours[2]. The average mortality of the first episode of variceal bleeding is reported to be up to 20%, with studies confirming a 2–3 fold increase in mortality amongst inpatients[3]. Therefore it is paramount that all junior doctors involved in acute admissions and inpatient care are able to recognise and manage suspected variceal bleeds appropriately.
**Aims & Methods:** The primary aim of this project was to appraise and then to improve the knowledge, skills and confidence of junior doctors in caring for patients with upper gastrointestinal bleeds (UGIB), to ultimately improve patient safety and outcomes. This objective was achieved through initially identifying areas of weakness in junior doctor's knowledge of managing an acute variceal upper GI Bleed. The areas identified were then the basis of a later rolled out dedicated Foundation Year one (FY) and two teaching session on acute variceal bleeding. An initial questionnaire was distributed and completed by 67 junior doctors (FY1-FY2) at the University Hospitals of Leicester in November 2015, all with jobs involving the acute medical take and providing ward cover. The questions on the questionnaire were devised around a real life case scenario. Junior doctors were then asked a series of questions and their perceived confidence and knowledge was sampled in a range of key areas i.e. management pre and post endoscopy, senior support and escalation, blood transfusion targets, knowledge and confidence in activating the major haemorrhage protocol and use of risk stratification tools such as the Blatchford score. Following evaluation of the initial questionnaire results a dedicated teaching session on variceal bleeds was devised and rolled out to 65 FY1's and FY2's. Following the teaching session the junior doctor's perceived confidence and knowledge on management of variceal bleeds was then re-assessed in January 2016.
**Results:** Following introduction of the teaching session all junior doctors expressed improved confidence in managing variceal UGIBs- which improved from 8% to 41% of junior doctors feeling confident. Additionally there were significant improvements identified in all areas assessed. Notably; correct pre-endoscopic management improved to 94% (from 36%), selecting appropriate transfusion targets improved from 45% to 76%, knowledge and understanding of risk stratification scores and how to activate the major haemorrhage protocol improved to 88% and 94% respectively (from 3% and 30% respectively). With inappropriate pre-endoscopic use of proton pump inhibitors falling from 25% to 0% after the introduction of the teaching session. This clinically would translate to better patient care, safety and outcomes.
**Conclusion:** Adopting a focused teaching programme for junior doctors on the management of acute variceal bleeds designed around pre-identified areas of weakness has proven to increase both knowledge and confidence in its specific management. Junior doctor teaching on core medical emergencies such as UGIBs should perhaps be incorporated into Trust induction, to ensure junior doctors are as prepared as possible on their first day in clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The aim of this study was to compare peptic ulcer bleeding (PUB) with upper gastrointestinal tumor bleeding (UGITB) while placing special emphasis on the incidence, outcomes including thirty-day re-bleeding rate, mortality and the need for blood transfusion.
**Aims & Methods:** A total of 2198 patients referred to our Emergency Department with upper gastrointestinal bleeding (UGIB) were included in this prospective study during 5 years (from January 2008 till December 2012); 796 with PUB and 61 with UGITB, found during urgent upper GI endoscopy performed within 24 hours of admission.
**Results:** Cumulative incidence of UGIB was 126/100000 in a 5-year period. 796(36.2%) patients had PUB and 61 (2.8%) patients had UGITB. UGITB was most often found in the stomach (58/95%); the tumors were dominantly malignant (55/90%), most of them adenocarcinoma (48/87.3%). Median age for PUB was 67, and for UGITB 76 years($p < 0.01$). PUB and UGITB were more common in men (62.3% and 52.5%). Re-bleeding occurred more often in patients with UGITB(19.7% vs 9.7%, $p < 0.01$), but a higher number of patients with PUB required surgical intervention due to uncontrolled bleeding (5.9% vs 3.3% $p < 0.01$). Thirty-day mortality showed no difference between the two groups (5.2% vs 7.2%). Transfusion of red blood cells was administered more often in patients with UGITB (75.4% vs 49.5%, $p < 0.01$), while patients with PUB received comparably higher volumes of transfused red blood cells.
**Conclusion:** Patients with UGITB have higher re-bleeding rates, require surgical intervention less often, and are more often treated with blood transfusion than PUB.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** sehrishreema1@hotmail.com
**Introduction:** Gastric variceal bleeding is not only life threatening, also contributes to high rates of morbidity, recurrent hospitalizations
**Aims & Methods:** We aimed to evaluate the efficacy and safety of endoscopic injection of N-butyl-2-cyanoacrylate (NBCA) for treatment of bleeding gastric varices (GV). Methods: Analysis of prospectively collected data of a cohort of patients with GV who underwent endoscopy for the treatment of bleeding GV from April 2013 to September 2015. Patients with gastric variceal bleeding underwent endoscopic treatment with a mixture of NBCA and Lipiodol. The success of GV eradication was assessed by repeat endoscopy after 3 weeks of intervention. Successful hemostasis, rebleeding rate and complications were observed.
**Results:** The cohort consisted of 33 consecutive patients that had undergone NBCA injection for GV. The mean age was $51 \pm 10$ years. The mean follow-up was $16 \pm 8$ months and the most common cause for GV was hepatitis C related liver cirrhosis (51.5%). Child-Pugh score at presentation for was A-21%; B-79%, and median MELD score at admission was 10. A median mixture volume of 4.5 mL, in 1 to 2 injections, was used, with immediate hemostasis rate of 100% and early rebleeding rate 3.8%. Mortality rate was 3.8%. No immediate or long-term complications of NBCA injection occurred in any of these cases during the time of follow-up.
**Conclusion:** NBCA injection of GV is a safe and successful therapeutic intervention. Patients with very early rebleeding was at higher risk of death. A minimum of 2 endoscopic sessions is required to significantly decrease the risk of rebleeding.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1518 COMPARISON OF GLASGOW–BLATCHFORD SCORE, ROCKALL SCORE, AND AIMS 65 SCORE FOR PREDICTING UPPER GASTROINTESTINAL BLEEDING OUTCOME IN KOREA

**J.W. Choe**, S.Y. Kim, J.J. Hyun, S.W. Jung, J.S. Koo, H.J. Yim, S.W. Lee
*Gastroenterology, Korea University Ansan Hospital, Seoul, South Korea; Korea University Medical Center, Korea University, Seoul, South Korea, Ansan/Korea, Republic of*

**Contact E-mail Address:** jwchoe@korea.ac.kr

**Introduction:** Various clinical scoring systems have been developed and validated to predict the clinical outcomes in patients with upper gastrointestinal bleeding (UGIB), including the Glasgow–Blatchford score (GBS), Rockall risk score (RS), and AIMS65 score (AIMS65). Several studies have evaluated the predictive accuracy of these systems, but the results vary greatly, potentially limiting the generalizability of the findings.
**Aims & Methods:** We simultaneously compared the performance of these three scoring systems in predicting clinical outcomes in patients presenting with UGIB in Korea. We retrospectively evaluated 143 patients with UGIB who visited our emergency department between August 2013 and August 2014. The accuracy of the three scoring systems was compared using the area under receiver-operating characteristics curves. The primary outcome was the need for blood transfusion, clinical endoscopic intervention, or ICU admission, while the secondary outcomes were re-bleeding and 30-day all-cause mortality.
**Results:** The median patient age was 57.9 years, and 30.8% were women. The causes of UGIB were gastric or duodenal ulcer in 84 (59%) patients, esophageal/gastric varices in 32 (38%), Mallory-Weiss syndrome in 16 (11%), and unknown in 11 (8%). Eighty-seven (61%) patients required blood transfusion; 83 (58%), endoscopic interventions; and 5, (3.5%) surgical interventions. Thirteen (9.1%) patients experienced re-bleeding, and 6 (4.2%) died within 30 days of admission. The GBS outperformed the RS and AIMS65 in predicting the need for endoscopic intervention. Further, the GBS and RS outperformed the AIMS65 in predicting the need for transfusion as well as for ICU admission. No significant differences were found in the ability to predict re-bleeding rates and 30-day all-cause mortality among the three scoring systems.
**Conclusion:** The GBS was more effective and accurate than the RS and AIMS65 in predicting the need for clinical interventions in Korean patients with UGIB. Relatively, the AIMS65 may not be suitable for predicting clinical outcomes in Korean patients with UGIB.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Oesophageal motility has been shown to be impaired in a minority of patient with chronic intestinal idiopathic pseudo-obstruction (CIIPO)[1] at traditional manometry. High resolution manometry (HRM) has improved the understanding of oesophageal pathophysiology in patients with oesophageal symptoms; however no studies have evaluated HRM in CIIPO patients.
**Aims & Methods:** To evaluate oesophageal motility with HRM in a cohort of patients with a confirmed diagnosis of CIIPO (chronic symptoms of obstruction, radiological evidence of distended gut with air-fluid levels and exclusion of any organic obstruction of the gut lumen). 15 CIIPO patients (6 M; 42 yrs; 29–50) who underwent HRM were retrospectively enrolled. 50 consecutive patients with oesophageal symptoms (dysphagia or typical/atypical oesophageal reflux symptoms) and a diagnosis of ineffective esophageal motility (IEM) served as a control group (18 M; 53 years; 39–68). Patients with secondary causes of chronic intestinal pseudo-obstruction, scleroderma, previous oesophageal and gastric surgery and eosinophilic oesophagitis were excluded. All diagnosis were based according to Chicago 3 Classification[2]. All patients underwent 10 single 5 ml water swallows (SS) and 2 multiple 10 ml rapid swallows (MRS) during HRM protocol. During MRS we evaluated the presence of motor inhibition, oesophagogastric pressure gradient (OGPG) as a measure of resistance to outflow and peristaltic reserve, which was considered to be present if MRS/SS Distal Contractile Index Ratio was > 1. Data are given as median and interquartile range (IQR). Mann-Whitney, Chi-squared or Fisher test were used when appropriate.
**Results:** All CIIPO patients had pathological HRM: one had type II achalasia, one oesophago-gastric junction obstruction (OGJO), one aperistalsis and 12 IEM. The 12 CIIPO patients with IEM were compared with our control group. No differences were seen between two groups comparing basal tone of the LES (9.5 mmHg; 6–16.5 vs 14 mmHg; 7–24), 4 second Integrated Relaxation Pressure (4 s IRP) (3 mmHg; 1.5–5 vs 3 mmHg; 1–6), Intrabolus Pressure (IBP) (14 mmHg; 3.5–17; 6 mmHg; 2–16) Distal Contractile Integral (DCI). Distal latency (DL) had a trend toward lower values in the CIIPO group compared to IEM group ($p = 0.07$) although no patients had DL < 4.5 sec. Number of failed waves (DCI < 100 mmHg.sec.cm) were similar between the two groups whereas number of ineffective waves (DCI < 450 mmHg.sec.cm) were higher in CIIPO group ($p = 0.001$). During MRS there were no differences considering motor inhibition (96% vs 90%) and OGPG (-0.5 mmHg; -2.8 to 1 vs 0.75 mmHg;-1.5 to 2.5) whereas MRS/SS DCI ratio ($p = 0.08$) and number of after contractions with MRS/SS DCI ratio > 1 ($p = 0.08$) had a tendency to be higher in CIIPO. Data are detailed in table 1.

**Table 1:** Data expressed as median; IQR

| | CIIPO (12) | IEM (50) | p value |
|---|---|---|---|
| **SS DCI (mmHg.sec.cm)** | 221; 136–471 | 324; 166–475 | 0.67 |
| **SS DL (sec)** | 6.9; 5.9–7.6 | 7.3; 6.6–8.2 | 0.07 |
| **SS waves with DCI < 450 mmHg.sec.cm** | 50% | 34% | 0.001 |
| **MRS DCI (mmHg.sec.cm)** | 560; 370–1151 | 469; 196–931 | 0.22 |
| **MRS/SS DCI ratio** † | 2.4; 2.2–2.9 | 1.5; 0.7–2.6 | 0.08 |
| **Waves with MRS/SS DCI Ratio >1**† | 9/10 (90%) | 28/45 (62%) | 0.08 |

†Evaluated in patients with presence of MRS after contraction, n = 10 in CIIPO and n = 45 in IEM.

**Conclusion:** HRM has identified oesophageal dismotility in all CIIPO patients, three major and 12 minor disorders. IEM of our CIIPO patients had similar HRM characteristics compared with patients with oesophageal symptoms with more ineffective waves in CIIPO patients, in which however peristaltic reserve was generally preserved as assessed during MRS.

**Introduction:** Idiopathic achalasia is a rare motility disorder of the esophagus (lifetime prevalence 1:10,000) characterized by impaired relaxation of the lower esophageal sphincter (LES) and disturbed esophageal peristalsis due to degeneration of inhibitory neurons within the myenteric plexus. The etiopathology is multifactorial with environmental and genetic factors being disease-associated, but the exact etiopathogenesis remains unknown. Recently a SNP rs28688207, located in HLA-DQ$\beta$ region on chromosome 6, leading to an 8-amino-acid insertion in the HLA-DQB1 subunit of the HLA-DQ receptor on the surface of antigen-presenting cells, has been identified as the strongest genetic risk variant for achalasia so far (Gockel et al., *Nat Genet*, 2014). With the introduction of high-resolution manometry (HRM), three subtypes of achalasia that have also different clinical presentation can be distinguished according to the Chicago classification: type I = 100% failed peristalsis, type II = panesophageal pressurization with ≥ 20% of swallows, type III = spastic contraction with ≥20% of swallows.
**Aims & Methods:** The aim of our study was to replicate the role of rs28688207 in achalasia pathogenesis in an independent case-control sample from the Czech Republic (204 patients, 220 controls). In addition, we performed the first genotype-phenotype (GxP) study to test whether rs28688207 is disease-associated to a particular HRM-subtype of achalasia. For the GxP analysis we used a cohort of patients including cases from the Czech Republic and Germany with detailed HRM data. From a total of 235 cases, 53 patients were diagnosed as achalasia type I, 147 as type II and 35 patients as type III according to the Chicago classification.

**Results:** Genotyping of rs28688207 in the case-control sample yielded a strong achalasia-association ($P = 1.22 \times 10^{-04}$). The frequency of 8-amino-acid insertion in HLA-DQB1 was present in 9.1% of patients while only in 2.7% of controls, which perfectly corresponds with the frequency seen in cases and controls in other countries in Central Europe. The GxP study revealed that rs28688207 is most prevalent in type I achalasia (11.3%) compared to type II (7.8%) and type III (4.3%), although this distribution was not statistically significant ($P = 0.266$).
**Conclusion:** Our results suggest that the 8-amino-acid insertion in HLA-DQB1 plays a pivotal role in achalasia etiopathogenesis. In addition, the insertion is most frequent in HRM-type I achalasia patients, followed by type II and III subsequently. It might be due to a small sample size of patients, that despite the clear trend of decreasing frequency from type I to type III achalasia, this was not statistically significant and larger number of patient samples with HRM data is needed in order to uncover whether the HLA-DQB1-insertion has an impact on achalasia also on the phenotypic level.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Per oral endoscopic myotomy (POEM) is effective to treat achalasia. Despite the lack of controlled studies, it is frequently proposed as first line treatment.
**Aims & Methods:** We aimed at determining the effect of first-line POEM on esophageal contractile activity as defined with high-resolution manometry (HRM) and searching for predictive factors of response to treatment. Achalasia patients referred for POEM were included in this study. Patients with previous endoscopic or surgical treatment were excluded. HRM was performed before and 3 months after POEM. HRM protocol consisted of 30-s baseline recording without swallowing, 10 5-ml water swallows in supine position and multiple water swallow (MWS) test (200 ml free drinking) in seated position. The following manometric parameters were analyzed: esophago-gastric junction (EGJ) resting pressure, median integrated relaxation pressure (IRP) of 10 swallows, percentage of 5-ml swallows associated with pan-esophageal pressurization, and occurrence of pan-esophageal pressurization during MWS. Esophageal motility disorders were defined using the Chicago Classification version 3.0. Esophageal symptoms were assessed using the Eckardt score. Data before and after POEM are expressed as median (range) or percentage and compared using paired t-test or Chi2 test.
**Results:** Pre and post POEM data were available in 59 patients (37 males, mean age 57 years, range 27–84). Eight patients (13%) had type I achalasia, 40 (69%) type II, 5 (8%) type III and 6 (10%) a variant form (EGJ outflow obstruction with normal or weak esophageal contractions). Manometry catheter did not pass through the EGJ in 7 patients before POEM and 3 after POEM. Results before and after POEM are presented in the Table. After POEM, IRP was normal (<15 mmHg) in 49/56 patients (87%). Post POEM esophageal contractions were observed in all patients with achalasia variant, in 80% of patients with type III achalasia, in 58% of patients with type II but none of patients with type I achalasia. Post POEM esophageal contractions were premature (spasm) in 6 patients (3 type II, 2 type III, and 1 variant). POEM was successful (Eckardt score < 3) in 52 patients (88%) at 3 months. Response rate was 100% in type I achalasia, 90% in type II, 60% in type III and 83% in variant ($p = 0.16$). The percentage of patients with at least 20% of swallows associated with pan-esophageal pressurization after POEM tended to be higher in case of good response compared to failure (31% vs 0%, $p = 0.09$). No other factor (age, symptom severity at inclusion, EGJ resting pressure, IRP before and after POEM, post POEM esophageal contractions, and occurrence of pan-esophageal pressurization during MWS) was associated with POEM failure at 3 months.

| | prePOEM | post POEM | p |
|---|---|---|---|
| Eckardt score | 6 (2–11) | 1 (0–5) | <0.01 |
| EGJ resting pressure (mmHg) | 23 (4–78) | 7 (0–25) | <0.01 |
| IRP (mmHg) | 18 (5–50) | 7 (0–22) | <0.01 |
| Percentage of esophageal contractions with pan-esophageal pressurization | 60 (0–100) | 0 (0–100) | <0.01 |
| Percentage of patients with at least 20% of contractions with pan-esophageal pressurization, n (%) | 45 (76%) | 16 (27%) | <0.01 |
| Patients with pan-esophageal pressurization during MWS, n (%) | 37/47 (79%) | 7/52 (14%) | <0.01 |

**Conclusion:** POEM is responsible for a significant decrease of EGJ resting and relaxation pressure. Type III achalasia might be associated with a lower response rate; however the difference is not significant. Reappearance of esophageal contractions was observed in half of the patients without impact on treatment response. MWS might not be useful to predict response to POEM in patients with achalasia.

**Contact E-mail Address:** eline.storlid@uib.no
**Introduction:** Upper gastrointestinal disorders affect up to 20% of adults in Western countries, and the origin of symptoms is poorly understood. We believe abnormal postprandial gastric accommodation to be of potential pathophysiological importance in patients with upper gastrointestinal symptoms.
**Aims & Methods:** We aimed to study normal physiology of the stomach and lower esophagus during and after food-intake by combining transabdominal ultrasound (US), a symptom score and multichannel high-resolution impedancemetry and manometry (HRIM) in a pilot study. After trans-nasal intubation, a HRIM-probe was distally positioned at angulus ventriculi, and a solution of 300 ml saline water with 67 g of glucose (255 kcal) was given. Our target variables (pressure changes, gastroesophageal reflux, stomach wall thickness and diameters, gastric wall stress and strain and upper gastrointestinal symptoms) enabled an evaluation of the postprandial adaptive accommodation reflex, and were recorded from shortly before until 30 minutes after the intake of fluid.
**Results:** 15 healthy volunteers (11 F/4 M, mean age 26.9 years), were included. All subjects accepted the 300 ml of fluid with few symptoms in general and minimal discomfort. Three subjects showed mild gastroesophageal reflux. At angulus ventriculi gastric pressure was significantly reduced from 6.2 mmHg (mean) shortly before intake, to a minimum of -1.2 mmHg after a median time of 75 seconds ($p < 0.0001$), rising to 3.9 mmHg at five minutes and to pre-intake-values within 20 minutes. The corresponding area and circumference showed a clear increase from shortly before intake (8.0 $cm^2$ (mean) and 11.3 cm respectively), to 14.1 $cm^2$ and 15.1 cm shortly after, both reaching a top level at five minutes, then slowly decreasing towards 30 minutes, but not to pre-intake-values. The corresponding calculated stress decreased significantly from 50.5 mmHg (mean) shortly before intake to 4.6 mmHg shortly after ($p = 0.0001$), subsequently rising to nearly pre-intake values after 5 minutes, and to 69.2 mmHg at 30 minutes.
**Conclusion:** US and HRIM enabled calculation of gastric wall stress and strain during the postprandial accommodation reflex, triggering few symptoms and scant reflux tendencies in healthy volunteers. We propose this to be a more physiological alternative to the barostat technique.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1523 STUDY OF DISTAL CONTRACTILE INTEGRAL IN INEFFECTIVE ESOPHAGEAL MOTILITY DIAGNOSIS AND ITS RELATION TO GASTROESOPHAGEAL REFLUX DISEASE

**Introduction:** High-resolution manometry has brought about a revolution in esophageal motility disorders, making it possible to identify new pressure patterns. Ineffective esophageal motility (IEM) is defined as ≥50% of ineffective swallows: Ineffective swallows can be classified as failed (Distal contractile integral (DCI) < 100 mmHgcmsg) or weak (DCI < 450). Historically IEM has been associated with gastroesophageal reflux disease (GERD), but it has not been proved whether it is the cause or the consequence.

**Aims & Methods:** The purpose of this study is to evaluate if a difference exists between the mean value of DCI in manometries with IEM diagnosis and normal manometries, as well as to check if patients with pathological pH monitoring had a DCI mean value lower than that of patients with normal pH monitoring. Retrospective and descriptive study of 116 high resolution manometries. Statistical comparison using $\chi^2$ test for normally distributed data and the Mann-Whitney U-test for non-normally distributed data. The data were analyzed using the program SPSS.20. A p value < 0.05 was established for signification

**Results:** 116 manometries were analyzed. 72 of them were measured on females (62.1%) averaging 53.65 year of age (range 23–81). According to the Chicago classification v3, 27 manometries (23.3%) reached IEM diagnostic criteria and 89 (76.7%) were normal. The mean of DCI readings in the normal manometry group was 1219.99 and the median was 1000 (range 442–4449). The mean DCI in the IEM group was 486.22 and the median was 409 (range 142–1527), p-value: < 0.01. 95th percentile of DCI in the IEM group was < 1454. 100 pH monitoring tests were carried out, and 59 of them were abnormal. In the 23 analysis carried out of a total of 27 patients in the IEM group, 13 (57%) showed pathological pH readings. There were no differences between pathological pH monitoring in the IEM group and that on the normal manometry group, p-value:0.786. The mean of DCI in patients with pathological pH monitoring was 978.24, the median was 834 (range 182–2346). The mean of DCI in patients with normal pH monitoring was 1249.93, the median was 981 (range 142–4449), p-value: 0.462

**Conclusion:** In this study we found significant differences in DCI values among IEM patients, as we conclude that patients with normal manometry readings have a higher DCI mean value than those in the IEM group. Therefore DCI may be an IEM diagnosis parameter. In this sample 95 percent of DCI values are below 1454; however, those values could have been influenced by 3 outliers. On the other hand, we didn't find significant differences in DCI between patients with pathological pH monitoring and patients with normal pH monitoring, which suggests that DCI is not connected with GERD. In addition, in our study the IEM group didn't have a higher incidence of GERD than the normal manometry group.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** High-resolution manometry (HRM) is currently the gold standard technique to investigate esophageal motility in patients with dysphagia. However, with routine HRM procedure and use of Chicago classification, a group of patients with dysphagia are considered as being normal and dysphagia remains unexplained.

**Aims & Methods:** The aim of this study is to assess the diagnostic value of solid bolus swallows in patients with dysphagia and normal HRM. Patients having dysphagia and normal HRM studies during January-October 2015 were selected. Solid bolus swallows of bread (1cm$^3$ single bread swallows and/or a sandwich meal) followed the routine water swallows on HRM. Patients with a double high pressure zone, esophageal diverticulum or history of antireflux surgery were excluded.

The patients were categorised to symptomatic and asymptomatic groups based on having dysphagia reproduced on bread swallows. Hospital odynophagia and dysphagia questionnaire (HODQ) score, integrated relaxation pressure (IRP), distal contractile integration (DCI), distal latency (DL) and peristaltic abnormality during water swallows were investigated and compared between groups. ROC curve was used to identify the optimum level of sensitivity and specificity of the significant parameters in identifying patients who have a meaningful abnormality on bread swallows.

**Results:** 72 patients referred with dysphagia and diagnosed with normal HRM were selected. In the asymptomatic group, 7/22 patients showed abnormality on bread swallows. In the symptomatic group, 45/50 showed abnormal motility. (P = 0.0001) ROC analysis showed that having > 33.3% abnormal bread swallows has sensitivity of 72%, specificity of 90.91% and likelihood ratio of 7.9 to detect patients who may have abnormal motility and dysphagia on bread swallows.

Analysis of water swallow parameters comparing the asymptomatic group against the symptomatic group with abnormal motility on bread swallows did not reveal any significant difference in HODQ score (P = 0.2), IRP (P = 0.17), DL (P = 0.3) and peristaltic abnormalities (P = 0.4).

**Conclusion:** Performing solid swallows on HRM can explain dysphagia in a considerable number of patients with dysphagia and normal routine HRM. This complementary test is readily available, and avoids the need for Barium swallowing and radiation exposure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Peroral endoscopic myotomy (POEM) is becoming a standard endoscopic procedure for esophageal achalasia. Nevertheless, mid- and long-term data should confirm favorable short-term outcomes of POEM. In this prospective, single-center study we report mid-term results of POEM.

**Aims & Methods:** Since 2012, a total of 139 POEM procedures have been performed in 136 patients with achalasia (61 women, 75 men, mean age 47). A follow up at 3, 6, 12, 24 and 36 months was completed in 109, 90, 76, 38 and 5 patients. The primary outcome was treatment success defined as an Eckardt score < 3 at 12 and 24 months (data at 36 months has not been analyzed due to a low number of patients who completed 36 M follow-up). Three months after POEM, endoscopy, high-resolution manometry and 24-hours pH metry monitoring were performed.

**Results:** A. PROCEDURE: POEM was successfully completed in most of the patients, two procedures failed due to submucosal fibrosis, one of these patients underwent successful re-POEM. The median length of the procedure was 67.5 minutes (range 28–185). The median myotomy length was 13 cm (6–19). In 71 patients (52.2%) capnoperitoneum had to be decompressed, and 66 patients (48.5%) experienced a subcutaneous emphysema which resolved spontaneously. Only one serious postoperative complication occurred and required prolonged hospitalization with thoracic drainage due to a pleural effusion. All remaining patients were dismissed on post-operative day 1 or 2. We observed the following minor complications: inadvertent mucosotomy 11x (7.9%); respiratory instability during POEM 2x (1.4%); bleeding at the entry site 4x

Data are presented as the mean ± SEM. a: $P < 0.05$, b: $P < 0.01$, c: $P < 0.0001$; *PI-IBS patients before vs. after FMT, ** Idiopathic IBS patients before vs. after FMT.

(2.8%); difficult entry site closure 2x (1.4%) and large subcutaneous emphysema 2x (1.4%). B. TREATMENT RESULTS: 3, 6, 12, and 24 months after POEM, treatment success was achieved in 105, 87, 75 and 33 patients 96% (95% CI: 93–100), 97% (92–100), 99% (94–100), and 87% (71–98). At 24 months, 5 patients (13.2%) experienced a disease recurrence; a majority of these patients (3 pts.) underwent the procedure among the first 20 operated patients. The median Eckardt score decreased from 7 to 0 at 3, 6, 12 months, and to 1 at 24 months; $p < 0.001$. Quality of life significantly improved, median Eyspach-Williams score was 105 (27–133) before POEM vs. 131 (70–144), 138 (98–144), 139 (107–144) and 140 (99–144) at 3, 6, 12 and 24 months after POEM, $p < 0.001$). Heartburn was present in 25 patients (22.9%), 19 (25%) and 13 (34.2%) at 3, 12 and 24 months and a total of 35 patients (33%) have been treated with proton pump inhibitors. A mild reflux esophagitis was diagnosed in 36 patients (33%) and a pathological gastro-esophageal reflux (DeMeester score $>14$) was detected in 35 (32%) patients.

**Conclusion:** POEM is a safe and effective treatment modality in patients with achalasia with excellent short term results. However, the 24 months recurrence rate was 18.4% which might be partially explained in consequence of a learning curve. Mild reflux esophagitis and pathological gastroesophageal reflux are present in more than one third of patients and regular treatment with a PPI should be considered in all patients after POEM.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1526 WHATS'S THE IMPACT OF CONTINUNG MEDICAL EDUCATION ON THE INCIDENCE OF ACHALASIA?

**A. Tebaibia**[1], M.A.A. Boudjella[2], N. Oumnia[1], D. Boutarene[1], M. Boucelma[1]
[1]*Dept. Of Internal Medicine, Kouba Hospital Internal Medicine Department, Algiers/Algeria*
[2]*Internal Medicine Department, Kouba hospital, Algiers/Algeria*

**Contact E-mail Address:** tebaibia@hotmail.com

**Introduction:** Achalasia is a rare esophageal motility disorder most probably underestimated. Few epidemiological studies around the world have been devoted to it.

**Aims & Methods:** to investigate the epidemiology of achalasia in our country and to determine the impact of continuing medical education on incidence of achalasia. This study was carried out in two steps (1990–1998 and 1999–2014) at our institution which is the national reference center in the management of the esophageal motility disorders. During the second step we conducted a campaign of Continuing Medical Education (CME), on diagnosis and therapeutic aspects of the disease, including its 48 provinces. Annual incidence and prevalence were calculated by relating the number of diagnosed cases to 100.000 inhabitants and we compared the incidence between the two periods. Each underwent barium swallow, upper endoscopy and esophageal manometry.

**Results:** From 1990 to 2014, 1256 patients were diagnosed with achalasia. Overall prevalence was 3.14/100.000 inhabitants (95% CI; 2.97–3.31). The mean annual incidence raised from 0.04 (95% IC; 0.028–0.052) during the 1990s to 0.27/100.000 (IC; 0.215–0.321) during the 2000s. The incidence of the disease was two and half times higher in the north and the center compared to the south of the country. Among 1256 patients, 129 (10%) were children and 97 (7.7%) had an Allgrove syndrome. Familial achalasia was noticed in 18 different families. Patients had dysphagia (99%), Regurgitation (83%), Chest pain (51%), heartburn 24.5% and weight loss (70%). The lower esophageal sphincter was hypertensive in 53% and hypotensive in 0.6%.

**Conclusion:** the mean incidence of achalasia in our country is at least 0.27/100.000 inhabitants. This study showed a good impact of CME on incidence of achalasia. The variability between different regions of the country is probably related to genetic and environmental factors.

**Contact E-mail Address:** tarek.mazzawi@med.uib.no

**Introduction:** Irritable bowel syndrome (IBS) is caused by several factors including altered gut microbiota and altered neuroendocrine system. The main trigger of the enteroendocrine cells is the luminal content of the gut. The densities of the gut enteroendocrine cells are abnormal in IBS patients (1). Faecal microbiota transplantation (FMT) has improved the symptoms of IBS patients (2). In a 5 year-follow-up after the Giardia outbreak in the year 2004 in Bergen, Norway, more than 50% of the patients still had abdominal complaints and were diagnosed to have post-infectious IBS (PI-IBS).

**Aims & Methods:** The aim of the study was to investigate the effect of FMT on the symptoms and duodenal enteroendocrine cells in patients with diarrhoea predominant IBS (IBS-D). The study included 12 patients with IBS-D according to Rome III criteria (3 females and 6 males, age range 21–44 years) and three patients were excluded. The patients were divided according to the cause of IBS into PI-IBS ($n = 4$) and idiopathic IBS ($n = 5$). All the patients received FMT, freshly donated from their relatives. The patients completed the following questionnaires before and 3 weeks after FMT: IBS symptom questionnaire, IBS-symptom severity scoring system (IBS-SSS), Bristol stool form scale, the Eysenck personality questionnaire (EPQN-12) and Hospital anxiety and depression (HAD). The patients underwent gastroscopies with biopsies taken from the descending part of the duodenum at baseline and 3 weeks after FMT. The biopsies were immunostained for all enteroendocrine cell types using ultraView Universal DAB Detection Kit and quantified using computerized image analysis. Duodenal biopsies from a group of 14 control subjects (9 females and 5 males, age range 26–70 years) previously immunostained and quantified (using the same techniques) for all enteroendocrine cell types were borrowed from another research project that belongs to our group (3).

**Results:** The scores of IBS symptoms were significantly reduced 3 weeks after receiving FMT; total ($P = 0.0001$), nausea ($P = 0.004$), bloating ($P = 0.0003$), abdominal pain ($P = 0.005$), constipation ($P = 0.02$), diarrhoea ($P = 0.0002$) and anorexia ($P = 0.096$). The total scores of IBS-SSS and Bristol stool form scale, but not EPQN-12 and HAD, were significantly reduced 3 weeks after receiving FMT ($P = 0.0002$, 0.02, 0.18 and 0.08, respectively). The densities of the duodenal enteroendocrine cells before and 3 weeks after receiving FMT are presented in Table 1.

**Conclusion:** This is the first study where the interaction between the gut microbiota and the enteroendocrine cells is reflected by a change in the densities of the duodenal enteroendocrine cells in IBS patients following FMT. The positive effects of FMT may be attributed to the crosstalk between the gut microbiota and the enteroendocrine cells and contributed to the improvement in symptoms of IBS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Functional heartburn (FH) is diagnosed in patients with negative endoscopy and pH monitoring who have resistant reflux symptoms after therapy with proton pump inhibitors (PPI) (Rome III). Antidepressants are frequently prescribed to treat FH, even though there is little evidence of their efficacy in such patients.
**Aims & Methods:** We performed a randomized trial to evaluate the efficacy of citalopram or amitriptyline versus no treatment on symptoms of patients with FH. Patients with normal endoscopy and typical reflux symptoms (heartburn, regurgitation), despite PPI twice daily, underwent ambulatory 24-hour pH monitoring. Distal esophageal acid exposure (% time pH $< 4$) and symptom index (SI) were measured. Patients with a normal distal esophageal acid exposure time and a negative SI were classified as having FH. Thereafter, they were randomly assigned to one of three treatment groups for 3 months: citalopram 20 mg, amitriptyline 50 mg, or observation. The end point was complete disappearance of reflux symptoms at the end of treatment.
**Results:** Over a two-year period, 43 patients (27 females; mean age $55 \pm 17$ years) were diagnosed with FH and were randomized to receive once daily citalopram ($n = 14$), amitriptyline ($n = 14$) or no treatment ($n = 15$). After 3-months follow-up, disappearance of reflux symptoms was reported by 5 (35.7%) patients treated with citalopram, 6 (42.8%) patients treated with amitriptyline, and 1 (6.7%) patient without treatment ($p = 0.033$ for no treatment vs. citalopram/and amitryptiline therapy).
**Conclusion:** Both citalopram and amitryptiline are effective pharmacological options in the symptomatic relief of patients with well characterized FH.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1529 BELCHING AND TRANSIT OF GASTRIC GAS IN HEALTHY HUMANS

**Introduction:** During meals, a wide range of gas volumes enters into the stomach. Ingested gas is mainly nitrogen, a poorly absorbed gas that needs active transport and evacuation to be eliminated from the gut. Evacuation of gastric gas can be achieved by 2 ways: gas emptying to the small intestine, or triggering of the belching reflex by gastric distension. However, the normal ways of transit and evacuation of free gastric gas have been poorly investigated.
**Aims & Methods:** Our aim was to study the dynamics of free gastric gas in healthy subjects, and the correlation between gas retention, rectal and oral gas evacuation. In 24 healthy volunteers without gastrointestinal symptoms (14 women and 10 men, age-range 21–33 yrs), 1500 ml of a mixture of non-absorbable gases was infused into the stomach, 5-cm caudal to the lower margin of the LES. In groups of 6 volunteers the following gas infusion rates were tested: 0 ml/min (sham infusion), 25 ml/min, 50 ml/min and 100 ml/min. In the subjects receiving sham infusion, 400 ml/min of gas were infused at the end of the study until belching occurred. Belching, by an esophageal multilumen impedance manometry catheter, and rectal gas evacuation, via a rectal tube connected to a barostat, were continuously recorded for 90 min.
**Results:** Sham infusion was associated to small rectal gas evacuation ($187 \pm 94$ ml after 90 min), and virtually no belching ($0 \pm 0$ belches). In contrast, gastric gas infusion induced a significant increment in rectal gas evacuation ($1129 \pm 281$ ml, $1362 \pm 410$ ml, and $1116 \pm 281$ ml of gas after infusion at 25, 50 and 100 ml/min, respectively; $p < 0.05$ vs sham infusion for all), and a minor increment of the recorded belching ($3 \pm 2$; $4 \pm 2$ and $4 \pm 2$ belches at 25, 50 and 100 ml/min, respectively; $p = 0.451$ vs sham) that were similar at all infusion rates. Infusion of gas at 400 ml/min induced belching in all subjects at a lower infused volume ($703 \pm 132$ ml) than the infused volume associated with first belching at the lower infusion rates ($1300 \pm 148$ ml, pooled data of infusion at 25–100 ml/min). Overall, there was a negative correlation between rectal gas evacuation and belching ($r = -0.66$; $p < 0.05$).
**Conclusion:** In healthy subjects, gastric gas is rapidly emptied to the small bowel and propelled to the rectum preventing gas retention and gastric distension. Only when gas arrives to the stomach at a very high rate the belching reflex, acting as a reserve defense mechanism, is activated and oral venting of gas occurs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1530 ROLE OF ACID REFLUX AND IMPACT OF HRM PARAMETERS IN PATIENTS WITH NON-OBSTRUCTIVE DYSPHAGIA

**M. Ribolsi**, D. Biasutto, P. Balestrieri, M. Cicala
*Gastroenterology, Campus Bio Medico University, Rome/Italy*

**Contact E-mail Address:** m.ribolsi@unicampus.it
**Introduction:** Non-obstructive dysphagia (NOD) is a real challenge in clinical practice. The role of gastro-esophageal reflux disease (GERD) in eliciting NOD is not yet fully elucidated. Moreover, it is still not clear how findings of high resolution manometry (HRM) may relate to esophageal bolus transit.
**Aims & Methods:** To assess the role of HRM findings, of GERD presence and of acid suppression in dysphagia perception. Method: 44 consecutive patients with recurrent dysphagia underwent combined HRM-impedance followed by 24 h impedance-pH. Dysphagia was scored on a 5-point Likert scale from 'occasionally' to 'always'. Patients performed upper endoscopy with biopsies within 3 months before to rule out hiatal hernia and/or eosinophilic esophagitis. HRM was performed in a semi-recumbent position with a catheter incorporating 36 solid state pressure sensors and 9 impedance segments. 10 saline (5 ml) swallows at 30-sec intervals were analyzed in each patient. Tracings were analyzed according to the Chicago classification v3.0. Bolus transit time (BTT) during HRM was the time between bolus entry in the proximal impedance segment to exit from the most distal segment. 44 GERD patients with typical symptoms, responding to PPIs, not complaining of dysphagia, underwent the same protocol. 18 NOD patients repeated the study while on PPIs (Esomeprazole 40 mg/o.i.d.), after a 4-week treatment.
**Results:** 4 NOD patients presenting evidence of outflow obstruction and 3 patients with achalasia were excluded. The remaining 37 NOD patients were considered for the analysis. 15/37 NOD patients (40%) and 19/44 (43%) GERD patients presented pathological acid exposure time (AET). HRM data are in Table 1. NOD AET+ patients showed a significantly lower mean DCI value than NOD AET-. Mean BTT values were similar in NOD and in GERD patients both with normal and abnormal AET. A significant correlation between DCI and BTT values was found only in NOD AET+ patients. 10/15 NOD AET+ and 8/22 NOD AET- patients repeated the protocol while on PPI. All these 18 NOD patients presented normal AET on treatment. Data are in Table 2. During PPI therapy, patients reported a dysphagia score significantly lower than off therapy. NOD AET+ patients, after 4 weeks of treatment, presented a significantly higher mean DCI value.

**Table 1**

| | NOD AET+ | NOD AET- | GERD AET+ | GERD AET- |
|---|---|---|---|---|
| IRP 4 sec (mmHg) | $8.3 \pm 1.4$ | $8.9 \pm 1.3$ | $7.9 \pm 2.1$ | $8.4 \pm 2.1$ |
| DL (sec) | $4.8 \pm 1.1$ | $4.9 \pm 1.1$ | $5.2 \pm 1.1$ | $5.2 \pm 1.1$ |
| DCI (mmHg-s-cm) | $669 \pm 298$* | $1438 \pm 597$ | $947 \pm 257$ | $1289 \pm 257$ |
| BTT (sec) | $13.8 \pm 4.6$ | $13.1 \pm 1.9$ | $13.4 \pm 3.1$ | $12.4 \pm 1.6$ |
| DCI-BTT correlation (Spearman Rho) | -0.71 (p 0.0027) | -0.39 (p 0.072) | -0.31 (p 0.09) | -0.33 (p 0.13) |

*$p < 0.01$ vs NOD AET-

**Table 2**

| | NOD AET+ | NOD AET+ on PPI | NOD AET- | NOD AET- on PPI |
|---|---|---|---|---|
| Dysphagia score | 4.1* | 1.4 | 3.2** | 1.8 |
| DCI (mmHg-s-cm) | $701 \pm 281$§ | $1038 \pm 327$ | $1047 \pm 127$ | $1122 \pm 111$ |
| BTT (sec) | $14.1 \pm 4.5$ | $13.2 \pm 1.7$ | $13.2 \pm 3.2$ | $12.5 \pm 1.5$ |

*$p < 0.01$ vs NOD AET+ on PPI ** $p < 0.05$ vs NOD AET- on PPI §$p < 0.05$ vs NOD AET+ on PPI

**Conclusion:** 40% of NOD patients showed a pathological AET and a lower esophageal contractile vigor. In NOD AET+ patients DCI correlates with BTT. Reduced dysphagia perception following acid suppression together with a significant increase of DCI, in a subgroup of NOD, strongly suggest that increased AET may enhance the perception of bolus impaction by sensitizing esophageal mucosa to its transit.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1531 SUPRAGASTRIC BELCHING (SGB) AND GASTRO-OESOPHAGEAL REFLUX: CAUSE AND EFFECT?

**J. Roscamp**, J. Patel, T. Wong, I. Miah, J. Jafari
*Oesophageal Physiology Laboratory, Guy's and St Thomas' Hospitals, London/United Kingdom*

**Contact E-mail Address:** joseph.roscamp@kcl.ac.uk
**Introduction:** Supragastric belching (SGB) is characterised by rapid antegrade and retrograde flow of air in the oesophagus that does not reach the stomach*. Whilst proactive SGB is a behavioural phenomenon, reactive SGB occurs in

response to a particular stimulus. Currently treatment for SGB is behavioural therapy however this may not be the most appropriate treatment for patients with reactive SGB. We aimed to ascertain prevalence of proactive versus reactive SGB in response to a certain pathological stimulus i.e. GOR.
**Aims & Methods:** The database of the Oesophageal Physiology Laboratory at Guy's Hospital London were retrospectively searched (November 2014 – present) for patients diagnosed with SGB (>13 SGBs within 24 hrs). The 24-hour pH-impedance studies were analysed to differentiate proactive SGB from reactive (proactive SGB being an SGB without preceding reflux event (or preceding event lasting < 1 second), and reactive SGB being an SGB with preceding reflux event (> 1 second)). A patient was then labelled as having predominantly reactive SGB (PR-SGB) if >60% of their SGB was reactive and having predominantly proactive SGB (PP-SGB) if >60% of their SGB was proactive. Reflux Diseases Questionnaire (RDQ) score was obtained for all patients. P value <0.05 was considered significant.
**Results:** 28 patients identified for this study (14 males (M), 14 females (F), mean age 51 [27–75]). 82% of patients had PP-SGB events, 11% PR-SGB and 7% had the same number of proactive and reactive SGB. The most common symptoms in patients with PR-SGB were: heartburn 66.6%, belching 66.6% and throat burning sensation 66.6% and, in patients with PP- SGB: belching 68%, heartburn 39% and regurgitation 21%. In total, in all 28 patients, proactive SGBs accounted for 1124 and reactive 216 of SGB events (19.22% of all SGBs being reactive). The 3 patients with PR- SGB had an average RDQ of 3.53, whilst the average RDQ for the patients with PP- SGB was significantly lower 2.36 ($p = 0.00004$). There was 1 patient with 100% proactive SGB and no patient with purely reactive SGB. The median presentation of reactive SGB was 15.38%.
**Conclusion:** Treating GORD may resolve SGB in a small group of patients and ameliorate potential psychological stress caused by a behavioural therapy referral. Whether the remaining SGB events are purely behavioural or in reaction to other types of stimuli other than GOR requires further investigation. Having a high RDQ score may help in identifying patients with PR-SGB.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1532 PROKINETICS FOR THE TREATMENT OF FUNCTIONAL DYSPEPSIA: A BAYESIAN NETWORK META-ANALYSIS

**C.S. Bang**, G.H. Baik, K.T. Suk, T.Y. Park, D.J. Kim
*Internal Medicine, Hallym universitiy College of Medicine, Chuncheon/Korea, Republic of*

**Contact E-mail Address:** cloudslove@naver.com
**Introduction:** Controversies persist regarding the effect of prokinetics for the treatment of functional dyspepsia (FD). The aim of this study was to assess the efficacy of prokinetics agents for the treatment of functional dyspepsia.
**Aims & Methods:** Randomized controlled trials (RCTs) of prokinetics for the treatment of FD were identified from core databases. Symptom response rates were extracted and analyzed using odds rations (ORs). A Bayesian network meta-analysis was performed using the Markov chain Monte Carlo method in WinBUGS and NetMetaXL.
**Results:** In total, 26 RCTs, which included 6789 patients with FD who treated 6 different prokinetics or placebo were identified and analyzed. Metoclopramide showed the best SURCA probability (92.3%), and better efficacy than those of itopride (OR: 2.79, 95% credible regions: 1.29–6.21), and acotiamide (OR: 3.07, 95% credible regions: 1.43–6.75), followed by trimebutine (SUCRA probability 75.9%), and mosapride (SUCRA probability 62.9%). Domperidone (SUCRA probability 62.6%) also showed better efficacy than those of itopride (OR: 1.37, 95% credible regions: 1.07–1.77), and acotiamide (OR: 1.51, 95% credible regions: 1.04–2.18).
**Conclusion:** In this analysis, metoclopramide showed best efficacy for the treatment of FD. Considering the adverse events related to metoclopramide or domperidone, short-term use of these agents or alternative use of trimebutine or mosapride could be recommended for the symptomatic relief of FD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Achalasia is a functional motility disorder of the esophagus. Peroral endoscopic myotomy (POEM) is a revolutionary therapy for achalasia that was first reported by Inoue and colleagues. (1) POEM has been performed worldwide, safely and with positive outcomes. However, complications associated with POEM are rarely reported. The objective of this study was to conduct a detailed review of the complications occurring after POEM and the predictive factors of these complications.
**Aims & Methods:** Between September 2011 and September 2015, 142 patients underwent POEM at our institution. Complications were graded according to the Clavien-Dindo classification system. The patients were classified into two groups as follows: (A) those without complications and (B) those with complications. Age, previous treatment of achalasia, preoperative comorbidities, symptom duration, type of achalasia (non-sigmoid vs. sigmoid), pre- and post-POEM Eckardt score, manometric findings, and treatment outcomes, including hospitalization duration and occurrence of complications, were compared between the groups by using chi-square and Student t tests.
**Results:** Of the 142 patients who underwent POEM, 17 (12.0%) experienced minor complications of grade £2. No other severe complications were observed in all the patients. Group A consisted of 125 patients; and group B, 17 patients. Operation time was significantly longer for group B than for group A (mean ± SD [range]: 205.9 ± 68.5 min [140–370 min] vs. 147.7 ± 44.9 min [75–345 min]; $p = 0.022$). Hospitalization duration was significantly longer for group B than for group A (mean ± SD [range]: 13.2 ± 10.7 days [10–50 days] vs. 7.1 ± 2.0 days [3–21 days]; $p < 0.001$. No statistically significant differences in age, previous treatment of achalasia, preoperative comorbidities, symptom duration, type of achalasia, Eckardt score, manometric findings, or mean duration of the myotomy procedure were found between the two groups. Significant decreases in Eckardt score and integrated relaxation pressure were achieved in both groups.
**Conclusion:** Minor complications occurred in only 12.0% of our patients, who were treated conservatively. No other severe complications were observed. POEM was safe and effective regardless of previous treatment of achalasia, symptom duration, type of achalasia, and manometric findings. Longer operating time was a predictive factor of complications occurring after POEM. In cases that need longer operating time, more attention is required in examinations after POEM.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[3]*Digestive Disease Center, Showa University Koto Toyosu Hospital, Tokyo/Japan*

**Contact E-mail Address:** hiro.shiwaku@gmail.com
**Introduction:** Peroral endoscopic myotomy (POEM), a revolutionary form of endoscopic treatment for esophageal achalasia, is currently the standard of therapy for this condition. However, few studies have investigated the incidence and management of gastroesophageal reflux disease (GERD) associated with the direction of the myotomy. In the present study, we gathered retrospective data from our hospital and compared the incidence and management of GERD when the myotomy was made in the anterior or posterior wall, which are the two main surgical approaches.
**Aims & Methods:** We included 152 patients who underwent POEM at our hospital between September 2011 and January 2016. Patients who could not undergo the postoperative examination after three months or who were being continuously treated with oral proton pump inhibitors (PPIs) for conditions other than esophageal achalasia were excluded.
**Results:** The myotomy was made in the anterior wall in 93 patients (group A) and in the posterior wall in 54 patients (group P). After three months, we interviewed the patients, performed endoscopic tests, conducted a 24-h pH test, and investigated GERD after POEM. We found no statistically significant differences between patients in groups A and P in terms of age, sex, type of achalasia, and body mass index. There was a statistically significant improvement in the Eckardt score in patients in both groups after the procedure. The incidence of erosive esophagitis measured using the Los Angeles classification [LA-(grade)] in patients in group A was LA-N 31%, LA-A 46%, LA-B 12%, LA-C 11%, and LA-D 0%. The corresponding rates in patients in group P were LA-N 18%,

LA-A 32%, LA-B 25%, LA-C 25%, and LA-D 0%. The amount of time with pH of <4 as a proportion of monitoring time was 7% and 24% in patients in groups A and P, respectively. This statistically significant difference indicated a higher rate of GERD in patients who received a posterior wall myotomy. Symptomatic GERD occurred in 12% and 14% of patients in groups A and P, respectively. There were no patients with GERD who were difficult to clinically manage through the use of oral PPIs.
**Conclusion:** In the present study, postoperative GERD was more common in patients in posterior myotomy, while GERD can be managed with the use of oral PPIs. If the same trend in the post-POEM incidence of GERD is seen in future studies, patients should be notified during the informed consent process that the need for ongoing oral PPI therapy will be more likely after POEM if a posterior wall myotomy is made.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The role of Gastroesophageal Reflux Disease (GERD) in causing extra-esophageal symptoms, is increasingly recognized with renewed interest. Nonallergic rhinitis (NAR) is defined as a compound of nasal symptoms in the absence of an allergic etiology and it is frequently observed in the clinical practice. Nasal cytology allows to identify the different NAR sub-types on the basis of the particular inflammatory cell infiltrate. Nonallergic rhinitis with neutrophils (NARNE) subtype pathogenesis highlights a chronic progressive inflammation process. To date, data about the etiopathogenetic role of the reflux in rhinitis and in particular in the form of NARNE are lacking.
**Aims & Methods:** To evaluate the effect of Proton Pump Inhibitor (PPI) therapy on the patients affected from both NARNE and GERD. Thirty-five patients referred to our ENT unit for nasal symptoms such as rhinorrhea, sneezing, and postnasal drip were enrolled. Visual analogue scale (VAS) for nasal symptoms, rhinomanometry, skin prick test and nasal cytology were performed. Exclusion criteria were infectious rhinosinusitis, ambient irritant exposure and/or a positive skin prick test. Of the 35 subjects with NAR, 20 (13F/7M, median age 48 years) showed the presence of neutrophils (neutrophils > 50% with absent spores and bacteria) at nasal cytology (NARNE) and were selected to perform a 24 hour pH-Impedance. Patients with a 24 hour pH-Impedance positive for GERD were treated with a high dose of oral PPI (40 mg x 2/day) for 8 weeks. A second pH-Impedance was performed during therapy whereas ENT examination and nasal cytology were performed at the end of treatment.
**Results:** Of the 20 patients with NARNE, 14 (70%) resulted to have pathological basal pH-Impedance values and 6 (30%) resulted to have normal basal values. PH-Impedance performed during PPI treatment showed the normalization of the number of refluxes (< 48) and pH values (< 4.2) in 9 (64.3%) out of the 14 patients with positive pH-Impedance at enrollment. PH-Impedance during treatment continued to be pathological in 3 (21.4%) patients with a pathological number of refluxes (2 with acid pH, 1 with normal pH values). Seven (77.8%) out of 9 patients with normal pH-Impedance values under treatment showed the simultaneous normalization of nasal cytology and symptom improvement whereas two (22.2%) subjects did not show any significant clinical and nasal cytology improvement. Two (14.3%) subjects experienced improvement in symptoms and showed the normalization of nasal cytology but refused to repeat the pH-Impedance during therapy.
**Conclusion:** Treatment with high dose of oral PPI for 8 weeks seemed to be effective in improving symptoms and in reducing nasal inflammation in a significant number of patients with NARNE and GERD diagnosis by pH-Impedance.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1536 LONG TERM CAPSAICIN INGESTION REDUCES SYMPTOMS IN PATIENTS WITH CHEMOSENSITIVE FUNCTIONAL DYSPEPSIA

V. Hammer, K. Hammer, M. Führer, **J. Hammer**
*Dept. Of Gastroenterology And Hepatology, Medical University of Vienna, Vienna/Austria*

**Contact E-mail Address:** Johann.Hammer@meduniwien.ac.at
**Introduction:** Capsaicin ingestion induces abnormal upper GI sensations in half of patients with functional dyspepsia, as can be demonstrated by the oral capsaicin capsule test (Hammer et al, *NGM* 2008, Führer et al, *NGM* 2011). Sensations induced by gastric capsaicin are distinct from sensations induced by stimulation of mechanoreceptors (Hammer & Vogelsang, *NGM* 2007). Repeated capsaicin intake can improve upper gastrointestinal complaints in patients with functional dyspepsia (Bortolotti et al, *APT* 2002). Long term capsaicin consumption affects chemo- and mechanoreceptors differently (Führer & Hammer, *NGM* 2009).
**Aims & Methods:** The aims of the present study was to investigate whether the ingestion of capsaicin over a four week period can improve symptoms of functional dyspepsia (FD) and if chemosensitive or rather non-chemosensitive patients benefit more from oral capsaicin intake. To determine their chemosensitivity n = 59 patients with FD received the oral capsaicin capsule test (0.75 mg capsaicin capsules, ingested in the fasting state). After a one week run-in period patients received capsaicin capsules (0.25 mg; tid) for four weeks and a standard numeric rating scale was filled out daily to determine the type and severity of symptoms. For each week the sum of each individual symptom score as well as an overall score was calculated. Results are given as mean±SEM, $p < 0.05$ was considered significant.
**Results:** 32 patients (54%) had a positive capsaicin test, thus were considered chemosensitive (caps pos), 27 (46%) were non-chemosensitive (caps neg). 14 patients did not finish the 4 week study (10 caps pos, 4 caps neg, $p < 0.05$), mainly because of pain in the first two study weeks. 45 patients finished the study (22 caps pos; 23 caps neg). Overall symptoms in the run-in period were comparable in the caps pos ($9.4 \pm 4.1$) and caps neg group ($7.1 \pm 3.3$) (NS). At the end of the 4 week treatment period symptoms were significantly reduced as compared to the run-in period in the caps pos group ($5.7 \pm 4.9$; $p < 0.05$), but not in the caps neg group (NS). Significant improvement of epigastric pain ($p < 0.01$), postprandial fullness ($p < 0.01$) and early satiation ($p < 0.05$) started at week 3, while epigastric burning did not significantly change (NS).
**Conclusion:** Chemosensitive FD patients may benefit from a 4 week trial of oral capsaicin, especially by improved epigastric pain, postprandial fullness and early satiety. However, a high dropout rate was observed, mainly due to pain developing in the early phase of treatment in the chemosensitive group. Considering capsaicin sensitivity as the entry criterion in this group, symptoms that develop after capsaicin ingestion is not surprising after all.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1537 THE OUTCOMES AND QUALITY OF LIFE OF CHINESE PATIENTS WITH ACHALASIA AFTER PERORAL ENDOSCOPIC MYOTOMY: A MULTI-CENTER CLINICAL STUDY

**N. Gao**, R. Li, D. Shi, D. Zhang, W. Chen
*Department of Gestroenterology, First Affiliated Hospital of Soochow University, Suzhou, Jiangsu, China, Suzhou/China*

**Contact E-mail Address:** carrie_gn@126.com
**Introduction:** To assess quality of life (QOL) and psychological state of patients with achalasia after peroral endoscopic myotomy (POEM).
**Aims & Methods:** Six hundred and eight-seven achalasia patients underwent POEM from Jan 2011 to December 2015. The data on clinical evaluation and QOL before therapy, at 1 month and 6 months postoperation were collected and analyzed. Meanwhile, Zung's Self-rating anxiety Scale (SAS) and self-rating depression scale (SDS) were used to assess the anxiety and depression.
**Results:** All the six hundred and eighty-seven patients underwent POEM successfully. By comparing the data of the preoperative with that of 1 month and 6 months after POEM respectively, we found that: mean Eckardt score decreased ($8.1 \pm 1.3$ vs $1.27 \pm 0.31$, $8.1 \pm 1.3$ vs $0.61 \pm 0.52$, all $p < 0.05$), esophagus diameter reduced (53.82 mm vs 32.1 mm, 53.82 mm vs 28.31 mm, all $p < 0.05$), and esophageal manometry declined (31.7 mmHg vs 12.3 mmHg, 31.7 mmHg vs 10.1 mmHg, all $p < 0.05$). No complications and recurrence occurred in all cases. At each time point, postoperative QOL scores were higher than those

of preoperative ($p < 0.05$). The anxiety and depression scores of preoperative patients were higher than normal group (SAS $51.32 \pm 7.26$ vs. $31.72 \pm 7.21$, SDS $53.17 \pm 5.98$ vs. $29.75 \pm 8.01$, all $p < 0.05$), which were closely related to the severity degree of symptom ($p < 0.05$). A comparison between the postoperative and preoperative groups (SAS $51.32 \pm 7.26$ vs. $37.2 \pm 7.18$, SDS $53.17 \pm 5.98$ vs. $35.72 \pm 7.36$, all $p < 0.05$) demonstrated a significent difference reduced by POEM.

**Conclusion:** POEM is safe and effective for treating achalasia, it can relieve clinic symptoms as well as improve patients' QOL, effectively relieving negative emotion.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1538 FUNCTIONAL DYSPEPSIA AND BINGE EATING DISORDERS IN ITALIAN MORBIDLY OBESE PATIENTS

**A. Santonicola**[1], F. Zingone[1], L. Pellegrini[1], C. Ciacci[1], P. Iovino[2]

[1]*Gastrointestinal Unit Department Of Medicine And Surgery, University Of Salerno, Baronissi-Salerno/Italy*

[2]*Gastrointestinal Unit, Department Of Medicine And Surgery, University of Salerno, Baronissi-Salerno/Italy*

**Contact E-mail Address:** antonellasantonicola83@gmail.com

**Introduction:** Binge Eating Disorder (BED) occurs in a subset ranging from 27 to 47% in severely obese persons undergoing bariatric surgery. BE disorders have been already associated with the experience of both upper and lower gastrointestinal (GI) symptoms.

**Aims & Methods:** We aimed to investigate the prevalence of Functional Dyspepsia (FD) and its two subgroups: the Postprandial Distress Syndrome (PDS) and the Epigastric Pain Syndrome (EPS) in a morbidly obese southern Italy adult population; to evaluate the association between FD and the presence of BED.

Methods. One hundred and forty-three consecutive morbidly obese patients were recruited from an outpatient clinic devoted to the surgical therapy of obesity and related disorders. All participants were questioned and scored for the presence or the frequency-intensity of 4 cardinal symptoms of FD according to Rome III criteria: early satiation, epigastric fullness, epigastric pain and burning. A psychologist performed a structured interview for psychological assessment and administered the Italian version of the Binge Eating Scale (BES).

**Results:** FD was found in 17/143 obese patients. 5/17 (29.4%) of obese patients with BED and 12/126 (9.5%) of obese patients without BED ($p = 0.003$). There was a significant association between obese patients with BED and PDS, while only one obese patients with BED fulfilled the diagnostic criteria for EPS ($p = 0.01$). Obese patients with BED showed significantly higher frequency-intensity scores for epigastric fullness ($1.90 \pm 1.91$vs $0.37 \pm 0.97$, $p = 0.003$) compared to obese patients without BED. No patients in both groups reported early satiation, and no difference in the frequency-intensity score of epigastric pain and burning was found between groups ($p = 0.79$ and $p = 0.21$, respectively).

**Conclusion:** Obese patients with a BED showed a significantly higher prevalence of Postprandial Distress Syndrome. Probably, the excessive intake of food over short time could overcome the functional accommodation and emptying, contributing to the genesis of GI symptoms. A greater knowledge of the pathophysiological mechanisms underlying these symptoms could be important in the clinical management of this emerging class of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Since the prokinetics, which had been introduced to the therapy of functional gastrointestinal diseases in the 70 s and 80 s, are not longer available due to restrictions of their marketing authorizations based on rare but severe side effects, well-proven therapeutic options gain increased attention. One of these is STW 5 (Iberogast), for which more than 5 decades of therapeutic experience in more than 60 Mio patients are available.

**Aims & Methods:** Whether also the available clinical data comply to modern standards for a proof of efficacy was now tested by a meta-analysis including the randomized placebo-controlled double blind trials available in the therapeutic indication functional dyspepsia. The original data from the trials were entered and evaluated regarding demografic data and primary endpoints (ANCOVA).

**Results:** The primary outcome variable, the validated gastrointestinal symptom score (GIS) [1], as well as the therapeutic dose (3 x 20 drops/day) were identical in all trials, so allowing a uniform evaluation. The full analysis set (FAS) included 557 patients (272 resp. 285 for placebo resp. verum). The mean age (48 resp. 49 years), the mean body size (in both groups 168.7 cm), the mean body weight (72.0 resp. 72.2 kg), the BMI (25.35 resp. 25.54), the gender disitribution (67.3 resp. 69.5% females), the duration of the disease at the time of inclusion and the baseline of the GIS (11.6 resp. 11.5 points) were very well comparable between both groups. For the primary variable GIS the difference between placebo and verum after 28 days of treatment showed a highly significant ($p < 0.0001$) difference between placebo and verum (6.7 resp. 4.7 points).

**Conclusion:** This meta analysis therefore clearly shows the efficacy of STW 5 (Iberogast) according to present standards and in addition the high quality of the trials, which is indicated e.g. by the very good balance between both patient groups. Additional insights can be expected from additional analyses, as e.g. the evaluation of different subgroups with specific predominant symptoms or demographic properties.

**Contact E-mail Address:** aquarious@seed.net.tw
**Introduction:** Gastroesophageal reflux disease (GERD), dyspepsia and irritable bowel syndrome (IBS) are highly prevalent gastrointestinal disorders in the general population. They frequently overlap with each other and affect quality of life.
**Aims & Methods:** The aim of the study was to investigate the impact of overlap on GERD symptom burden. We also investigate whether GERD overlapping dyspepsia or/and IBS would have an impact on clinical and psychological features as compared with GERD alone. We performed a nested case-control study in a GERD cohort. 2752 subjects were initially screened from a health check-up population, and 273 subjects were enrolled for the final analysis. We compared the clinical and psychological factors between subjects with GERD alone and with overlap of two or all three diseases. All participants underwent an evaluation with questionnaires including Reflux Disease Questionnaire score, Pittsburgh Sleep Quality Index, Taiwanese Depression Questionnaire, and State-Trait Anxiety Inventory before receiving endoscopic exam. Dyspepsia and IBS are based on the Rome III diagnostic criteria. Metabolic syndrome was defined by the National Cholesterol Education Program Adult Treatment Panel III definition.
**Results:** Among the GERD population, 26 with IBS (GERD-I), 60 with dyspepsia (GERD-D), and 25 subjects with overlap of all three conditions (GERD-I + D). GERD-D and GERD-I + D subjects had more severe GERD symptoms as compared subjects with GERD alone ($P < 0.001$). Subjects with overlapping dyspepsia or/and IBS showed a significant increase in the severity of depression than subjects with GERD alone ($P < 0.001$). Notably, sleep quality and anxiety scores did not differ significantly between subjects with overlapping diseases and GERD alone.
**Conclusion:** Our study demonstrates that disease overlap in GERD population is associated with greater symptom burden and greater depression. We also highlight that clinical awareness of such overlapping diseases would improve the therapeutic strategy of GERD in clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Acotiamide, with gastroprokinetic activity, is used for treating functional dyspepsia (FD), and postprandial distress syndrome (PDS). For epigastric pain syndrome (EPS), acid-suppressive agents are recommended. Many FD patients have PDS and EPS symptoms, suggesting combination therapy with acotiamide and acid-suppressive agents may be more effective; however, a randomized placebo-controlled study is lacking. We conducted this study to investigate the effect of famotidine, an acid-suppressive agent, on acotiamide in FD treatment.
**Aims & Methods:** Fifty FD patients were randomized blindly to receive famotidine or placebo with acotiamide for four weeks. Efficacy was assessed by an overall treatment effect (OTE) every two weeks, based on weekly changes of individual total, PDS and EPS symptom scores, and epigastralgia-related, or epigastric fullness-related, impairment of quality of life (QOL).
**Results:** From the OTE assessment, patients who felt affected by treatment comprised 30.4% (39.1%) and 16.7% (45.8%) of famotidine and placebo groups, respectively, after two (four) weeks of treatment, with no significant difference between famotidine and placebo groups. Total individual symptom scores after four weeks' treatment were significantly decreased compared with pretreatment scores for famotidine and placebo groups. As for QOL impairment, a significant improvement was observed between pre- and post-treatments for famotidine and placebo groups, but was not observed between groups. Patients with markedly decreased ( > 50%) EPS symptom scores after two week treatments were significantly greater for the famotidine (57%) than the placebo (24%) group ($P = 0.004$).
**Conclusion:** Famotidine plus acotiamide may be effective in improving EPS symptoms at an early stage of treatment for FD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** POEM represents a less invasive alternative, as compared with conventional laparoscopic Heller myotomy, for achalasia patients. It cannot be excluded, however, that the apparently high efficacy of POEM may be hampered by an excessive incidence of post-POEM reflux disease
**Aims & Methods:** Relevant publications in which patients affected by achalasia underwent POEM treatment were identified by PubMed databases for the period 2010–2016. From each study, the outcomes considered were incidence of post-procedure reflux (according to two subcategories: reflux symptoms and endoscopic findings) at follow-up.Since primary studies considered different time ranges, we pre-defined to pool outcomes at early (<12 months) and late (>12 months)) follow-up. Data were analyzed using fixed-effect model and random-effect model. Heterogeneity was assessed using the $I_2$ test. Per-protocol analyses were reported.
**Results:** A total of 35 reports were included, accounting for a total of 2,208 cases with post-POEM follow-up with a median of 9 months(range 2–44). Regarding incidence of post-POEM reflux symptoms meta-analysis yields an overall pooled rate of 22.1% (95% CIs: 19.2–25.2] with significant heterogeneity($I^2$=54.5% $p < 0.001$). The short and long-term outcome was 20.8% [random-effect pooled estimate,95%CIs:17.0–25.2%] and 23.8% [random-effect pooled estimate,95% CIs: 20.2–26.2%] respectively. Significant intra-group heterogeneity was observed for short-time incidence ($I^2 = 59.6\%$;$p < 0.00$) while low heterogeneity was found for the long-term outcome($I^2 = 34.2\%$,$p = 0.1445$). However no inter-group heterogeneity was noted ($p = 0.313$),supporting the pooling of all studies into one pooled measure. According to meta-regression analysis, duration of follow-up(<12 months vs >12 months) was not associated with reflux symptoms ($p = 0.111$). However the geographical location where the study was performed (Europe/USA vs Asia) affected the overall outcome. The chance of being symptomatic over time was greater in studies performed in Europe/USA than that in studies performed in Asia (ORs, 1.66;95%CIs 1.26–2.18;$p < 0.001$). The Egger test was not significant for publication bias (regression coefficient, 0.40;$p = 0.561$). The overall pooled rate of all endoscopic findings at the follow-up was 36.6% [95% CIs:26.6–48.0%]. Differences between short term and long term outcome were not statistically significant($p = 0.837$). Although there was significant heterogeneity across the trials $I^2 = 85\%$;$p < .001$, a sensitivity analysis suggested that the data were not affected by the sequential exclusion of any particular trial from the pooled analysis. When restricting analysis to esophagitis of grade C or D, the overall post-procedure rate was 3.7% [95%CIs: 2.6–4.9%]. Low heterogeneity was found for this outcome [$I^2 = 31.3\%$[0%; 62.3%];$p = 0.11$]. The Egger test was not significant for publication bias [$p = 0.4217$]].
**Conclusion:** Incidence of reflux-related symptoms or endoscopic findings is quite frequent after POEM, occurring in 1 every 5 and 3 patients, respectively. However, occurrence of severe post-POEM esophagitis is quite rare, reassuring on the overall safety of the procedure.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1543 ESOPHAGEAL BASELINE IMPEDANCE AS A MARKER OF PATHOLOGICAL GASTROESOPHAGEAL REFLUX IN CHILDREN

**Ł. Cichy**[1], K. Fyderek[2]

**Introduction:** It is believed that the low esophageal baseline impedance (BI) may reflect a compromised integrity of the esophageal mucosa and its increased sensitivity to hydrochloric acid.
**Aims & Methods:** The aim of the study was to analyze the esophageal baseline impedance and its correlation with the classical pH-metry parameters as a markers of pathological gastroesophageal reflux (GER) diagnosed based on the examination of 24-hour esophageal pH-impedance monitoring (MII-pH). Twenty-four-hour pH-impedance monitoring was performed in 77 children with suspected gastroesophageal reflux (42 boys, aged 5.4–17.9, average 11.4

years). Based on the results of the MII-pH study (the total duration of reflux episodes ≥ 1.4%) pathological GER was found in 24 children. Taking into account the pH-metry parameters GER patients were divided into two subgroups: group A - acidic GER (fT pH < 4 above 4.2%) (n = 14) and group B - weakly acidic GER (fT pH < 4 under 4.2%) (n = 10). The remaining patients – group C (n = 53) did not show the characteristics of patological GER. BI measurements were obtained in the distal esophagus in a continuous 6-hour period between 11:00 pm and 5:00 am during sleep. The results were compared between the groups and correlated with the classical pH-metry parameters (fT pH < 4 - total, upright and supine, the number of episodes > 5 min., duration of the longest episode and the total number of reflux episodes).
**Results:** The lowest esophageal baseline impedance has been shown in group A (median 1243 Ω), intermediate in group B (median 2184 Ω), the highest in group C (median 3081 Ω). Statistically significant differences of BI were found between groups ($X^2 = 14.97$, $p = 0.0006$), especially between groups A and C ($p = 0.000001$), and B and C ($p = 0.0079$). Regarding the whole studied group a statistically significant negative correlation were found between the BI and all analyzed pH-metry parameters ($r = -0.3$ up to $-0.55$; $p = 0.007$ up to $p = 0.0000$), whereas in the subgroups such relationship was only observed between the total number of reflux episodes in group B ($r = -0.75$; $p = 0.01$) and the fT pH < 4 above 4.2% in the supine position in group A ($r = -0.55$; $p = 0.03$).
**Conclusion:** Analysis of the esophageal baseline impedance may be an additional, useful parameter in the diagnosis of pathological gastroesophageal reflux in children.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** High-resolution manometry (HRM) provides information on esophagogastric junction (EGJ) morphology, being able to distinguish whether the lower esophageal sphincter (LES) and crural diaphragm (CD) are superimposed or separated. Actually, three different subtypes can be described by means of HRM, and it was recently demonstrated that increasing separation between LES and CD could cause a gradual and significant increase of reflux. Type I morphology is the group with the lowest incidence of a positive impedance-pH test. However, this latter type also includes in its definition the presence of LES-CD axial separation up to 1 cm.
**Aims & Methods:** The aim of this study was to verify if splitting the EGJ Type I into two sub-types could better correlate with a positive impedance-pH test in patients with reflux symptoms. Consecutive patients with heartburn and/or regurgitation and a recent endoscopic assessment were enrolled. All patients underwent HRM to assess the EGJ and 10 single water swallows to evaluate the esophageal peristalsis and EGJ function. The tracings were analyzed and each EGJ was classified based on the Chicago Classification (CC) 3.0. EGJ Type I was further divided into Type IA, a complete overlap of LES and CD, and Type IB, a minimal separation, with LES located from the upper border of CD (in correspondence of pressure inversion point, 0.0 cm) to 1 cm above. The patients then underwent impedance-pH testing off-therapy. We measured the esophageal acid exposure time (AET), number of total impedance-detected reflux episodes and symptom association analysis using symptom association probability (SAP + if ≥95%) and symptom index (SI+ if ≥50%).
**Results:** We enrolled 168 [75M/93F; mean age 47 (18–81)] consecutive patients and identified 101 (60.1%) patients with Type I EGJ, 37 (22%) with Type II EGJ and 30 (17.9%) with Type III EGJ. Patients with Type III EGJ had an higher median number of reflux episodes, a greater mean AET and had more frequently a positive symptoms association compared to patients with Type II and Type I EGJ (Table 1). Overall, Type I subjects showed a positive MII-pH in 45.5% of cases, with the lowest value of number of reflux episodes, AET and positive symptom association. Using the sub-classification, we identified 54 (53.6%) Type IA and 47 (46.5%) Type IB subjects. Type IB had a higher number of reflux episodes (42 vs. 28, $p < 0.03$), a greater mean AET (4.7 vs. 2.9, $p < 0.05$) and a greater positive symptom association (54% vs. 26%, $p < 0.02$) compared to Type IA. Type IB morphology had a more frequent probability to show a positive MII-pH than Type IA (70.2% vs. 30%, $p < 0.001$).
**Conclusion:** With increasing separation between the LES and the CD patients had a gradually and significantly increase of reflux episodes and esophageal acid exposure. The sub-classification of EGJ Type I can be useful to better estimate an abnormal impedance-pH testing in GERD patients and it supports the role of the intra-abdominal LES segment in preventing reflux.

### P1545 EXTENDED BRAVO STUDIES (>48 HRS) OFFER AN ADDITIONAL DIAGNOSTIC YIELD OF GASTRO-OESOPHAGEAL REFLUX DISEASE (GORD) IN PATIENTS WITH NORMAL MULTICHANNEL INTRALUMINAL IMPEDANCE-PH (MII-PH) STUDIES

**Contact E-mail Address:** tzechris@gmail.com

**Introduction:** MII-pH catheter studies measure both acid and non-acid reflux and are considered by some to be the gold standard in the diagnosis of GORD. Wireless pH capsule (Bravo) may increase the diagnostic yield of standard 24 hr catheter-based studies with prolonged monitoring by overcoming the limitation of day-to-day reflux variability and patients are able to perform activities of daily living without the discomfort of the nasal catheter.
**Aims & Methods:** This study aims to assess the additional diagnostic yield of extended Bravo recordings (up to 96 hours) in patients with negative 24 hr MII-pH results. A total of 44 patients with typical GORD symptoms but negative 24 hr MII-pH studies off proton pump inhibitor(PPI) were referred for Bravo capsule studies. Bravo studies were performed off PPI over an extended period beyond 48 hrs (up to 96 hrs). Bravo cases positive for AET were analysed using the Bravo 'Worst Day Analysis' (WDA) and 'Average Day Analysis' (ADA). Reference values for MII-pH and Bravo equivalent were adopted from internationally established studies (Table 1). Subgroup analyses were subsequently made on cohorts whose MII-pH showed normal AET with (A) normal number of total reflux events (TRE), (B) normal number of non-acid reflux (NAR) events and (C) increased number of NAR events. Subgroups (B) and (C) have normal number of acid reflux events. Statistical analysis was performed using SPSS V20.
Results:
Our study group (male = 14, female = 30) with a mean age of 48 years, successfully completed Bravo studies up to 96 hours in 77.3% and beyond 48 hours in 97.7%. Using the WDA and ADA respectively, Bravo (AET cut-off > 4.2%) captured an additional 59.1% and 43.2% of patients with increased AET ($p < 0.001$) in cases with normal AET on MII-pH. In MII-pH subgroups (A), (B) and (C), Bravo WDA was able to reveal an additional positive AET of 61.8%($p < 0.001$), 60.9%($p < 0.001$) and 50.0%($p = 0.016$) respectively compared to MII-pH while Bravo ADA showed a similar albeit smaller additional yield of 44.1% ($p < 0.001$), 43.5% ($p < 0.002$) and 35.7% (not significant). Results were similar using other internationally published Bravo AET limits of > 4.4% and > 5.3% (Table1). Inclusion of symptom reflux association in Bravo cases with increased AET also showed additional diagnostic yield over MII-pH ranging from 42.9–47.7% ($p \leq 0.031$) across all subgroups.
**Conclusion:** Extended Bravo studies managed to procure a diagnosis of GORD in more than half of cases with an initial normal MII-pH but persistent symptoms. Half of the patients with increased NAR events on MII-pH also showed positive acid reflux on prolonged testing using Bravo. This additional yield has the potential to alter diagnosis from functional heartburn/hypersensitive esophagus to GORD in difficult cases and affect management by intensifying acid suppression therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Aetiology of gastro-esophageal reflux disease (GERD) is multifactorial, but incompetence of the esophagogastric junction (EGJ) appears to be of crucial importance. Established manometric metrics for assessment of EGJ contractility and barrier function are sub-optimal, potentially because they are based on a very brief (up to 30 s), not necessarily representative section of the manometric investigation.

**Aims & Methods:** This prospective, case-control study aimed to test the performance of a novel, high-resolution manometry (HRM) parameter reflecting EGJ function over a prolonged period of time in the assessment of patients with suspected GERD.Patients with reflux symptoms and healthy controls (HC) underwent HRM with ten water swallows and 24-hour pH ± impedance measurements. EGJ morphology [1], lower esophageal sphincter pressure integral (LES-PI) [2], EGJ-contractile integral (EGJ-CI) [3] were compared with total-EGJ-CI, a novel parameter summarizing EGJ contractility during the entire HRM protocol (~ 5 min). Interaction with peristaltic function assessed by distal contractile integral (DCI) was evaluated. Esophageal acid exposure ≥ 4.2%/24 h (A-Reflux-pos) or ≥ 73 reflux episodes in 24 h (V-Reflux-pos) were considered pathological.

**Results:** 65 HC and 452 patients completed HRM, 380 (84%) patients underwent ambulatory reflux-monitoring. LES-PI, EGJ-CI and total-EGJ-CI correlated with EGJ-morphology subtypes and mean DCI (all $P < .00001$). Only total-EGJ-CI was consistently lower in A-Reflux-pos and V-Reflux-pos subjects compared with HC and patients without GERD. Total-EGJ-CI was also the single best parameter for prediction of pathological reflux (optimal cut-off 47 mmHg*cm, AUC 0.746, $P < .0001$). This cut-off value, approximately 1 SD below the mean normal value, showed modest sensitivity 54% and PPV 46%, but good specificity 85% and NPV 89% for GERD diagnosis.

**Table 1:** HRM-Parameters in HC and subgroups of patients

| | HC (n = 64) | A-reflux-neg (n = 116) | A-reflux-pos (n = 122) | V-reflux-neg (n = 114) | V-reflux-pos (n = 28) |
|---|---|---|---|---|---|
| **LES-PI mmHg*cm*s** | 105 [31–185] | 87 [27–245] | 62*° [7–157] | 140 [59–273] | 72° [15–175] |
| **EGJ-CI mmHg*cm** | 63 [48–86] | 61 [35–86] | 49** [25–71] | 69 [47–87] | 46*°° [31–65] |
| **total-EGJ-CI mmH*cm** | 63 [51–78] | 62 [42–85] | 46**°° [24–68] | 68 [56–85] | 47**°° [38–64] |

Data are given as median [IQR], p-values are corrected for multiple comparisons. *$p < 0.05$ vs HC, **$p < 0.01$ vs HC, ° $p < 0.05$ vs reflux-negative, °° $p < 0.01$ vs. reflux-negative

**Conclusion:** Total-EGJ-CI, a new metric that summarizes EGJ contractility over time, allows an improved assessment of EGJ-barrier function. Pathological reflux is unlikely if this metric is within the upper two-thirds of the normal range. These findings underline the crucial importance of EGJ contractility for barrier function and reflux protection.

**Introduction:** The diagnosis of laryngopharyngeal reflux (LPR) is currently based on a combination of the patient history with laryngoscopic or ambulatory pH and intraluminal impedance (MII-pH); however, none of these findings alone is specific for the diagnosis of LPR. We aimed to compare the baseline characteristics and esophageal baseline impedance (BI) values between patients with and without LPR symptoms.

**Aims & Methods:** We retrospectively analyzed data from the patients with LPR as study group and nonerosive reflux disease (NERD) patients without LPR as controls. All patients who performed esophagogastro-duodenoscopy, esophageal manometry and MII-pH were accepted for the analysis. Patients with a history of endoscopically documented hiatal hernia (> 2 cm), erosive esophagitis, Barrett esophagus, history of manometrically documented esophageal motility disorders, other ENT pathologies were excluded from analysis. All MII-pH parameters and BI were analyzed from six levels (3,5,7,9,15 and 17 cm above LES). We accepted proximal BI as the mean of 15 (Z2) and 17 (Z1) cm above Lower esophageal sphincter (LES) and distal BI as the mean of 3 (Z6) and 5 (Z5) cm above LES. Additionally, to determine the exposure levels of different esophageal segments, we analyzed the ratio of BI measurements between the proximal and distal segments of esophagus as the proximal to distal ratio. In addition to MII-pH parameters, we compared the proximal BI, distal BI and Proximal to distal ratio values between patients with LPR and patients without LPR.

**Results:** 123 patients with LPR and 49 NERD patients (controls) were included in this study. All MII-pH findings were not different between groups (Table 1). However, BI analysis showed that patients with LPR symptoms had significantly lower proximal BI values ($1997 \pm 51$vs $2245 \pm 109$, $p < 0.05$) and proximal-to-distal ratio ($1.28 \pm 0.05$ vs $1.53 \pm 0.09$, $p < 0.05$) than the control group (Table 1). But, distal BI was not different between groups.

**Table 1:** The multichannel intraluminal impedance and pH monitorization and Baseline impedance analysis of patients with and without LPR. The number of reflux episodes and amount of acid reflux were lower but not significant in patients with LPR symptoms. However, the proximal BI and Proximal to diatal ratio were significantly lower in patients with LPR (Data are expressed as Mean ± SEM, *$p < 0.05$,**$p < 0.01$. Proximal BI: Mean BI of 15 and 17 cm above LES; Distal BI: Mean BI of 3 and 5 cm of LES; Proximal to distal ratio: Proximal BI/Distal BI)

| | Patients with LPR Symptoms (n = 123) | Patients without LPR Symptoms (n = 49) |
|---|---|---|
| Acid Exposure time (%) | 6.8 ± 1.05 | 6.1 ± 0.81 |
| Total reflux Episodes (n) | 44.4 ± 2.4 | 52.0 ± 3.4 |
| Acid Reflux (n) | 28 ± 2 | 33.6 ± 2.6 |
| Weak/Non-acid reflux | 15.7 ± 1.3 | 18.6 ± 2.06 |
| Proximal Reflux rate (%) | 33.4 ± 1.8 | 33.8 ± 3.7 |
| Proximal BI (Mean Z1 + Z2) | 1997 ± 51* | 2245 ± 109 |
| Distal BI (Mean Z5 + Z6) | 1809 ± 64 | 1666 ± 111 |
| Proximal to distal ratio | 1.28 ± 0.05** | 1.53 ± 0.09 |

**Conclusion:** LPR represents one of the most difficult disorders on the GERD spectrum, both in terms of diagnosis and treatment. There are currently no established diagnostic criteria, and a strong need. We found that patients with pathologic LPR symptom scores have lower proximal BI levels and lower proximal-to-distal ratios, which may reflect the proximal mucosal noxious effect of the refluxate. These results may indicate that LPR symptoms may be due to chronic acid exposure in the proximal segments of esophagus, and the proximal-to-distal ratio may be used as a new metric for diagnosis. Prospective studies are needed to confirm or refute this metric.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1548 SHOULD MEALS BE BLOCKED DURING AMBULATORY PH MONITORING?

**E. Athanasakos**[1], S. Harrington[1], L. Neilan[1], A. Raeburn[1], N. Zarate-Lopez[1], A. Emmanuel[1], R. Sweis[2]

**Introduction:** The pH sensor cannot differentiate retrograde from anterograde bolus movement. Physiologists often block meals in pH studies to reduce the artefact of acid-containing food/fluids; however there is no clear evidence with regards to the appropriateness of this practice. The aim of this study was to compare results of ambulatory pH monitoring without and with meals blocked in patients being investigated for reflux symptoms.
**Aims & Methods:** Standard pH parameters were compared without and with meals blocked in consecutive patients presenting to University College London Hospital Oesophageal Unit, a tertiary referral centre. T-test was used for quantitative and chi square for qualitative variables. Results are presented as mean-standard deviation(SD)
**Results:** pH studies for 99 patients with reflux-like symptoms were collected prospectively over 3 months. Under 17 hour recordings ($n=2$) or studies ON acid-reducing therapy ($n=6$) were excluded. Mean age of the 91 remaining patients (M31:F60) was $50\pm15$ years. Time spent without and with meals blocked was $1388\pm100$ and $1243\pm114$ minutes respectively ($p<0.001$); $145\pm111$ min difference. There was no difference in the quantitative or qualitative Total reflux (% time pH < 4; TR), Upright reflux (UR) or Supine Reflux (SR) when analysed without and with meals excluded.(Table) At individual level, meal exclusion changed TR/UR/SR to become negative in 4 and positive in 2 patients; average 5% (range 2.5–23 min) of the mealtime was taken up swallowing acid-containing products. Food diary occasionally provided guidance, although quality of self-reports was widely variable.

| | Meal Included | Meal Excluded | p | # positive (meal included) | # positive (meal excluded) | p |
|---|---|---|---|---|---|---|
| Total Reflux | 5.95 (7.05)% | 6.09 (7.73)% | 0.461 | 42 | 41 | 1.000 |
| Upright Reflux | 6.00 (6.28)% | 6.38 (6.87)% | 0.382 | 33 | 32 | 1.000 |
| Supine Reflux | 5.91 (11.58)% | 5.85 (11.61)% | 0.486 | 44 | 43 | 1.000 |

There was no difference in qualitative ($p=0.538$) or quantitative ($p=0.338$) Symptom Index (SI) when meals were not blocked (12 positive; mean $16.9\pm22.6\%$) compared to when meals were blcked (16 positive; mean $18.4\pm25.4\%$). Also there was no difference in any pH parameters between the two groups with all simptoms pooled, or with typical (heartburn, regurgitation, chest pain; $n=59$) and atypical symptoms (laryngopharyngeal reflux, cough, belch, dysphagia; $n=33$) analysed separately ($p=$ NS for all). Furthermore there was no difference in any pH parameter when results were analysed with ($n=43$) or without ($n=48$) a hiatus hernia ($p=$ NS for all).
**Conclusion:** In 93% of patients, routine blocking of meals had no impact on the final report. In a small minority, the artefact of swallowing acidic products as well as shortening of the 24 hour study to exclude meals (average ≥2 hours) can also change results from positive to negative and vice versa.

**Introduction:** Barrett's Esophagus (BE) is a metaplastic and precancerous condition. It is induced by bile and acid reflux and defined by the presence of intestinal-type tissue in the esophagus. The morphology of this tissue resembles a posterior phenotype, as observed in the colon. Identifying the cause of this positional misspecification can lead to a better understanding of BE pathophysiology. HOX genes encode master regulators of anterior to posterior specification in organogenesis and tissue homeostasis. The 3' to 5' sequence of HOX genes corresponds to the sequence in which they act along the anterior to posterior axes of the body. This property is termed collinearity and links clustering to function. Acquired deregulation of HOX genes during adulthood is linked to carcinogenesis. However, HOX collinearity has not been thoroughly investigated in the human gut, nor in BE.
**Aims & Methods:** The aim of this study was to characterize HOX expression along the gut and in BE in order to compare expression patterns. Furthermore, potential causes and consequences of HOX gene aberrations were investigated. Expression of 39 HOX genes was determined by RT-qPCR in tissues taken from 9 locations along the gut of 3 control patients, in squamous and BE tissues of 13 BE patients, and in esophageal adenocarcinoma (EAC) biopsies of 9 patients. Expression of 11 HOXA cluster genes were determined in columnar lined esophagus without intestinal metaplasia, and in intestinal metaplasia of the stomach. Squamous esophageal cell lines HET-1 A and EPC2-hTERT were exposed to acid and bile to simulate gastro esophageal reflux disease (GERD). HOXA13 RNA-ISH was performed and HOXA13 was transduced and overexpressed in EPC2-hTERT.
**Results:** HOX cluster gene expression differed significantly along the gut. In general, HOX gene expression was highest in the colon with exception of the HOXC cluster expression. HOXA cluster gene expression was the highest compared to other clusters. The most posterior highly expressed HOX cluster members in the esophagus of the control patients were A7, B7, C8, and D8 and in the rectum A13, B13, C10, and D13. BE tissue was characterized by upregulation of HOXA10, 11, and 13, B3, 6, 7, 8, 9, and 13, and C6, 9, 10, and 11. Downregulated in BE were HOXA1, 4, and 7. For clusters A and B, the HOX pattern observed in BE was similar to that seen in colon epithelium. The HOXA cluster genes, determined in columnar lined esophagus without intestinal metaplasia, i.e. without goblet cells, showed similar aberrations to those found in BE with goblet cells. In fact, aberrant expression of HOXA cluster genes could be detected in the squamous epithelium taken 5 cm above the z-line of BE patients, when compared with control patients. Furthermore, the aberrant HOX gene expression pattern found in BE, remains present in its sequela EAC. Intestinal metaplasia of the stomach has a similar HOX gene expression when compared to intestinal metaplasia of the esophagus. HOXA and B cluster expression patterns adhere to the collinear property and have similar expression patterns in BE when compared to the colon. Therefore, the posterior members of these clusters could well be responsible for the posterior morphology observed in BE. HOXA13, highly overexpressed in BE and intestinal metaplasia of the stomach, was chosen for further studies. HOXA13 mRNA was visualized in the epithelial cells of BE tissue, its sequela EAC, and intestinal metaplasia of the stomach. Exposure of two esophageal cell lines to acid and bile led to up regulation of HOXA13. Furthermore, induced overexpression of HOXA13 in turn upregulated expression of KRT7 and COX2, both involved in BE.
**Conclusion:** HOX gene collinearity is present along the adult human gut. HOX gene rearrangements are found in BE and intestinal metaplasia of the stomach, both resulting in a similar colon like HOX expression pattern. Aberrant HOX expression occurs early in the pathogenesis of BE and remains present in its sequela EAC. Acid and bile exposure leads to upregulation of the posterior HOXA13 in an in vitro GERD model. Furthermore, HOXA13 overexpression induces BE specific gene products.

**Introduction:** Low distal mucosal baseline impedance (BI) can be considered a proxy of damaged mucosal integrity [1] and has been associated with acid hypersensitivity [1,2]. Furthermore, BI is known to be low in Barrett's oesophagus [3]. However, the influence of epithelium type and distance from the lower oesophageal sphincter (LOS) on mucosal BI are less well studied.
**Aims & Methods:** We aimed to characterize distal mucosal BI in Barrett's oesophagus in relation to epithelium type (columnar vs. squamous) and distance from the LOS. Twenty-six patients with Barrett's oesophagus (mean age: $64.2 \pm 7.3$ years) were compared with 12 healthy controls (mean age: $54.9 \pm 10.7$ years). Barrett segment length was measured endoscopically. A pH-impedance probe with six impedance channels and one pH channel was placed in the oesophagus. After adjustment to the probe, mucosal BI 17, 15, 9, 7, 5, and 3 cm above the LOS was measured for five minutes. This measurement was followed by a standard ambulatory pH measurement 5 cm above the LOS. Based on endoscopy findings, BI data for squamous and columnar epithelium in patients were analysed separately, while data from channels overlapping both types of epithelium were excluded.
**Results:** Patients had a mean Barrett segment length of $5.3 \pm 4.2$ cm circular and $6.6 \pm 4.0$ cm maximal. At 5 cm above the LOS, BI in squamous epithelium was 33% lower in patients with Barrett's oesophagus ($n = 7$) than in controls ($P = 0.001$). Comparing epithelium types in patients, BI was 80% higher in patients having squamous ($n = 7$) compared with those having columnar epithelium ($n = 15$) at 5 cm above the LOS ($P < 0.001$). In patients, BI overall decreased linearly with shorter distance from the LOS ($P < 0.001$). This was also true in separate squamous ($P < 0.001$) or columnar epithelium in patients ($P < 0.001$), but not in controls ($P = 0.6$). In patients, BI decreased linearly with increasing maximal Barrett segment length ($P < 0.001$), which was also true in separate columnar epithelium ($P = 0.003$). This correlation was not present in separate squamous epithelium in patients ($P = 0.6$). Ambulatory acid exposure was greater in patients than in controls ($P = 0.04$). Overall, mucosal BI decreased with greater acid exposure ($P = 0.009$).
**Conclusion:** Distal squamous mucosal BI in patients with Barrett's oesophagus was lower compared with columnar mucosa in patients and compared with healthy controls. Furthermore, BI generally decreased with shorter distance from the LOS and with greater acid exposure. Thus, we suggest that greater distal oesophageal acid exposure in Barrett's oesophagus impairs mucosal integrity as measured by a lower BI. This mucosal damage may partly explain the acid hypersensitivity reported in patients with Barrett's oesophagus [2].
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Barrett's esophagus (BE) is the precursor lesion of esophageal adenocarcinoma (EAC). None of the current clinical or endoscopic criteria are able to accurately predict which patients will progress from BE to EAC. Immunohistochemical (IHC) biomarkers can be applied to intact histological morphology, and are relatively easy applicable in daily practice.
**Aims & Methods:** This study aimed to provide a systematic review and meta-analyses of all published studies on IHC biomarkers as predictors of neoplastic progression in BE. Thereto, MEDLINE, EMBASE, Web of Science, CENTRAL, Pubmed publisher, and Google scholar were searched. All studies on IHC biomarkers in BE progression were included. Two authors independently extracted data. An inverse variance random-effect model was used. Meta-analyses were performed for biomarkers studied more than once. Pooled estimates of effect were calculated and results investigated for statistical heterogeneity by the I-squared test ($I^2$). If enough studies were present, sensitivity analyses and sub-analyses were performed. The sub-analyses were performed to investigate whether IHC biomarkers had a predictive value independent of the presence of LGD.
**Results:** IHC biomarkers studied more than once were p53, Cyclin A, Cyclin D, and aspergillus oryzae lectin (AOL). The IHC biomarker investigated most frequently was p53, it was included in 12 studies, which contained 2023 patients, of which 372 cases. In the meta-analyses aberrant p53 IHC staining was significantly associated with the risk of neoplastic progression in BE patients with an OR of 4.15 (95% CI 1.96 to 8.81). A sub-analysis stratifying for the presence or absence of LGD showed that aberrant p53 IHC staining was associated with neoplastic progression with an OR of 4.13 (95% CI 2.36 to 7.21). This association was confirmed for both non-dysplastic BE, and BE with low grade dysplasia individually. Of the other IHC biomarkers Cyclin A (OR 1.54, 95% CI 0.62 to 3.79), Cyclin D (OR 1.87, 95% CI 0.17 to 20.63), and AOL, only AOL appeared to be able to predict neoplastic progression in BE patients with an OR of 3.04 (95% CI 2.05 to 4.49).

Overview of meta-analyses performed

| Analysis | Studies | Cases | Controls | OR | 95% CI | $I^2$ |
|---|---|---|---|---|---|---|
| p53 (main) | 12 | 372 | 1651 | 6.67 | 3.64–12.22 | 55% |
| p53 (excluded small studies) | 6 | 323 | 1287 | 4.40 | 2.30–8.40 | 63% |
| p53 (also excluded unadjusted ORs) | 5 | 289 | 1124 | 4.15 | 1.96–8.81 | 68% |
| p53 (also excluded abstracts) | 4 | 149 | 985 | 5.23 | 2.09–13.03 | 64% |
| p53 (only ORs stratified for histology) | 7 | 316 | 1221 | 4.13 | 2.36–7.21 | 41% |
| p53 (only non-dysplastic BE) | 2 | 61 | 659 | 6.12 | 2.99–12.52 | 0% |
| p53 (only BE with LGD) | 4 | 37 | 145 | 8.64 | 3.62–20.62 | 0% |
| Cyclin A | 3 | 235 | 415 | 1.54 | 0.62–3.79 | 71% |
| Cyclin D | 2 | 46 | 212 | 1.87 | 0.17–20.63 | 87% |
| AOL | 2 | 204 | 369 | 3.04 | 1.74–4.49 | 0% |

**Conclusion:** In conclusion, p53 is the most studied IHC biomarker for neoplastic progression in patients with BE. Aberrant p53 IHC is significantly associated with an increased risk of neoplastic progression in BE patients, which appears to be independent of dysplasia grade.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Radiofrequency ablation (RFA), combined with endoscopic mucosal resection (EMR) of visible lesions, can be used as a primary treatment for low-grade dysplasia (LGD), high-grade dysplasia (HGD) and early adenocarcinoma (EAC) in Barrett's esophagus (BE). Success rates for long-term complete remission of intestinal metaplasia (CR-IM) outside clinical trials have been reported to be 62%.

**Aims & Methods:** In this study we wanted to assess possible risk factors for recurrence of IM after CR-IM is achieved. Between February 2008 and August 2015, data from 7 centers performing RFA were prospectively collected in the Belgian RFA registry. CR-IM was defined as biopsy-proven absence of intestinal metaplasia (IM) and dysplasia with endoscopic remission of BE. Follow-up (FU) was calculated from the time CR-IM was achieved. A univariate analysis was performed to assess and detect possible risk factors for recurrent disease in patients with a minimum of 6 months FU. We assessed demographic, disease related and procedure related factors.

**Results:** 279 patients (mean age 65; 84.5% men) were included in the Belgian RFA registry. 60% received EMR prior to RFA. 44 patients were still under treatment at the time of analysis, 18 discontinued treatment and treatment failed in 23 patients. CR-IM was achieved in 194 patients (ITT: 82.5%, PP: 89.4%). 185 entered FU (median FU time: 735 days). Recurrent disease with biopsy proven intestinal metaplasia under the neo Z-line occurred in 63 patients (mean time to recurrence 445 days + /- 362) and there was sustained remission in 122 patients (ITT: 63%, PP: 66%). Histology of recurrence was IM (38), HGD/adenocarcinoma (17), LGD (7) and unknown (1). 158 patients (mean age 65, 88% men) with a FU of more than six months, were included in the univariate analysis to assess possible risk factors for recurrent disease. No significant association was found between recurrence of disease and sex, age, prior EMR, worst histology before treatment, length of the BE (Prague classification), size of hiatal hernia and number of RFA sessions (see table). As a result, no multivariate analysis could be performed.

**Conclusion:** In this analysis of the multicenter Belgian RFA registry we found sustained CR-IM rate of 66%. We could not identify patient, disease or procedure related risk factors to predict an increased risk for recurrence. Therefore surveillance endoscopy after treatment and ablation of dysplastic Barrett's remains necessary.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1554 DURABILITY OF RADIOFREQUENCY ABLATION IN BARRETT'S OESOPHAGUS WITH DYSPLASIA: A SEVEN-YEAR AUSTRALIAN EXPERIENCE

**Introduction:** Radiofrequency ablation can eradicate dysplasia and intestinal mataplasia in patients with dysplastic Barrett's Oesophagus.

**Aims & Methods:** This prospective cohort study aims at assessing the long-term eradication of dysplasia and intestinal metaplasia, and durability of neosquamous epithelium in patients with dysplastic Barrett's Oesophagus treated with radiofrequency ablation (RFA) in a metropolitan tertiary referral centre. All patients with dysplastic Barrett's Oesophagus treated with RFA from November 2008 to February 2016 were identified. Patients were followed up for a mean time of 3.3 years. Follow up of eradication of dysplasia and intestinal metaplasia was measured from the first RFA treatment session. Durability of neosquamous epithelium was measured from the first documentation of dysplasia or intestinal metaplasia eradication.

**Results:** RFA treatment was used in 153 patients with dysplastic Barrett's Oesophagus. Of these patients, 134 (88%) were male with a mean age of 72. At the time of referral, 19 (12%) patients had early cancer (EC), 73 (48%) patients had high grade dysplasia (HGD) and 61 (40%) patients had low grade dysplasia (LGD). One hundred and twelve (73%) patients also underwent endoscopic mucosal resection (EMR). After 1 year, 102 of 116 (88%) patients had complete eradication of all dysplasia (CE-D) and 68 of 116 (59%) had complete eradication of intestinal metaplasia (CE-IM). After 2 years, 71 of 79 (90%) patients had CE-D and 56 of 79 (71%) patients had CE-IM. After 3 years, there was CE-D in 43 of 45 (96%) patients and CE-IM in 35 of 46 (76%) patients. By 4 years, 26 of 26 (100%) patients had CE-D and 20 of 26 (77%) patients had CE-IM. After 5 years, 17 of 17 (100%) had CE-D and 15 of 17 (83%) had CE-IM. Kaplan Meier analysis showed that at 3 years, dysplasia remained eradicated in 88% of patients while intestinal metaplasia remained eradicated in 67% of patients. At 5 years, dysplasia remained eradicated in 84% of patients and intestinal metaplasia remained eradicated in 56% of patients. There were 15 patients with relapse of dysplasia; 8 (53%) patients had recurrence of LGD, 6 (40%) patients with HGD and 1 (7%) patient had recurrence of EC. Thirteen of these 15 (87%) patients had subsequent CE-D with ongoing RFA and EMR. There were no deaths related to relapse of disease. Of the 33 patients with relapse of intestinal metaplasia, 13 (39%) also had recurrence of visible Barrett's on gastroscopy. Twenty-one (68%) patients had subsequent CE-IM with further RFA therapy.

**Conclusion:** Majority of patients with dysplastic Barrett's Oesophagus treated with RFA therapy remain in remission. However, there is still a significant rate of recurrence of dysplasia and intestinal metaplasia. This indicates that long term surveillance of patients with dysplastic Barrett's Oesophagus is mandatory.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1555 MULTIFOCAL NITROUS OXIDE CRYOBALLOON ABLATION WITH OR WITHOUT ENDOSCOPIC MUCOSAL RESECTION (EMR) FOR TREATMENT OF NEOPLASTIC BARRETT'S ESOPHAGUS: PRELIMINARY RESULTS OF A PROSPECTIVE CLINICAL TRIAL IN TREATMENT-NAÏVE AND PREVIOUSLY ABLATED PATIENTS

**Introduction:** Radiofrequency ablation (RFA) is highly effective for treatment of BE. However, post-ablation pain, strictures, and bleeding can develop. Endoscopic cryotherapy (Cryo) can successfully eradicate neoplastic BE, including refractory disease, with low stricture rate and no bleeding. A new portable battery-powered system (cryoballoon focal ablation system (CbFAS)(1) with a small hand-held device converts liquid nitrous oxide to gas resulting in an ice patch of approximately 2 $cm^2$. The gas is contained within a low pressure compliant through-the-scope balloon making contact with the mucosa, obviating the need for intraluminal suction.

**Aims & Methods:** We aimed to determine the safety and efficacy of nitrous oxide Cryo using a CbFAS for eradication of neoplastic Barrett's esophagus. In a single center, prospective single-arm clinical trial, consecutive BE patients with confirmed neoplasia (LGD, HGD, and/or T1aECA) without prior therapy (''treatment-naïve'') or persistent/recurrent disease despite prior therapies (''previously ablated'') were treated with CbFAS at dose 10 seconds of ice per site. EMR was performed prior to Cryo for lesions. Ablations were delivered from distal to proximal, beginning at the gastric cardia/GE junction, to include all visible BE with WLE-HRE and NBI, followed by treatment of skip areas. Treatments were repeated every 10–12 weeks until eradication of intestinal metaplasia (IM). Patients were included if there was biopsy-proven BE > 1 cm (Prague M1 or greater), no limit on length. Maximum number of ablations for each treatment session was 24.

**Results:** 40 patients (15 with prior ablation) with low-grade dysplasia (LGD n = 13), high-grade dysplasia (HGD n = 24) or intramucosal cancer (n = 3) have had 83 treatments (Table 1). EMR rate was 35%. Median number of cryoablations was 9.8 per session (IQR 6–21). To date, all procedures were successfully completed (all targeted sites ablated) except for 3 with balloon migrations across strictures leading to incomplete ablation, subsequently successful. Mean ablation and procedure times were 18.3 (IQR 13–31) and 30.5 (24–44) minutes, respectively. 24 enrolled patients were evaluable with at least 1 negative set of biopsies from the GEJ to prior Z line level. The remaining 16 patients have completed treatment and are awaiting follow-up biopsy procedures. Median number of ablation procedures was 2 (IQR 1–3, maximum 4). Short-term complete response for all dysplasia (CRD) to date is 10/11(90%) of treatment-naïve and 13/13(100%) previously ablated patients. To date, combined with EMR for nodular BE, overall CR-D and CR-IM rates are 23/24(96%) and 23/24(96%), respectively, with no difference by BE length or history of prior ablation. There were 2 minor balloon tears and 1 upper GI bleeding due to ulcers in a patient taking aspirin. Post-ablation pain requiring narcotics was reported in 10/40 (25%), majority post-procedure while in PACU, only 2 (5%) requiring narcotic after day 1. Immediate post-ablation pain score (Likert scale 1–10) was 1.9 (IQR 0–2.5) but decreased 0 by 24 hours (IQR 0–2). 4 patients developed mild dysphagia (1 resolved, 2 inflammatory stenoses dilated at next scheduled follow-up procedure). The one treatment failure was a patient with extensive multifocal nodular intramucosal cancer and HGD in a treatment-naive BE Prague C9M9 who had multiple EMR (total 50% circumferential) and developed high-grade stricture requiring 2 interval dilations and rescue APC. The patient opted to have surgery, results pending. No patient has had a persistent symptomatic stricture, including 10 with a pre-existing post EMR/RFA stricture. No buried BE has been detected.

**Conclusion:** Multifocal nitrous oxide cryoballoon ablation is a promising, safe, and potentially effective endoscopic treatment for primary or rescue therapy of BE-associated neoplasia. Device improvements are ongoing and larger multicenter comparative clinical trials are planned to assess long-term safety and efficacy.

**Disclosure of Interest:** M.I. Canto: This investigator-initiated clinical trial is supported by a research grant from C2 Therapeutics, Inc, California, USA
All other authors have declared no conflicts of interest.

**Introduction:** Endoscopic resection (ER) followed by radiofrequency ablation is advocated as the treatment of choice for management of early Barrett's neoplasia. Endoscopic submucosal dissection (ESD) is an emerging technique for resection of early Barrett's cancers that enables removal of the cancer en bloc and can lead to lower recurrence rates. However, it may be associated with a higher risk of complications including bleeding, perforation and stricture formation.

**Aims & Methods:** The aim of this study was to report safety and efficacy outcomes from a series of 100 patients undergoing ESD for suspected Barrett's cancer. This was a prospective analysis of outcome and follow up data collected from the Barrett's endoscopic resection database in our tertiary centre between 2008–2016. Patients underwent ablation of the residual Barrett's oesophagus only once clear of neoplasia on biopsy after at least 2 follow ups (6–12 months post resection).

**Results:** 100 ESD resections for suspected Barrett's cancers were performed in this time period by a single expert endoscopist (PB). The mean age of this cohort was 72 years with a mean Barrett's circumference (C) of 4 cm and length (M) of 6 cm. The mean length of follow up was 1.7 years. 74% of the lesions were classified as Paris IIA and Is lesions. The mean circumferential extent of resection involved 1/3 of the circumference with an average procedure time of 81 minutes. 67% of the patients in this series had intramucosal cancer and 16% had submucosal cancer on final histology. 11% had high-grade dysplasia and 6% had low-grade dysplasia. The endoscopic prediction of cancer was accurate in 83% of cases.

Outcomes of ESD for Suspected Barrett's Cancer

| | En bloc resection rate | R0 resection for cancer* | Complication rate** | Recurrence of cancer/HGD on endoscopic follow up | Cure rate of neoplasia after further ER |
|---|---|---|---|---|---|
| Number of patients(%) | 91/100 (91%) | 63/83 (75.9%) | 3/100 (3%) | 15/85 (17.6%) | 79/85 (92.9%) |

*R0 resection for cancer = clear of cancer at both horizontal and deep margins
**Complication rate: Bleeding (1%), Perforation (0%), Strictures (2%)

Means comparison testing demonstrated that the size of the lesion was a significant predictor of R1 resection (mean size in R0 group 30.4 mm versus R1 group 39.6 mm, p = 0.02). 85% of the patients were entered into endoscopic follow up and recurrence of cancer or high grade dysplasia was identified in 15 patients. 13/15 (86.7%) underwent further endoscopic resection and are now clear of cancer whilst 2 went on to have radiotherapy in view of poor fitness for surgery. Ultimately, an endoscopic cure was achieved in 79/85 (92.9%) of patients on the endoscopic follow up pathway even prior to being offered ablative therapy.

**Conclusion:** This is the largest reported series of ESD demonstrating its safety and efficacy as a resection technique for suspected Barrett's cancer. 85% of patients in this series successfully avoided more invasive surgery/oesophagectomy. The recurrence rate of Barrett's neoplasia is low following ESD and almost all recurrences were managed successfully with further endoscopic resection. ¾ of patients with Barrett's cancer achieved R0 resection. This was reflected in an even higher overall endoscopic cure rate which further strengthens the case for ESD in Barrett's cancer.

## P1557 SAFETY OF RADIOFREQUENCY ABLATION FOLLOWING ENDOSCOPIC RESECTION IN BARRETT'S NEOPLASIA: DOES RESECTION METHOD MATTER?

**S. Subramaniam**, F.J.Q. Chedgy, K. Kandiah, S. Thayalasekaran, P. Bhandari
*Gastroenterology, Queen Alexandra Hospital, Portsmouth/United Kingdom*

**Contact E-mail Address:** shar811@googlemail.com

**Introduction:** The current standard of treating Barrett's neoplasia is resection of visible lesions followed by ablative therapy to the Barrett's segment. Endoscopic mucosal resection (EMR) is the conventional method of resection although there is growing evidence for the use of endoscopic submucosal dissection (ESD). Radiofrequency ablation (RFA) is a safe and effective ablation technique but carries a risk of complications including bleeding, stricture and perforation. ESD is associated with much deeper submucosal dissection then EMR, resulting in a deeper and thicker scar. This has been a cause for concern whilst performing RFA after ESD and experts have raised the possibility of higher stricture or perforation rates with RFA after ESD.

**Aims & Methods:** Aims: To compare the safety and efficacy of radiofrequency ablation following EMR and ESD and to ascertain if there are any significant differences. Methods: An electronic database (from 2007–2015) of all patients who had endoscopic resections (EMR or ESD) for Barrett's neoplasia followed by RFA was analysed. Data was collected on patient demographics, Barrett's length, lesion size, number of ablations required and follow up period. The

clearance of neoplasia (high grade dysplasia/intramucosal cancer) was also recorded (CE-N) along with procedural complications including bleeding, perforation and strictures.
**Results:** There were 30 patients in the EMR + RFA group (average age 73.1 years) compared to 19 in the ESD + RFA group (average age 74.6 years). Patients received circumferential ablation (HALO 360) or focal ablation (HALO 90/60/Ultra) depending on the extent of residual Barrett's oesophagus post endoscopic resection. Table 1 shows the outcome of RFA following EMR or ESD. ESD was started in our institution later than EMR and that is reflected in lower numbers and shorter follow up in the ESD cohort but it is otherwise a well matched population.

**Table 1:** Outcome of RFA following EMR vs ESD

| | EMR + RFA | ESD + RFA |
|---|---|---|
| Number of patients | 30 | 19 |
| Mean follow up (years) | 4.1 | 1.6 |
| Mean Barrett's length (cm) | 7.4 | 7.1 |
| Mean lesion size (mm) | 20.4 | 26.7 |
| Mean number of ablations | 1.9 | 1.7 |
| CE-Neoplasia | 93.3% | 94.7% |
| Bleeding (n, %) | 0 | 1 (5.3%) |
| Perforation (n, %) | 0 | 0 |
| Stricture (n, %) | 2 (6.7%) | 0 |

**Conclusion:** This is the first UK series reporting on the safety and efficacy of RFA after ESD. RFA following ESD or EMR is equally safe and effective and the endoscopic resection method is not a significant factor when planning ablation therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1558 WHAT IS THE CLINICAL IMPORTANCE OF AN INCIDENTAL IRREGULAR Z LINE? A LONG-TERM FOLLOW- UP STUDY

**D. Itskoviz**, A. Vilkin, I. Zvidi, Y. Niv, R. Dickman
*Gastroenterology, Rabin Medical Center, Petach Tiqva/Israel*

**Contact E-mail Address:** mditskov@gmail.com
**Introduction:** Barrett's esophagus (BE) is a well-known complication of gastro-esophageal reflux disease (GERD). In a previous study, we described a high prevalence of specialized intestinal metaplasia (SIM) in patients with an incidental irregular Z line. However, the clinical importance of SIM, and particularly, the development of BE or dysplasia during long-term follow-up in patients with an incidental irregular Z line is unclear.
**Aims & Methods:** We aimed to evaluate the long-term development of BE, dysplasia and esophageal adenocarcinoma in patients diagnosed with an irregular Z line, with or without SIM, on routine upper endoscopy. Methods: In our previously described cohort, 166 out of 2000 consecutive patients (8%) were diagnosed with an incidental irregular Z line. Of those with irregular Z line, 43% were identified with SIM. In this prospective, continuation study, electronic medical files of all patients who were previously diagnosed with an irregular Z line were re-assessed after a median follow-up of 68 months. Patients with an irregular Z line were divided into two groups: Patients with SIM (positive SIM group) and without SIM (negative SIM group). The prevalence of long-term development of BE, dysplasia and esophageal adenocarcinoma were compared between the groups.
**Results:** In the present study, at least one follow-up upper endoscopy was performed in 102 (61%) patients with an irregular Z line. Of those who were available for follow-up, 50 patients were identified with SIM during their first upper endoscopy (positive SIM group), and 52 patients did not have SIM during their first upper endoscopy (negative SIM group). Barrett's esophagus was evident in 16 positive SIM patients (16/50 [32%]) and in two negative SIM patients (2/52 [4%]), $p < 0.005$. Four (8%) positive SIM patients were found to have BE with low grade dysplasia (three with long segment ( > 3 cm) and one with short segment BE: Both negative SIM patients developed short segment BE without dysplasia ($p < 0.005$). None of the patients who were available for follow-up developed high grade dysplasia, or esophageal adenocarcinoma.

**Table 1:** Long-term follow-up endoscopic and pathologic findings of the available cohort (102 patients) with an incidental irregular Z line

| Number | Positive SIM Group 50 | Negative SIM Group 52 | p-value |
|---|---|---|---|
| Male gender N (%) | 39 (78) | 39 (75) | NS |
| Age (mean ± SD) | 64 ± 11 | 60 ± 15 | NS |
| Barrett's Esophagus (BE) N (%) | 16 (32) | 2 (4) | < 0.005 |
| Low grade dysplasia N (%) | 4 (8) | 0 | < 0.005 |

**Conclusion:** After a median 5 years follow-up, BE and low grade dysplasia were diagnosed more frequently in patients who had a prior irregular Z line with SIM, than in those without SIM.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[5]*Oblikue Consulting S.L., Barcelona/Spain*

**Contact E-mail Address:** jestebanl@yahoo.es
**Introduction:** While there is a strong agreement on how to treat patients diagnosed with Barrett's Oesophagus (BE) and High Grade Dysplasia (HGD) or Early Adenocarcinoma (EAC), the optimum treatment choice for patient diagnosed with Low Grade Dysplasia (LGD) is still widely discussed.
**Aims & Methods:** The objective of this study is to assess the cost-effectiveness of endoscopic treatment for LGD patients compared with standard of care in Spain. A 15-year horizon Markov model was developed to represent the evolution of the disease in 65-year-old patients diagnosed with BE and LGD in Spain. The therapeutic strategies compared were: immediate endoscopic treatment based on radiofrequency ablation (RFA) with endoscopic mucosal resection for visible, nodular areas followed by endoscopic surveillance vs. endoscopic surveillance alone. Patient treated with RFA eradicated dysplasia, both dysplasia and intestinal metaplasia (IM) or none according to recently published evidence by Phoa et al. (2014). The model considered six health states (1. Cured with antecedents – patients without dysplasia and IM or patients cured after surgical intervention; 2. BE without dysplasia – patients without dysplasia but with persistent IM; 3. LDG; 4. HGD; 5. EAC and 6. Death). Transition probabilities and utility values associated to each health state were obtained according to disease natural history from published literature and validated by three local clinical experts. Clinical management patterns and resource use were modelled according to the Spanish clinical practice and were obtained from clinical experts. Unit costs and pharmacologic costs were extracted from Spanish medical cost databases and expressed in euros of 2016. The National Health System perspective was considered, including the following costs: procedures and endoscopic surveillance cost, drug acquisition cost (ex-factory), surgical intervention, follow-up expenses and complications cost (perforation and stricture). An annual 3% discount rate was applied for costs and outcomes. One-way sensitivity analyses was performed to test the robustness of the model and uncertainty around base case parameters.
**Results:** Initiating treatment with RFA reduces the number of EAC progressions and avoids the need for oesophagostomy by 9%. Overall, for 65-year-old LGD patients, endoscopic treatment with RFA compared to endoscopic surveillance increases life expectancy by 0.08 life-years [0.54 Quality-Adjusted Life Years (QALY)] at an incremental cost of €9,346, that would mean an incremental cost-effectiveness ratio of €17,365 per QALY gained. Although cost-effectiveness of endoscopic treatment persisted in most of univariant scenarios, as expected, model outcomes resulted sensitive to the difference in inputs used to model the transition and quality of life of patients with LGD compared to patients with BE and no dysplasia or patients cured with antecedents.
**Conclusion:** The present evaluation indicates that endoscopic treatment with RFA is a cost-effective option compared to endoscopic surveillance only for the treatment of patients diagnosed with BE and LGD in Spain considering a willingness-to-pay threshold of €30,000 per QALY gained.

**Introduction:** Radiofrequency ablation can eradicate dysplasia and intestinal metaplasia in patients with dysplastic Barrett's Oesophagus. However, treatment response may be variable.

**Aims & Methods:** This prospective cohort study aims to determine the factors that affect response to radiofrequency ablation for Barrett's Oesophagus with dysplasia in a tertiary metropolian referral centre. All patients with dysplastic Barrett's Oesophagus treated with regular proton pump inhibitor (PPI) twice a day and with radiofrequency ablation (RFA) from Novbember 2008 to February 2016 were identified. These patients were sorted into two groups according to their response to RFA treatment: Good Responders (GR) (defined as eradication of dysplasia and intestinal metaplasia within 3 or less treatment sessions) and Poor Responders (PR) (defined as patients requiring 4 or more treatment sessions). This was then compared with the patients' age, gender, presence of hiatus hernia, hiatus hernia size, circumferential and maximal length of Barrett's Oesophagus based on Prague classification, grade of dysplasia on histology at referral, and presence of oesophagitis on gastroscopy.

**Results:** Of the 118 patients who have received RFA treatment for dysplastic Barrett's Oesophagus, ninety-seven (82%) patients were classified as Good Responders and 21 (18%) patients were classified as Poor Responders. PR have a longer circumferential length of Barrett's Oesophagus compared to GR (mean length of 8.38 cm vs 3.20 cm, respectively; $p < 0.0001$). PR also had a longer maximal length of Barrett's Oesophagus compared to GR (mean length of 9.71 cm vs 5.22 cm, respectively; $p < 0.0001$). There were a higher number of patients with oesophagitis identified on gastroscopy despite regular PPI therapy in the PR group compared to GR group (8 [40%] vs 7 [10%] respectively; $p = 0.004$). Twenty patients (95%) within the PR group had a hiatus hernia compared to 94 (97%) patients in the GR group, $p = 0.548$. The mean size of hiatus hernias in the PR group and GR group were of 3.61 cm vs 3.09 cm respectively; $p = 0.2068$. PR have a higher proportion of high grade dysplasias and a lower proportion of low grade dysplasias at referral compared to GR (11 [52%] vs 42 [44%], $p = 0.8870$ and 7 [33%] vs 38 [40%]; $p = 0.8870$, respectively). Patients' age and gender did not affect treatment response to RFA.

**Conclusion:** In patients with dysplastic Barrett's Oesophagus, factors such as circumferential and maximal length of Barrett's Oesophagus and presence of oesophagitis on gastroscopy despite regular PPI therapy are associated with poorer response to RFA therapy. Presence of hiatus hernia, hiatus hernia size, grade of dysplasia on histology, age and gender did not affect treatment response to RFA.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1561 LYMPH NODE METASTASIS RISK IN BARRETT'S ADENOCARCINOMA DEPENDING ON THE DEPTH OF TUMOUR INVASION: SHOULD WE ENLARGE THE CURATIVE CRITERIA FOR ENDOSCOPIC RESECTIONS?

**Introduction:** The incidence of oesophageal adenocarcinoma has increased greatly in the western world during the recent decades. However, it is still unclear whether endoscopic treatment can be considered curative for adenocarcinomas invading the upper third of the oesophageal submucosa (sm1).

**Objective:** This multicentre retrospective cohort study aims to assess the risk of lymph node metastasis (LNM) according to the tumour invasion depth through the oesophageal mucosa and submucosa to determine whether endoscopic treatment can be considered curative for early stage adenocarcinoma.

**Methods:** All patients undergoing surgery or endoscopic treatment with curative intent for superficial oesophageal adenocarcinomas (T1a/b) developed on Barrett's oesophagus were included.

**Results:** 201 early stage adenocarcinoma (T1a/b), in 182 patients were included. During the follow up 8 (3.9%) patients developed LNM. The TNM stage of these tumours was: 2 T1m1/2 (2/81; 2.5%), 2 sm1 (2/31: 6.4%), 4 sm2/3 (4/30: 13.3%). The two patients with a T1m1/2 that presented LNM had lymphovascular invasion and a R1 resection respectively. The tumour invasion depths of sm1 patients were 10 µm and 100 µm beyond the muscularis mucosae and both had G3, undifferentiated tumours. Among the G1/G2 tumours without lymphovascular invasion, the risk of LNM was respectively 2.3% (1/43) for m1/m2 lesions, 0% (0/29) for m3 lesions, 0% (0/19) for sm1 lesions, 12.5% (2/16) for sm2/3 lesions

| | Number of lesions | G1/G2 | LNM | Lymphovascular invasion | Risk of LNM |
|---|---|---|---|---|---|
| m1/2 | 81 | 49 (MD: 27) | 2 | 6 | 2.5% |
| m3 | 59 | 34 (MD: 22) | 0 | 0 | 0% |
| sm1 | 31 | 22 (MD: 5) | 2 | 0 | 6.4% |
| sm2/3 | 30 | 19 (MD: 2) | 4 | 7 | 13.3% |

Missing data: MD 21 (10.4%) recurrences occurred and were treated endoscopically for 22 of them and 3 patients had to undergo complementary oesophageal surgery. 69 (37.9%) patients required further curative procedures (Radiofrequency ablation, endoscopic mucosal resection, Endoscopic submucosal dissection, radiotherapy, chemotherapy, Argon plasma coagulation) for local recurrences or to remove the remaining Barrett's tissue. Metachronous oesophageal adenocarcinoma was found in 22 (10.9%)patients and 3(1.5%) patients presented a metachronous local recurrence associated with LNM and metastasis, two years after the initial procedure for two patients and 8 years for the third patient. 41 patients presented an oesophageal stenosis after the initial procedure (endoscopy $n = 30$, surgery $n = 11$) which were all managed successfully endoscopically.

**Conclusion:** Endoscopic treatment for low-risk (i.e. G1/G2 tumours without any lymphovascular invasion) oesophageal adenocarcinoma arising from Barrett's oesophagus with a tumour invasion depth strictly below 500 µm in the submucosa can be considered safe and effective. The removal of the remaining Barrett's oesophagus should be considered as a therapeutic goal, and patients should all go through a strict and lifelong endoscopic surveillance program in order to detect and treat early stage local recurrences.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1562 REDUCING PATIENT'S BURDEN. A MINIMALISTIC APPROACH TO RADIOFREQUENCY ABLATION IN BARRETT'S EPITHELIUM ACHIEVING COMPLETE ERADICATION

**A.W. Gotink**, P. Didden, M.J. Bruno, A.D. Koch
*Department Of Gastroenterology And Hepatology, Erasmus MC, University Medical Center Rotterdam, Rotterdam/Netherlands*

**Contact E-mail Address:** a.gotink@erasmusmc.nl

**Introduction:** Radiofrequency ablation (RFA) is an effective and accepted method for the eradication of Barrett's oesophagus. Guidelines advise eradicating high-grade dysplasia (HGD) and/or residual Barrett's after complete endoscopic resection of an intramucosal cancer. After primary circumferential ablation using the HALO$^{360}$ balloon catheter, a subsequent focal RFA session is advised at follow-up to eradicate residual Barrett's but also to routinely perform an additional ablation of the neo-Z-line, irrespective of its endoscopic appearance. The rationale behind this is that often there is insufficient contact between the balloon-based electrode and the mucosa at this level. The aim of this study is to evaluate whether taking biopsies of the neo-Z-line to prove complete eradication of the intestinal metaplasia (CE-IM) and/or dysplasia (CE-D) after the primary ablation, can reduce the number of subsequent ablations of the neo-Z-line.

**Aims & Methods:** All Barrett's oesophagus patients undergoing circumferential RFA (HALO$^{360}$) at a single tertiary center were prospectively registered. After 3 months, eradication of the Barrett's epithelium was evaluated endoscopically. 4-quadrant biopsies were taken just below the neo-Z-line in all patients with complete endoscopic eradication (CEE) of the Barrett segment or when the neo-Z-line was completely eradicated but residual Barrett's more proximal remained. Primary outcome measures were the number of patients with CEE, CE-IM and CE-D, and subsequently how many additional ablation sessions were prevented.

**Results:** 24 patients underwent RFA (HALO$^{360}$) between January 2012 and December 2014. In 19 patients (79%) an endoscopic mucosal resection (EMR) was performed prior to RFA. 15 patients (62%) had CEE of the neo-Z-line after a single RFA session and in 13 patients (54%) biopsies were taken just below the neo-Z-line. Biopsy results demonstrated intestinal metaplasia (IM) with dysplasia in 1 patient (4%), IM but CE-D in 4 patients (17%), and CE-IM in 8 patients (33%). After a mean follow-up of 19 months (range 8–32 months), 7 patients (29%) had persistent CE-IM. Three of these patients underwent additional treatment of proximal residual Barrett's islands by EMR or RFA, and one patient underwent an EMR at the gastro-oesophageal junction for suspicion of buried Barrett's, but pathologically this was not confirmed.

**Conclusion:** This study demonstrates that it is clinically relevant to take biopsies of the neo-Z-line after primary circumferential ablation (HALO$^{360}$) when complete endoscopic eradication of Barrett's oesophagus is observed. In at least 29% of patients, additional ablation of the neo-Z-line can be omitted, which has a significant impact on patient burden, stricture risk and treatment associated costs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1563 TEMPORAL TRENDS OF CLINICAL CHARACTERISTICS OF BARRETT'S ESOPHAGUS IN RECENT TEN YEARS IN SOUTH CHINA

X. Yang[1], **Z. Zhang**[1], W. Sha[2], Q. Wang[1]
[1]*Gi, Guangdong General Hospital, Guangzhou/China*

**Contact E-mail Address:** 503274480@qq.com

**Introduction:** Recent studies have reported that the incidence of esophageal adenocarcinoma (EA) in the west had become the fastest rising cancer, which is higher than esophageal squamous cell carcinoma (ESCC) [1–4]. Clinical data of the invasive esophageal cancer cases diagnosed between 1998 and 2003 (n = 65.926) which cover 83% of the US population, collected by the National Program of Cancer Registries or the Surveillance, Epidemiology, and End Results program, showed that the average incidence of ESCC fell by 3.6% yearly whereas the EA increased by 2.1% yearly. The trend of ESCC decreased in both genders and most of the racial or ethnic groups, whereas the EA occurred more in the white or non-Hispanic men [2]. Except for white or non-Hispanic men, ESCC rates were similar to, or greater than, adenocarcinoma rates for men and women of all other races and ethnicities. The largest decrease in ESCC rates occurred in the West census region, which also exhibited no increase in EA rates. The rate of regional and distant-staged EA increased, while rates for local-staged EA remained stable [2]. BE is defined as an oesophagus in which any portion of the normal distal squamous epithelial lining has been replaced by metaplastic columnar epithelium, which is clearly visible endoscopically ($\geq$ 1 cm) above the GOJ and confirmed histopathologically from oesophageal biopsies [5]. The incidence of BE was increased very fast all around the world [1–2]. In the West, BE is considered the major risk factor for EA deterioration and one of the most important precancerous lesion of EA [3]. Studies showed that 2% to 5% of BE could be developed to EA which was 30 to 150 times that of normal people [3]. The prognosis of EA was extremely bad and the 5-year survival rate was only 13% to 15% [1]. The process from BE to EA is a long interval of time and steps, which consists of intestinal metaplasia, low-grade dysplasia, high-grade dysplasia, carcinoma in situ, adenocarcinoma infiltrating. Therefore, early detection and treatment for BE is an important way to prevent EA. In order to provide the evidence of early detection and intervention of BE in China, present study was aimed to evaluate the clinical and endoscopic characteristics of BE.

**Aims & Methods:** The study aimed at evaluating the trend of clinical characteristics of BE in Guangdong area in recent 10 years. Clinical data of 612 patients with BE diagnosed by endoscopy in Guangdong General Hospital from Jan. 2005 to Dec. 2014 were collected and analyzed. The patients were divided into two groups from Jan. 2005 to Dec. 2009 and Jan. 2010 to Dec. 2014.

**Results:** The detection rate of BE was 0.7% (612/87805) in general, which showed an increasing trend from 0.32% in 2005 to 1.29% in 2014. When compared with that in the anterior 5 years, the detection rate of BE in the posterior 5 years rised obviously (0.4% VS 1.0%, p = 0.04). Pathologically, intestinal metaplasia was detected in 13.8% of BE, and there was a significant difference between the two periods (15.1% VS 10.5%, p < 0.04).

**Conclusion:** The detection rate of BE under gastroscopy rises from 2005 to 2014, which may reflect the rising incidence of BE in Guangdong area. The constituent ratio of intestinal metaplasia type of BE is growing, which supports the viewpoint that intestinal metaplasia is the precancerous lesion of esophageal adenocarcinoma.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Oesophageal cancer is the fifth commonest cause of cancer death in the UK, and the incidence of adenocarcinoma is rising. Patients are often without symptoms until the tumour has grown to be inoperable, and the survival for this cancer remains poor. Early diagnosis is crucial to improve survival. Barrett's oesophagus is the pre- cancerous lesion. The British Society of Gastroenterology (BSG) recommends regular surveillance depending on endoscopic and histological findings in order to identify oesophageal cancers at an earlier stage, therefore reducing mortality. There is evidence from previous studies on Barrett's highlighting poor adherence to surveillance intervals, documentation of Barrett's length as well as biopsy protocol. Pooling of Barrett's patients on dedicated Barrett's lists may help with better adherence to guidelines and may enhance detection of dysplasia with better outcomes for patients.

**Aims & Methods:** We aimed to investigate whether a 'dedicated' Barrett's surveillance list improved diagnosis and adherence to the BSG guidelines compared to more 'ad-hoc' surveillance on routine lists. Method: This retrospective study analysed all patients undergoing endoscopy for Barrett's surveillance at a North London hospital over a one-year period. We looked at documentation of the Prague Classification; adherence to the Seattle Protocol; exclusion of Barrett's; biopsy results; and follow up.

**Results:** 76 patients underwent surveillance, with 42 (55%) being performed during the 7 dedicated lists. The dedicated list excluded Barrett's at endoscopy in 7 cases (9.2%) compared to only 1 (1.3%) in the routine list. Documentation was also significantly better with 85% of patients having the Prague Classification recorded, compared to only 32% in the routine group (p < 0.001). Also notable are the 7 patients in the routine group that had missing or erroneous information relating to the Seattle protocol. Adherence to the Seattle protocol was equally poor in both groups (dedicated = 49%, routine = 58%). There was no difference in histology results between the 2 groups. The follow up showed no correlation with the initial list, and frequently didn't adhere to the BSG guidance.

**Conclusion:** We provide evidence that dedicated lists improve both diagnosis and documentation in patients attending for Barrett's surveillance. However, there still appears to be considerable scope for improving adherence to biopsy protocols and follow up plans. The proven benefit of dedicated endoscopic lists could be extended to dedicated follow up clinics to better subsequent management. Despite the stated shortcomings we recommend trials of dedicated lists on a wider scale to investigate whether this has a definite improvement in patient experience and management.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1565 CLINICAL FEASIBILITY OF ENDOSCOPIC SUBMUCOSAL DISSECTION WITH MINIMUM LATERAL MARGIN OF SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA

**Introduction:** Endoscopic submucosal dissection (ESD) is an accepted modality for superficial esophageal squamous cell carcinoma (SESCC) leading to en bloc resections and the ability to achieve R0 resection. Esophageal stricture following ESD has been associated with wide mucosal defects greater than three quarter of the luminal circumference[1]. Oral prednisolone or locoregional steroid injections have shown promising results for the prevention of esophageal stricture following ESD[2–3] although some patients developed dysphagia and required repeated endoscopic balloon dilation even after steroid therapies. As iodine staining clearly visualized the margin of SESCC, we applied a border with energy devices and commenced the incision just outside the applied marks to minimize the excision size for large SESCC. This retrospective study aimed to clarify clinical feasibility of ESD with minimum lateral margin of SESCC.

**Aims & Methods:** During 2005 and 2013, 268 consecutive patients with 289 SESCCs underwent ESD at our institution. Of these, 198 patients who underwent endoscopic clearance for initial SESCC and were followed up without any additional treatment were included for analysis. In this study, endoscopic clearance was defined as en bloc resection of SESCC histologically confined to epithelium (EP), lamina propria mucosa (LPM) or muscularis mucosa (MM) without lympovascular invasion and with free vertical margin regardless of the lateral margin. R0 resection was defined as en bloc resection with histologically free lateral and vertical margins. This study excluded 62 patients who didn't meet the criteria of endoscopic clearance and 8 patients who underwent any additional treatment. The majority of patients underwent EGD surveillance on an annual or biannual basis. In addition, computed tomography was performed every 6 months or 1 year to identify lymph node and distant metastases in patients with MM invasion. This study evaluated short- and long-term outcomes including local recurrence in patients with SESCC undergoing endoscopic clearance.

**Results:** Of 198 patients underwent endoscopic clearance with ESD, 137 (69.2%) and 61 (30.8%) patients were classified into R0 and non-R0 group, respectively. Patients and lesions characteristics in both groups were as follows (R0: non-R0): median age (years, (range)) = 67(37–86):70(40–83), male/female = 115/22:52/9, lesion location (Upper/Middle/Lower/) = 10/84/43:5/33/23, the median tumor size (mm, (range)), 23(5–60):30(12–85) (P < 0.01), invasion depth (EP/LPM/MM) = 27/90/20:4/44/13, rates of the mucosal defects greater than three quarter of the luminal circumference = 13.9%(16/137):70.4%(42/61) (P < 0.01), the stricture rates = 11.7%(16/137):19.7%(12/61) (P = 0.14). The median follow-up periods were 3.2 years and 3.9 years in R0 and non-R0 group, respectively. There was no local or nodal recurrence in any group. Cumulative incidence of metachronous SESCC at 3-year is 19.0% and 17.5% in R0 and non-R0 group, respectively (P = 0.63). One patient died of metachronous SESCC in R0 group and none died of esophageal cancer in non-R0 group. The 3-year overall survival rates were 99.1% and 98.3% in in R0 group and non-R0 group, respectively (P = 0.89).

**Conclusion:** ESD for SESCC with minimum lateral margins with our institutions' strategy was oncologically acceptable and this approach could minimize the extent of the resection defect and potentially reduce esophageal stricture after ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Histological assessment of intramucosal tumors in Barrett's esophagus is important for appropriate therapeutic strategy. In general, high-grade dysplasia, which is nearly identical to intramucosal adenocarcinoma in Japan, and adenocarcinoma are recommended to be treated immediately. However, diagnostic criteria remain subjective, and reproducibility is a big problem.
**Aims & Methods:** The present study aimed to clarify the potential of Ki-67 and p53 immunohistochemistry as an objective criterion by comparing intramucosal cancer with submucosal invasive cancer. Totally 39 superficial Barrett's esophageal adenocarcinoma (24 mucosal cancers and 15 submucosal cancers) in 38 cases, diagnosed by Japanese expert pathologists and resected by endoscopic submucosal dissection (ESD) of surgery between January 2013 to December 2014, were enrolled to this study. Immunohistochemistry for Ki-67 and p53 was performed to each representative section. Ki-67 staining pattern was categorized into two groups: diffuse pattern (positive cells showed diffuse distribution including the surface epithelium) or localized pattern (positive cells were localized to the lower two-third of the crypts). p53 staining was categorized into two groups: normal (wild type) or abnormal (overexpression or loss). Evaluation was performed in intramucosal cancers (Group M), mucosal component of submucosal invasive cancers (Group SM-m), and submucosal component of submucosal invasive cancers (Group SM-sm).
**Results:** Poorly differentiated components were frequently observed in Group SM-sm (73%) compared with Group M and Group SM-m (17% and 40%, respectively). Ki-67 diffuse pattern was more frequent than localized pattern in mucosal cancers (67% and 33%, respectively), whereas all of the submucosal cancers showed diffuse pattern. Abnormal expression of p53 was frequent in all groups (Group M: 83%, Group SM-m: 67%, Group SM-sm: 67%). All of the 8 lesions with Ki-67 localized pattern were intramucosal well-differentiated adenocarcinoma without lymphovascular invasion or lymph node metastasis, despite the high rate of p53 abnormality (6/8, 75%).
**Conclusion:** Majority of intramucosal cancers had identical characteristics to submucosal invasive cancers in terms of Ki-67 and p53 expression patterns. These intramucosal cancers may have invasive potential and therefore have indication for immediate treatment. Immunohistochemistry can be an objective criterion for management of intramucosal tumors in Barrett's esophagus.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1567 PROGNOSIS AND TREATMENT AFTER RECURRENT ESOPHAGEAL CANCER FOLLOWING R0 ESOPHAGECTOMY

**T. Tanaka**, S. Matono, N. Mori, H. Hino, K. Kadoya, R. Nishida, K. Saisho, Y. Akagi
*Surgery, Kurume University, Kurume/Japan*

**Contact E-mail Address:** totanaka@med.kurume-u.ac.jp

**Introduction:** Esophageal cancer is a highly aggressive malignancy with a high rate of recurrence even after R0 resection.
**Aims & Methods:** The aim of this study was to identify prognostic factors associated with survival of patients with recurrence after R0 esophagectomy for esophageal cancer. A prospective database identified 328 patients who underwent R0 esophagectomy for esophageal squamous cell carcinoma in Kurume University Hospital between January 2000 and December 2014. Of these, 105 patients (32%) developed recurrence. Univariate and multivarite cox regression analyses were used to determine the factors affecting survival after recurrence. Post-recurrence survival was defined as the time between the first recurrence and death or last follow-up.
**Results:** There were 101 males and 4 females, with a median age of 64 years (44–81). Of these, 24 patients (23%) had pT1 tumor, 14 (13%) had pT2 tumor, and 67 (64%) had pT3 tumor. Median time to recurrence was 10.2 months (range 1–49) and 102 patients (97%) developed recurrence within 3 years after surgery. Patients with pT3 cancer developed recurrence earlier than those with pT1–2 cancer (10 months vs 16 months, $P = 0.0006$). Distant recurrence occurred in 71 patients (68%) including 13 patients with both distant and locoregional recurrence, and 34 patients (32%) had locoregional recurrence only. Thirty-five patients (33%) had a single site of recurrence, and 70 patients (67%) had two or more recurrence site. Ninety-one patients (87%) received anticancer treatment; chemoradiotherapy was employed in 38 patients, chemotherapy in 30 patients, radiotherapy in 7 patients, and surgery in 16 patients (including 14 patients with chemotherapy and/or radiotherapy). Fourteen patients (13%) received best supportive care alone. Median post-recurrence survival was 10.4 months (range 1–140), and the overall 1- and 3- year survival rates were 48 and 19%, respectively. Type of recurrence (local vs distant), number of locations (single vs multiple), treatment (anti-cancer vs BSC), and pT at the time of esophagectomy were significantly associated with post-recurrence survival in univariate analysis. Age ( $< 65$ vs $\geq 65$), gender, nodal status (pN0–1 vs pN2–3), and histologic grade (well vs mode or poor) did not affect the survival. In multivariate analysis, type of recurrence (HR 0.561, 95% CI 0.322–0.948; $P = 0.0305$), treatment (HR 0.485, 95% CI 0.264–0.952; $P = 0.0362$), and pT (HR 0.561, 95% CI 0.333–0.924; $P = 0.0229$) were identified as independent prognostic factors associated with post-recurrence survival.
**Conclusion:** In patients with recurrence after R0 resection for esophageal squamous cell carcinoma, distant recurrence, advanced pT stage, and no anticancer treatment were independent prognostic factors associated with worse post-recurrence survival. Although survival after recurrence was poor, treatment could prolong survival and could lead to cure in selected patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1568 OUTCOMES OF SM INVASIVE BARRETT'S CANCERS FOLLOWING ENDOSCOPIC RESECTION: RADICAL INTERVENTION IS NOT ALWAYS REQUIRED?

**F.J. q., J. Chedgy**, S. Subramaniam, K. Kandiah, S. Thayalasekaran, P. Bhandari
*Endoscopy, Queen Alexandra Hospital, Portsmouth/United Kingdom*

**Contact E-mail Address:** ferguschedgy@yahoo.co.uk

**Introduction:** Endoscopic resection (ER) of Barrett's cancer with curative intent is extremely effective for lesions limited to the mucosal layer of the oesophagus. Lesions extending beyond the muscularis mucosae into the submucosa are considered for radical therapy due to risk of lymph node metastases. Radical treatment is not without risk, reported mortality of oesophagectomy is 2–5%.
**Aims & Methods:** All patients referred for ER of Barrett's cancer had data collected prospectively between 2006 and 2015. The database was interrogated by independent researchers blinded to the endoscopic procedures for patients with SM invasive cancers.
**Results:** 261 endoscopic resections were performed in 182 patients during the study period. 26 (14%) patients were identified as having SM invasion following endoscopic resection. 12 had undergone endoscopic submucosal dissection (ESD) and 14 endoscopic mucosal resection (EMR). 22 (85%) lesions were superficially submucosally invasive (SM1), 4 were > SM1 (15%). Table 1 shows outcomes after endoscopic resection. Mean disease free survival was 4.31 years (Range 0.7 to 10.8) in this cohort. 3 patients died of recurrent cancer, 3 patients died of co-morbid conditions.

| | SM1 | >SM1 | Presence of LVI* | Poor Differentiation | Clear of Cancer at follow up |
|---|---|---|---|---|---|
| Endoscopic follow up n = 9 | 9 | 0 | 2 | 1 | 9 |
| Surgery n = 6 | 5 | 1 | 2 | 2 | 5 |
| Chemoradiotherapy n = 7 | 5 | 2 | 2 | 5 | 6 |
| No Intervention n = 4 | 3 | 1 | 0 | 3 | n/a |

*LVI: Lymphovascular Invasion All 9 patients in the endoscopy group were clear of cancer at follow up. There was 1 recurrence that was treated with further ER. Of the 6 patients undergoing surgery 5 had no residual neoplasia in the oesophagectomy specimen (pTxN0M0). 1 patient had a pT1N0M0 cancer with LVI and signet ring cells and died 2 years after surgery. 1 patient was considered for surgery but was turned down due to comorbidities and subsequently died of cancer 6 years following endoscopic resection. 3 patients have been discharged to their referring centres for consideration of surgery. 7 patients underwent chemoradiotherapy. 6 of the 7 patients treated with chemoradiotherapy were clear of recurrence on follow up. 1 patient developed recurrence of cancer and died 2 years after ER.

**Conclusion:** This data further challenges the current paradigm of radical therapy following ER of SM1 Barrett's cancers. Outcomes for patients managed endoscopically are excellent. 5 patients undergoing surgery in our cohort had no residual disease in the oesophagectomy specimen and potentially could have undergone endoscopic follow up alone. Patients found to have SM1 lesions without poor prognostic features can effectively be managed without radical intervention. SM invasive cancers require an individualised management plan tailored to histology and co-morbidities. There does not appear to be a demonstrable difference between chemoradiotherapy and surgery.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1569 TOPICAL MITOMYCIN C TREATMENT FOR RELIEVING ESOPHAGEAL RADIATION-INDUCED STENOSIS

L. Zhao, X. Wang, L. Liu, M. Wang, **Z. Fan**
*Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China*

**Contact E-mail Address:** fanzhining@njmu.edu.cn

**Introduction:** Radiation-induced stenosis is common after esophageal cancer treatment, especially at proximal esophagus. Instead of stent placement, endoscopic dilation combined with topical mitomycin C treatment has been reported to improve benign esophageal dysphagia. This study was designed to evaluate the safety and efficacy of this strategy for radiation-induced stricture.

**Aims & Methods:** Patients with esophageal strictures were divided into 2 groups, including dilation in association with mitomycin C injection (mitomycin C group) and dilation in association with saline injection (dilation group). Patients' age, sex, type of stricture, stricture location, number of previous dilations, diameters before and after dilation, and dysphagia-free period were compared.

**Results:** A total of 17 patients were enrolled into this study, including 7 in mitomycin C group and 10 in dilation group. There were no significant difference in baseline characteristics of patients, such as age, sex, type of stricture, stricture location, and number of previous dilations. The major complication was one patient in mitomycin C group with perforation ($P < 0.05$). The minor complications were reported for 4 in mitomycin C group, and 6 in dilation group ($P > 0.05$). The mean dysphagia-free period was $6.33 \pm 1.48$ months in the mitomycin C group, and $3.26 \pm 1.13$ months in the dilation group ($P < 0.05$).

**Conclusion:** Endoscopic dilation combined with topical mitomycin C therapy could prolong the esophageal dysphagia-free period and reduce the frequency of endoscopic dilation, which would be the potential strategy for refractory esophageal stricture.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1570 RADIOFREQUENCY ABLATION (RFA) IN PATIENTS WITH BARRETT'S ESOPHAGUS RELATED NEOPLASIA – LONG-TERM OUTCOMES OF THE CZECH NATIONAL RFA DATABASE

**Introduction:** Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is a standard endoscopic treatment of early Barrett's esophagus related neoplasia (BORN). We analyzed prospectively collected data from a Czech national database that follows the outcomes of patients with BORN, which have undergone treatment with RFA.

**Aims & Methods:** We collected data from 4 centers (Prague 2x, Ostrava and Olomouc), which perform RFA in the Czech Republic. A total of 170 patients underwent RFA for BORN from April 2009 to April 2016 and 136 patients (115 males, mean age 64), who have already completed the endoscopic treatment, were included into the analysis. Fifty-six patients (41%) were diagnosed with low-grade dysplasia (LGD), 46 (34%) patients with high-grade dysplasia (HGD) and 34 (25%) with early adenocarcinoma (EAC). Mean length of the Barrett's esophagus (BE) segments was 4.5 cm (range 1–13 cm). In 65 patients (48%), RFA was combined with ER or endoscopic submucosal dissection of all visible lesions. After treatment, the patients have undergone regular endoscopic surveillance with multiple biopsies (neo-Z-line and esophagus).

**Results:** Complete remission of IM (CR-IM) and complete remission of neoplasia (CR-N) were achieved in 72.8% (95% CI 64.5–80.1%) and 98.5% (95% CI 94.8–99.8%), respectively. Among 37 patients without CR-IM (27%), 29 (78%) did not have macroscopic signs of BE. During the follow-up, there were 21 recurrences (21%, 21/98 pts) of IM and all of them occurred at the level of neo-Z-line. In 13 of these patients (62%), there were no signs of macroscopic recurrence of BE. Six patients (5%, 6/133 pts) had recurrent neoplasia (5x LGD, 1x HGD). All patients with macroscopic recurrence of BE (8 pts) or dysplasia (6 pts) underwent successful endoscopic re-treatment except for one patient with persistent LGD at the macroscopically normal neo-Z-line who entered endoscopic surveillance. In a multivariate logistic regression analysis, the diagnosis of cancer was an independent risk factor for persistent IM after RFA (p-value = 0.038), but persistent IM at the level of macroscopically normal neo-Z-line was not a risk factor for BORN recurrence. We have not detected buried glands beneath the neosquamous epithelium in any patient. We noticed treatment-related adverse events in 23 patients (17%): 13x chest pain, 8x stricture, 1 x injury of tongue and 1x submucosal tear after balloon calibration. One patient experienced a perforation during balloon dilatation of a post-RFA fibrous stricture and he underwent esophagectomy. All the remaining strictures were managed successfully endoscopically.

**Conclusion:** Radiofrequency ablation is effective in achieving remission of Barrett's esophagus related neoplasia. The recurrence rate of IM/neoplasia was not negligible and patients after successful RFA for BORN still need endoscopic surveillance. Diagnosis of cancer is a risk factor for persistent IM after RFA.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1571 EPIDEMIOLOGY OF ESOPHAGEAL ADENOCARCINOMA IN THE CZECH REPUBLIC. ARE WE AT THE BREAKPOINT OF INCIDENCE?

**R. Kroupa**[1], T. Pavlik[2], M. Dastych[1], S. Konecny[1], J. Dolina[1]
[1]*Department Of Internal Medicine And Gastroenterology, University Hospital and Faculty of Medicine, Masaryks University Brno, Brno/Czech Republic*
[2]*Institute of Biostatistic and Analyses, Masaryk Univerzity, Brno, Czech Republic, Brno/Czech Republic*

**Contact E-mail Address:** rkroupa@fnbrno.cz

**Introduction:** Incidence of esophageal adenocarcinoma (EAC) has increased substantially in developed countries during the past decades. Majority of cases are believed to arise from intestinal metaplasia – Barrett's esophagus, the condition strongly associated with long-term gastroesophageal reflux disease. No data describing epidemiology of histological subtypes of esophageal cancer has been published in the Czech Republic yet.

**Aims & Methods:** Aim of the study was to analyze trends of incidence of esophageal cancer in view of histological types in the Czech Republic. Data from National Cancer Registry regarding esophageal cancer were analysed according to histological main types – adenocarcinoma (EAC), squamous and other types. The changes in incidence during last 30 years were described.

**Results:** Population-based reliable data from National Cancer Registry including histological characteristic are available from years 1984–2013. Adjusted incidence of esophageal cancer generally doubled from 1.7 per 100 000 in years 1984–1988 to 3.16 in years 2009–2013. Adjusted incidence of EAC increased almost four-fold from 0.32 per 100 000 to 1.26 per 100 000 in the same period. Incidence of EAC was about seven-fold higher in men than in women without significant changes in time. Squamous carcinoma was still predominant: 73% in year 1984, 62% in year 2000 and 57% in 2013. The proportion of EAC was increasing from: 18% in 1984, 30% in 2000 and 38% in 2013. We observed a"breakpoint" in the incidence of EAC during the last years. From year 2010 the number of new cases of EAC is rising very slowly.

**Conclusion:** Incidence of EAC in the Czech Republic increased four-fold during last 30 years. Adenoncarcinomas represent still less than half from all oesophageal cancers and its increase is relatively slower in the last years. A broad use of potent drugs for gastroesophageal reflux treatment – proton pump inhibitors during last 20 years may be responsible for slower increase of EAC recently.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Surgery and concurrent chemoradiotherapy are widely accepted alternatives for the curative treatment of patients with early stage or locally advanced esophageal cancer. Impossible endoscopic passage due to resistance is intermittently experienced in esophageal cancer patients. The objective of this study was to evaluate the prognostic influence of endoscopic passage in early stage or locally advanced esophageal squamous cell carcinoma patients treated with surgery or concurrent chemoradiotherapy.

**Aims & Methods:** This retrospective case-control study was based on medical records from a single tertiary medical center located in Daejeon, Republic of Korea. The records of 317 patients with esophageal squamous cell carcinoma treated with surgery or concurrent chemoradiotherapy between January 2009 and December 2015 were reviewed, and 160 patients were ultimately selected. These 160 patients were divided into two groups based on their endoscopic passage findings: group A (possible endoscopic passage group), and group B (impossible endoscopic passage group, including patients requiring a pediatric endoscope for passage due to resistance). We then compared the clinical and endoscopic characteristics of these two groups retrospectively.

**Results:** Of the 160 enrolled patients, 92 (57.5%) patients were assigned to group A and 68 (42.5%) to group B. Early stage esophageal squamous cell carcinoma (stage I, II) was significantly more prevalent in group A than in group B patients ($P < 0.05$), and endoscopic stents were less frequently required in group A than

in group B patients ($P < 0.05$). Overall survival was better in group A than in group B patients (85.5% vs 41.4%, $P < 0.05$). Progression-free survival was better in group A than in group B patients (52.3% vs 20.7%, $P < 0.05$). Especially, Similar results came out, even if only patients who underwent concurrent chemoradiotherapy ($n = 92$) have analyzed. Of the 92 enrolled patients, 58 (63%) patients were assigned to group A and 34 (37%) to group B. Overall survival was better in group A than in group B patients (83.8% vs 40.9%, $P < 0.05$), and progression-free survival was better in group A than in group B patients (48.3% vs 23.7%, $P < 0.05$).

**Conclusion:** Our data suggest that endoscopic passage was an important prognostic factor in terms of overall survival and progression-free survival in patients with early stage or locally advanced esophageal squamous cell carcinoma treated with surgery or concurrent chemoradiotherapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Department Of Gastroenterology, Hepatology And Infectious Diseases, Otto-von-Guericke University Magdeburg, Magdeburg/Germany*

**Contact E-mail Address:** m.venerito@med.ovgu.de

**Introduction:** *Helicobacter pylori*-induced gastric atrophy (GA) and intestinal metaplasia (IM) are risk factors for gastric ulcer (GU) and intestinal-type gastric cancer (GC).

**Aims & Methods:** We aimed to determine the prevalence of GA and IM in patients with GU and duodenal ulcer (DU) in a tertiary hospital of Saxony-Anhalt, Germany, a region at increased risk for gastric cancer. Methods. Histology based on at least 4 gastric biopsies was available in 1073 (62.3%) out of the 1722 patients (male 60%, mean age 65.7 years) with endoscopic GU and DU diagnosed by January 1st 2004 to December 31st 2014. Demographics, intake of aspirin/non-steroidal anti-inflammatory drugs (NSAIDs), and ulcer localization were documented. Patients with positive results for at least one assay among histology, 13C-urease breath test, rapid urease test or serology were considered *H. pylori*-positive.

**Results:** Overall, 47.3% of patients had GU, 42.2% had DU and 10.5% had ulcers in both localisations. The prevalence of *H. pylori* infection, aspirin/NSAID intake and the presence of both risk factors was 35.1%, 38.7% and 13.0% respectively. Prevalence of extensive GA/IM (excluding mild/moderate GA/IM confined to the antrum) was significantly higher in patients with GU compared to DU (20.3% vs. 6.4%, respectively, $p < 0.0001$). Patients with ulcers of the gastric corpus/fundus were more likely to have extensive GA/IM compared to those with ulcers located in the gastric antrum/duodenum (OR 2.83; 95% CI: 1.868- 4.285). The prevalence of mild GA/IM was higher among patients with *H. pylori* infection compared to non-infected patients (20.5% vs. 12.5%, $p < 0.0001$), whereas the prevalence of extensive GA/IM was independent of *H. pylori* infection (13.3% vs. 14.3%). Prevalence of GA/IM of any grading did not differ between patients with and without aspirin/NSAID intake (30.1% vs. 29.6%), independently from ulcer location.

**Conclusion:** The high prevalence of GA/IM in patients with GU may account for the increased risk of intestinal-type GC in this population. The more proximal the ulcer location, the higher was the likelihood of having GA/IM. After early exclusion of a malignant ulcer, follow-up endoscopy should be offered to patients with GU and extensive GA/IM.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Proton-pump inhibitors (PPIs) are often prescribed in combination with thienopyridines. Conflicting results exist as to whether PPIs diminish the efficacy of clopidogrel (1–3).

**Aims & Methods:** We sought to evaluate the influence of pantoprazole, indicated as relatively less influent than other PPIs, on the antiplatelet effect of clopidogrel, considering a stratification of the population for the presence of cytochrome (CYP) 2 C19 polymorphism. Forty patients who received dual antiplatelet therapy, were randomized between pantoprazole ($n = 20$) or ranitidine ($n = 20$). The platelet aggregation was evaluated by impedance aggregometry (in Ohm) induced by with 5 $\mu$M adenosin diphosphate (ADP), on baseline (D0) and 8 days after acid-lowering treatments (D9). CYP2C19 was genotyped by polymerase chain reaction–restriction fragment length polymorphism.

**Results:** Demographic, clinical and procedural data and the prevalence of CYP2C19 polymorphism were similar between the two groups. After co-treatment, the percentage of clopidogrel low-response (CLR) was 11.1% (2/18) in the pantoprazole group and 10.5% (2/19) in the ranitidine group ($P = 0.954$). Not statistically differences were observed for the values of impedance with ADP stimulus after acid-lowering treatments. At the multiple regression analysis, only event of ST-elevation myocardial infarction was marginally associated with a reduced antiplatelet effect (OR: 12.07, 95% CI: 0.84–173.78). However, pantoprazole use did not affect the antiplatelet effect considering of CYP2C19 polymorphism.

**Conclusion:** This randomized trial showed pantoprazole does not increase platelet aggregation in patients treated with dual antiplatelet therapy after correction for the bias of CYP2C19 polymorphism.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic atrophic gastritis (CAG) represents a stomach precancerous condition often related with *Helicobacter pylori* (H.p.) infection. This feature is characterized by hypo- achloridria due to loss of appropriate gastric glands. Gastropanel® is a non-invasive test able to detect both CAG and H.p. infection. This test is defined as a "serological biopsy" pointing out both morphological and functional status of gastric mucosa.

**Aims & Methods:** The aim of the present study is to investigate the frequence of CAG in a study population in primary care setting by means of a non-invasive test.

Ten thousand dyspeptic patients were enrolled from two different areas of North-East of Italy. In the first one –Group A-, 7,400 patients were enrolled (M:F = 1,2:2, mean age 53 years) from 2003 to 2014, in the second one –Group B- 2,600 patients (M:F = 1,5:2,3, mean age 56 years) were enrolled from 2011 to 2013.

Upper GI endoscopy with biopsies sampling according with Sydney classification or O.L.G.A. staging and Gastropanel® (Biohit Oyj, Helsinki, Finland) were performed in every patients.

Serological diagnosis of CAG was assessed by means of a feature of PGI $< 25$ microg/L, G-17 $> 14$ pmol/L; histological diagnosis of CAG following the criteria of both Sydney system and O.L.G.A. staging.

**Results:** Overall, CAG was diagnosed by serology in 716 out of 10.000 patients. In Group A population the diagnosis of CAG was made in 608 patients (mean

age 57 years), in 2,492 a diagnosis of non-atrophic gastritis (N.A.G.) related with H.p. infection was assessed (mean age 54), in 879 patients a normal gastric morpho-functional assessment was described (mean age 44).
In Group B population the diagnosis of CAG was made in 108 patients (mean age 58 years) in 643 a diagnosis of NAG related with H.p. infection was performed (mean age 59), in 721 patients a normal gastric morpho-functional assessment was detected (mean age 47).
**Conclusion:** Overall, a picture of CAG was found in the investigated population in 7.16% out of patients.
In Group A CAG was found in 608 out of 7,400 patients (8.2%), in Group B in 108 out of 2,600 patients (4.15%).
The mean age of subjects with CAG was higher than in patients with NAG H.p related and normal population in both the two areas (Group A: CAG = 57 yrs, NAG h.p. 54 yrs, normal subjects 44 yrs; Group B: CAG 58 yrs, NAG H.p. 59 yrs, normal subject 47 yrs).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1576 RECOVERY OF GASTRIC FUNCTION IN CHRONIC ATROPHIC GASTRITIS: A 3 YEARS STUDY

**F. Di Mario**[1], S. Landi[1], S. Grillo[1], G. Grande[2], M. Franceschi[3], R. Cannizzaro[4], N. Dal Bo'[1], A. Gnocchi[1], V. Corrente[1], A. Bertele[5], F. Baldassarre[1], M. Rugge[6]

**Contact E-mail Address:** francesco.dimario@unipr.it
**Introduction:** The relationship between *Helicobacter pylori* (*H. pylori*) eradication and atrophic changes in the gastric mucosa has not yet been fully elucidated. Although some studies report a partial restoration of serum pepsinogen I (PGI) levels after eradication, it is not clear whether this finding reflects gastric mucosal healing on a morphological level. L-cysteine, an agent capable of reducing acetaldehyde production after food intake, has recently been proposed for prevention of gastric carcinogenesis in patients with atrophic gastritis.
**Aims & Methods:** To assess modifications in gastric function after L-cysteine administration in moderate-severe chronic, atrophic, body gastritis by means of PGI, PGII and G-17 serum levels. 17 patients (11 men, mean age 47.2 yrs, range 27–65 yrs), with histological diagnosis of moderate to severe chronic, atrophic, body gastritis (according to the O.L.G.A. staging system) and PGI serum levels < 25 microg/L, underwent upper gastrointestinal endoscopy with gastric biopsy samplings and PGI, PGII and G-17 measurement by means of Gastropanel® (Biohit Oyj, Helsinki, Finland). All patients were *Helicobacter pylori* negative at baseline. 6 out of 17 patients had autoimmune gastritis while 11 of them reported previous H.p. infection. All the patients were treated with L-cysteine (100 mg three times daily) for 36 months. Serum PGI, PGII and G-17 were measured at baseline and after 3, 6, 12, 24, 36 months after starting therapy.
**Results:**

| Patients(n°17) | Basal Value | T_3m | T_6m | T_12m | T_24m | T_36m | p Value |
|---|---|---|---|---|---|---|---|
| PG1(mcg/L, mean) | 8.42 | 10.58 | 11.45 | 12.19 | 13.88 | 14.21 | 0.0001 |
| G17(pg/L, mean) | 51.33 | 43.13 | 38.66 | 34.41 | 28.34 | 26.03 | 0.0041 |

Results are summarized in the Table.
**Conclusion:** After L-cysteine administration, patients with chronic, atrophic, body gastritis showed long-lasting improvements of physiological gastric function, reflected by a significant increase of PGI levels and a parallel decrease of G-17 serum levels over a 36 months follow-up period.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1577 LONG-TERM OUTCOMES OF ENDOSCOPIC RESECTION FOR PAPILLARY ADENOCARCINOMA IN EGC

**J.J. Hwang**[1], J.P. Han[1], Y.S. Cho[1], J. Cho[1], H.K. Kim[2], B.M. Ko[1], S.J. Hong[1], I.K. Jung[1], J.S. Lee[1]

**Introduction:** Although papillary adenocarcinoma (PAC) of stomach is classified as a differentiated-type cancer, some studies have reported that it has more aggressive feature than tubular adenocarcinoma. This study aimed to evaluate the outcomes of PAC diagnosed after endoscopic resection for early gastric cancer (EGC).
**Aims & Methods:** PAC was defined when papillary structures were revealed in more than 50% of resected tumor. The therapeutic outcomes were assessed retrospectively in 33 EGCs diagnosed as PAC after endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD). The long-term outcomes were evaluated in 19 patients after excluding 14 patients with less than 12 months of follow-up period.
**Results:** Thirty-three PACs were treated with EMR (n = 19, 57.6%) and ESD (n = 14, 42.4%). The mean size of tumors was 23.2 mm, and most of them were located in lower- (n = 18, 54.5%) and mid- (n = 12, 36.4%) third of the stomach. The rates of complete resection and curative resection were 81.8% (78.9% in EMR, 85.7% in ESD) and 78.8% (79.0% in EMR, 78.6% in ESD), respectively. For non-curative resection (n = 7), 3 underwent additional treatment (1ESD, 2 surgical treatment), and 4 were not followed up without additional treatment. No local or distant recurrence occurred after complete resection or additional treatment for non-curative resection during a mean follow-up period of 30.3 months.
**Conclusion:** Endoscopic resection for PAC showed acceptable therapeutic and long-term outcomes. Surveillance can be considered without additional treatment for PAC if the resected lesion shows curative resection that meets the definition of complete resection and the absolute or expanded ESD criteria on the pathological result from endoscopic treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1578 PROPOSAL FOR A NEW AGGRESSIVE VARIANT OF GASTRIC ADENOCARCINOMA OF FUNDIC GLAND TYPE (A MULTICENTER STUDY OF 50 CASES)

**H. Ueyama**[1], T. Yao[2], A. Nagahara[3], Y. Akazawa[1], H. Komori[1], T. Takeda[1], K. Matsumoto[1], K. Matsumoto[1], M. Hojo[1], S. Watanabe[1]

**Contact E-mail Address:** psyro@juntendo.ac.jp
**Introduction:** We previously proposed gastric adenocarcinoma of fundic gland type (chief cell predominant type, GAFG-CCP) as a new form of gastric adenocarcinoma with distinct clinicopathological and endoscopic features ((1) Ueyama H. *Am. J. Surg. Pathol* 2010, (2) Ueyama H. *Endoscopy* 2014, (3) Ueyama H. *Stomach and intestine* 2015). GAFG-CCP is defined by positive immunohistochemical staining for pepsinogen-I (a marker of chief cells) and/or H+K+-ATPase (a marker of parietal cells) and is not associated with *H. pylori* infection. With regard to biological behavior, GAFG-CCP is considered less aggressive because it exhibits low cellular atypia, no lymphovascular invasion, low proliferative activity, a lack of p53 protein overexpression, and good prognosis. We also analyzed the molecular events of GAFG, and suggested that a progression of GAFG, at least in part, might be associated with GNAS mutations. Recently, many cases of an aggressive variant of GAFG with high cellular atypia have been discovered. This variant exhibited differentiation toward gastric foveolar epithelium in addition to fundic gland differentiation, and it was designated gastric adenocarcinoma of fundic gland mucosal type (GAFGM). However, the clinicopathological features of GAFGM have not been well investigated.
**Aims & Methods:** The aim of this study was to clarify the clinicopathological features of GAFGM by comparisons with pure GAFG. A total of 50 GAFG cases from January 2008 to December 2015 were retrospectively collected from 24 institutions. We performed an immunohistochemical analysis using MUC5AC (a marker of foveolar epithelial cells) and MUC6 (a marker of mucous neck cells) to classify these GAFG cases as pure GAFG (MUC5AC+, <10%·MUC6+·pepsinogen-I+, n = 34) or GAFGM (MUC5AC+, ≥10%·MUC6+·pepsinogen-I+, n = 16). We then compared the pure GAFG and GAFGM cases via a clinicopathological evaluation.
**Results:** There were no significant differences between the two groups (pure GAFGs vs. GAFGMs) in the following findings: location of lesion (U/M/L), 31/3/0 vs. 11/4/1; method of treatment (ESD/EMR/OPE), 24/6/4 vs. 9/1/6; depth of invasion (M/SM), 7/27 vs. 2/14; lymph node metastasis, 0/3 vs. 1/9; proliferative activity (mean MIB1-LI, %), 6.1 vs. 8.9; p53 protein overexpression (+/-), 0/34 vs. 2/9; and *H. pylori* infection (positive/negative/after eradication), 3/20/3 vs. 1/7/1. Macroscopically, the depressed type was observed more often in GAFGMs (protruded/flat/depressed type, 22/4/8 vs. 6/0/10, p = 0.07). The size of the tumor (10 ± 7.7 mm vs. 24.2 ± 20 mm, $p < 0.05$) and depth of submucosal invasion (278.9 ± 277.5 $\mu$m vs. 1182.1 ± 1428.2 $\mu$m, $p < 0.05$) were significantly greater in GAFGMs than in pure GAFGs. Furthermore, the rates of lymphatic and venous invasion were significantly higher in GAFGMs than in pure GAFGs (2.9% vs. 37.5%, $p < 0.01$). Immunohistochemically, pure GAFGs presented positivity for pepsinogen-I > MUC6 (70.6%); in contrast, GAFGMs presented positivity for MUC6 > pepsinogen-I (87.5%) ($p < 0.001$). The predominant cell differentiation type in GAFGMs did not differ significantly between fundic gland cells and foveolar epithelial cells. Activating mutations in GNAS were found more frequently in GAFGMs (50%, 3/6) than in GAFGs (9%, 1/11) (p = 0.09).
**Conclusion:** GAFGM should be categorized as a new aggressive variant of GAFG that has high malignant potential, differentiates predominantly toward MUC5AC and MUC6, and might be associated with GNAS mutations.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1579 THE ELEMENTS THAT MAY CAUSE THE DIFFICULTY TO DIAGNOSE EARLY GASTRIC CANCER AFTER HELICOBACTER PYLORI ERADICATION

**T. Wakatsuki**, S. Furutachi, H. Yamashita
*Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan*

**Contact E-mail Address:** t_wakatsuki0530@yahoo.co.jp

**Introduction:** Narrow band imaging with magnifying endoscopy (NBI-ME) criteria for early gastric cancers (EGC) were based on the microvascular architecture and/or microsurface structure with clear demarcation between the cancerous area and surrounding non-neoplastic area. EGC after successful *Helicobacter pylori* eradication is often difficult to diagnose. Therefore careful observation is required in these cases. One of the elements that makes the diagnosis difficult is the non-neoplastic epithelium which cover the periphery of the cancer and some might exist among the cancer tubules after eradication. This might leads to the unclear demarcation under NBI-ME.

**Aims & Methods:** The aim of this study is to clarify the histopathological characteristics to maximize the accuracy of the diagnosis. This is a retrospective control study. There were 199 cases of EGC performed endoscopic submucosal dissection (ESD) between November 2011 and October 2015 in Okayama Medical Center. We included 19 lesions from 14 patients who had received *H. pylori* eradication in the eradication group. As a control group, 19 lesions from 19 patients who had persistent *H. pylori* infection and had not received eradication in the same period were selected and were matched the background to the eradication group. The specimens after ESD were cut by 2 mm width. The retrospective evaluation of histopathological findings was performed in both groups which includes 74 sections with lesions from eradication group and 79 sections with lesions from control group. We evaluated 1) the rate of sections that contains non-neoplastic epithelium covering the carcinoma, 2) the length of the non-neoplastic epithelium, 3) the rate of sections that non- neoplastic tubules exist among cancer tubules, 4) the ratio of the area where non-neoplastic tubules exist in tumor lesion. In the eradication group, each cancer area of sections were divided equally into 4 parts, 2 central parts as 'center area' and 2 marginal parts as 'marginal area'.

**Results:** The rate of sections that contains non-neoplastic epithelium covering the carcinoma was 63.5% (47/74) in the eradication group, which was significantly higher by 35.4% (28/79) than the control group ($p = 0.009$). The average length of the non-neoplastic epithelium covering the carcinoma was 1.07 mm in the eradication group, and was 0.81 mm in the control group. The rate of sections that non-neoplastic tubules exist among the cancer tubules was 20.3% (15/74) in the eradication group was significantly higher ($p = 0.004$) than the control group (10.1% (8/79)). In the eradication group, the area where non- neoplastic tubules exist among the cancer tubules was 21.1% in center part, 78.9% in marginal part.

**Conclusion:** In the eradication group, both rate of sections that contains non-neoplastic epithelium covering the carcinoma and non-neoplastic tubules exist among the cancer tubules were significantly higher than the control group. And non-neoplastic tubules existed more in the marginal part. Thus, it can be said that these results lead the demarcation becomes unclear in the EGC after eradication.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1580 THE YIELD OF PEPSINOGEN TESTING IN A GENERAL POPULATION SAMPLE OF CAUCASIAN ORIGIN

**O. Sjomina**[1], J. Pavlova[1], P. Janovics[1], I. Kikuste[1], A. Vanags[2], I. Tolmanis[2], D. Rudzite[1], I. Polaka[1], I. Kojalo[1], I. Liepniece-Karele[1], S. Isajevs[1], D. Santare[1], V. Pirags[1], J. Pahomova[3], V. Dzerve[4], M. Leja[1]

[3]*P.Stradins Clinical Hospital, Riga/Latvia*
[4]*Institute Of Cardiology And Regenerative Medicine, University of Latvia, Riga/Latvia*

**Contact E-mail Address:** olga_sjomina@inbox.lv

**Introduction:** Pepsinogen testing has been suggested to be the best available non-invasive screening tool for atrophy as the precursor of gastric cancer by several international guidelines, including by Kyoto international consensus and Maastricht V. However, studies addressing the yield of this type of screening are originating predominantly from Asia; little evidence is available from general population studies in Caucasians.

**Aims & Methods:** Individuals from a cross-sectional population-based study in Latvia with decreased pepsinogen levels during the recruitment were invited to undergo upper endoscopy with a proper biopsy work up. The results of the initial tests have been described elsewhere[1]. Blood samples were obtained prior to the endoscopy. Pepsinogen I and II was measured in plasma simultaneously from either in the initial or the follow-up sample by a latex-agglutination test system (from Eiken Chemical Co., Tokyo, Japan). Moderately decreased pepsinogen results were considered if PgI≤70 ng/ml and PgI/PgII≤3, but severely decreased if PgI≤30 ng/ml and PgI/PgII≤2; the remaining cases were considered to have normal pepsinogen levels. The presence/absence of the gastric mucosal lesions was scored according to the OLGA and OLGIM staging systems. The presence of *H. pylori* IgG was assessed serologically (Mikrogen Diagnostik, Neuried, Germany).

**Results:** Results from 259 individuals (31.7% men; median age 58 years, range 22–88) were available for the analysis. The median follow-up interval was 3.5 years (range 3–6 years). Two gastric cancer cases (0.8%) and 29 cases with dysplasia (11.2%) were identified. Moderately decreased pepsinogens according to the results from the initial sample collected during the recruitment process was found in 133 subjects (51.4%), severely decreased – in 57 cases (22.1%). The distribution of the precancerous lesions between the groups is given in the Table. No significant further decrease in the pepsinogen values was observed between the initial and follow-up samples.

**Conclusion:** Pepsinogen detection could be a useful tool for identification of subjects at increased risk for developing gastric cancer in general Caucasian population; however only the minority of individuals with decreased pepsinogen levels are presenting with advanced gastric mucosal lesions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1581 FACTORS THAT ARE ASSOCIATED WITH UPGRADE DIAGNOSIS TO SUBMUCOSA OR LYMPHOVASCULAR INVASIVE EARLY GASTRIC CANCER FROM HIGH GRADE DYSPLASIA

R. Daegon, D. Kang, H. Kim, C. Choi, S. Park, S. Kim, H. Nam, J. Jeon, **J. Cho, J. Park, S. Lee**
*Division Of Gastroenterology, Department Of Internal Medicine, Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of*

**Contact E-mail Address:** happy2639@hanmail.net

**Introduction:** Gastric high-grade dysplasia (HGD) is a precancerous lesion. Although Vienna classification recommend endoscopicresection for gastric HGD, 50–70% lesions of resected gastric HGD were diagnosed as gastric cancer. In addition, it is also emerging as a submucosal (SM) cancer or lymphovascular invasion cancer.

**Aims & Methods:** The purpose of the present study is to evaluate predictable factors for pathologic upgrade diagnosis to early gastriccancer (EGC) in patients who HGD diagnosed by endoscopic biopsy and underwent ESD. Additionally, we investigated the risk factors associated with SM cancer or lymphovascular invasion cancer. Between November 2008 and August 2015, a retrospective analysis of a prospective database was conducted at a single tertiary referral center. A total of 295 ESD procedures were carried out for gastric HGD lesions identified by EFB. The rate of being diagnosed with cancer and the predictable factors for upgrade diagnosis to cancer were analyzed.

**Results:** En bloc resection and complete resection rate were 98.6% and 98.9% of the total 295 ESD cases. Pathologic discrepancy between EFB and final resection was 65.8% (194/295). One hundred fifty-two lesions (51.5%) were finally diagnosed EGC (126 mucosal cancers, 26 submucosal cancers, 3 lymphovascular invasion cases) by ESD. Forty two lesions (14.2%) were diagnosed rather downgrade, such as low-grade dysplasia (LGD 37, gastritis 3 and hyperplastic polyp 2). Multivariate analysis revealed that lesion central depression

(OR 3.069 [95% CI 1.528~6.167]), surface redness (OR 2.006 [95% CI 1.011~3.981]) and nodular surface (OR 3.210 [95% CI 1.541~6.688]) were significant risk factors associated with EGC. Additionally, multivariate analysis revealed that only SM fibrosis (OR3.643 [95% CI 1.478~8.981]) was significant risk factor associated with SM cancer or lymphovascular in vasion cancer.
**Conclusion:** Risk factors associated with diagnosed with EGC in HGD patients in the endoscopic biopsy were central depression, surface redness and nodular surface. Futhermore, if you see a SM fibrosis during the ESD procedure SM or lymphovascular invasion cancer probability is higher. Therefore patients with these risk factors should be explained that they may require further surgery in some cases.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1582 WHAT ARE THE FACTORS ASSOCIATED WITH DIFFICULT GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION?

R. Daegon, D. Kang, H. Kim, C. Choi, S. Park, S. Kim, **J. Cho**, H. Nam, J. Park
*Division Of Gastroenterology, Department Of Internal Medicine, Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of*

**Contact E-mail Address:** happy2639@hanmail.net
**Introduction:** Endoscopic submucosal dissection (ESD) is a widely accepted treatment for gastric superficial neoplasm. ESD can lead to serious complications, such as aspiration pneumonia and perforation.
**Aims & Methods:** The aim of this study was to define the difficult ESD and to know the associated factors with difficult ESD. Between January 2012 and September 2014, a total of 1052 ESD procedure were performed at Pusan National University Yangsan Hospital. Difficult ESD was defined by any one of three factors: long procedure time (≥60 minutes), piecemeal resection or occurrence of perforation. To know the associated factors with difficult ESD, clinico-patholgic features and endoscopic findings were analyzed.
**Results:** The rate of difficult ESD was 9.8% (104/1052). Long procedure time (>60 minutes) was 4.8% (51/1052), piecemeal resection was 6.6% (70/1052) and perforation was 0.5% (6/1052). By multivariate analysis, tumor size (≥20 mm) (odds ratio [OR] 2.7; 95% confidence interval [CI] 1.7–4.3), submucosal fibrosis (OR 3.8; 95% CI 2.4–6.1), location of upper third (OR 2.0; 95% CI 1.1–3.8) and submucosal invasion (OR 2.0; 95% CI 1.1–3.8) were associated with difficult ESD.
**Conclusion:** Lesions with size larger than 20 mm, location of upper third, lesions with submucosal fibrosis were associated factors related with difficult ESD. Before performing ESD for lesions which have these risk factors, endoscopists should perform ESD more precisely, and inform the patients about the possible complications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1583 CLINICAL IMPACT OF OBESITY FOR THE PATIENTS WHO UNDERGO ENDOSCOPIC SUBMUCOSAL DISSECTION

**D. Kang**[1], J.M. Park[2], M. Choi[3]

[3]*Inetrnal Medicine, The Catholic University of Korea, Seoul/Korea, Republic of*

**Contact E-mail Address:** etiria@gmail.com
**Introduction:** Obesity is considered one of the unfavorable factors for perioperative outcomes in gastric cancer patients. This study aimed to investigate the clinical impact of overweight or obesity in the patients who received endoscopic submucosal dissection (ESD) with gastric adenoma or early gastric cancer.
**Aims & Methods:** A total of 1571 consecutive patients with gastric neoplasia who underwent ESD at Seoul St. Mary's hospital between December 2010 and March 2016 were enrolled for the study. We analyzed 1181 cases retrospectively, which were divided into three groups by patient's body mass index (BMI) according to the International Obesity Task Force criteria for the Asia-Pacific population: Normal (BMI $< 23\,kg/m^2$, n = 411), Overweight ($23 \leq BMI < 25\,kg/m^2$, n = 312), and Obesity group ($BMI \geq 25\,kg/m^2$, n = 458). Demographics, endoscopic findings, pathologic results and clinical outcomes were analyzed.
**Results:** No significant differences were observed in failure of procedure, en-bloc resection rate, resection margin involvement, invasion into submucosa, or lymphovascular invasion of tumor cells between three groups. In contrast, men were more overweight or obese, and overweight and obesity patients showed longer procedure time (normal vs. overweight vs. obesity, $42.2 \pm 42.6$ vs. $43.8 \pm 35.6$ vs. $49.8 \pm 46.6$ respectively; $p = 0.001$ by Jonckheere-Terpstra test) and the number of the cases which spent 60 minutes or longer were also different (17.3% vs. 22.4% vs. 25.8% respectively, $p = 0.010$). The three groups did not show significant differences in the complication rates including perforation, early and delayed bleeding and subsequent operation after non-curative ESD. We analyzed the factors in relation with longer procedure time over 60 minutes. In univariate analysis, male ($p < 0.001$), obesity ($p = 0.003$), body lesions in longitudinal axis ($p < 0.001$), lesions of lesser curvature ($p = 0.018$), resected lesion size ($p < 0.001$), cancer pathology ($p < 0.001$), tumor invasion into submucosa ($p < 0.001$), and occurrence of the complications ($p < 0.001$) were significantly associated with the longer operation time. In multivariate analysis, we found that male sex ($p = 0.008$), obesity ($p = 0.007$), higher location of the lesion ($p = 0.000$), submucosal invasion ($p = 0.012$) and occurrence of the complication ($p = 0.001$) were independent factors associated with longer procedure time.
**Conclusion:** These results showed that obesity or overweight was not directly associated with clinical outcomes. However, obesity or overweight influenced longer procedure time. Although gastric ESD might be difficult in the obesity patients, it can be performed safely with sufficient precaution.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1584 ENDOSCOPIC PAPILLECTOMY FOR AMPULLARY ADENOMAS: AN ITALIAN SINGLE CENTRE EXPERIENCE

**F. Parmeggiani**, M. Cavina, P. Cecinato, F. Azzolini, V. Iori, G. Sereni, C. Tioli, F. Decembrino, R. Zecchini, R. Sassatelli
*Unit Of Gastroenterology And Digestive Endoscopy, Arcispedale Santa Maria Nuova-IRCCS, reggio emilia/Italy*

**Contact E-mail Address:** francescaparmeggiani@libero.it
**Introduction:** Endoscopic papillectomy (EP) has been recognized as a safe and valuable therapeutic procedure for ampullary adenomas that can obviate the need for potentially major surgical intervention. This study aims to evaluate the effectiveness, the safety and the outcome of this technique.
**Aims & Methods:** In this study we considered all the consecutive patients underwent endoscopic papillectomy because of ampullary tumor at Arcispedale Santa Maria Nuova (Reggio Emilia, Italy) between January 2001 and January 2014. Only patients with diagnosis of ampullary adenoma on the endoscopic resection specimen were included in the analysis. The primary outcome of the study was the technical success of the papillectomy, defined as: a) complete endoscopic removal, even in multiple sessions, confirmed by the absence of residues at histology at the first follow-up; b) endoscopically treated recurrence. Technical failure was defined when at least one of the following criteria was met: a) histology > pT1; b) residual adenomatous tissue not suitable of endoscopic resection; or c) recurrence referred to surgery. The secondary outcomes were the incidence of adverse events, the incidence of recurrence, and the comparison of these outcomes between patients with sporadic ampullary adenomas (SAA) and patients with FAP-associated ones.
**Results:** Among 106 patients with a sospiciuos ampullary tumor, 56 underwent PE for ampullary adenomas: 20 FAP and 36 SAA. Male:38/56 (68%), Median age: 62 ys (20–91); Median size of the lesion: 16 mm (5–80). 49 patients (87.5%) completed at least 24 months follow up. Technical success was achieved in 40 patients (75%): 18 (90%) FAP and 22 (61%) SAA. Mean number of endoscopic session to complete resection was 1.6 (1–4). Recurrence rate (during a 24 month FU) was 7 (12.5%): 3 FAP (15%), 4 SAA (11%); 2 of these (3.5%) were referred to surgery. Morbidity rate was 16.1%, included bleeding in 5 patients (8.9%), and 4 acute pancreatitis (7.1%), all conservatively treated. No perforation or death occurred. Histology showed: nonspecific changes (10.7%), low-grade dysplasia (37.5%), high-grade dysplasia (39.3%) and carcinoma (10.7%). No carcinoma in the FAP group. Biopsy sampling accuracy was higher for low-grade dysplasia (76.2%) compared with high-grade dysplasia (25.0%) or carcinoma (0%) in both group.
**Conclusion:** Endoscopic papillectomy of selected ampullary tumors is a safe and effective procedure and, since it can achieve a complete endoscopic resection, it should be established as the first-line therapy of ampullary adenomas, representing a viable alternative to surgical therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Advanced gastric cancer (AGC) patients with colorectal obstruction usually underwent palliative therapy by using self-expandable metal stent (SEMS) placement or surgery. However, the clinical efficacy and impact of carcinomatosis and ascites status have not been evaluated in patients with colorectal obstruction by AGC according to treatment modalities.
**Aims & Methods:** We retrospectively evaluated 232 patients with colorectal obstruction in AGC that were diagnosed between 2006 and 2014. The study population was analyzed by the patency and overall survival between SEMS placement versus surgery according to carcinomatosis and ascites status.

**Results:** The median age of the study population (126 men, 106 women) was 55 years (SD 12.8). During the follow-up period (mean 24 months, SD 32), 185 (79.7%) patients deployed SEMS and 47 (20.3%) patients received palliative colorectal surgery. The clinical success (57.3% vs 78.7%, P = 0.007) and technical success rate (74.1% vs 93.6%, P = 0.004) were higher in the palliative surgery group than the SEMS placement group. On multivariate analysis, over three lesions of obstruction (HR, 0.237; 95% CI, 0.065–0.860; P = 0.029) and SEMS placement (HR, 0.340; 95% CI, 0.127–0.911; P = 0.032) were independent factor of clinical success. The relative risk of reobstruction was associated with right side of the bowel obstruction (HR, 0.443; 95% CI, 0.211–0.929; P = 0.031), post-chemotherapy (HR, 1.836; 95% CI, 1.006–3.353; P = 0.048), and SEMS placement (HR, 4.022; 95% CI, 1.253–12.913; P = 0.019). The patency of palliative surgery group was longer than the SEMS placement group (P = 0.003 by log-rank test). In subgroup analysis, the patients with good performance who had carcinomatosis with ascites, the patency duration was longer in the surgery group than in the SEMS placement group (P = 0.002 by log-rank test). In patients who had neither carcinomatosis nor ascites, patency duration was longer in the surgery group than in the SEMS placement group (P = 0.041 by log-rank test). In a subgroup of patients who had carcinomatosis without ascites, patency duration was not significantly different between surgery groups and the SEMS placement groups (P = 0.371 by log-rank test). The overall survival rates were not significantly different between surgery and the SEMS placement groups according to carcinomatosis with ascites status.
**Conclusion:** The efficacy of palliative treatment modality for bowel obstruction caused by AGC was affected by carcinomatosis and ascites status.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Laparoscopic endoscopic cooperative surgery (LECS) for gastrointestinal stromal tumors (GIST) was developed in 2008 in Japan and enables the dissection of lesions in a less invasive manner. Recently, modified LECS, such as non-exposed endoscopic wall-inversion surgery (NEWS), and the combination of laparoscopic and endoscopic approaches to neoplasia with a non-exposure technique (CLEAN-NET) were introduced to avoid tumor cells seeding into the peritoneal cavity. We describe a novel method of non-exposure LECS (Closed LECS) for GIST of the stomach.
**Aims & Methods:** Between January 2015 and October 2015, a total of four consecutive patients with GIST of the stomach less than 30 mm in diameter were treated by Closed LECS, which was performed as follows: The patient was placed in a supine position under general anesthesia. A 12 mm camera port was inserted into the umbilicus, and then 5 mm trocars were placed in the upper right and left, and lower left quadrants; a 12 mm trocar was placed in the right lower quadrant. Spotty endoscopic cautery was performed just around the lesion. A circumferential incision into the mucosa was made after the submucosal injection of glycerol. Subsequently, serosal markings were made by laparoscopic surgery under endoscopic guidance. Keeping the surgical sponge retained inside, the seromuscular layer was continuously sutured, allowing inversion of the lesion. Finally, the seromuscular layer was dissected by endoscopy until its complete removal. The lesion was orally extracted using an endoscopic retrieval device. The frequency of successful en bloc resection, the duration of the procedure and the incidence of complications were evaluated.
**Results:** The clinicopathological characteristics were as follows: Study subjects comprised a male and three females with a median age of 66 years (range, 56–68). The median size of the tumor was 16.5 mm (13–20). Three lesions were located in the upper third, and one in the middle third of the stomach [A1]. A preoperative diagnosis was obtained in all cases. A forceps biopsy led to a GIST diagnosis in two cases with delle, whereas endoscopic ultrasound-guided fine-needle aspiration was needed in two cases without delle. En bloc resection was achieved in all cases, with a median procedure duration of 218 min (188–280). Intraoperative perforation occurred in one case at the greater curvature in the upper third of the stomach [A2], and was successfully managed by laparoscopic suturing. No cases developed postoperative complications such as bleeding, pneumonia, anastomosis insufficiency, delayed gastric empting, or surgical site infection. All patients commenced oral intake on postoperative day 2 and were discharged after median postoperative hospital stays of 9 days (8–10).
**Conclusion:** Closed LECS could be one of the treatment options for gastric GIST, especially in patients with delle.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1587 GASTROINTESTINAL STROMAL TUMORS IN THE STOMACH - LONG-TERM PROGNOSIS AFTER CURATIVE RESECTION

**Introduction:** Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors that arises from the gastrointestinal tract, [1]GISTs originate from interstitial cells of Cajal, intestinal pacemaker cells in the gastrointestinal tract. Gastrointestinal stromal tumors (GISTs) in the stomach are characterized by diverse spectrum of morphological and clinical features, ranging from benign to malignant.
**Aims & Methods:** The aim of this study was to evaluate the prognosis of gastric GISTs after curative resection. A total of 155 patients underwent surgery for gastric GIST at Pusan National University Hospital between February 2001 and June 2012. Of them, 10 patients were excluded because of other concomitant malignancy such as gastric cancer. Clinicopathologic features such as age, gender, tumor location, tumor size, mitotic count(/50 high power field [HPF]), histopathologic finding (spindle, epithelioid, mixed), National Institutes of Health(NIH) classification, 7th UICC/AJCC TNM system and recurrence were retrospectively analyzed.
**Results:**

| | N = 145 (%) |
|---|---|
| Median FU duration (month, range) | 43.9 (6.1–144.1) |
| Recurrences | |
| Yes | 9 (6.2) |
| No | 136 (93.8) |
| NIH classification | |
| Very low | 0/25 (0) |
| Low | 0/65 (0) |
| Intermediate | 3/23 (13.0) |
| High | 6/33 (18.2) |
| 7th UICC/AJCC TNM system | |
| I | 1/96 (1.0) |
| II | 3/34 (8.8) |
| IIIA | 4/10 (40) |
| IIIB | 1/5 (20) |
| Recurrent site (N = 11) | |
| Liver | 5 (45.5) |
| Peritoneum | 3 (27.3) |
| Spleen | 2 (18.2) |
| Operation site | 1 (9.1) |

A total of 145 patients were included into final analysis: 64 males and 81 females, with a mean age of 58.0 years. The median tumor size was 3.1 cm (range, 0.7−26 cm). Complete surgical resection was performed in 144 patients (99.3%): one case was ruptured GIST at the time of diagnosis. During median follow-up period of 43.9 months (6.1−144.1 months), 11 recurrent lesions were observed in 9 patients. The most common site was the liver (45.4%), followed by the peritoneal cavity (27.3%), operation site (18.2%) and spleen (9.1%), respectively. According to the NIH classification, all 9 cases were intermediate or high risk group: 3 of 23 intermediate risk cases (13.0%) and 6 of 33 high risk cases (18.2%). According to the 7th UICC/AJCC TNM system, 1 case of tumor

recurrence occurred in stage I, 3 cases in stage II, 4 cases in stage IIIA, 1 case in stage IIIB. The recurrence rate of each stage was 1.0% in stage I, 8.8% in stage II, 40% in stage IIIA, 20% in stage IIIB.
**Conclusion:** The recurrence occurred in the 9 patients. The recurrence rate of gastric GISTs after curative resection was 6.4%. Almost recurred cases occurred in the advanced stage, but this rate was lower than that of previous Western reports.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1588 IS RADICAL SURGERY NECESSARY IN ALL PATIENTS WHO ARE DIAGNOSED WITH EARLY GASTRIC CANCER WITH DEEP SUBMUCOSAL INVASION? RETROSPECTIVE STUDY IN A SINGLE CENTER

**S. Kono**, M. Fukuzawa, T. Itoi
*Gastroenterology And Hepatology, Tokyo Medical University, Shinjuku/Japan*

**Contact E-mail Address:** Shin_kono0527@yahoo.co.jp

**Introduction:** The indication of Endoscopic submucosal dissection (ESD) for early gastric cancer has been extended on the basis of non-inferiority to a treatment outcome of the surgical resection. Therefore, radical surgery is routinely performed for patients who do not meet the curative criteria for ESD due to the risk of lymph node metastasis (LNM). However, this standard therapeutic option may be excessive given the lower number of patients with LNM.
**Aims & Methods:** The purpose of this study is to investigate the clinicopathological factors that influence the probability of LNM in early gastric cancer with deep submucosal (SM) invasion. We reviewed 119 consecutive patients who were diagnosed with early gastric cancer with deep SM invasion after gastrectomy and lymph node dissection between November 2007 and February 2016. Of 119 cases, 19 were performed ESD before gastrectomy. In this study, according to curative criteria for ESD, we determined a deep SM invasion as a depth for more than 500$\mu$m from the muscularis propria. Statistical calculations were performed using SPSS (version 22, Chicago, IL, United States). The data were statistically analyzed using the chi-squared test and an unpaired Student's t test. The independent factors for LNM were analyzed by binary logistic regression analysis.
**Results:** The patient characteristics as follows; male/female: 89/39, mean age $68.8 \pm 11.8$, histological subtype: intestinal/diffuse/gastric carcinoma with lymphoid stroma 69/40/10, location: lower third/middle third/upper third 62/38/19. Of 119 cases, 29 (24.4%) showed LNM. Increased tumor size ($p = 0.001$), lymphovascular invasion($p < 0.001$), the poorly differentiated component ($p < 0.001$), and women ($p = 0.021$) were associated with LNM. Otherwise, gross type, depth of invasion, histological subtype, and location were not associated with LNM. Furthermore, we investigated the independent predictive risk factors for LNM using binary logistic regression analysis. Tumour size ($p = 0.001$, adjusted Odds ratio (OR): 1.05), lymphovascular invasion ($p = 0.025$, adjusted OR: 7.92), and the poorly differentiated component ($p = 0.025$, adjusted OR: 6.43) were independent predictive risk factors for LNM in early gastric cancer with deep SM invasion.
**Conclusion:** Our data represented that lymphovascular invasion and the poorly differentiated component are important factor for the risk of LNM in the gastric cancer with deep SM invasion. This means that no additional treatment after ESD may be an acceptable option for deep SM invasive gastric cancer without those two risk factors. In the near future, appropriate personalized treatment strategies must be required strongly all over the world. As a matter of course, not all patients with deep SM invasive gastric cancer may need for radical surgery.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1589 ANALYSIS OF MICROVASCULAR DENSITY IN GASTRIC TUMOR USING MAGNIFYING ENDOSCOPY COMBINED WITH A NARROW-BAND IMAGING SYSTEM

**M. Kawamura**, H. Naganuma, R. Shibuya, T. Kikuchi, Y. Sakai, F. Nagasaki, E. Nomura, N. Suzuki, E. Saito
*Sendai City Hospital Dept. of Gastroenterology, Sendai/Japan*

**Contact E-mail Address:** dq8m-kwmr@asahi-net.or.jp

**Introduction:** Differential diagnosis between early gastric carcinoma and low-grade adenoma (LDA) is difficult by conventional endoscopy. The narrow-band imaging (NBI) system allows endoscopic observation of minute microvessels in the gastric mucosa. However several studies have reported characteristics of microvessels in gastric carcinoma by magnifying endoscopy with NBI (ME-NBI), differentiation between gastric carcinoma and LDA observed by ME-NBI is still unknown.
**Aims & Methods:** This study aimed to evaluate the microvascular density of gastric tumors (gastric carcinoma and LDA) using ME-NBI. Forty-two differentiated type carcinoma, 10 undifferentiated type carcinoma and 5 LDA were evaluated. The microvessels observed using ME-NBI were extracted from stored still images and the microvascular density was analyzed. Histological vascular density in resected specimens was also evaluated using CD34 immunostaining.
**Results:** The color of tumor appeared mainly reddish in the carcinoma and discolored in the LDA. There were significant differences between the microvascular density in carcinoma and LDA ($8.92 \pm 4.85\%$ vs $1.96 \pm 0.96\%$; $P < 0.01$) using ME-NBI. Vascular density assessed histologically also differed significantly between carcinoma and LDA in both the whole mucosal ($5.32 \pm 3.06\%$ vs $2.24 \pm 0.67\%$; $P < 0.05$) and the superficial mucosal layers (0–100 $\mu$m) ($5.86 \pm 3.57\%$ vs $2.05 \pm 0.49\%$). There was good agreement between ME-NBI and histologically assessed microvascular density in both the whole ($r = 0.667$; $P < 0.001$) and superficial mucosal layers ($r = 0.673$; $P < 0.001$). White opaque substance (WOS) were seen in eight patients of carcinoma and 4 patients of LDA. In almost all cases with WOS, the appearance of the carcinoma was discolored.
**Conclusion:** There was a close relationship between ME-NBI assessed microvascular density and histologically assessed vascular density in mucosal layer. Microvascular density differed significantly between the gastric carcinoma and LDA assessed using ME-NBI.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Poorly cohesive carcinoma (Signet ring cell carcinoma, SRC) is a poorly differentiated cancer of the stomach. Generally, poorly differentiated cancer is believed to show poor prognosis and aggressive behavior. Recently, however, there is debate on the aggressiveness of SRC in early gastric cancer (EGC). We therefore studied post-operation biopsies to investigate the aggressiveness of SRC in EGC.
**Aims & Methods:** We reviewed medical records of patients with EGC who had surgery from January 2011 to December 2015 in a tertiary hospital in Daejeon, South Korea. We evaluated the histologic type, invasion depth, lymphatic invasion and lymph node(LN) metastasis after surgery.
**Results:** 823 EGC lesions from 789 patients were studied. 497 patients had well to moderate differentiated cancer while 65 had poorly differentiated cancer, 187 had SRC, 26 had poorly differentiated with SRC, 37 had mixed type, and 10 patients had medullary carcinoma. LN metastasis was associated with the histologic type of EGC ($p = 0.000$). 9% of differentiated cancer, 21.5% of poorly differentiated cancer, 10.2% of SRC, 11.5% of poor differentiation with SRC, 29.7% of mixed type and 20% of medullary type showed LN metastasis. The risk of SRC was not higher than well to moderated differentiated cancer ($OR = 1.1$, $p = 0.658$). Risk of mixed cancer was highest compared with differentiated cancer ($OR = 4.25$, $p = 0.000$). Risk of lympathic invasion was also similar with LN metastasis. Compared with differentiated cancer, Odds ratio of SRC was 0.79 ($p = 0.191$). There was no LN metastasis in SRC below $< 1$ cm (0/27). 5 LN metastasis were found only in SRC below $< 2$ cm (5/102, 4.9%). 3 LN metastasis were found in

mucosal cancer of SRC (3/120, 2.5%) and 2 LN metastasis in SM1 cancer (2/17, 11.76%).
**Conclusion:** Our results show that LN metastasis and lymphatic invasion is not more aggressive in SRC when compared to differentiated cancer. SRC may be considered a candidate for endoscopic treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1591 LYMPHOCYTIC GASTRITIS IS PRESENT IN CELIAC DISEASE AND IMPROVES AFTER GLUTEN-FREE DIET

**D. Gabrieli**[1], G. Valerii[1], F. Ciccone[1], M. Di Ruscio[1], D. Serva[1], A. Capannolo[1], A. Viscido[1], D. Melideo[1], F. Giuseppe[1], S. Necozione[2], G. Latella[1]

[2]*Epidemiology Unit, Univerity of L'Aquila-S.Salvatore Hospital, L'Aquila/Italy*

**Contact E-mail Address:** doloresgabrieli@gmail.com
**Introduction:** Chronic gastritis appears to be more common in patients with celiac disease (CD).
**Aims & Methods:** Aim of this study is to evaluate the frequency of lymphocytic gastritis (LG), chronic active gastritis (CAG) and chronic inactive gastritis (CIG) in a cohort of patients with CD, and their histological changes after treatment with a gluten-free diet. Methods: A five-year prospective study including all consecutive patients with a new diagnosis of CD performed at our GI Unit, in the period between January 2010 and January 2015. All gastric and duodenal biopsy specimens at the time of the diagnosis of CD and at the first endoscopic control after 18–24 months on gluten-free diet were analyzed. CD diagnosis was made in the presence of anti-tissue transglutaminases and/or anti-endomisial antibodies associated with specific alterations at histological evaluation of duodenal biopsies, according to the modified Marsh-Oberhuber classification. Gastric lesions were classified according to the Updated Sydney System. Giemsa staining was used for histological diagnosis of *Helicobacter pylori* infection and immunohistochemical staining for the diagnosis of LG, defined as a dense proliferation of intraepithelial lymphocytes (more than 25 lymphocytes per 100 epithelial cells). Anti-gastric parietal cell antibodies were assayed by enzyme-linked immunosorbent assay (ELISA). Demographic, clinical, and laboratory data were collected.
**Results:** 250 patients with CD were enrolled (191 F, 59 M, mean age 34 years at the diagnosis). At the time of CD diagnosis, histological examination showed normal gastric mucosa in 78 patients (31.2%), LG in 32 (12.8%), CAG in 74 (29.6%), and CIG in 66 (26.4%). Out of 32 patients with LG, 20 (62.5%) were *H. pylori* negative and all of them showed an improvement of gastritis after gluten free diet. Out of 74 patients with CAG, 30 (40.5%) were *H. pylori* negative and one third of them showed an improvement of gastritis after gluten-free diet. Out of 66 patients with CIG, 63 (95.4%) patients were *H. pylori* negative. LG is significantly associated to histological improvement after gluten-free diet compared to other types of gastritis ($p = 0.0039$).
**Conclusion:** Subtypes of gastritis have different probability to be influenced by the gluten-free diet. LG is present in a significant number (13%) of CD patients and seems to improve as well as duodenal lesions after gluten-free diet. Two-thirds of LG are not associated with *H. pylori* infection. Both CAG and CIG are also significantly associated with coeliac disease, despite less influenced by gluten-free diet.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Upper-gastrointestinal (GI) symptoms are a common reason for self-treatment with Over the Counter medications. (OTC). However data are scarce on the typology of GI complaints for which individuals seek self-medication and more importantly, on the prevalence of the alarm symptoms in this population.
**Aims & Methods:** The aim of this study was to investigate the: a. the nature of GI symptoms that people intend to self-medicate b. the prevalence of alarm symptoms c. adherence to referral advice given by the pharmacist d. self-reported efficaccy and frequency of use of OTC medication for minor complaints. Methods: This descriptive study was conducted in 13 pharmacies located in Tirana, the capital of Albania. the study was conducted from November 2015 till January 2016. Participants ($N = 192$) completed a questionnaire to assess symptoms characteristics and previous medical consulting. Based on this information the pharmacist referred subjects to the physician or advised for self-treatment. Four weeks later, participants were presented a follow-up questionnaire evaluating their adherence to referral advice or efficaccy of self-treatment.
**Results:** The most frequently reported GI symptoms were burning retrosternal discomfort (39.2%), acid regurtation (56.2%) and postprandial fullness (61.2%). At least one alarm symptom was present in 22.4% of the individuals, with difficulty in swallowing being the most prevalent (14.4%). Although 21% of the patients were referred, only 41.7% of them contacted a physician. Almost all (95.1%) of the remaining customers who were advised self-treatment reported symptom relief with the OTC drug obtained.
**Conclusion:** Mild gastrointestinal symptoms will mostly resolve with self-treatment. Yet, the value of pharmacist counseling on OTC treatment should be recognized, as community pharmacist can play an important role in distinguishing symptoms that warrant further medical examination.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1593 SHOULD GENERAL PHYSICIANS/INTERNISTS OR GI SPECIALISTS MANAGE PEPTIC ULCER DISEASE?

**B. Porter**[1], L. Lim[2], R. Logan[1]
[1]*Department Of Gastroenterology, Kings College Hospital, London/United Kingdom*
[2]*Gastroenterology, King's College Hospital, London/United Kingdom*

**Contact E-mail Address:** benedictporter@nhs.net
**Introduction:** *H. pylori* is the cause of >90% of duodenal ulcers (DU) and >60% gastric ulcers (GU) with eradication of infection curing the ulcer diathesis and preventing recurrence. National UK guidelines recommend testing for *H. pylori* in all patients with DU & GU and treating those found to be infected[1].
**Aims & Methods:** To assess if patients with PUD are being cured by eradication of *H. pylori*. Methods: analysis of endoscopy database with linked electronic case note review from 2012–2106. *H. pylori* status was assessed by CLO-test or using stool antigen (HpSA) prior to treatment. Eradication was assessed by $^{13}$C-Urea Breath test or repeat HpSA at least 6 weeks after finishing treatment.
**Results:** From Dec 2012-March 2016, 413 patients (69% men, mean age 59yr range 12–95yrs), were found to have DU ($n = 209$), GU ($n = 186$) or both ($n = 18$) at the time of their endoscopy. 52% of patients were inpatients, of whom 33% were undergoing OGD due to upper GI bleeding. Overall CLO test was done in 263/413 (76%) with results available for 53% of whom 37% were positive. However only 62% of those found to be infected were given eradication therapy. Subsequently a UBT test to assess eradication occurred in only 50% (HpSA in 3%), and was negative in only 76%. Analysis of the data by supervising speciality showed the following:

Outcomes by general internist vs GI specialist

| | Generalist / Internist | GI specialist | Significance ($\chi^2$) |
|---|---|---|---|
| DU(n)/GU(n)/PU(n) | 169/164/12 | 40/22/6 | |
| CLO-test taken | 263/345 (76%) | 68/68 (100%) | $p < 0.0001$ |
| CLO-test result available | 147/345 (43%) | 68/68 (100%) | $p < 0.0001$ |
| CLO-test positive | 96/147 (65%) | 68/68 (100%) | $p = 0.01$ |
| Hp eradication given | 96/96 (100%) | 68/68 (100%) | |
| patients lost to follow-up | 60/96 (63%) | 8/68 (12%) | $p < 0.0001$ |
| Hp eradication assessed | 36 | 60 | |
| % eradicated | 17/36 (47%) | 56/60 (94%) | $p < 0.0001$ |
| NICE standard achieved | 17/96 (18%) | 56/68 (82%) | $p < 0.0001$ |

**Conclusion:** The opportunity to cure peptic ulcer disease by Hp testing and eradication of *H. pylori* in those found to be infected is not being taken in patients admitted to hospital, particularly if under the care of general physicians. Patients with *H. pylori*-associated PUD should be looked after by GI specialists with an interest in *H. pylori*.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Increasing the appropriateness of use of upper GI endoscopy is important to improve the quality of care while containing costs.
**Aims & Methods:** Aim of this study was to evaluate the appropriateness of upper GI endoscopy in out-patients through a strict selection of endoscopy prescriptions, Gastropanel introduction and endoscopic activity reorganization. A total of 5192 upper GI endoscopy requests were prospectively evaluated from July 2013 to July 2015. The upper GI endoscopy reservation was managed by our Endoscopy Unit and all the prescriptions were evaluated by a senior endoscopist. All the requests were evaluated within 24 hours. The endoscopist evaluated if the prescription was appropriated and decided the timing. In some cases, the endoscopist could either cancel the request or chose a less invasive examination (i.e. Gastropanel) which evaluates serum levels of gastrin 17 (G17), Pepsinogen I (PGI) and II (PGII) and *Helicobacter pylori* (Hp) antibodies.
**Results:** 540 of 5192 upper GI endoscopy requests (10.4%, age 50 years, range 14–91) were judged inappropriate. The cancelled requests were due in 66 cases for dyspepsia, 307 for gastroesophageal reflux disease (GERD), 34 for cases without written indication, 113 for wrong follow-up, 20 for other indications. 282 of 540 patients did Gastropanel and showed in 94 normal values, in 48 normal values but in PPI therapy, in 56 an Hp infection, in 30 an Hp eradication, in 50 GERD and in 4 an atrophic gastritis. In the last 4 cases, an upper GI endoscopy was done immediately after Gastropanel reporting. 105 of 540 cancelled requests performed a upper GI endoscopy within 2 years (range 1–22 months) after evaluation: 71 of 105 (67.5%) were normal and no cancer was found.
**Conclusion:** This strategy, based on a strict control of the prescription, is effective to increase the appropriateness without any additional public cost. The use of Gastropanel improves patient selection for upper GI endoscopy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Eradication of *Helicobacter pylori* (HP) with acid inhibitors and antibiotics have a success rate of 90%. Unfortunately, resistance to the treatment has been seen despite treatment with various antibiotic regimes [1].
**Aims & Methods:** Aims • To describe the clinical, pathological, microbiological and immunological phenotypes in patients resistant to repeated and various treatment regimes. • To examine the effect of levofloxacin on the efficacy to obtain eradication of HP. Methods There were 4 groups of patients: Group 1: HP treatment resistant after at least two different treatment regimes where patients were included: Group 2: patients with newly diagnosed HP infection; Group 3: patients with previously treated to eradication of HP infection Group 4: patients with normal endoscopy including HP status. Group 1 and group 2 were both treated with acid suppressive agent whereas the antibiotic regime was amoxicillin/levofloxacine and amoxicillin/clarytromycin, respectively. The gastric biopsies were analysed for histological changes according to the Sidney classification, mucosal gene-expressions of TH1, TH2, TH17 og T-reg cytokines performed byRT-PCR technique, whereas HP resistance were examined according to conventional methods.
**Results:** The number of patients included were 42, 50, 61and 32 in the four groups, respectively. No significant differences were found in dyspeptic symptoms between the groups. HP was successfully eradicated in 89% and 73% in group 1 and Group 2, respectively. Sydney classification showed significant higher infiltration of neutrofils and monocytes in group 2 compared to group 1, 3 and 4. When comparing the cytokines, the resistant group had significantly lower gene transcript for TNF alpha and IL.10, whereas significantly higher gene transcript for all cytokines were observed when compared to the previously eradicated group and no infection group (table 1). In group 1 there was more clarithromycin and metronidazole resistance than in group 2 at non-significant level, tetracyclin resistance was low in both groups whereas Amoxicillin resistance was not observed in any of the Groups. In the control endoscopy after treatment metronidazole resistance was observe in 1 patient in group 1, and clarythromycin and metronidazole resistance were observed in 1 and 3 patients, respectively.

**Table 1:** Gene expression in groups relative to the resistant infection Group

| Gene | ANOVA P | Newly diagnosed | Previously eradicated | No infection |
|---|---|---|---|---|
| **TNF alpha** | <0.0005 | 2.2(1.4–3.4)* | 0.36(0.22–0.58)* | 0.54(0.34–0.87)* |
| **IL17A** | <0.0005 | 1.9(0.9–3.9)n.s. | 0.13(0.06–0.30)* | 0.07(0.03–0.25)* |
| **IL33** | 0.001 | 1.2(0.8–1.9)n.s. | 1.8(1.1–3.0)* | 2.8(1.7–4.5)* |
| **IL10** | <0.0005 | 3.0(1.7–5.2)* | 0.31(0.16–0.60)* | 0.33(0.18–0.61)* |
| **TGFB1** | <0.0005 | 1.3(0.9–1.8)n.s. | 0.53(0.37–0.76)* | 0.64(0.45–0.91)* |
| **TBX** | <0.0005 | 1.3(0.9–1.9)n.s. | 0.43(0.28–0.65)* | 0.62(0.41–0.95)* |
| **FOXP3** | <0.0005 | 2.4(1.4–4.1)* | 0.34(0.18–0.62)* | 0.38(0.21–0.67)* |

Values are fold difference (95% CI) P value for contrast vs. the resistant infection group. Asterisk indicates significant contrast.
**Conclusion:** Levofloxacine is highly effective to eradicate HP in previously treatment- resistant patients. This treatment- resistant cohort had a lower histological inflammation, lower proinflammatory cytokine profile, and high resistance against clarithromycin and metronidazole compared to the cohort of newly diagnosed HP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Institute Of Pathology, Otto-von-Guericke University, Magdeburg/Germany*

**Contact E-mail Address:** arne.kandulski@med.ovgu.de
**Introduction:** *H. pylori* infection leads to chronic gastritis with further development of premalignant conditions (atrophy, intestinal metaplasia), which are the known risk factors for gastric cancer. Besides bacterial virulence factors the inflammatory mucosal micromilieu determines the course of gastritis. The mucosal Th17 response has been suggested to crucially influence malignant progression but has not been studied in detail in humans.
**Aims & Methods:** To characterize the human mucosal Th17 response ex vivo and *H. pylori*-specific activation of human CD4+ T cells in vitro. Analysis of mucosal gene expression and immunohistochemical staining of RORyt and IL-17 in antrum mucosa of 66 *H. pylori*-negative and 91 *H. pylori*-positive prospectively recruited patients. We established a human in vitro system using *H. pylori*-specific (*H. pylori* BCM300) antigen presenting cells (APC) to activate CD4+ T cells. APC and CD4+ T cells were isolated from human PBMC of *H. pylori*-negative donors. Th17 immune response was analyzed by IL-17 protein secretion and gene expression in CD4+ T cells as well as STAT3/p-STAT3 pathway in CD4+ T cells upon activation with *H. pylori*-specific APCs by WB analysis.
**Results:** *H. pylori*-positive patients showed 2.8–14.4-fold gene expression of RORyt and IL-17 in antrum mucosa. These findings were confirmed by immunohistochemistry demonstrating infiltrating CD4/RORyt positive T cells in the mucosa of *H. pylori*-infected patients. In in vitro model, *H. pylori*-specific activation of CD4+ T cells leads to induction of IL-17 gene expression and IL-17 secretion. Furthermore, we demonstrate the *H. pylori*-dependent activation of STAT3/p-STAT3 pathway that is crucial for Th17 development and immune response.
**Conclusion:** The inflammatory micromilieu determine the course of *H. pylori* gastritis. For malignant progression Th17 immune response is discussed as a promoting condition in animal models. This is one of the first studies characterizing mucosal *H. pylori*-specific Th17 immune response in human CD4+ T cells using ex vivo and in vitro models.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1597 CURCUMIN UPREGULATES INDOLEAMINE 2,3-DIOXYGENASE (IDO) AND DOWNREGULATES INTERLEUKIN (IL)-17 PRODUCTION IN HELICOBACTER PYLORI-INFECTED HUMAN GASTRIC MUCOSA

**T. La Russa**, E. Suraci, S. Gervasi, R. Placida, R. Marasco, M. Imeneo, F. Luzza
*Health Of Sciences, Università degli Studi Magna Graecia, Catanzaro/Italy*

**Contact E-mail Address:** tiziana.larussa@gmail.com

**Introduction:** IL-17 plays a role in the host response against *H. pylori* and, possibly, in its clearance/persistence. We demonstrated that an enhanced expression of IDO, the enzyme promoting the effector T-cells apoptosis and the differentiation of regulatory T cells, downregulates Th17 pathway in *H. pylori*-infected human gastric mucosa. The phytochemical compound curcumin was suggested as an anti-*H. pylori* agent due to its anti-inflammatory, anti-oxidant and anti-microbial properties.

**Aims & Methods:** Five antral biopsies were taken from 11 patients (6 M, median age 51 years, range 20–74) who underwent upper gastrointestinal endoscopy for dyspeptic symptoms: 1 for urease quick test (Eurospital, Trieste, Italy), 2 for histology (Giemsa staining for *H. pylori* and modified Sydney System for gastritis score), and 2 for organ culture. A C13-urea breath test was also performed (at least two tests positive and all the three tests negative to be considered *H. pylori*-infected or uninfected). Biopsy samples were immediately placed in an organ culture chamber and treated with and without curcumin 200 μM (Sigma, St. Louis, MO, USA) for 6 hours and 20 hours. Preliminary experiments were performed in order to optimize the time course (4, 6, 12, 20 and 24 hours). The expression of IDO protein and that of IL-17 were determined by Western blotting in total proteins extracted from gastric biopsy cultures, after 6 and 20 hours, respectively. The ratio of IDO and IL-17 with beta-actin was calculated by densitometry and values expressed as means ± SD arbitrary units (a.u.).

**Results:** As expected, inflammatory changes were more severe in gastric mucosal samples from *H. pylori*-infected ($n = 7$) than uninfected ($n = 4$) patients (gastritis score $5.8 \pm 1.9$ vs $1.4 \pm 1.5$, $p < 0.01$). IDO significantly increased in *H. pylori*-infected gastric mucosal samples treated with curcumin compared with untreated samples ($0.71 \pm 0.20$ a.u. vs $0.38 \pm 0.11$ a.u., $p = 0.01$). In the same patients, a significant reduction in IL-17 levels was found in samples treated with curcumin compared with those untreated ($0.37 \pm 0.18$ a.u. vs $0.53 \pm 0.20$ a.u., $p = 0.004$). Levels of both IDO and IL-17 were very low in untreated *H. pylori*-uninfected samples and did not significantly change in curcumin-treated samples.

**Conclusion:** This study demonstrates, for the first time, that curcumin enhances IDO expression and downregulates IL-17 production in *H. pylori*-infected human gastric mucosa. This could be part of the complex anti-inflammatory effect exerted by curcumin, supporting the potential immunomodulatory role of the compound in *H. pylori* infection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1598 DECREASED GHRELIN RELEASE: POTENTIAL LINK BETWEEN HELICOBACTER PYLORI INFECTION AND CARDIOVASCULAR DISEASE?

**A. Gaus**[1], P. Layer[1], V. Andresen[1], J.J. Holst[2], J. Keller[1]

[2]*Panum Institute, University of Copenhagen, Copenhagen/Denmark*

**Contact E-mail Address:** a.gaus@ik-h.de

**Introduction:** Both HP infection and decreased ghrelin release have been shown to increase the risk of cardiovascular (CV) disease. Thus, it is intriguing to speculate that HP-induced atrophic gastritis with reduced release of ghrelin from the gastric mucosa (1) may promote CV disease in HP infection. On the other hand, ghrelin release is also associated with classical CV risk factors such as obesity and diabetes.

**Aims & Methods:** We aimed to clarify whether HP infection is an independent risk factor for decreased interdigestive and postprandial ghrelin release. Patients received a 420 kcal test meal. Blood samples for ghrelin and blood glucose measurements were drawn at regular intervals for 3 hours. Traditional CV risk factors including age, gender, body mass index (BMI), total cholesterol, low-density lipoprotein cholesterol (LDL), high-density lipoprotein cholesterol (HDL), triglycerides, HbA1c, smoking habits, family history, prevalence of arterial hypertension and diabetes were evaluated. Carotid intima-media thickness was determined sonographically. HP infection was diagnosed based on specific immunological and/or histological testing.

**Results:** 58 subjects were included (39 females). Fasting and postprandial ghrelin release correlated inversely with fasting and postprandial blood glucose concentration as well as with HbA1c ($p < 0.05$). Accordingly, diabetics ($N = 13$) had significantly lower ghrelin release than patients without diabetes. Furthermore, postprandial ghrelin release was inversely correlated with BMI ($p = 0.005$) and LDL ($p = 0.02$) and was directly associated with HDL ($p = 0.0004$). Males ($N = 19$) had significantly lower postprandial ghrelin release than females ($N = 39$) (mean ± SEM: $462 \pm 37$ vs. $659 \pm 42$ pg/mL, $p = 0.001$) and ghrelin was significantly reduced in HP-positive patients ($N = 16$) ($468 \pm 36$ vs. $661 \pm 41$ pg/mL, $p = 0.001$). Multivariate linear regression analysis revealed that only sex and HP status were independent predictors of postprandial ghrelin release.

**Conclusion:** Decreased ghrelin release in HP infection is not a consequence of its association with classical CV risk factors such as disturbed blood glucose control, dyslipidemia and obesity. Since ghrelin exerts protective effects on the CV system, its impaired release may be of pathophysiological importance for explaining the association between HP infection and CV disease.

## P1599 THE PREDICTORS OF THE GASTRODUODENAL ZONE EROSIVE-ULCERATIVE LESIONS DEVELOPMENT IN PATIENTS WITH LEUKEMIA

**I. Skrypnyk**[1], G. Maslova[2], R. Skrypnyk[1]
[1]*Internal Medicine #1Ukrainian Medical Stomatological Academy Internal Medicine, Poltava/Ukraine*
[2]*Internal Medicine#1, Ukrainian Medical Stomatological Academe, Poltava/Ukraine*

**Contact E-mail Address:** scrin69@yandex.ru

**Introduction:** Patients with acute (AL) and chronic leukemia (CL) during chemotherapy have high risk of the secondary polyorganic complications development. The development of erosive-ulceretive lesions (EUL) of mucosal layer in gastroduodenal zone (GDZ) limits the dose maintenance and cytotostatic therapy regimes, aggravate early and late chemotherapy results.

**Aims & Methods:** We aimed to examine the role of impaired resistance mucosal barrier in the GDZ EUL development in patients with AL and CL. Material and methods: 159 patients with AL and CL were examined and divided into 2 groups depending on types of leukemia: I ($n = 78$) – AL patients; II ($n = 81$) – CL patients, aged 17–77 years; 87(54.7%) males, 72(45.3%) females. During the 1st course of chemotherapy the presence of chronic gastritis (CG), ulcer disease (UD), *Helicobacter pylori* (HP) infection, mucosal barrier status was assessed. The patients groups I and II were divided into subgroups according to the upper endoscopy Results: I-A ($n = 44$) – AL patients without GDZ EUL; I-B ($n = 34$) – AL patients with GDZ EUL; II-A ($n = 62$) – CL patients without GDZ EUL; II-B ($n = 19$) – CL patients with GDZ EUL. Mucosal barrier status was estimated by the concentations of N-acetylneuraminic acid (NANA) in serum and the level of its excretion in the urine, protein-bound and unbound fucose concentration in blood serum and fucose urinary level before chemotherapy.

**Results:** By the clinical records the presence of the chronic GI diseases in 24 (30.7%) AL patients I and 35 (43.2%) CL patients II groups was estimated, HP-infection – in 47 (60.2%) AL patients of group I and 54 (66.6%) CL patients of group II. EUL on upper GI segment were revealed in 34 (43.6%) patients of I and in 19 (23.4%) patients of II groups, in 16 (47%) and 15 (78.9%) patients of them were estimated CG, UD, HP-infection – in 28 (82.3%) and 17 (89.4%) respectively. During assessment of mucosal barrier status the increased serum NANA concentration in 1.2 times was noticed in patients of I-A subgroup, in I-B and II-B subgroups with EUL in GDZ during chemotherapy – in 1.3 times ($p < 0.05$) compared with normal. The level of NANA excretion was elevated in patients of I-A, II-A subgroups in 1.36 and 1.34 times and in patients of I-B, II-B subgroups in 1.5 and 1.4 times compare with normal ($p < 0.01$). In patients of I-A, II-A subgroups protein-bound fucose concentration decreased in 1.5 and 1.36 times respectively ($p < 0.05$), and in patients of I-B, II-B subgroups in 2,5 and 2 times respectively ($p < 0.01$) compared with normal values. The level of fucose urinary excretion in pts of I-A, II-A subgroups decreased in 1.2 and in patients of II-A, II-B subgroups – in 2 and 1,9 times respectively ($p < 0.001$) compared with normal.

**Conclusion:** In patients with acute and chronic leukemia the highest risk of the GDZ EUL development was observed in patients with CG, UD, HP-infection in anamnesis, that was accompanied with impaired resistance of GDZ mucosal barrier. The impairment barrier function is characterized by increased sialoproteins degradation, decreased fucoproteins synthesis. It can be considered as the risk factor of the GDZ EUL of mucosal layer development during chemotherapy.

## P1600 COMPARISON BETWEEN A POTASSIUM-COMPETITIVE ACID BLOCKER AND A PROTON PUMP INHIBITOR FOR THE EFFICACY OF HELICOBACTER PYLORI ERADICATION IN JAPANESE PATIENTS

**Y. Yamaguchi**, H. Noda, S. Noguchi, T. Yoshimine, S. Goji, K. Adachi, Y. Tamura, S. Izawa, M. Ebi, S. Yamamoto, N. Ogasawara, Y. Funaki, M. Sasaki, K. Kasugai

**Introduction:** *Helicobacter pylori* (*H. pylori*) is one of the most prevalent bacterial pathogens and is associated with upper gastrointestinal disorders such as gastritis, peptic ulcers, functional dyspepsia, gastric mucosa-associated lymphoid tissue lymphoma, and gastric cancer [1][2][3]. Eradication of *H. pylori* infection is reported to provide an effective approach to curing or preventing these *H. pylori*-associated diseases [4][5]. In Japan, 7-day triple therapy for *H.*

*pylori* including clarithromycin (CAM) was approved in 2000. However, antibiotic resistance subsequently reduced this rate to an unacceptable level (70%). Vonoprazan, an orally bioavailable potassium-competitive acid blocker (P-CAB), was approved in 2014 for use in Japan. This could improve eradication rates by increasing the intragastric pH, thus increasing bacterial antibiotic susceptibility.

**Aims & Methods:** This study compared the efficacy of 7-day triple therapies that included amoxicillin, CAM, and P-CAB or proton pump inhibitor (PPI). We prospectively analyzed *H. pylori* eradication rates in 146 patients receiving 7-day triple therapy containing P-CAB (April 2014 to September 2015), and in 1305 patients retrospectively who received 7-day triple therapy containing PPI (April 2011 to September 2015).

**Results:** *H. pylori* was eradicated in 89.7% (131/146) of P-CAB-treated patients; this was significantly higher than the PPI-treated patients (73.9%; 965/1305; $p < 0.05$). The eradication rates in P-CAB-treated CAM-sensitive and CAM-resistant patients were 100% (44/44) and 87.5% (28/32), respectively; these were significantly higher than the corresponding rates in PPI-treated patients (88.0% [22/25] and 53.8% [7/13], $p < 0.05$).

**Conclusion:** P-CAB improved the efficacy of CAM-containing 7-day triple therapy in patients with CAM-resistant *H. pylori*. P-CAB is considered to exceedingly develop the strategy for *H. pylori* eradication worldwide.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1601 EFFICACY AND TOLERABILITY OF A TRIPLE THERAPY CONTAINING A POTASSIUM-COMPETITIVE ACID BLOCKER AS FIRST-LINE TREATMENT FOR HELICOBACTER PYLORI INFECTION

**S. Suzuki**, T. Gotoda, C. Kusano, K. Iwatsuka, M. Moriyama
*Division Of Gastroenterology And Hepatology, Department Of Medicine, Nihon University School of Medicine, Tokyo/Japan*

**Contact E-mail Address:** s.sho.salubriter.mail@gmail.com

**Introduction:** Potassium-competitive acid blocker (P-CAB) is a new class of gastric acid inhibitory agents. Vonoprazan (VPZ) is a novel, orally active P-CAB. The acid inhibitory effect of VPZ was shown to be greater than that of proton pump inhibitor (PPI). However, the efficacy of VPZ for *Helicobacter pylori* (*H. pylori*) eradication treatment remains unknown.

**Aims & Methods:** This study evaluated the efficacy and tolerability of VPZ as first-line *H. pylori* eradication treatment compared with PPI-based triple therapies. We retrospectively reviewed the medical records of 733 consecutive patients who received first-line *H. pylori* eradication treatment at Yuri Kumiai General Hospital between January 2013 and January 2016. Patients who received 7-day VPZ-based therapy (vonoprazan 20 mg + amoxicillin 750 mg + clarithromycin 200 mg twice/day) were compared with those who received 7-day lansoprazole (LPZ) or rabeprazole (RPZ) based therapies (lansoprazole 30 mg / rabeprazole 20 mg + amoxicillin 750 mg + clarithromycin 200 mg twice/day). The successful eradication and adverse event rates of VPZ therapy were compared with those of LPZ or RPZ therapies.

**Results:** Among 733 patients who received first-line *H. pylori* eradication treatment, 253 patients were received VPZ therapy, 402 patients were received LPZ therapy, and 78 patients were received RPZ therapy. The eradication rates of VPZ therapy were significantly higher than both LPZ and RPZ therapies in intention-to-treat (87.8% vs. 74.1%; $p < 0.001$ / 87.8% vs. 74.4%; $p = 0.004$,) and per-protocol analyses (90.2% vs. 78.0%; $p < 0.001$ / 90.2% vs. 77.3%; $p = 0.003$). There was no significant difference in the incidence of adverse events between the three therapies except skin rash. The incidence of skin rash was significantly higher with VPZ than with LPZ therapy (5.1% vs 1.5%; $p = 0.007$). No patients discontinued *H. pylori* eradication treatment because of adverse events.

**Conclusion:** 7-day VPZ-based triple therapy was more effective than 7-day PPI-based triple therapies as a first-line *H. pylori* eradication treatment. Although the incidence of skin rash was higher with VPZ therapy, 7-day VPZ-based triple therapy was generally well tolerated.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1602 A COMPARATIVE STUDY OF POTASSIUM-COMPETITIVE ACID BLOCKER (VONOPRAZAN) AND PROTON POMP INHIBITORS IN HELICOBACTER PYLORI ERADICATION THERAPY

**H. Suda**, K. Sakurai, Y. Ido, T. Takeichi, A. Okuda, K. Hasuda, M. Masahiro Hattori
*Hattori Clinic, Kumamoto/Japan*

**Contact E-mail Address:** sudahiro0825@gmail.com

**Introduction:** Triple therapy, proton pomp inhibitor (PPI) combined with antibiotics for *H. pylori* eradication has been shown to be effective for *H. pylori* related upper gastrointestinal diseases. Recently, the eradication rate of the first-line treatment has been reported to decrease due to the increased prevalence of Clarithromycin (CAM) resistant, thus more effective strategy is required. Potassium-competitive acid blockers (P-CABs) are new class of gastric acid suppressant agents, which lead to more intensive and longer acid suppression than PPIs. As maintaining intragastric pH higher is crucial in *H. pylori* eradication therapy, we assume P-CABs might be more effective than PPIs in *H. pylori* eradication.

**Aims & Methods:** We retrospectively evaluated the clinical effectiveness and safety of Vonoprazan 20 mg (P-CAB)-based eradication therapy compared to conventional PPI-based therapies. We investigated data of our *H. pylori*-positive patients administered the first-line (with Clarithromycin and Amoxicillin) ($n = 1353$) and the second-line (with Metronitazole and Amoxicillin) ($n = 261$) eradication therapy from April 2014 to December 2015 at Hattori clinic. The primary endpoint was the assessment of eradication rates by Full analysis set (FAS). The secondary endpoints were the evaluations of adverse events (AE) and related factors for *H. pylori* eradication therapy.

**Results:** In the first-line treatment, the eradication rates of Vonoprazan (VPZ), Esomeprazol (EPZ), Raveprazole (RPZ) and Lansoprazole (LPZ) were 87.9% (95% CI: 84.9–90.5%), 71.6% (95% CI: 67.5–75.5%), 62.9% (95% CI: 52.0–72.9%), 57.3% (95% CI: 50.4–64.1%), respectively. The eradication rate VPZ was significantly higher than that of other PPIs ($P < 0.05$). Interestingly, smoking decreased the eradication rate (non-smoker: 68.1%, smoker; 56.6%) in PPI group ($P = 0.013$). By contrast, smoking did not affect the eradication rate (non-smoker; 87.3%, smoker; 91.3%) in VPZ group ($P = 0.34$). Sex, age, obesity, alcohol habit and the degree of atrophic gastritis were not predicting factors. The AE incidence of VPZ (61/546; 11.2%) was higher than that of EPZ (39/507; 7.7%), though there was no significant difference ($P = 0.054$). Meanwhile, there were no significant differences in the second-line treatment, including the eradication rate, predicting factors and AE incidence.

**Conclusion:** VPZ might be superior to conventional PPIs in the first-line *H. pylori* eradication therapy, especially for the smoking patients. However, it is necessary to be careful with AEs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1603 EFFECT OF VONOPRAZAN IN TRIPLE THERAPY FOR ERADICATION OF HELICOBACTER PYLORI: INTERIM ANALYSIS OF A SINGLE-CENTRE RANDOMISED CONTROLLED TRIAL

**H. Sasaki**, K. Fujimasa, M. Yamasaki, T. Fujioka, H. Makita, T. Yamasaki, N. Tokuhiro, T. Satoh
*Section Of Gastroenterology, Makita General Hospital, Tokyo/Japan*

**Contact E-mail Address:** black_velvet881@yahoo.co.jp

**Introduction:** Vonoprazan (VPZ) is new potassium-competitive acid blocker. Recently, a phase III randomised study of VPZ for eradication therapy of *Helicobacter pylori* (*H. pylori*) infection was published. The study was a non-inferiority trial that compared VPZ to lansoprazole in *H. pylori* eradication therapy. However, a comparative trial to determine the advantage of VPZ over existing acid blocker has not been conducted. We therefore performed a randomised controlled trial to confirm the effectiveness of VPZ in the eradication of *H. pylori* infection and to elucidate its advantages.

**Aims & Methods:** We aimed to determine the effectiveness and advantage of VPZ in triple therapy eradication of *H. pylori* infection. Subjects comprised patients undergoing eradication therapy for *H. pylori* infection in our hospital. Patients with a history of eradication therapy, gastrectomy, or allergy to medications in triple therapy were excluded. Written informed consent was obtained for each patient. This trial was performed as a randomised open-labelled clinical study with the permission of an institutional review board. Each patient was randomly enrolled for VPZ therapy group (VPZ 20 mg, amoxicillin 750 mg, clarithromycin 200 mg, twice a day for 7 days) or esomeprazole (EPZ) therapy group (EPZ 20 mg, amoxicillin 750 mg, clarithromycin 200 mg, twice a day for 7 days). Before starting therapy, we checked the background characteristics of each patient (age; gender; weight; height; drinking habit; smoking habit; use of probiotics, bismuth, PPI, or P-cab; and endoscopic findings). After the therapy, we asked about medication compliance and side effects. The primary endpoint was the eradication rate. The secondary endpoints were the rates of side effects. The target number of cases was 240 (120 cases in each group). Because of the ethical point of view, we performed an interim analysis when the number of cases per protocol reached 100.

**Results:** Of the 110 patients who were recruited, 10 dropped out. We allocated 57 patients to VPZ therapy group. For VPZ therapy group and EPZ therapy group, the eradication rates were 93.0% (95% confidence interval, 85.1%-100.9%) and 83.7% (95% confidence interval, 73.9%-95.5%) respectively, and the rates of side effects were 16.4% (95% confidence interval, 6.0%-26.8%) and 28.9%

(95% confidence interval, 17.2%-40.6%) respectively. For each group, no statistically significant difference in eradication rate was seen. **Discussion:** We performed an interim analysis as the number of cases per protocol reached 100. The results of univariate analysis (chi-square test) of eradication rate and rate of side effects for each therapy were p = 0.143 and p = 0.117 respectively. Although there were no statistically significant differences, the VPZ group revealed trends of high eradication rates and low rates of side effects. However, this analysis did not show any evident advantages of VPZ over EPZ; therefore, we decided to go on the current study.
**Conclusion:** The findings suggest that VPZ is effective in eradication of *H. pylori* infection. The advantage of VPZ has not yet been determined.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1604 A COMPARISON BETWEEN HYBRID AND CONCOMITANT REGIMENS FOR HELICOBACTER PYLORI ERADICATION: A RANDOMIZED CLINICAL TRIAL

**Z. Bari**[1], S. Alhooei[2], H. Fakheri[1], V. Hosseini[1], I. Maleki[1], S.M. Valizadeh[1], T. Taghvaei[1], A. Kazemi[1]
[1]*Gut And Liver Research Center, Mazandaran University of Medical Sciences, Sari/Iran*
[2]*Golestan University of Medical Sciences, Gorgan/Iran*

**Contact E-mail Address:** zohreb252@yahoo.com
**Introduction:** *Helicobacter pylori* infection is an important issue in global health, since almost half of the world's population is infected by the organism. Also, the infection is associated with peptic ulcer disease, gastric adenocarcinoma and lymphoma.
**Aims & Methods:** Two hundred and fifty-two patients with naïve *H. pylori* infection and peptic ulcer disease were randomly divided to receive either hybrid regimen (Pantoprazole 40 mg BID and Amoxicillin 1 gr BID for 14 days, accompanied by Clarithromycin 500 mg BID and Metronidazole 500 mg BID just during the last 7 days) or concomitant regimen (Pantoprazole 40 mg, Amoxicillin 1 gr, Clarithromycin 500 mg and Metronidazole 500 mg, all twice daily for 10 days). Eight weeks after therapy, $^{14}$C- Urease Breath test was performed to confirm eradication.
**Results:** According to intention to treat analysis, the eradication rates were 87.3% (95% confidence interval = 81.4 – 93.1) and 80.9% (95% CI = 74–87.8) in hybrid and concomitant groups, respectively (p = 0.38). Per-protocol eradication rates were 89.3% (95% CI = 83.8–94.7) and 83.1% (95% CI = 76.3–89.8), respectively (p = 0.19). The rates of severe side effects were not statistically different between the two groups (4% vs. 8.7%).
**Conclusion:** Fourteen-day hybrid therapy can be considered as a nearly acceptable regimen with few severe side effects in Iran. However, it seems that the efficacy of this therapy is decreasing as the resistance rates to antibiotics are increasing. We suggest further studies to assess the efficacy of a more prolonged concomitant therapy for *H. pylori* eradication in Iran.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1605 COMPARISON OF LEVOFLOXACIN -AND CLARTHROMYCIN-CONTAINING SEQUENTIAL THERAPIES FOR HELICOBACTER PYLORI ERADICATION IN IRAN; A RANDOMIZED CLINICAL TRIAL

**M. Mokhtare**, S. Agah, M. Nikkhah, M. Masoodi
*Colorectal Research Center, Rasoul-e-Akram Hospital, Iran University Of Medical Sciences, Tehran/Iran*

**Contact E-mail Address:** marjanmokhtare@yahoo.com
**Introduction:** The prevalence of clarithromycin resistance has increased in different regions of the world and is known to be responsible for most of *Helicobacter pylori* (*H. pylori*) treatment failures. Levofloxacin-containing regimens can be used as first-line therapy in the regions that clarithromycin resistance rate is more than 20% and levofloxacin resistance rate is less than 10%.
**Aims & Methods:** We aimed the study to compare these two sequential therapies for *H. pylori* eradication in Iran. Method:One hundred and eighty-six patients with peptic ulcer disease and naive for *H. pylori* treatment, were randomized in the study. Group A; 92 patients received: esomeprazole 40 mg/bid, amoxicillin 1 gr/bid for the first 5 days, followed by esomeprazole 40 mg/bid, levofloxacin 500 mg/bid and tinidazole 500 mg/bid for the second 5 days. Group B, 94 patients received: the same regimen except for levofloxacin replaced by clarithromycin 500 mg/bid. $C^{14}$ urea breath test was done 8 weeks after the treatment for evaluation of *H. pylori* eradication.
**Results:** One hundred and seventy-two patients(86 patients in each group)completed the study. The intention-to- treat eradication rates were 85.1% (95% CI = 77.9 to 92.3) and 83.7% (95% CI = 76.2 to 91.2) (p = 0.302) and per-protocol eradication rates were 93.0% (95% CI = 87.6 to 98.4) and 90.0% (95% CI = 83.6 to 96.3) (p = 0.420) for group A and B, respectively. The compliance rate was excellent for both groups. No significant differences in incidence of adverse effects were seen between groups. One drug interruption was recorded due to severe bitter taste and nausea in group B.
**Conclusion:** Levofloxacin-containing sequential regimen showed to be safe and effective and it can be replaced by conventional sequential therapy in high clarithromycin resistance area, as a first line therapy. However, based on our recent study clarithromycin sequential therapy has had still a good eradication rate in Tehran.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** zhouxiaoying0926@sina.cn
**Introduction:** The aim of the present open-label, randomized control trial was to determine the clinical efficacy and safety of two one-week bismuth-containing quadruple regimens and one levofloxacin-based triple regimen for the eradication of *H. pylori* infection in treatment- naïve patients. The influence of susceptibility and host CYP2C19 polymorphisms on the efficacy was also evaluated.
**Aims & Methods:** Eligible patients were randomly to receive esomeprazole and colloidal bismuth pectin along with clarithromycin and amoxicillin (EBCA), esomeprazole and colloidal bismuth pectin along with levofloxacin and amoxicillin (EBLA), or esomeprazole along levofloxacin and amoxicillin (ELA) for one week. The primary outcome was the eradication rate in the intention-to-treat (ITT) and per-protocol (PP) analyses.
**Results:** Overall, 270 patients were randomized. The eradication rates in the above three groups were 80.25%, 89.66% and 81.93% in PP analysis and 72.22%, 86.66% and 75.56% in ITT analysis, respectively. The eradication rate of EBLA was significantly higher than that of EBCA (P = 0.016) in ITT analysis. No significant differences were found among these groups in terms of adverse effects and compliance. The efficacy was significantly affected by levofloxacin resistance for EBLA (P = 0.01) and ELA (P = 0.04), but not by polymorphisms of CYP2C19 gene for any of the three groups.
**Conclusion:** One-week bismuth-containing quadruple therapies and levofloxacin-based triple therapy can all obtain an acceptable eradication rate and levofloxacin-based quadruple regimen exhibits the highest eradication rate. The antibiotic resistant rate of levofloxacin was associated with the eradication rate.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Success or failure of *H. pylori* (HP) eradication mainly depends on sensitivity of antibiotics for HP and drug adherence of patients. So far now, several proton pomp inhibitors (PPIs) have been used in eradication, most of

reports said that success rate of eradication approximated from 70 to 80% on Amoxicillin (AMX) and Clarithromycin (CAM) based triple therapy in Japan. Recently the ratio of CAM resistance in Japan comes up to over 30%, we have to overcome CAM resistance using any contrivance. On the other hand, recently the stability of continuous gastric acid suppression with PPIs is one of most important factors. At the point of gastric acid suppression, we expect one of strong PPIs Esomeprazol (EPZ).

**Aims & Methods:** The aim of this study is to elucidate effects of drug sensitivity test for HP and CYP2C19 polymorphism on EPZ based triple therapy regimens (EAC/EAM).

This study is a single-center, prospective case study at Heiwadai clinic, Nerima-ku Tokyo, Japan during 15 months from June. 2013 to Aug. 2014. The 167 patients had made entry, and a total of 76 patients (HP positive) were enrolled (26 men and 50 women). Mean age of patients was 57.9 years old. Fisher's exact test was used in all statistical analyses. Regimen of EAC (1st eradication) was EPZ (40) b.i.d., AMX (1.500) b.i.d. plus CAM (400) b.i.d. for 7 days. Regimen of EAM (2nd eradication) was EPZ (40) b.i.d., AMX (1.500) b.i.d. plus MNZ (500) b.i.d. for 7 days. Diagnosis of HP infection was done with rapid urease test and cultivation of HP on EGD. Drug sensitivity test for HP about CAM and MNZ were done with biopsy samples.

**Results:** Success rate of 1st eradication is ITT = 73.6% (56/76) and PPT = 74.7% (56/75). Success rate of 2nd eradication ITT = 100% (17/17) and PPT = 100% (17/17). Resistance of CAM was 30.4% (17/56) and MNZ was 0% (0/17). CYP2C19 polymorphisms were as follows EM: extensive metabolizer 81.6% (62/76), Homo (1/1) 37.1% (23/62), Hetero (1/2, 1/3) 62.9% (39/62) and PM: poor metabolizer 18.4% (14/76). Even if in the cases of CAM resistance, EAC regimen showed relatively higher success rate (64.5%) rather than previous success rate (about 30%) on other PPIs based regimens as 1st eradication. And also EAC regimen showed significantly high eradication rate (90.6%), even if on EM in the cases of CAM sensitive. In particular, EAC regimen showed significantly high eradication rate (100%), on homo-EM in the cases of CAM sensitive. In addition, EAM regimen showed very high success rate (100%) on 2nd eradication.

**Conclusion:** EPZ-based triple therapy regimens (EAC/EAM) on HP eradication showed high success rate even if on EM of CYP2C19 polymorphism or CAM resistance. And also these regimens showed relatively higher success rate rather than previous success rate on other PPIs based regimens.

## SMALL INTESTINAL III – POSTER EXHIBITION

### P1608 THE CLINICAL AND PHENOTYPIC ASSESSMENT OF SERONEGATIVE VILLOUS ATROPHY; A PROSPECTIVE UK CENTRE EXPERIENCE EVALUATING 200 CASES OVER A 15-YEAR PERIOD (2000–2015)

**I. Aziz**[1], M. F. Peerally[1], J. Barnes[1], V. Kandasamy[1], J. C. Whiteley[1], D. Partridge[1], P. Vergani[1], S. S. Cross[1], P. H. Green[2], D. S. Sanders[1]
[1]*Academic Department Of Gastroenterology, Royal Hallamshire Hospital, Sheffield, South Yorkshire/United Kingdom*
[2]*Celiac Disease Center, Department of Medicine, Columbia University College of Physicians and Surgeons, New York/United States of America*

**Contact E-mail Address:** imy_aziz9@yahoo.co.uk

**Introduction:** Seronegative villous atrophy (SNVA) occurs in 6–22% of coeliac cases. However, there are other causes of SNVA. More recently angiotensin-2-receptor-blockers have been reported as an association but data on SNVA has been limited to centres evaluating complex case referrals and not SNVA in general.

**Aims & Methods:** We aimed to provide clinical outcomes and associations in the largest prospective study overseeing all newcomers with SNVA.

Over a 15-year period (2000–2015) we evaluated 200 adult patients with SNVA at a UK secondary/tertiary-care centre. A diagnosis of either seronegative celiac disease (SNCD) or SN-non-CD was reached. Baseline comparisons were made between the groups, with 343 seropositive CD subjects serving as controls.

**Results:** Of the 200 SNVA cases, SNCD represented 31% (n = 62) and SN-non-CD 69% (n = 138). The HLA-DQ2/8 genotype was present in 61%, with a 51% positive predictive value for SNCD. The breakdown of identifiable causes in the SN-non-CD group include infections (27%, n = 54), inflammatory/immune-mediated disorders (17.5%, n = 35) and drugs (6.5%, n = 13; two cases related to angiotensin-2-receptor-blockers). However, no cause was found in 18% (n = 36) and of these 72% (n = 26/36) spontaneously normalised duodenal histology whilst consuming a gluten-enriched diet. Following multivariable logistic regression analysis a novel independent factor associated with SN-non-CD was non-Caucasian ethnicity (odds ratio 17.2, p = 0.002); in fact, 66% of non-Caucasians had *Helicobacter pylori* and/or alternate gastrointestinal infections. On immunohistochemistry all villous atrophy groups stained positive for CD8-T-cytotoxic intraepithelial lymphocytes. However, additional CD4-T-helper intraepithelial lymphocytes were occasionally seen in SN-non-CD mimicking the changes associated with refractory CD.

**Conclusion:** Most patients with SNVA do not have celiac disease and hence should not be placed on a gluten-free diet without further investigations. Moreover, a subgroup shows spontaneous histological resolution whilst consuming gluten. The presence of non-Caucasian ethnicity should prompt search for an infective aetiology. The role of phenotyping intraepithelial lymphocytes for diagnostic purposes can potentially be misleading.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1609 PREVALENCE OF DYSBIOSIS AND EFFECT OF LOW FODMAP DIET IN CELIAC DISEASE PATIENTS WITH IBS-LIKE SYMPTOMS

**I. Strindmo**[1], K. Nuland[1], G. Kahrs[2], J.G. Hatlebakk[1]
[1]*Department Of Clinical Medicine, University of Bergen, Bergen/Norway*
[2]*Department Of Medicine, Haukeland University Hospital, Bergen/Norway*

**Contact E-mail Address:** i.strindmo@gmail.com

**Introduction:** A subgroup of celiac disease patients have IBS (irritable bowel syndrome)-like symtoms despite following a gluten free diet (GFD). It is unknown whether the microbiota in these patients differs from an IBS- and a healthy population, and whether it changes during diet interventions.

**Aims & Methods:** To study the microbiota profile in patients with celiac disease patients and any change with diet intervention to improve symptoms. 40 celiac disease patients with IBS-like symptoms confirmed by the Rome III-criteria and IBS-SSS (symptom severity scale) were compared to Norwegian IBS and healthy cohorts, and randomized as follows: Group A had a more strict GFD for 6 weeks, whilst patients in group B reduced FODMAPs in their GFD. Faecal samples at baseline and 6 weeks. IBS-SSS at BL, 3 and 6 weeks. The faecal samples were analysed by the GA-Map Method (Genetic Analysis AS) for bacteria and Dysbiosis Index (DI) 1–5, where DI > 2 is clinically relevant. Statistics: T-test, Mann-Whitney U, Fisher's linear discriminant analysis.

**Results:** FODMAP intake was reduced from 12 g to 2 g/day (p = 0.0001) in group B only and IBS-SSS improved in both groups. 45% of the patients had dysbiosis at baseline, compared to 73% in an IBS cohort (p < 0.0091) and 16% in healthy controls (p < 0.0007), with a mean score of 2.5 ± 1.1 vs. 3.0 ± 1.0 and 1.7 ± 0.7, respectively. The patients had significantly more Bacilli and Prevotella than healthy controls. In group A (18 F/2 M, age 39 ± 15), dysbiosis stayed constant on diet, but more patients had severe dysbiosis (DI > 3), 15% vs. 25% (p = 0.85). In group B (15 F/5 M, age 44 ± 12), fewer patients had dysbiosis after diet, 60% vs. 50% (p = 0.79). Responders to low FODMAP diet had less *Lactobacilli* and *Firmicutes* (*Clostridia*), and more *Atopobium* at baseline.

**Conclusion:** Celiac disease patients with IBS-like symptoms had less severe dysbiosis than an IBS-population, but more than healthy controls. We found that the level of *Lactobacilli*, *Firmicutes* (*Clostridia*) and *Atopobium* predicted response to the low FODMAP diet.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1610 HAPTOGLOBIN-2 GENE EXPRESSION IN CELIAC DISEASE, NON CELIAC GLUTEN SENSITIVITY AND TYPE 1 DIABETIC PATIENTS

**Introduction:** Haptoglobin (HP) function has long been known as a scavenger for hemoglobin used as a marker for general inflammation before the discovery of C-reactive protein (Asleh et al. 2003). Human HP appears in three different genotypes: Hp1–1, Hp2–1, and Hp2–2 (Maeda et al. 1984) and many studies have shown association between diseases and the HP phenotype/genotype (Quaye 2008). The HP2–2 phenotype has been associated with worse prognosis of several infectious diseases (Delanghe et al. 1998; Kasvosve et al. 2000), autoimmune disorders such as celiac disease (Tripathi et al. 2009) and neurological disorders (Gloria-Bottini et al. 2008; Maes et al. 2001). Recently, our group has discovered the precursor of haptoglobin-2 (pHP2) is active as zonulin (Tripathi et al. 2009). Zonulin is a protein able to regulate intestinal permeability by reversible disassembly of intercellular tight junctions and has been associated with some autoimmune disorders, diseases of the nervous system, and neoplastic conditions (Fasano 2011). Therefore, our hypothesis is that people with one or two copies of HP2 gene (HP2–1 or HP2–2 genotype) produce more zonulin leading to increased intestinal permeability and will develop a more severe clinical outcome.

**Aims & Methods:** To determine the genotype/phenotype distribution of haptoglobin in celiac disease (CD), non-celiac gluten sensitivity (NCGS), type 1 diabetes (T1D) and first degree relatives of T1D (T1DR). Material and Methods: Samples were obtained retrospectively using biorepository material. HP genotype were done with specific primers designed in exon 2 and exon 5 of HP1 corresponding to exons 2 and 7 of HP2 amplified by high fidelity PCR system. After PCR the amplicons were run on a 1% agarose gel and read under a UV bulb. The

size difference allowed differentiation of the two genotypes (HP1: 2.5 kb and HP2: 5.3 kb). When blood was not available, serum were used to phenotype the individuals by western blot. Serum total proteins were denaturated, separated by size in an electrophoresis gel and then transferred to a PVDF membrane. Imnunoblotting were performed using an anti-zonulin antibody.
**Results:** 1210 individuals were genotyped or phenotyped. HP distribution was statistical different ($p < 0.01$) in all analyzed population comparing to control group ($n = 99$) which frequency was 20.2, 51.5 and 28.3% for HP1–1, HP2–1 and HP2–2 respectively. We observed a decrease in HP1–1 frequency (NCGS 10.6, CD 13.4, T1D 41.3 and T1DR 16.3) and an increase in HP2–2 frequency (NCGS 47.1, CD 44.6, T1D 38.4 and T1DR 43.2).
**Conclusion:** Our data reported for the first time an increased frequency of HP2 gene among celiac disease, NCGS, T1D and first degree relatives of T1D individuals. Interestingly, NCGS showed a higher frequency of HP 2–2 compared to the other diseases that could play a role in the pathogenesis of this controversial clinical entity.

### P1611 BONE MINERAL DENSITY PREDICTS DUODENAL MUCOSAL HEALING IN ADULT PATIENTS WITH CELIAC DISEASE ON GLUTEN-FREE DIET

**T. La Russa**, E. Suraci, R. Marasco, M. Imeneo, F. Luzza
*Health Of Sciences, Università degli Studi Magna Graecia, Catanzaro/Italy*

**Contact E-mail Address:** tiziana.larussa@gmail.com

**Introduction:** A long-term impairment of bone mineral density (BMD) is frequent in some otherwise healthy CD patients on GFD. The normalization of intestinal mucosa is still difficult to predict.
**Aims & Methods:** To investigate the role of dual-energy X-ray absorptiometry (DXA) scan to assess duodenal mucosal healing (DMH) in patients with celiac disease (CD) on a gluten-free diet (GFD). Sixty-four consecutive CD adult patients (18 male and 46 female; median age 36 years, range 18–69) on GFD and with negative CD-related serology were recruited. Clinical features of patients and calcium balance were investigated. After a median period of 6 year GFD (range 2–33 years), patients underwent repeat duodenal biopsy and DXA scan to assess BMD. Data were analysed using unpaired Student's t-test and chi-square or Fisher's exact test as required. A multivariate logistic regression analysis (SPSS Statistic 16.0; IBM, Armonk, NY, USA) was performed. A level of $p < 0.05$ was considered statistically significant.
**Results:** Twenty-four patients (38%) displayed normal BMD and 40 (62%) low BMD, 47 (73%) DMH and 17 (27%) duodenal mucosal lesions. All patients but one with normal BMD (23 of 24, 96%) showed DMH, while among those with low BMD 24 did (60%) and 16 did not (40%) show DMH. At multivariate analysis, being older (OR 1.1, 95% CI 1.03–1.18) and having CD diagnosed at an older age (OR 1.09, 95% CI 1.03–1.16) were associated with low BMD; in turn, having normal BMD was the only variable independently associated with DMH (OR 17.5, 95% CI 1.6–192).
**Conclusion:** In CD patients, particularly those older and with late onset disease, BMD recovery is not guaranteed, notwithstanding strict adherence to diet and negative serology. In this series, a normal DXA scan identified CD patients with DMH, thus being a potential useful tool to plan endoscopic resampling.

### P1612 COELIAC DISEASE IN INDIVIDUALS WITH FERTILITY PROBLEMS – A REGIONAL EXPERIENCE

**K. Macfarlane**[1], H.N. Haboubi[1], J. Bailey[1], E. Thomas[1], A. Abdul-Sattar[1], K. Younas[2], A. Gebril[2], H. Thompson-Jones[1], Z. Shehadeh[2], A. Bunkheila[2], C. Ch'Ng[1]
[1]*Department Of Gastroenterology, Singleton Hospital, Swansea/United Kingdom*
[2]*Department Of Obstetrics And Gynaecology, Singleton Hospital, Swansea/United Kingdom*

**Contact E-mail Address:** kirstymacfarlane100@gmail.com

**Introduction:** Coeliac disease affects at 1 in 100 people in Europe but probably only a quarter of people with the condition are clinically diagnosed. It has already been linked to many autoimmune disorders, anaemia, osteoporosis, neurological disorders, unexplained hypertransaminasaemia and infertility/subfertility. There is, however, conflicting evidence of the association between infertility and coeliac disease.
**Aims & Methods:** We aim to prospectively investigate the prevalence of coeliac disease in a cohort of patients seeking fertility treatment in a regional centre in the UK. Between October 2013 to October 2015, all male and female patients attending a specialist fertility clinic in a regional referral centre serving the South West Wales were offered a screening blood test for coeliac disease using IgA class tTG whilst excluding IgA deficiency. All patients met the National Institute for Clinical Excellence (NICE) Guidelines for the diagnosis of fertility problems. Patients with known coeliac disease will be included in the prevalence calculation. The study was approved and supported financially by ABMU Health Board R&D department
**Results:** Sixty-four patients agreed to participate. 47 (73%) were female and 17 (27%) were male. An elevated IgA anti-tTG level (median 14 U/ml, range 11 U/ml to 64 U/ml) (normal level < 10 U/ml), was detected in 4.7% of patients i.e. 1 of 17 male patients (5.9%) and 2 of 47 female patients (4.3%) had elevated IgA tTG levels. None of the patients approached were known to have coeliac disease and none of the patients with raised IgA tTG were anaemic (median Hb 144; range 140 – 156, compared to median 138 and range 112 – 172 for patients with normal IgA tTG) or known to have associated conditions.
**Conclusion:** In the preliminary data, there is an increased prevalence of a positive screening test for coeliac disease among the male (4.7%) and female (5.9%) cohorts of patients with fertility problem as compared to the known prevalence for the general population (1%) (1). The prospective study is ongoing and if the prevalence is confirmed on a larger cohort, it is recommended that a coeliac screen should form part of the basic tests for the investigation of infertility.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1613 OVERWEIGHT STATUS AT DIAGNOSIS OF CELIAC DISEASE IN ADULTS INCREASES RISK FOR METABOLIC SYNDROME AFTER GLUTEN EXCLUSION

**K. Efthymakis**, M. Serio, F. Del Cotto, A. Milano, F. Laterza, A. Bonitatibus, M. Neri
*Dept. Of Medicine And Ageing Sciences, G. D'Annunzio University and Foundation, Chieti/Italy*

**Contact E-mail Address:** efkn78@gmail.com

**Introduction:** Metabolic syndrome (MetS) has been previously reported in celiac disease (CD) patients both at presentation and as a result of a gluten-free diet (GFD). Both inflammatory response to gluten ingestion and dietary factors coupled with an improved intestinal absorption after GFD have been previously put forth as potential causes of metabolic imbalance. Evidence to support causal hypotheses are lacking and data regarding prevalence and response to GFD are conflicting.
**Aims & Methods:** The aims of this study were to evaluate the prevalence of MetS at CD presentation, assess response to GFD and identify potential subgroups at risk. We included consecutive adult anti-tTG positive, biopsy proven celiacs. MetS was defined according to the Harmonized criteria[1], after assessing abdominal circumference (AC), arterial pressure, high-density lipoprotein cholesterol (HDL), triglyceride (TGL) and blood glucose titers.
**Results:** We evaluated 81 celiac adults (mean age = 38.1 ± 14.3 years, F/M = 5:1) at diagnosis and after GFD (mean duration 3.6 ± 1.8 years). Histology was graded according to the Corazza-Villanacci classification (Grade A = 10.1%, B = 53.7%, C = 36.2%). Mean anti-tTG levels at onset were 67.1 ± 18.9 vs 4.5 ± 2.2U/dl after GFD. MetS, defined as presence of any 3 out of the 5 criteria, was present at diagnosis in 27.4% of cases, and overall it was not influenced by GFD (25.7%). No difference was observed also for TGL and systolic pressure values. On the contrary, AC (80.8 ± 9.7 vs 83 ± 10.6 cm, $p < 0.001$) and HDL (50.7 ± 13.7 vs 55.9 ± 12.6 mg/dl, $p = 0.007$) increased, while blood glucose (92.4 ± 9.9 vs 87.6 ± 9.7 mg/dl, $p = 0.04$) and diastolic pressure (75.7 ± 12.5 vs 70.7 ± 9.7 mmHg, $p = 0.001$) improved. Baseline BMI did not correlate to MetS at CD diagnosis. However, after GFD, subjects with MetS presented a higher BMI when compared to non-MetS (25.5 ± 4.1 vs 20.9 ± 2.9, $p = 0.001$). Furthermore, subjects overweight at diagnosis showed a relative risk of 4.82 (95%CI: 2.08–11.18) for MetS after GFD when confronted with normal/underweight patients (MetS prevalence after GFD 64.3% vs 13.3% respectively, odds ratio 11.7, $p < 0.001$). Age but not sex or atrophy correlated with MetS both at diagnosis and after GFD.
**Conclusion:** Met-S prevalence in adult celiacs in our sample was comparable to previously reported figures for the general population[2]. We also noted no difference in overall prevalence after GFD, contrary to previous studies reporting variably higher or lower prevalence[3,4]. Uniquely, we detected an almost 5-fold relative risk for MetS after GFD in patients who were overweight at CD diagnosis, with a corresponding 125% increase of MetS prevalence in this subgroup. While the inflammatory nature of the active CD has been suggested as the cause of MetS in a malabsorptive syndrome, our data show that arguably milder phenotypes such as overweight patients, are more at risk after dietary intervention.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Celiac disease has a prevalence of 1:70 to 1:300 in most countries (1). Population based studies using serological screeingn with biopsy verification improved our understanding of Celiac disease epidemiology. Data about Celiac disease in the Middle East reigon specially in Kuwait are limited.
**Aims & Methods:** We aimed at estimating the prevalence of Celiac disease among symptomatic patients in Kuwait. We retrospectively analyzed data of 1954 consecutive patients who had symptoms justifying testing for Celiac serology between 2010 and 2015. They were subjected to Celiac serology testing (either human tissue transglutaminase antibody or anti-endomysial antibody). Patients who had at least one positive Celiac serology were subjected also to endoscopy and duodenal biopsy to confirm diagnosis of Celiac disease. Celiac disease diagnosis was based upon concordance between serology and histopathology.
**Results:** A total of 1954 patients were referred for Celiac serology testing; 182 (9.3%) were having positive Celiac serology. Among those 182 patients; 91 (50%) were Kuwaitis and 91 (50%) were non- Kuwaitis; 60 (33%) were males and 122 (67%) were females. Diagnosis of Celiac disease was confirmed by endoscopy and duodenal biopsies in 50 (2.55%) patients. Diagnosis of Celiac disease was more common in non-Kuwaiti than Kuwaiti and in females more than males.
**Conclusion:** Celiac disease can be an underestimated problem in symptomatic Kuwaiti and non-Kuwaiti patients. Larger population based studies are warranted to accurately estimates prevalence of celiac disease in Kuwait.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ml3228@cumc.columbia.edu
**Introduction:** Patients with celiac disease (CD) often have articular complaints, and small prior studies suggest an association with Ehler-Danlos Syndrome (EDS) and Joint Hypermobility Syndrome (JHS).
**Aims & Methods:** This cohort study compared all individuals in Sweden diagnosed with CD based on small intestinal biopsy between 1969–2008 (n = 28.631) to 139,832 matched reference individuals, and to a second reference group undergoing biopsy without having CD (n = 16.104). Rates of EDS/JHS were determined based on diagnostic codes in the Swedish Patient Register. Hazard ratios (HRs) for EDS/JHS were estimated through Cox regression.
**Results:** There were 45 and 148 cases of EDS/JHS in patients with CD and reference individuals, respectively. This corresponds to a 49% increased risk of EDS/JHS in CD (95%CI = 1.07–2.07). The HR for EDS was 2.43 (95%CI = 1.20–4.91) and for JHS 1.34 (95%CI = 0.93–1.95). Compared to reference individuals undergoing intestinal biopsy, CD was not a risk factor for EDS/JHS. A stronger association was seen in patients initially diagnosed with EDS/JHS and subsequently diagnosed with CD (Odds Ratio = 2.29; 95%CI = 1.21–4.34).
**Conclusion:** Individuals with CD have higher risk of EDS/JHS than the general population, which may be due to surveillance bias or factors intrinsic to celiac development.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Capsule endoscopy (CE) may play a role in coeliac disease (CD).
**Aims & Methods:** Retrospective multicenter observational study. Two-hundred and fifty-eight patients (mean age: 46.5 ± 16.9 years, 31% men) who underwent a CE from 2003 to 2016 at 14 European centres were included. They were classified in Group A (equivocal diagnosis, n = 80) and Group B (nonresponsive CD and/or persisting symptoms, n = 178). Baseline characteristics, serology and HLA typing were collected. Diagnostic yield was defined as endoscopic markers of CD or other enteropathy. Clinical impact of CE and patient outcome were also assessed.
**Results:** Patients with antibody-negative villous atrophy (Group A1, n = 18, 7%) achieved an 83.3% diagnostic yield. Gluten-free diet was successfully indicated in 7 of 9 cases (77.78%). Among the Marsh I-II patients (Group A2, n = 57, 22.1%), there were cases with a positive serology (n = 17, 29.8%), and a positive HLA (n = 23, 40.3%). Diagnostic yield was 61.4%, identifying diffuse or patchy CD atrophy (n = 26, 45.6%) and complicated CD (n = 6, 10.5%). Considering patients refusing conventional gastroscopy (Group A3, n = 5, 2%), there were 4 (80%) diagnosed of CD by CE. CE achieved a 64.7% diagnostic yield within coeliac patients (Group B, n = 178, 69%). Twenty jejunoileitis (11.2%) and 7 lymphomas (3.9%) were detected. The diagnostic yield of CE in Group A was not statistically different than that of CE in Group B (66.3% vs. 65.7% respectively, p = 0.935). Globally, CE (mean small bowel time: 259.5 ± 97.5 min) achieved a 65.7% clinical impact. This device has modified the diet (n = 82, 49.1%, with a positive response in 81.7%), indicated new procedures (n = 58, 34.7%, with 33 balloon-assisted enteroscopies), new drugs (n = 25, 15%) and surgery (n = 3, 1.8%). Other inflammatory enteropathies were diagnosed in 13 cases (5%, 7 patients with Crohn's disease). There were no complications related to CE.
**Conclusion:** CE may have a high diagnostic yield and modify the outcome of patients with CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1617 HOW MUCH GLUTEN IS THE GENERAL POPULATION CONSUMING AND DOES IT RELATE TO SYMPTOMS?

**M. Kurien**, I. Aziz, N. Trott, D. Brien, H. George, L. Marks, J. Richardson, R. Rigby, D.S. Sanders
*Dept. Of Gastroenterology, Royal Hallamshire Hospital, Sheffield/United Kingdom*

**Contact E-mail Address:** mattkurien@hotmail.com
**Introduction:** Gluten is a ubiquitous part of a Western diet. It is implicated for causing an array of disorders, which have both intestinal and/or extraintestinal manifestations. Our understanding of this heterogeneous group of gluten-related disorders is advancing, however uncertainty exists as to how much gluten the general population is consuming. This study aims to address this knowledge gap and also assess the prevalence of self-reported gluten sensitivity within the general population.
**Aims & Methods:** Between September and October 2015 a population-based survey was undertaken in Sheffield, UK. Members of the general public, all over the age of 16 years, were invited to complete a modified version of a previously validated written questionnaire. This questionnaire assessed demographic information, GI conditions and also determined the presence of gluten sensitivity (GS). In addition, total gluten consumption was calculated using a food frequency questionnaire. Participants were asked about their use of a gluten-free diet (GFD), and whether they had seen a healthcare professional for their symptoms. A diagnosis of coeliac disease (CD) was determined if individuals had a doctor diagnosis of CD, and were also taking a GFD.
**Results:** 1003 adults completed the population-based survey (59% female, median age 31 years (16–86years). The mean consumption of gluten per day for this group was 13.2 g (s.d = 9.2 g). The self-reported prevalence of GS was

32.5% (326/1003, female 70% [$P < 0.0001$], age range 17–82, median age 35yrs), with 3.7% (38/1003) on a GFD and 1.1% (12/1003) having CD. The proportion of GS individuals who had seen a doctor for their symptoms was 18.3% (65/326). Individuals with GS had an increased prevalence of fulfilling the Rome III criteria for irritable bowel syndrome, in comparison with those without GS (31.3% vs. 5.61%, odds ratio 7.66, $p < 0.0001$). In addition, mean daily consumption of gluten was considerably lower in this GS group compared to the non GS group (10.8 g vs. 14.4 g, $p < 0.0001$).
**Conclusion:** This is the first study assessing gluten consumption in a UK population. Findings from our work highlight that sensitivity to gluten-based products is common, and that affected individuals have a higher prevalence of IBS. Although only a minority of individuals maintained a GFD, individuals with gluten-related symptoms evidently were electing to reduce their gluten consumption.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1618 A SELF-ADMINISTERED BLIND GLUTEN CHALLENGE ASSOCIATED TO AN ANDROID/IOS APPLICATION (TEST33®) TO DIAGNOSE NON-CELIAC GLUTEN SENSITIVITY

**L. Elli**[1], L. Roncoroni[1], C. Tomba[1], A. Catania[2], V. Lombardo[1], D. Conte[3], F. Branchi[1], F. Ferretti[1], M.T. Bardella[1]

**Contact E-mail Address:** lucelli@yahoo.com
**Introduction:** Non-celiac gluten sensitivity (NCGS) is a syndrome characterized by the quick onset of intestinal and/or extraintestinal symptoms after the ingestion of gluten containing food, in absence of celiac disease and wheat allergy. International Guidelines indicate blind gluten challenge as the unique diagnostic test for NCGS. Test33® is a commercially available kit incorporating a blind gluten challenge.
**Aims & Methods:** Our aim was to evaluate the efficacy of Test33® in NCGS diagnosis and gluten-related symptoms Test33™ is a commercially available kit containing undistinguishable gluten and placebo capsules identifiable through a unique code. The kit is integrated by an application (app). Patient downloads the app on him/her smartphone or tablets (Ios or android) and it guides him/her through the administration of the capsules, their sequence and evaluation of symptoms by means of 33 10-cm long VASs on the screen of their devices. 10 VASs evaluated gastrointestinal symptoms and 23 VASs extraintestinal ones. After a three-week-long gluten-free diet (GFD), responsive patients (indicated by the app) were randomly assigned to gluten intake (5.6 g/day) or placebo for seven days, followed by washout and crossover (one week each). The challenge is self-administered at home by the patient who previously excluded celiac disease and wheat allergy. The primary endpoint was the worsening of symptoms (VAS increase $\geq 3$ cm) during gluten ingestion compared to placebo to define NCGS.
**Results:** 69 patients (55 females, $38 \pm 18$ years of age) made the test and 61 (88%) completed the challenge and symptomatic VASs. In 93% of cases VASs values significantly improved after GFD. During the blind challenge none of the symptoms worsened during placebo assumption phase. On the contrary, among gastrointestinal symptoms, abdominal pain, constipation, meteorism and bloating resulted significantly worsened by blind gluten ingestion compared to placebo ($3.1 \pm 3.0$ vs $2.2 \pm 2.0$, $3.3 \pm 3.0$ vs $2.4 \pm 2.7$, $4.9 \pm 3.5$ vs $3.8 \pm 3.2$, $4.2 \pm 3.0$ vs $2.8 \pm 3.0$, respectively); among extraintestinal symptoms, joint and muscolar pain were significantly worsened by blind gluten ingestion compared to placebo ($3.3 \pm 3.3$ vs $2.5 \pm 3.0$ and $2.8 \pm 2.6$ vs $1.9 \pm 2.0$, respectively). Six females out of 61 subjects (6%, $31 \pm 16$ years old) satisfied critera for NCGS diagnosis. In these patients 13 (39%) VAS values significantly worsened after gluten ingestion compared to the 6 (18%) altered by gluten in the whole cohort of patients.
**Conclusion:** The self-administered blind gluten challenge supported by a dedicated app (Test33®) effectively evidenced NCGS patients among suspected individuals. Moreover, it evidenced those symptoms (intestinal and extraintestinal) strictly correlated to the blind gluten ingestion.

**Introduction:** The study aimed to identify factors associated with sustained parenteral nutrition (PN) volume reduction and early vs. late responders among PN-dependent short bowel syndrome patients treated with teduglutide (TED).
**Aims & Methods:** The study population was 43 patients receiving TED in a 24-week randomized placebo-controlled trial (STEPS: NCT00798967; EudraCT2008–006193-15) who could continue TED up to 24 months in the open-label extension (STEPS-2: NCT00930644; EudraCT2009–011679-65). Time to sustained PN volume reduction (i.e., PN volume reduction $\geq$20% at 2 consecutive visits) was calculated using Kaplan-Meier analysis. Multivariable Cox model was used to identify factors associated with sustained PN volume reduction. Among patients achieving sustained PN volume reduction, baseline characteristics were compared between early (PN volume reduction $\geq$20% at week 20 and 24) vs. late responders (sustained PN volume reduction at 2 consecutive visits after week 24).
**Results:** The median time to sustained PN volume reduction was 4.2 months. Patients with stoma, compared to those without, were significantly more likely to achieve sustained PN volume reduction (HR=5.6; $P = 0.01$). Patients with an ileocecal valve, compared to those without ($HR = 0.1$; $P = 0.03$), and patients with major intestinal resection due to vascular disease, compared to those with Crohn's disease ($HR = 0.2$; $P = 0.02$), were significantly less likely to achieve sustained PN volume reduction. Compared to late responders ($n = 7$), early responders ($n = 27$) were less likely to have colon-in-continuity (52% vs. 100%; $P = 0.02$) and ileocecal valve (0% vs. 29%; $P < 0.01$), and had smaller mean percentage of colon remaining (25% vs. 57%; $P = 0.02$). The median time to sustained PN volume reduction was 3.7 months for early responders and 7.8 months for late responders.
**Conclusion:** Presence of stoma and absence of ileocaecal valve are good prognosis factors for achieving sustained PN volume reduction while vascular disease as cause of intestinal resection is a negative prognosis factor. Certain anatomical factors were significantly different between early and late responders.

## P1620 LACTOSE MALABSORPTION IN SUBJECTS WITH SELF-PERCEIVED MILK INTOLERANCE ASSESSED WITH THE ROMA III QUESTIONNAIRE FOR IBS

**F. Valiante**, A. Buda, M. De Bona, A. Bellumat, M. Tollardo, M. De Boni
*Gi Oncological Surgery, UOC Gastroenterology, Feltre/Italy*

**Contact E-mail Address:** flavio.valiante@gmail.com
**Introduction:** Lactose malabsorption is a common condition with symptoms similar to those in functional disorders. IBS patients often attribute their symptoms to the intake of food, particularly milk and dairy products. Lactose hydrogen breath test (HBT) is the method of choice to identify lactose malabsorption and this test is increasingly prescribed by primary care physicians and gastroenterologists in patients reporting milk intolerance.
**Aims & Methods:** The aim of this study was to determine in a cohort of patients with self-perceived lactose intolerance whether a preliminary assessment with the Rome III questionnaire for IBS was able to discriminate patients with lactose malabsorption from those with functional disorders only.396 consecutive patients (90 M, 272 F, median age 38, range 18–78) with self-perceived milk intolerance and referred to our Unit for a lactose HBT by a general practitioner or a gastroenterologist were studied. After an oral challenge with 20 g of lactose, end-expiratory breath samples were collected before and at 30 min intervals for 3 hours. A positive test was defined as an increase in hydrogen above basal levels greater than 20 ppm and defined lactose malabsorption. All patients

underwent anti-tissue transglutaminase (anti-tTG), total IgA assay and completed the Rome III questionnaire before performing HBT.
**Results:** Thirty-four patients (8.5%) were anti-tTG positive with normal IgA and celiac disease diagnosis was confirmed by histology. A total of 245 (67.6%) patients were diagnosed as having IBS, including 67 (27.3%) with diarrhea (IBS-D), 30 (12.2%) with constipation (IBS-C), 73 (29.7%) alternating diarrhea and constipation (IBS-M) and 75 (30.6%) unclassified (IBS-U). A positive HBT was found in 105 (42.8%) patients with IBS and in 53 (45.2%) patients among those who did not fulfilled Rome III criteria ($p = 0.5$). No differences among subgroups identified by the Rome III criteria and between patients referred by either a primary care physician or gastroenterologist were found.
**Conclusion:** Lactose malabsorption has a similar prevalence in patients with and without IBS. The Rome III diagnostic questionnaire failed to discriminate subjects with lactose malabsorption among patients with subjective perception of milk intolerance. In these patients, the completion of the Rome III questionnaire for IBS before performing a lactose HBT is not justified in the daily practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1621 POST HOC ANALYSIS OF POLYPS IN 9 SHORT BOWEL SYNDROME PATIENTS TREATED WITH TEDUGLUTIDE

**Introduction:** Preclinical data raise the possibility that teduglutide may be associated with a risk of small intestinal and/or colonic neoplasia.
**Aims & Methods:** This report aims to evaluate data from 2 clinical trials in patients with short bowel syndrome (SBS) who reported polyps at baseline or during long-term teduglutide treatment. Post hoc analysis of data was reported in patient e-case forms (eCRFs) regarding gastrointestinal polyps at baseline and over the course of 2 therapeutic trials of teduglutide (STEPS: NCT00798967, EudraCT2008–006193-15; STEPS-2: NCT00930644, EudraCT2009–011679-65). A baseline colonoscopy was required unless a normal colonoscopy had been performed $<6$ months before screening. Patients with benign polyps removed prerandomisation were eligible for enrolment.
**Results:** Of the patients enrolled (STEPS, $n = 86$; STEPS-2, $n = 88$), 54 who had not undergone prior colectomy received a baseline colonoscopy and 50 received a study completion colonoscopy (remaining patients refused or no colon was present). Baseline colonic polyps were reported in 9 patients (ages 39–75 years; women, 67%); per inclusion criteria they were removed before treatment initiation. By the end of STEPS-2, 9 patients (ages 35–63 years; women, 67%) had reported polyps. In 6 of these 9 patients, polyps were recorded as a treatment-emergent adverse event (TEAE). Patients had been on teduglutide for 3 months (1 patient, TEAE), 8 months (1 patient, TEAE), 10 months (1 patient, TEAE), 24 months (5 patients, 3 TEAE) and 30 months (1 patient, 0 TEAE) at polyp detection. Polyp locations were colon (7 patients), duodenum (1 patient), and unknown (1 patient). Recorded polyp sizes were 2–7 mm (4 patients). 7 patient eCRFs noted that biopsies were performed; 2 recorded low-grade dysplasia (rectal/colorectal polyps), but none recorded overt malignancy.
**Conclusion:** Polyps were reported in 9 of 50 patients receiving long-term teduglutide who had a colonoscopy at study completion (106.3 patient-years exposure). There were no reports of malignancy related to the presence of these polyps. Additional information regarding polyp incidence will be acquired from an ongoing SBS registry.

[3]*Gastroenterology And Hepatology, Jikei Univesity School Of Medicine, Tokyo/Japan*

**Contact E-mail Address:** ryosukem71@gmail.com
**Introduction:** Both small intestine capsule endoscopy (SCE) and balloon-assisted enteroscopy (BAE) play an important role in the diagnosis of small intestinal tumors. However, the usefulness of both modalities is still unclear. To confirm their utility and diagnostic ability, we aimed to examine cases of small intestinal tumors diagnosed using SCE and BAE at our institute, and compare them with those diagnosed using computed tomography (CT) or magnetic resonance imaging (MRI).
**Aims & Methods:** Between April 2008 and March 2016, 668 and 507 patients underwent BAE and SCE, respectively, at our institute. Of these, 59 (34 men and 25 women; median age, 62 years) were confirmed as having small intestinal tumors and were included in this study to determine the usefulness of the aforementioned diagnostic modalities for small intestinal tumors. The utility of CT, MRI, SCE, and BAE was investigated and retrospectively compared for all the cases.
**Results:** No adverse effects were observed for any modality. The chief complaints were unidentified anemia/obscure gastrointestinal bleeding (17 cases, 29%); suspicion of tumor based on the results of other diagnostic modalities, without abdominal symptoms (16 cases, 27%); and abdominal symptoms (12 cases, 20%). The final diagnoses of the 59 cases were small intestinal cancer (15 cases, 29.6% [10 primary/5 metastases]), non-epithelial tumor (15 cases, 25.5%), malignant lymphoma (14 cases, 24.7%), and hereditary polyposis (12 cases, 20.3%). BAE was performed for all the cases, and SCE was performed for 28 of the 59 cases. CT/MRI was performed for 57 cases, excluding 2 cases with Peutz-Jeghers syndrome. In 19 (32.2%) of the 59 cases, the tumor was not detected by CT/MRI. These cases were non-epithelial tumors (7 cases, 36.8%), hereditary polyposis (6 cases, 31.6%), small intestinal cancer (3 cases, 15.8% [2 primary/1 metastasis]), and malignant lymphoma (3 cases, 15.8%). BAE detected the tumor in 19 cases, and SCE was performed in 13 of these 19 cases. Four (30.8%) of the 13 cases were not detected as small intestinal tumors but as malignant lymphoma in 1 case and non-epithelial tumor in 3 cases. By using SCE and/or BAE, even cases that were not detected on CT/MRI as small intestinal tumors because of their small size and slight mucosal changes were detected.
**Conclusion:** For patients with suspected small intestinal tumors, imaging modalities for the small intestine are useful for diagnosis. However, in some cases, small intestinal tumors are difficult to detect by CT/MRI studies because of their size and mucosal changes. For cases that are strongly suspected to be small intestinal tumors, performing SCE and/or BAE should be considered, even when no lesions are detected by CT/MRI.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1623 DOUBLE BALLOON ENTEROSCOPY IN SMALL BOWEL TUMORS: 11 YEARS' EXPERIENCE AT A TERTIARY-CARE HOSPITAL

**M. Gravito-Soares**, E. Gravito-Soares, S. Lopes, N. Almeida, P. Figueiredo, C. Sofia
*Gastroenterology, Coimbra Hospital, Coimbra/Portugal*

**Contact E-mail Address:** ms18498@gmail.com
**Introduction:** The small bowel tumors prevalence is 3–6%, being 5.5% in Portugal. In our center, the prevalence of malignant small bowel tumors was 9.4% between 2005 and 2008. Double-balloon enteroscopy (DBE) is the gold standard in a suspicion of small bowel tumors.
**Aims & Methods:** We aimed to characterize the small bowel tumors detected by DBE and the diagnostic value of DBE in small bowel tumors. This was a retrospective study of DBE performed between January 2005 and November 2015, which included all patients with a suspected small bowel pathology and negative previous conventional study. Collected clinical, endoscopic, imagiological and surgical data of diagnosed tumors. Evaluation of DBE diagnosis value comparing with Capsule endoscopy and CT enterography.
**Results:** Performed 267 DBE in 213 patients, 55.8% males and mean age of $60.4 \pm 17.8$yo. The main indication for DBE was obscure gastrointestinal bleeding in 62.5%, being occult in 71.9% of cases. Performed 187(70.0%) exams by anterograde route, 73(27.3%) by retrograde route and 7(2.6%) by both routes. Lesions were detected by DBE in 66.3%(177/267) of cases, mainly angioectasias (67/177; 37.8%). Thirty-two small bowel tumors in 30 patients were diagnosed. The diagnosis by DBE was 87.5%(28/32). Biopsies were obtained in 59.4% of tumors with 3 of them negative (15.8%). Most tumors were sub-epithelial lesions (17/32; 53.1%), malignant lesions (19/32; 59.4%) and localized in jejunum (21/32; 65.6%). The main diagnosis of malignant tumors was gastrointestinal stromal tumors in 21.9%(7/32), adenocarcinoma in 15.6%(5/32), lymphoma in 5.8%(3/32) and metastatic tumors in 5.8%(3/32). According to the final diagnosis, DBE showed high diagnostic accuracy (93.4%; $p < 0.001$) comparing with Capsule endoscopy (86.1%; $p < 0.001$) and CT enterography (72.9%; $p = 0.032$).
**Conclusion:** Small bowel tumors diagnosis was 12.0%(32/267) by DBE and malignant in 7.1%(19/267) of exams. DBE is a useful tool with high diagnostic

accuracy in the study of small bowel tumors comparing with CT enterography or capsule endoscopy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1624 RISK FACTORS FOR ADVANCED SMALL BOWEL DISEASE IN FAMILIAL ADENOMATOUS POLYPOSIS: A PROSPECTIVE, SINGLE-CENTER STUDY

**Contact E-mail Address:** mariannysulbaran@gmail.com
**Introduction:** Prophylactic colectomy in patients with Familial Adenomatous Polyposis (FAP) has risen the importance for defining more effective strategies for small bowel disease prevention and management. Duodenal adenocarcinoma and ampullary carcinoma relative risks in FAP have been estimated 100 to 330 times higher than in general population. Moreover duodenal adenomatosis prevalence varies among different populations across the world. However risk factors that predict advanced small bowel disease have not been clearly established.
**Aims & Methods:** The aim of this study is to determine clinical features associated with the development of advanced duodenal polyposis, jejunal polyposis and ampullary adenomas in a Brazilian population of patients with FAP. This is a single referral center, prospective study of a cohort of 63 patients with clinical and or genetic diagnosis of FAP. All patients were evaluated with lateral and forward view gastroduodenoscopy. Duodenal polyposis was classified according to Spigelman staging system and ampullary adenomas were also identified. Patients graded as Spigelman III or IV underwent double balloon endoscopy (DBE) for jejunal examination.
**Results:** A total of 63 patients from 48 families with FAP were included in this study. Duodenal adenomatosis stage 0-II was detected in 51, 80.95% (22 male/29 female) patients at a mean age of 35.34 years. Advanced duodenal polyposis (Spigelman III or IV) was present in 12, 19.05% (7 male/5 female) patients at a mean age of 37.2 years. There was no statistically significant difference between the severity of duodenal polyposis and age or gender. There were 26 family members related to 11 different families. The familial distribution of duodenal polyposis severity is presented in the table below, showing that there was a correlation of Spigelman score among different first-degree relatives from each family.

| Family | Number of relatives studied | Spigelman score of family members |
|---|---|---|
| 1 | 2 | IV,IV |
| 2 | 2 | IV,IV |
| 3 | 3 | II,II,0 |
| 4 | 3 | I,0,0 |
| 5 | 2 | 0,0 |
| 6 | 2 | II,0 |
| 7 | 2 | II,II |
| 8 | 2 | 0,0 |
| 9 | 4 | II,II,I,0 |
| 10 | 2 | III,II |
| 11 | 2 | III,II |

Minor ampullary adenomas (defined as adenomas less than 10 mm, without villous architecture or high-grade dysplasia) were detected in 6 patients (5 male/1 female) from 6 different families at a median age of 35.33 years. Three patients with ampullary adenomas were graded as Spigelman III, two patients as Spigelman II and one as O. DBE has been performed in 9 cases of duodenal polyposis graded as Spigelman III or IV. Of those, 7 patients presented small tubular adenomas with low-grade dysplasia located in proximal jejunum and 2 had no jejunal polyps.
**Conclusion:** 1. Advanced duodenal polyposis phenotype is predictable upon disease severity of a first-degree relative; 2. Jejunal endoscopic surveillance is advised in patients with Spigelman III/IV duodenal polyposis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Small-intestine neuroendocrine neoplasms (SINENs) are heterogeneous neoplasms arising from endocrine cells of the intestinal mucosa. Ki-67 is the main determinant of prognosis in NENs. However, the search for new prognostic makers represents a key point with regard to SINENS. The oncofetal protein IMP3 plays a role in cell growth and its expression has a prognostic value in lung neoplasms. To date, though, there have been no studies focusing on IMP3 role in ileal neuroendocrine tumors.
**Aims & Methods:** Our research aimed to investigate whether IMP3 protein can be detected in SINENs and developed as a new clinical tissue prognostic biomarker for these tumors From January 1998 to August 2015, all the consecutive SINEN patients suitable for surgery were included: 51 patients (34 males, median age 68 years) had SINENs. Each neoplasm was classified according to the WHO 2010 classification, based on the Ki-67 index. In all the cases IMP3 expression was evaluated on primary tumors and, when available, on nodal and distant metastases. The medical records and pathological slides of these patients were used to determine the clinical characteristics, pathological diagnoses, and outcome information
**Results:** In present series, 24 patients (47%) had NENs of grade 1 (G1), 5 (10%) had G2 and 22 (43%) had G3 NENs. The overall 5-year and 10-year survival rate was 53.9% and 42% respectively. Overall, IMP3 was was espressed in 32 out of 57 primary tumors (56%), 19 out of 36 nodal metastases (53%) and 12 out of 22 liver metastases (54%). of the patients. At Cox proportional hazards regression grading was the major factor influencing both OS and PFS at univariate ($p = 0.0002$ and 0.005, respectively) and multivariate analysis ($p = 0.0003$ and 0.005, respectively). Also IMP3 expression at the nodal metastases resulted a factor significantly associated with PFS at both univariate ($p = 0.006$) and multivariate analysis ($p = 0.023$, HR 2.39). IMP3 expression did not correlate with the Ki-67 index ($p =$ n.s.) When considering IMP3 expression classified as scores, in the whole series PFS resulted significantly different, with cases with 2+and 1+ scores showing a worse PFS compared to cases with 0 scores ($p = 0.0015$).
**Conclusion:** In this study, IMP3 at the nodal site resulted to be associated with low PFS in SINENs, independently of the Ki-67 index. In SINENs patients the strong association between IMP3 expression in lymph node metastases and the increased risk of recurrence represents new interesting evidence We suggest that the integration of IMP3 and Ki-67 would help better stratify the risk of progression in SINENs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** alvaromalcala@gmail.com
**Introduction:** Gastrointestinal stromal tumors (GIST) are mesenchymal neoplasms that arise from the cells of Cajal in the gastrointestinal (GI) tract. While most GISTs are located in the stomach, 30% of GISTs are found in the small bowel. Small-bowel GISTs tend to be more aggressive and have a worse prognosis with a 5-year survival rate for patients with small-bowel malignant GISTs is approximately 25%. Therefore, an early diagnosis is mandatory. Patients with GIST usually present with obscure gastrointestinal bleeding, which results from a surface ulceration and necrosis. However there is a lack of information about the endoscopic characterization of GIST, especially when using deep enteroscopy such as single and double balloon enteroscopy methods.
**Aims & Methods:** The aim of this case study is to describe the endoscopic spectrum of small bowel GISTs. This is an observational, retrospective, consecutive case series of patients with small bowel GIST of patients included in a prospective database. All procedures were performed by one therapeutic endoscopist. The following information was collected: description of all the lesions, pictures, at least 6 biopsies of each case, ocation of the lesion, indication, procedure time, and instruments used, submucosal injection solutions, complications and follow-up.
**Results:** A total of 10 smalll bowel GISTs were found during a three year period (6 male, 4 female). All patients presented with obscure gastrointestinal bleeding (overt, n = 8, occult, n = 2). The mean age of the patients was 52 years (range 28 to 68). Seven patients had a previous capsule endoscopys study, which was negative in three. Most GISTs were present in the proximal or middle small bowel (n = 7). Computed tomography showed a large mesenteric tumor in one patient (with a huge necrotic small bowel tumor). We defined the endoscopic characteristics based on shape and mucosal surface. The endoscopic tumor characteristics could be categorized as follows: submucosal round (n = 4), submucosal sessile (n = 2), and invasive/penetrating) (n = 4). The mucosa overlying the tumor was normal (n = 4), grooved (n = 3) or frankly ulcerated (n = 1). Biopsy was negative in all patients with normal mucosa but showed tumor in all patients with ulcerations. Regardless of biopsy results, all patients were sent for surgery. Nine resections were carried out. One patient refused surgery. There were no complications of endoscopy in this cohort.
**Conclusion:** This is the largest series of small bowel GISTs documented by double balloon enteroscopy. Our series shows that GISTs have a wider spectrum of endoscopic characteristics than previously described. The round type with normal overlying mucosa was equally prevalent as the grooved or ulcerated variant. This is important to know, as capsule endoscopy and traditional enteroscopy with biopsies may be falsely negative. Endosocopist should be aware of this wide spectrum of presentation of small bowel GIST.

**Contact E-mail Address:** rchuttan@bidmc.harvard.edu
**Introduction:** Traditional gastric balloons for weight loss require endoscopy and anesthesia for placement and removal. Elipse™ (Allurion Technologies, Wellesley, MA USA) is the first procedureless gastric balloon. The balloon is swallowed, resides in the stomach for 4 months, and is then excreted.
**Aims & Methods:** The objectives of this study were to assess the safety of Elipse™ and to measure its short and long-term effects on weight loss, quality of life, and participant preference. Each participant swallowed one Elipse™ device, which was filled with 550 mL of filling fluid through a thin delivery catheter that was then removed. Three different anti-emetic regimens (ondansetron, aprepitant, and ondansetron + aprepitant) were tried throughout the study. Weight and body composition were measured every 2 weeks by bio-impedance during balloon therapy. After balloon passage, weight was measured monthly although there was no dietary counseling provided. Quality of life was assessed at baseline and at trial exit using the Impact of Weight on Quality of Life (IWQoL) questionnaire. At trial exit, participants were asked if they would recommend Elipse™ to a friend or repeat it if they regained weight.
**Results:** Thirty-four participants were enrolled with a mean BMI of 34.8 kg/m$^2$. At 4 months, the mean weight loss was 10.0 kg, percent total body weight loss (%TBL) was 10.0%, and percent excess weight loss (%EWL) was 39%. 100% of the weight lost was from fat. All adverse events were either self-limiting or resolved with medication. Vomiting was significantly reduced using a combination of ondansetron and aprepitant. All balloons were safely excreted. At trial exit, IWQoL scores improved across all domains. In the absence of any post-balloon dietary counseling, 93% and 63% of the weight lost was maintained at 6-month and 9-month follow-up, respectively. 93% and 86% of participants would recommend Elipse™ to a friend or repeat it if they regained weight, respectively.
**Conclusion:** Elipse™ leads to weight loss on par with endoscopic balloons but does so without endoscopy and anesthesia and without sacrificing safety or the participant experience. In addition, in the absence of post-balloon dietary counseling, participants maintained nearly two-thirds of the weight lost during therapy at 9-month follow-up.

## P1628 CHILD WEIGHT STATUS INFLUENCES THE IMPROVEMENT IN INSULIN SENSITIVITY FOLLOWING A SHORT-TERM ENERGY RESTRICTION IN SEVERELY OBESE PATIENTS

**Introduction:** Ectopic lipid accumulation is a common factor underlying non-alcoholic fatty liver disease (NAFLD) and Type 2 diabetes (DM). Adipose tissue capacity that is fixed in adolescence and overwhelmed in obesity in adulthood is one explanation for this deposition. Acute energy restriction has been shown to reduce lipid deposits in the liver and reverse DM.
**Aims & Methods:** We aimed to investigate whether childhood weight status modifies the metabolic response following acute energy restriction in patients awaiting bariatric surgery. We analysed the self-reported childhood weight status recorded as a part of a randomised controlled trial (EnR-Lin study) comparing a food-based diet (FD) with a meal replacement plan (MRP) (LighterLife Ltd., U.K.) over two weeks prior to bariatric surgery. Clinical and anthropometric data and fasting blood were collected pre and post diet. Liver biopsies were taken during surgery.
**Results:** 60 participants were recruited and 54 completed the study; FD n = 26, MRP n = 28. Baseline demographic features (Table 1), dietary energy intake and weight loss post-diet were not significantly different between diet groups. However, the FD had higher reported intake of carbohydrate (median 52% compared to 38%), whereas the MRP had higher intakes of protein (median 37% compared to 30%) and fat (median 25% compared to 19%). All three macronutrient intakes were statistically different between groups ($P < 0.001$). 61% of all participants reported being overweight or obese as a child (OC) (n = 33). This subgroup had higher median body mass index (BMI) pre and post diet, pre 51.9kgm-2, post 50.3kgm-2, lean childhood BMI group pre 47.3kgm-2, post 46.2kgm-2. However, BMI change post-diet was not statistically significant between the two childhood weight groups ($P = 0.65$). Liver histology results post-diet were also not significantly different between diet groups. When separated for childhood weight status, as well as diet, OC on the FD had significantly higher levels of steatosis ($P = 0.006$), and portal inflammation ($P = 0.006$) compared to the lean group post-diet. There was no significant difference between results in childhood weight groups on the MRP. Reduction in insulin resistance as estimated by Homeostatic Model Assessment (HOMAIR) was significant following MRP, median (range) -1.0 (-26.3–5.9) ($p = 0.02$) when compared with FD -0.1 (-9.1–18.7) ($p = 0.91$). Reduction in HOMAIR remains significant only in the MRP OC group median (range) -1.0 (-26.3–3.0) $P = 0.01$ as opposed to lean -0.04 (-5.9–5.9) $P = 0.64$.

**Table 1:** Baseline characteristics of patients

| | Food-based diet (n = 26) | Meal plan (n = 28) |
|---|---|---|
| Gender: female/ male | 22/4 | 22/6 |
| Age in years: median (range) | 47 (25–65) | 42 (24–59) |
| Body mass index in kg/m$^2$: median (range) | 51.1 (42–69) | 50.1 (42–63) |
| No. with Type 2 Diabetes (%) | 8 (31) | 8 (29) |
| No. overweight or obese in childhood (%) | 17 (65) | 16 (57) |

**Conclusion:** People who were overweight or obese in childhood had a greater increase in insulin sensitivity following an energy restrictive meal replacement plan. This could indicate that both adipose tissue capacity and type of diet, including macronutrient intake, could affect insulin sensitivity following energy restriction in severe obesity.
**Disclosure of Interest:** E. Baldry: LighterLife provided their products free of charge for the study.
All other authors have declared no conflicts of interest.

## P1629 ARGON PLASMA COAGULATION FOR FAILED ROUX-AND-Y GASTRIC BYPASS (RYGB): AN ENDOSCOPIC ALTERNATIVE IN BARIATRIC PATIENTS WITH WEIGHT REGAIN

**B. Q. Sander**[1], G. A. P. Baretta[1], J. I. b. Scarparo[1], R. Fittipaldi-Fernandez[1], J. Schemberk[1], M. P. Sander[2], M. Galvao Neto[1]

[2]*Bariatric Endoscopy, Clínica Sander, Belo Horizonte/Brazil*

**Contact E-mail Address:** brunosander@hotmail.com
**Introduction:** The weight regained has been a described growing problem in patients after bariatric surgery, especially at long term. This weight regained is multifactorial and often associated with dilation of gastrojejunostomy (GJ), allowing a faster gastric emptying and therefore greater food intake. For the patients with significant weight regain after failed conservative approach, some revisional procedures had be attempted and more recently endoscopic revisional procedures had being described.
**Aims & Methods:** To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastro-enteric anastomosis in patients who have undergone Roux-and-Y Gastric Bypass (RYGB) for morbid obesity and regained weight associated to dilation of the GJ. From Jan-2014 to Feb-2016 385 RYGB subjects with weight regain, a dilated anastomosis (more than 18 mm in diameter) and at least 2 years from procedure were submitted APC application at GJ had their data reviewed from a prospective designed databank. Interval between an APC session applications was 60 days, with a maximum of 03 applications. APC set was at 2–3 L/m with 65–85 W. GJ diameter target was to reduced it up to 8–12 mm estimated with pre-measured open grasper. At first APC session pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. At each following session weight, BMI and estimated GJ diameter were taken. Complications during treatment were also collected. Data were analyzed with descriptive statistics, student's t-test and Spearman correlation.
**Results:** Of the 385 patients, 85.2% were women and 14.8% were men. Average time between bariatric surgery and the first APC was 90.31 months (±43.32. Range: 24–182) and average weight regained in this interval was 23.36 kg (±11.72. Range: 5–64). The mean diameter of the anastomosis was 23.63 mm (±5.11. Range: 14–50) and the average number of APC sessions were 1.72 times (±0.68. Range: 1–3). The average reduction of anastomotic diameter was 14.71 mm (±7.21. Range: 2–35) and the final average diameter was 11.7 mm (±3.88. Range: 5–31). The average weight loss between the first and last APC was 14.08 kg (±6.21. Range: -3.42–34.77) and the average decrease of BMI was 4.79 kg/m$^2$ (±2.78. Range: -1.47–12.12). 93 patients (24.15%) did not achieve the target GJ diameter and 03 patient (0.78%) did not lose weight even with the desired GJ diameter. From the 88 subjects followed up to 6 months no regain weight was noted. Of the 385 patients APC, 42 (10.9%) required dilation balloon due to symptomatic stenosis at least once. No further complications were reported.
**Conclusion:** Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Dept. Of Gastroenterology, Dept. Of Clinical Nutrition, Medical University of Lodz, Lodz/Poland*

**Contact E-mail Address:** ewawk@op.pl
**Introduction:** Obesity is a chronic metabolic disease associated with the pathological accumulation of body fat. During menopause a significant role in the biosynthesis of estrogen is caused by aromatase, including current in subcutaneous adipose tissue and adipocytes. It is responsible for the conversion of testosterone to estradiol and androstenedione to estrone. It contributes significantly to the increase in estrogen levels. Aromatase deficiency leads to impaired balance of estrogen-progesterone. As a result, excess fat is accumulated in the abdominal skin coatings, and visceral fat in the abdomen (android obesity "apple" type). This type of obesity is exposed more in women, who eat meals with to many calories and so low physical activity.
**Aims & Methods:** The aim of the study was to evaluate the effect of reducing diet in overweight and obese postmenopausal women on: concentration of selected sex hormones, feeling of hunger and satiety, psycho-emotional state. The study involved 97 women (44–65 aged) who consented to the study. The inclusion criteria were: lack of menstruation or irregular menstruation during last 12 months, right health condition, without coexisting organic diseases, normal body weight, obese, overweight woman, especially with gained weight during menopause, patients with vasomotor disturbances, hot flushes, headache, night sweats, patients with emotional disorders, fatigue, irritability, attention deficit disorder, memory and sleep impairment, mood swings, symptoms which testify dysthymia or depression. Patients were divided into three groups based on their BMI, which was calculated: group I control - 32 woman with normal body weight (BMI 18.5–24.9 kg/m$^2$), group II - 33 overweight woman (BMI 25–29.9 kg/m$^2$), group III – 32 obese woman (BMI > 30 kg/m$^2$). Each of the patients' body weight was measured. On this basis hiperalimentation syndrom was defined. Moreover waist / hip ratio (WHR - waist-hip ratio) was calculated. The content of fat was determined by measuring the skin-folds of fat and body composition analysis - using a body composition analyzer Bodystat QuadScan 4000, based on a non-invasive method of bioimpedance (BIA, bioelectrical impedance analysis). Immunoassay routinely determined in the serum concentration of the sex hormones estradiol, follicle-stimulating hormone (FSH), dehydroepiandrosterone sulfate (DHEA-S), and rostenedione. Patients completed nutrition questionnaires and in group II and III body weight reducing diet was recommended. Evaluation of the patients' mood was performed useing the Beck scale (BDI, Beck Depression Inventory). Evaluation of the patients' anxiety disorders was performed useing Hamilton Anxiety Scale (HAS, Hamilton Anxiety Scale) and intensity of appetite was determined using visual analogue scale – VAS. The study was performed at the beginning and after three months of observation.
**Results:** It was shown that diet reducing weight gain used for three months in postmenopausal women with a BMI above 25 kg/m$^2$ significantly lower BMI, reduces body fat and levels of sex hormones (DHEA-S, androstenedione and FSH – in obese women) and improves mood.
**Conclusion:** The use of a three-month diet reducing weight gain in postmenopausal women with overweight and obesity showed a signifficant affect on: reduction of body fat, mood improvement, development of healthy eating habits, improvement of emotional state, decrease in the levels of sex hormones (DHEA-S, androstenedione and FSH – in obese women) to the value similar for the group of women with normal body weight. In postmenopausal period overweight and obesity women should remain under the care of an experienced dietician. The well-constructed individual weight-reducing diet, systematic assessment of effectiveness and concious mind of its use can bring measurable benefits in the fight with obesity which is a modern disease of civilisation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1631 USING AN INTRAGASTRIC BALLOON FOR A SECOND TIME: IS IT A GOOD ATTEMPT?

**R.J. Fittipaldi-Fernandez**[1], C.F. Diestel[2], M. Passos Galvão Neto[3]

[2]*Nutrition Division, Rio de Janeiro State University, Rio de Janeiro/Brazil*
[3]*Gastro Obeso Center, Sao Paulo/Brazil*

**Contact E-mail Address:** ricfittipaldi@hotmail.com
**Introduction:** The intragastric balloon use associated with a multidisciplinary approach aiming changes in lifestyle have shown efficacy in the treatment of overweight/ obesity and its corelated diseases. However, some patients may regain weight, and seek in the use of intragastric balloon for the second time a valid treatment option.
**Aims & Methods:** We aimed to evaluate the efficacy and complications of a second implant of intragastric balloon, with a minimum interval of six months between the removal of the first and second implant. Methods: We used intragastric balloons Orbera, with volume between 600–700 ml. The first balloon remained for a period of six months. The implant of the second balloon occurred after a minimum of six months in patients who had weight regained. Data were analysed using descriptive statistical methods and student t-test. Thet level of significance was set at $p < 0.05$.
**Results:** 71 patients had the balloon implanted for the second time at least six months (mean of 25.74 ± 12.94 months) after the removal of the first balloon. Of these, 25 had an early removal (balloon explant less than a month after

implantation) of the balloon due to intolerance (35.21%). Of the remaining 46 patients, 35 were women. The percent weight regain in relationship to first treatment weight lost was 99.71 ± 44.9 (range: 5.00–255.56). The patients showed a significant lower final BMI (mean: 29.61 ± 4.20 kg/m$^2$; range:20.08–42.98) than the initial BMI (mean: 35.27 ± 5.49 kg/m$^2$; range: 27.05–52.96) ($p < 0.0001$). The average weight loss in kilograms was 15.27 ± 8.78 (range 3.0–35.0). The percent total body weight loss (%TBWL) was 15.54 ± 7.95 (range: 3.26–40.23), and the percent excess weight loss (%EWL) of 60.57 ± 35.37 (range: 10.87–194.61). The success rate of treatment (> 25% EWL) was 91.30%. However, BMI reduction, weight loss in Kg, %TBWL and %EWL were significantly lower than in the first treatment ($p < 0.0001$, $p < 0.0001$, $p < 0.0001$, $p = 0.0004$, respectively)

**Conclusion:** Use an intragastric balloon for the second time to treat obesity still proves to be effective, though to a lesser extent than in the first treatment, and with a high rate of complications (early balloon removal), a fact that should be thoroughly discussed and considered with the patient before making the choice of using this treatment again.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1632 CD24 POLYMORPHISMS ARE ASSOCIATED WITH OBESITY RISK

I. Boustanai[1], D. Sion[1], N. Shemesh[2], S. Shapira[2], D. Kazanov[2], S. Zigdon[2], L. Galazan[2], A. Leshno[2], S. Abu-Abeid[3], S. Kraus[3], **N. Arber**[2]

**Introduction:** Obesity is a global epidemic and a major risk factor for various health catastrophes. It is amultifactorial disease and has genetic and environmental etiology. Several studies have suggested candidate genesthat may predispose to obesity. CD24 is a small, mucin-like glycoprotein that is expressed in many humanmalignancies (Sagiv, et al., 2006). We have recently found that CD24 knockout male (but not female) mice are obesewith hyper insulin sensitivity than their wild-type (WT) littermates. Four single nucleotide polymorphisms (SNPs) in theCD24 gene are known to affect cancer risk and autoimmune diseases. C170T CD24 SNP results in the replacementof alanine by valine. This amino acid change is associated with increased risk for multiple sclerosis (MS), systemiclupus erythematosus (SLE) and cancer risk (Huang, et al., 2015).

**Aims & Methods:** We aimed to evaluate whether SNPs in the CD24 gene are associated with increased obesity risk. Methods: Genomic DNA was extracted from peripheral blood leukocytes of 158 obese Israeli patients (BMI ≥ 30; 122males and 36 females), as well as age and gender-matched healthy controls (BMI ≤ 27; 178 males, 23 females).Samples were genotyped for the CD24 SNPs: C170T (rs8734), TG1527del (rs3838646), A1626G (rs1058881) andA1056G (rs1058818) by real-time PCR using Custom TaqMan® SNP allelic discrimination assays. $\chi 2$ test was usedto examine whether the CD24 gene polymorphism is associated with obesity. An association was consideredstatistically significant if $p < 0.05$.

**Results:** C170T SNP is more prevalent in obese male than in normal weight males ($p = 0.087$), even after ageadjustment ($p = 0.028$; correlation coefficient = 1.367). This trend was not observed in obese females. This correlationbecomes more significant for the obese males (>50 year) (p=0.03; correlation coefficient = 3.558), Nocorrelation was found between the other three SNPs, in the 3'UTR, and the risk for obesity.

**Conclusion:** The genetic variation C170T CD24 may be an important determinant for obesity in men, in particularabove 50 year old. There is a need for a prospective life style intervention, in this group of patients, which may preventobesity later in life.

## P1633 LYSOZYME FRACTION FROM DONKEY MILK (DM) SUPPORTS VISCERAL ANTINOCICEPTIVE PROPERTIES OF DM, REDUCES PROTEASE ACTIVITY AND RESTORES ANTIMICROBIAL LEVELS IN PANETH CELLS IN A MODEL OF CHRONIC STRESS IN MICE

**S. Yvon**[1], V. Bézirard[2], V. Tondereau[1], C. Harkat[1], G. Jard[3], H. Tormo[3], D. Ali Haimoud-Lekhal[3], M. Peter[3], H. Eutamene[4]

**Contact E-mail Address:** sophie.yvon@toulouse.inra.fr

**Introduction:** Irritable bowel syndrome (IBS) is a functional gastrointestinal disorder characterized by abdominal pain or discomfort associated with a low-grade mucosal inflammation and luminal protease activity increased [1]. Stressful life events trigger IBS symptoms. Chronic stress paradigms were developed in animals to mimic changes in visceral sensitivity seen in IBS patients. In mice, passive avoidance stress is associated with hypersensitivity to rectal distension. Several studies suggest that probiotics or specific dietary interventions may have beneficial effects in IBS patients [2]. Donkey milk (DM) has important nutritional properties for humans linked to its similar composition to human milk. In particular, DM presents high levels of antimicrobial peptides such as lysozyme and lactoferrin [3].

**Aims & Methods:** Therefore, using a chronic water avoidance stress (WAS) model, we aimed to evaluate whether 1) WAS modified visceral sensitivity, serine protease activity in feces, and lysozyme expression in Paneth cells (PC) and 2) an oral DM supplementary diet can alleviate these alterations and 3) the positive effects of DM are supported by the abundance of antimicrobial peptides in DM i.e. lysozyme. Male C57BL/6 mice were used in this study. During 9 days, mice were submitted to a sham stress or to a WAS session for 1 h and orally received DM (0.2 mL, 5400UI of lysozyme), fraction of DM containing lysozyme (FL) (equivalent dose of lysozyme) or water (0.2 mL). In a 1$^{st}$ series of experiments, at day 9, visceral sensitivity response to CRD was assessed after the last WAS or sham session. In a 2$^{nd}$ series of experiments, both feces and ileal samples were collected to quantify fecal serine protease activity by enzymatic assay, and the lysozyme expression in PC by immunostaining, respectively.

**Results:** Compared to sham treatment, WAS significantly induced visceral hypersensitivity in response to CRD, significantly increased fecal serine protease activity, and promoted a drastic decrease of lysozyme levels contained in ileal PC. Under basal conditions a treatment with DM or FL did not modify visceral sensitivity in response to CRD. A chronic administration of DM or FL was able to significantly reduce abdominal contractions induced by WAS. In addition, DM and FL normalize both the fecal serine protease activity and lysozyme levels in PC altered by WAS.

**Conclusion:** DM given as a supplementary diet alleviates WAS-induced functional alterations i.e visceral hypersensitivity, fecal serine protease increased and the fall in antimicrobial peptides contained in PC. Interestingly, all these beneficial effects are supported by the high level in Lysozyme contained in DM.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1635 DEVELOPMENT AND VALIDATION OF A GLIADIN 33-MER-BASED IMMO-ASSAY FOR THE MONITORING OF A GLUTEN-FREE DIET

**D. Rehan**[1], F. Armbruster[1], J. Stein[2]
[1]*Immundiagnostik AG, Bensheim/Germany*
[2]*Crohn Colitis Centre Rhein-Main, Frankfurt/Germany*

**Contact E-mail Address:** dmitri.rehan@immundiagnostik.com

**Introduction:** Even today, strict adherence to a gluten-free diet is regarded as the only effective therapy for coeliac disease. However, suitable markers for the monitoring of diet adherence and detection of gluten contaminants are still lacking. The commonly tested IgA and IgG antibodies are of limited use, since their decline under a gluten-free diet is protracted (up to 1 year).

**Aims & Methods:** Given the high stability of various 3-mer gliadin peptides (33mPs), a sandwich ELISA was developed based on monoclonal antibodies. After extraction of ethanol, this ELISA allows the definition of related peptides up to 2 ng/g stool and shows a linear correlation two times the power of ten.

**Results:** In subjects (n = 5) with a daily intake of 20 g gluten, the test showed 117.8 (68.6–234.1)ng 33mPs/g, compared to 1.8 (0.4–3.0)ng 33mPs/g in individuals adhering to a gluten-free diet.

**Conclusion:** In this cohort, levels of 3-mer-rich gluten peptides in stool showed a significant positive correlation to respective daily gluten intake. The novel ELISA is the first test to allow realtime monitoring of adherence to a gluten-free diet and detect possible gluten contaminants.

**Introduction:** Glucagon like Peptide-2 (GLP-2) is a protrophic gastrointestinal hormone that promotes regeneration of the intestinal mucosa and improves

intestinal absorptive function. Teduglutide (TED), a GLP-2 analogue, was recently approved for the treatment of short bowl syndrome (SBS) in patients with chronic intestinal failure who are dependent on parenteral nutrition (PN).
**Aims & Methods:** Single center-based clinical and paraclinical data from patient records of 11 patients with benign SBS were retrospectively analysed. Nutritional status was assessed by body weight, albumin and transferrin concentration and bioelectrical impedance analysis (BIA).
**Results:** Fifteen patients have been treated with TED at this center thus far. This is an interim analysis of 11 patients. Twelve weeks after initiation of TED treatment (0.05 mg/kg) patients had a 28% reduction in PN volume needs ($n = 10$; $p = 0.007$) and a 15% reduction in kcal needs ($n = 10$; $p = 0.027$) with a simultaneous weight increase of 4.5% ($n = 8$; $p = 0.04$). After a mean treatment of 43 weeks (SD = 20.1 wks.) patients gained a mean of 1.1 total infusion-free days and two (18%) out of 11 patients were completely weaned off PN. Albumin und transferrin levels remained constant throughout PN-reduction. Patients had a significant reduction in stool frequency and an increase in stool consistency ($n = 10$; $p = 0.003$ and $p = 0.03$ resp.). Analysis of BIA parameters showed a significant increase in intracellular water ($n = 5$; $p = 0.041$), lean body mass and body fat percentage ($n = 5$; $p = 0.043$) demonstrating a specific beneficial effect on body composition.
**Conclusion:** The analysis of initial clinical data on long-term use of TED for SBS patients demonstrates improved intestinal function through increased fluid and nutrient absorption as well as increased body weight. Furthermore functionally relevant body composition was improved as shown by BIA-analysis of nutritional status beyond body weight. Study of TED effects in clinical routine will support future decision making in clinical practice.

**Contact E-mail Address:** shirsch@inta.uchile.cl
**Introduction:** Folic acid (FA) consumption at high levels has been associated with colon cancer risk. Several mechanisms have been proposed to explain this association. The Notch signal pathway has been implicated in the regulation of cellular proliferation.
**Aims & Methods:** Folic acid promotes **stemness** on HT-29 cell line, via Notch1 signaling activation. Methods: We cultured HT-29 cells with 3 different conditions, without folic acid, with 400 nM folic acid or 5-methyl tetrahydrofolic acid (5-MTHF). We analyzed the expression of stem cell markers and Notch-1 pathway related genes by real time PCR in all 3 conditions.
**Results:** The supplementation with folic acid or 5-MTHF increase migration of HT-29 cells, the expression of NANOG, SOX-2, POUF-5 (stem cell markers, $p < 0.05$) and HES-1 (activation of Notch-1 pathway, $p < 0.05$).
**Conclusion:** Folic acid or 5-MTHF supplementation increase **stemness** and migration on HT-29 cell line that could be associated with aggressiveness of colorectal cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Numerous clinical studies have demonstrated that consumption of oat beta-glucans has been associated with potential health benefits for humans, such as reduction of postprandial glucose, decreasing serum cholesterol or colorectal cancer prevention. Many studies also have shown that these natural polysaccharides have antioxidant properties. To our knowledge, no prior study has been conducted to determine the antioxidant effects of oat beta-glucans supplementation in chronic gastritis patients.
**Aims & Methods:** The aim of this study was to determine the effect of high (2 000 000 – 3 000 000 g/mol) or low (30 000 – 90 000 g/mol) molecular weight of oat beta-glucans on selected parameters of the antioxidant potential of the blood and plasma samples in patients with chronic gastritis. 48 patients aged 23–74 years were randomly assigned to either a placebo group, receiving an oral dose of 100 ml 3% solution of potato starch (Placebo), or to one of the treatment groups receiving oral dose of 100 ml high (G1) or low (G2) molecular weight beta-glucans for 4 weeks. Easily digestible diet was recommended for all groups. Plasma total antioxidant status (TAS) and the levels of glutathione peroxidase (GPx), glutathione reductase (GR) and whole blood superoxide dismutases (SODs) were examined using Randox Reagents (United Kingdom). Whole blood reduced (GSH) and oxidized (GSSG) glutathione level were measured according to Rebrin, Forster, and Sohal (2007).
**Results:** Before the intervention, activity of SODs and GR was significantly higher in G2 group compared with placebo group. The results showed that the activity of GR was significantly lower after the dietary supplementation of G2. The level of SODs observed in the placebo group was significantly higher than those observed in other grups. The diet supplementation of G1 significantly increased levels of GSSG in the blood. GSSG levels also increased in Placebo. In the case of GPx activity we observed a statistically significant decrease in placebo group. No significant changes were observed regarding other parameters examined.
**Conclusion:** Changes limited to oxidized glutathione and glutathione reductase levels show that selected dose and form of oral beta-glucans exert no significant effect on oxidative stress in patients with chronic gastritis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** heinz.albrecht@uk-erlangen.de
**Introduction:** A very effective method for long-term enteral feeding or stomach decompression is the use of a percutaneous gastrostomy (PEG) or sometimes jejunostomy (PEJ). Under certain circumstances, such as inadequate transillumination, endoscopic placement of PEG/PEJ-tubes is impossible. In these cases computed tomography (CT)-guided PEG/PEJ may represent an alternative technique. In this study, we evaluate indications, results and complications of CT-guided PEG/PEJ.
**Aims & Methods:** A total of 102 consecutive referred patients were enrolled in the study. Patients came to the endoscopy unit of our department to undergo a CT-guided PEG/PEJ for long-term intragastric/intrajejunal feeding ($n = 57$) or decompression ($n = 45$). The majority of the patients ($n = 98$) received a pull-through PEG/PEJ with simultaneous gastroscopy/jejunoscopy. Dose length product (DLP) and the effective dose (in mSv) for every patient was calculated.
**Results:** Altogether, gastrostomy/jejunostomy tube placement was successful in 87.3% of patients (89/102). Feeding PEG/PEJ-tube placement was successfully completed in 91.2% of patients (52/57), decompressive PEG/PEJ-tube placement was likewise successfully completed in 82.2% of patients (37/45). No procedure-related mortality was observed. Minor complications such as tube dysfunction, local bleeding, minimal leakage or local skin infection were observed in 13 patients. Complication rate was similar in both the feeding and the decompression group ($p = 0.9$).
**Conclusion:** CT-guided PEG/PEJ is a feasible and safe method with a low procedure-related morbidity rate for the group of patients where endoscopic placement via transillumination is not successful. Thus, the procedure is an attractive alternative to surgical tube placement. Long-term complications, which are mainly tube disturbances, can be treated easily.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1640 PERFORMANCE OF THREE PROGNOSTIC RISK SCORES IN PREDICTING OUTCOMES IN ELDERLY NON-MALIGNANT PATIENTS AFTER PERCUTANEOUS GASTROSTOMY

**Ç. Kalkan**[1], A. Ç. Kartal[2], F. Karakaya[1], A. Tüzün[2], I. Soykan[3]

[3]*Ankara University, Faclty of Medicine, Ankara/Turkey*

**Contact E-mail Address:** isoykan@medicine.ankara.edu.tr
**Introduction:** Percutaneous endoscopic gastrostomy (PEG) is a safe and useful method for patients who have difficulty in oral feeding with normal functioning gastrointestinal (GI) tract. Percutaneous endoscopic gastrostomy is mainly indicated for patients who are expected to require non-oral nutritional support for more than 4 weeks.

**Aims & Methods:** The aims of this study were to determine the performance of "Geriatric Nutritional Risk Index" (GNRI), "Malnutrition Universal Screening Tool" (MUST) and "Portsmouth-Physiological and Operative Severity Score for the enUmeration of Mortality and morbidity" (P-POSSUM) for predicting short and long-term mortality in elderly patients who had undergone PEG procedure due to non-malignant conditions. This study included 155 elderly patients patients who had undergone percutaneous endoscopic gastrostomy procedure due to non-malignant conditions. GNRI, MUST and P-POSSUM scores were calculated. The ability of these scores to predict short and long-term mortality was determined.
**Results:** The overall mean survival period was $9.59 \pm 6.0$ months and mortality rate was 80.6%. The performance of GNRI was superior to MUST and P-POSSUM in predicting long-term survival of PEG patients; 94.1% of patients were alive with a cut-off value of 90 for GNRI (sensitivity: 92% CI 85.9–95.6 and specificity: 90% CI 74.3–96.5). Kaplan-Meier survival analysis of GNRI showed that patients ($n = 7$) with a GNRI score of $> 98$ before the PEG procedure had the longest survival time, while patients ($n = 102$) with a GNRI score of $< 82$ had the worst outcome.
**Conclusion:** A scoring system such as GNRI should be considered as a risk scoring system for predicting early and late mortality at percutaneous endoscopic gastrostomy and also assist in making decisions such as timing of percutaneous endoscopic gastrostomy procedure.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Although use of enteral tube feeding is a common condition in patients who compromise the passage of food along the digestive tract, there is limited data available on how well internal medicine trainees know about enteral feeding tube. This study aimed to identify current knowledge, attitudes and experiences of internal medicine trainees towards enteral feeding tube in Korea.
**Aims & Methods:** A prospective survey was performed among trainees of internal medicine in 13 hospitals. A 17-item questionnaire addressed knowledge about enteral feeding tube, experience of complications and their clinical practice changes to these complications.
**Results:** Overall, 269 internal medicine trainees (162 male, mean age $31.54 \pm 3.30$) completed the questionnaire. Over half of the respondents (150, 56%) answered that they often encounter patients who use enteral feeding tube. However, only 39.2% of respondents had ever received education about enteral feeding tubes. Only 38.8% of trainees felt they had an adequate knowledge about this subject and 29.1% stated that they provided appropriate information to patients with enteral nutrition (EN). The majority agreed to the cost effectiveness and priority of EN compared to peripheral nutrition. However, only 31.3% correctly estimated the optimal replacement time of nasogastric (NG) tube. Although over half of the respondents had experiences complications of NG tube, their attitude toward these complications varied widely. In addition, 86.9% of trainees answered that they were willing to receive education regarding enteral feeding tube, if provided.
**Conclusion:** Many internal medicine trainees lack knowledge about enteral feeding tubes and their practice varied widely. Implementation of an adequate training system with regard to enteral feeding tube is necessary for internal medicine trainees to improve the quality of healthcare.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1642 THIRTY-DAY MORTALITY AFTER PERCUTANEOUS GASTROSTOMY BY ENDOSCOPIC VERSUS RADIOLOGIC PLACEMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS

**J.H. Lim**, S.H. Choi, C. Lee, J.I. Yang, J.S. Kim
*Seoul National University Hospital, Healthcare System Gangnam Cenger, Health Research Institute, Seoul/Korea, Republic of*

**Contact E-mail Address:** limz00@gmail.com

**Introduction:** A percutaneous gastrostomy can be placed either endoscopically (percutaneous endoscopic gastrostomy, PEG) or radiologically (radiologically inserted gastrostomy, RIG). However, there is no consistent evidence of the safety and efficacy of PEG compared to RIG. Recently, 30-day mortality has become considered as the most important surrogate index for evaluating the safety and efficacy of percutaneous gastrostomy.
**Aims & Methods:** The aim of this meta-analysis was to compare the 30-day mortality rates between PEG and RIG. Major electronic databases (MEDLINE, EMBASE, Scopus, and Cochrane library) were queried for comparative studies on the two insertion techniques of gastrostomy among adults with swallowing disturbance. The primary outcome was the 30-day mortality rate after gastrostomy insertion. Forest and funnel plots were generated for outcomes using STATA version 14.0.
**Results:** Fifteen studies ($n = 2.183$) met the inclusion criteria. PEG was associated with a lower risk of 30-day mortality after tube placement compared with RIG (odds ratio [OR] 0.60; 95% confidence interval [CI] 0.38–0.94; $P = 0.026$). The pooled prevalence of 30-day mortality of PEG was 5.5% (95% CI, 4.0–6.9%) and that of RIG was 10.5% (95% CI, 6.8–14.3%). No publication bias was noted.
**Conclusion:** The present meta-analysis demonstrated that PEG is associated with a lower probability of 30-day mortality compared to RIG, suggesting that PEG should be considered as the first choice for long-term enteral tube feeding. Further prospective randomized studies are needed to evaluate and compare the safety of these two different methods of gastrostomy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1643 SERUM TRACE ELEMENTS AND PROTEINS BEFORE ENDOSCOPIC GASTROSTOMY AND DURING LONG-TERM ENTERAL FEEDING

**J. Fonseca**[1], C. A. Santos[2]
[1]*Instituto Superior de Ciencias da Saúde Egas Moniz, Monte da Caparica/Portugal*
[2]*Gene Artificial Feeding Team, Hospital Garcia de Orta, Almada/Portugal*

**Contact E-mail Address:** jorgedafonseca@hotmail.com

**Introduction:** Patients who underwent endoscopic gastrostomy (PEG) present protein-energy malnutrition, but little is known about Trace Elements (TE), Zinc (Zn), Copper (Cu), Selenium (Se), Iron (Fe), Chromium (Cr).
**Aims & Methods:** Our aim was to evaluate serum protein and TE evolution during the first 3 months after gastrostomy with homemade PEG feeding, and the relationship of TE with proteins and the nature of the underlying disorder. Methods: Prospective observational study during a 3-month period after gastrostomy. Data was collected at initial PEG procedure (T0), after 4 (T1) and 12 weeks (T3). Initial evaluation included: age, gender, underlying disorder causing dysphagia (Neurological Dysphagia: ND; Head and Neck Cancer: HNC), NRS-2002, BMI. At T0, T1 and T3 a blood sample was collected for TE, albumin and transferrin. We used ferrozine colorimetric method for Fe evaluation; Inductively Coupled Plasma-Atomic Emission Spectroscopy for Zn/Cu; Furnace Atomic Absorption Spectroscopy for Se/Cr. After the gastrostomy all patients were fed with homemade meals.
**Results:** Initial: 146 patients (89 males), 21–95 years: HNC-56; ND-90. Low BMI in 78. NRS-2002 $\leq$ in all patients. At T0 low values mostly for Zn ($n = 122$) and Fe ($n = 69$), but less for Se ($n = 31$), Cu ($n = 16$), Cr ($n = 7$); low albumin in 77, low transferrin in 94 and 66 with both proteins low. Only for Zn, significant differences ($t_{140.326} = -2.642$, $p < 0.01$) between the groups of underlying disease (low in 93% of HNC patients, 78% ND patients). Except for Zn, low TE cannot be related with age, gender, BMI, serum proteins levels or underlying disease. There was a correlation between albumin and Zn ($r = 0.197$, $p = 0.025$), and Fe ($r = 0.415$, $p = 0.000$). Evolution T0-T3: Serum protein increase, most patients reaching normal, with significant differences between the three moments for albumin ($p = 0.000$) and transferrin ($p = 0.014$). For TE we observed slow evolution. Most patients still displaying low Zn at T3, with significant differences between the 3 moments ($p = 0.011$). Other TE increased, but normalization was incomplete at T3. For Fe positive correlations were detected with albumin and transferrin. No relationship was found at T1 and T3 between Se, Cu and Cr with the groups of underlying diseases or proteins.
**Conclusion:** When gastrostomy was performed, patients display low serum proteins and TE namely Zn, but also Fe, less striking regarding others TE. Low proteins were associated with low TE. Low serum proteins are normalized but low TE cannot be correct during 3 months of homemade enteral feeding. Teams taking care of PEG patients should use systematic TE supplementation.

## P1644 TREATMENT OF SHORT BOWEL SYNDROME WITH GLP-2-ANALOGUE TEDUGLUTIDE – FIRST CLINICAL DATA FROM TUEBINGEN UNIVERSITY HOSPITAL, GERMANY

**M. Schoeler**, S. Bernhard, T. Klag, H. Mühlberg, N. Malek, M. Götz, J. Wehkamp
*Gastroenterology, University Hospital Tuebingen, Tuebingen/Germany*

**Contact E-mail Address:** marc.schoeler@med.uni-tuebingen.de
**Introduction:** Teduglutide is a novel therapeutic agent in the therapy of short bowel syndrome. In phase III - trials it proved to significantly reduce parenteral nutrition. Since its introduction in 2014 we have treated 15 patients in our outpatient centre.
**Aims & Methods:** Data was aquired with the help of a specialized nursing service. Thirst, body weight, oral fluid intake, urinary output, frequency of bowel movements and bowel movement consistency as well as amount of parenteral nutrition (days per week as well as total intake) were regularly measured. The reduction of parenteral nutrition was decided upon individually with regard to clinical parameters.
**Results:** We collected data from 11 of our 15 patients. All patients wished to continue therapy with Teduglutide and declared a general improvement of their situation. The average lenth of treatment (in march 2016) was 26.4 weeks (7.0–56.0, SD 16.1. All five patients with inial heavy thirst lost it within the first four weeks of treatment. In four patients days of parenteral nutrition was reduced by one day per week. After 12 weeks ($n = 8$, $\mu = 13.1$, $SD = 6.7$, $p < 0.05$) and 24 weeks ($n = 7$, $\mu = 14.4$, $SD = 8.7$, $p < 0.05$) there was a significant reduction in bowel movement frequency (baseline $\mu = 18.0$, $SD = 7.0$). All patients declared a solidification of their bowel movements. Body weight, urinary output and days of parental infusion per week did not change significantly.
**Conclusion:** All patients tolerated Teduglutide well and wished to continue treatment. Reduction of thirst (which was 100% if present before treatment) as well as significant reduction in bowel movement frequency seem to be early clinical markers for a response to treatment. Other markers of bowel functioning as body weight, urinary output and demand in parenteral nutrition vary strongly within the different individuals and demanda longer observation period. Reduction of parenteral nutrition takes time and should not be hastened. Independently from parenteral nutrition patients report a considerable improvement of their situation under treatment with Teduglutide.
**Disclosure of Interest:** J. Wehkamp: receives research funding from Shire Pharmaceuticals

## P1645 ADJUSTING THE TIMING OF REFEEDING AFTER PERCUTANEOUS ENDOSCOPIC GASTROSTOMY PLACEMENT - WHEN EARLY IS NOT TOO EARLY!

**T. Cúrdia Gonçalves**[1], S. Monteiro[1], M. Barbosa[1], S. Xavier[2], P. Boal Carvalho[1], C. Marinho[1], J. Cotter[1]
[1]*Gastroenterology, Hospital da Senhora da Oliveira, Guimarães/Portugal*
[2]*Gastrenterology, Hospital Senhora da Oliveira, Guimarães/Portugal*

**Contact E-mail Address:** tiagomcg@hotmail.com
**Introduction:** Although historically the timing of refeeding after the placement of a percutaneous endoscopic gastrostomy (PEG) was delayed over a period of 24 hours, several studies have shown that shortening of this interval is safe.
**Aims & Methods:** The aim of this study was to compare the safety of refeeding at 4 hours with refeeding at 24 hours after PEG placement in a center with a specialized multidisciplinary consultation. This was a prospective single-center, randomized, controlled study, including 81 patients who were submitted to PEG between May/2014 and February/2016. Two groups were established: group A (refeeding 4 hours after PEG placement) included 33 patients, while group B (refeeding 24 hours after PEG placement) included 48 patients. For comparison of complications between the two groups $\chi^2$, t -student and Fisher's exact tests were used.
**Results:** From the 81 enrolled patients enrolled, 60 were women and the average age was $79 \pm 11$ years. The main indications for PEG placement were dysphagia after ischemic stroke (33.3%), Alzheimer's disease (25.9%), and vascular dementia (18.5%). Regarding the complications registered after the procedure, there were no significant differences between the groups, namely on inflammation of the stoma ($p = 1.000$), gastric contents leakage ($p = 0.133$), fever ($p = 0.475$), vomiting ($p = 0.153$), or local bleeding ($p = 0.133$). Although gastric residual volume was greater in group A, this difference was not statistically significant (47 vs. 20 mL; $p = 0.183$). Melena, diarrhea or peritonitis were not reported in any of the patients during the post-procedural period. During the follow-up, 6 patients died, but none of the deaths were related to PEG placement, and there were no significant differences between groups ($p = 1.000$).
**Conclusion:** Refeeding patients as early as 4 hours after PEG placement was not associated with an increased number of local or systemic complications, thus it should be routinely implemented in all patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1646 ANAESTHETIST ASSISTED PERCUTANEOUS ENDOSCOPIC GASTROSTOMY WITH GASTROPEXY; A SAFE AND EFFICIENT PROCEDURE

**I. Stasinos**[1], M. Lim[2], H. Dent[3], C. Nunes[4]

**Contact E-mail Address:** Ioannisstasinos@nhs.net
**Introduction:** Percutaneous endoscopic gastrostomy (PEG) with gastropexy is recommended for percutaneous feeding tube placement in patients with oropharyngeal or oesophageal malignancy. It is also advantageous in patients with neuromuscular disease as it allows the placement of a balloon device saving them from the need of a second intervention. The aim of this study is to to evaluate the efficacy and safety of PEG gastropexy performed with an anaesthetist's assistance. The study was particularly concerned with comfort scores, morbidity and mortality.
**Aims & Methods:** Adult PEG gastropexies performed electively at a district general hospital between June 2011 to June 2015 were evaluated retrospectively. All the procedures were performed by two experienced endoscopists with an anaesthetist's assistance. Midazolam and remifentanil via target controlled infusion (TCI) were used for deep analgesia. Age, gender, physical status according to the American Society of Anaesthetists (ASA) classification system, indication for procedure and comfort scores using the modified Gloucester Scale (1 = no discomfort to 5 = severe discomfort) were recorded. Immediate complication, 8-day readmission and 30-day mortality rate were also measured.
**Results:** A total of 165 patients underwent 166 procedures. The mean age was 63+/- 9.06 years and the male to female ratio was 3:1. 143 patients were classified ASA II, 21 ASA III and 1 ASA IV. Indications included oropharynageal malignancy (152), motor neuron disease (7), oesophageal malignancy (3), thyroid malignancy (2), achalasia (1) and chronic liver disease (1). All procedures were successfully completed. There were no immediate complications. The mean comfort score was 1.11 ($SD = 0.37$). The mean hospital stay was 1.3 days ($SD = 2.18$) days. The mortality rate 30 days post procedure was 0%. 4 patients were readmitted within 8 days post procedure. 2 of these admissions were related to the procedure. One was due to a dislodged PEG tube and the other due to infection around the PEG site.
**Conclusion:** Anaesthetist-assisted PEG gastropexy is a safe and efficient procedure. This service can be implemented in a district general hospital requiring short hospital stay even for patients at risk of ventilatory impairment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1647 EFFECT OF ENTERAL NUTRITION ON METABOLIC SYMDROME WITH NONALCOHOLIC FATTY LIVER DISEASE IN ELDERLY PATIENTS

**W. Wang**
*Gastroenterology, Beijing Hospital, Beijing/China*

**Contact E-mail Address:** wangwei-beijingyiyuan@hotmail.com
**Introduction:** We aimed to observe the effects of enteral nutrition on metabolic symdrome (MS) with nonalcoholic fatty liver disease (NAFLD) in elderly patients.
**Methods:** The 109 patients with MS and NAFLD were randomized into group EN ($n = 55$) and TPN ($n = 54$). The EN group received aggressive enteral nutrition therapy; the TPN group got the treatment of total parenteral nutrition. The body mass index (BMI), the blood liver function, glucose, blood liquid and hepatic ultrasonography were observed in two groups.
**Results:** After treatment of 1 month, there was significant improvement in the level of BMI, 2HBG, HbA1c, ALT, AST, BIL, TG, LDL-C ($P < 0.05$) in two groups in comparison with pretherapy. In the changes, of hepatic ultrasonography was improved but not significantly. In the TPN group the observations were counter to the EN group.
**Conclusion:** EN support is superior to TPN in aspects of avoiding increasing the glucose and fat metabolism, in imaging changes of NAFLD, and could improve treatment in elderly patients with MS and NAFLD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## VC01 A CASE OF ESOPHAGEAL CANCER DERIVED FROM GIANT DIVERTICULUM TREATED BY ESD AND THORACOSCOPIC COLLABORATION SURGERY

**T. Oyama**, A. Takahashi, N. Yorimitsu
*Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan*

**Contact E-mail Address:** oyama@coral.ocn.ne.jp
**Introduction:** Endoscopic submucosal dissection (ESD) has been widely accepted for treatment of early gastrointestinal cancer in Japan. The main complication of ESD is perforation. ESD for esophageal squamous cell carcinoma (SCC) existing in a diverticulum is impossible to perform without perforation. Therefore, we performed a combination therapy between ESD and thoracoscopic surgery for the lesion.
**Aims & Methods:** A 60-year-old male who had esophageal SCC was referred to our hospital. Esophagography showed a diverticulum in the right side of middle thoracic esophagus. Endoscopy revealed a reddish 0-IIc lesion within the diverticulum and the lesion spread around the diverticulum. NBI endoscopy showed a well-demarcated brownish area. And, a loop-like irregular micro-vascular pattern was observed by NBI magnified endoscopy. A well-demarcated unstained area was revealed by iodine staining, and the size was more than half circumference. No lymph node and distant metastasis was diagnosed by CT scan and EUS. Therefore, the SCC was diagnosed as T1a without lymph node metastasis. The standard therapy for esophageal SCC in diverticulum is esophagectomy, because ESD may cause perforation. But, the patient didn't want to be treated by esophagectomy. Therefore, a corroboration therapy between ESD and thoracoscopic surgery was planned.
**Results:** At first, esophageal diverticulum was observed by a surgeon with thoracoscopy after intubated general anesthesia, and adhesion around the diverticulum was dissected. Next, ESD was performed by a hook knife. Severe fibrosis existed around the diverticulum, therefore proper muscle was cut with the diverticulum resulting a big perforation. Lung was observed through the perforation after ESD. Finally, the perforation was closed by the surgeon using thoracoscopy. 50 mg triamcinolone was injected into the submucosal layer on the artificial ulcer to prevent stricture. The patient felt no complaint, and was discharged 7 days after this treatment. The size of resected specimen was 47 x 43 mm, and pathological diagnosis was squamous cell carcinoma in esophageal diverticulum, the invasion depth was T1a; however SCC invaded submucosal layer through proper esophageal gland in only one point without lymph vascular involvement, lateral and vertical margin was negative, the size of SCC was 36 x 25 mm. R0 resection was achieved by this combination therapy.
**Conclusion:** Combined therapy of ESD and thoracoscopy is a minimally invasive surgery. Therefore, it is a good option for the treatment of a superficial SCC with esophageal diverticulum.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## VC02 NOVEL TECHNIQUE TO RELAX THE LOWER ESOPHAGEAL SPHINCTER (LES) DURING CHALLENGING PER ORAL ENDOSCOPIC MYOTOMY (POEM)

**M. Bukhari**, V. Kumbhari, Y. H. Chavez, S. Ngamruengphong, A. Ismail, P. Saxena, M. Elzein, M. Khashab
*Dept. Of Gastroenterology, Johns Hopkins University, Baltimore/United States of America*

**Contact E-mail Address:** mbukhar4@jhmi.edu
**Introduction:** Amyl nitrite is easily administered in an inhaled form and results in potent, short-acting (2 minutes) smooth muscle relaxation. Therefore, amyl nitrite can be used to transiently relax the lower esophageal sphincter (LES). Its use has been reported during barium esophagogram in order to distinguish patients with pseudoachalasia from those with idiopathic achalasia. One study demonstrated that diameter of the LES increased by more than 3 mm in patients with idiopathic achalasia in response to amyl nitrite.[1] Peroral endoscopic myotomy (POEM) is a purely endoscopic procedure aimed at obliterating pressure at the LES for the palliation of symptoms in achalasia. POEM involves creation of a submucosal tunnel for which dissection of submucosal fibers should be carried out close to the muscle layer surface to avoid mucosal injury. Intraprocedurally, when the LES is tight the dissection of the fibers can be challenging to perform safely without a risk of mucosal injury.
**Aims & Methods:** In this video we demonstrate two cases of utilizing amyl nitrite inhalation to relax the lower esophageal sphincter to facilitate submucosal tunneling during POEM.
**Results:** Cases: The first case is a 59-year-old male who underwent POEM for type III achalasia. During submucosal tunneling, the distal esophagus and LES were spastic inhibiting the advancement of the endoscope through the LES. The decision was made to use amyl nitrite was used to relax the LES. A 10 cc syringe was connected to the ventilation circuit. One ampule of amyl nitrite was placed inside the syringe. Patient was ventilated with a bag for 10 minutes. A second ampule of amyl nitrite was added and the distal esophagus and LES effectively relaxed and facilitating creation of the submucosal tunnel. During amyl nitrite administration his heart rate maximally increased by 10 bpm from base line of 70 bpm and blood pressure decrease to 95/68 from base of 117/70 mmHg. The second case is a 38-year-old female who underwent POEM for type II achalasia. During POEM, the LES found to be tight preventing effective and safe submucoal tunneling. A total of 9 ampules of amyl nitrite were given to relax the LES and facilitate submucosal dissection and tunneling safely. Her heart rate transiently increased by a maximum of 10 bpm from baseline to a max 95 bpm and the blood pressure drop to 80 mmHg from a baseline of116 mmH. Both patients were admitted to the hospital for observation as part of routine clinical care. Cine eophagogram 24 hours later showed no leak. Both patients were discharged home on soft diet and returned to clinic 4 weeks later with complete resolution of the symptoms.
**Conclusion:** Conclusion: Amyl nitrite is safe and effective method to relax the LES (figure 1). This technique may be utilized in patients where the creation of a submucosal tunnel through the LES may have otherwise not been safely performed.
**Disclosure of Interest:** M. Khashab: Dr. Khashab is a consultant for Boston Scientific. All other authors have no relevant disclosures.

**Introduction:** Hepatogastrostomy (HGS) is a novel method of the biliary decompression performed under the EUS. The migration of the metallic stent (MS) into the omental bursa is an ominous complication. The MS migration is caused by an inward pushing force of the gastric wall induced by the released side of the MS during the deployment, because the spindle shape of the released side of the MS makes a pushing force from outside due to the dynamic reason. To avoid the migration, MS is released after the echoendoscope is drawn back at the level of lower esophagus, when the introducer is inserted into the intrahepatic bile duct. However, under this method we cannot verify the MS release visually.
**Aims & Methods:** To achieve the successful deployment under visual condition, we conduct the pilot study of the intra-conduit release of the metallic stent before the deployment. The safety and feasibility are validated. HGS was performed with liner array echoendoscope and 19 G needle. After puncturing an intrahepatic duct, 0.025 inch guidewire (Visiglide, Olympus, Japan) was inserted. Then, the double lumen catheter (Uneven Double Lumen Catheter, Piolax, Japan) was inserted to dilate the needle track and to exchange the previous guidewire into the 0.035 inch stiff one. The introducer of the covered Wallflex (10 mm-8cm) or covered Niti-S (10 mm-10cm) was inserted over the wire. Subsequently, the deep up-angle of the scope was taken to attach the gastric wall on the liver. After accommodating the introducer position, MS deployment was commenced. Before the complete release of the MS, the outer sheath was retracted deeply enough into the scope conduit, that was confirmed under the fluoroscopy. After the up-angle position and the elevator of the scope were relaxed, the introducer was extruded from the conduit. The spindle shape of the MS was observed under the endoscopic view because the counteraction conducted from the pushed introducer made the tip of the scope separate from the gastric wall.
**Results:** Between April 2011 and March 2016, we performed HGS using this procedure on 14 cases with malignant distal biliary stricture. In 13 cases (92.9%), the successful deployment was achieved. In a failure case, who had Child's reconstruction after the pancreatoduodenectomy, we could not attach the gastric wall to the liver enough. As only 8 cm MS was available at that time, we deployed 10 cm plastic stent transiently. MS migration into the stomach as a late complication was observed in two patients who had moderate cholangitis. However, these patients had no peritonitis and recovered after the deployment of another MS through the fistula.
**Conclusion:** The intra-conduit MS release method before the complete deployment is safe and feasible. MS of 10 cm length is preferable in this method.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## VC04 GASTRIC PERFORATION DUE TO DUODENAL-JEJUNAL BYPASS SLEEVE: NON-SURGICAL, ENDOSCOPIC REMOVAL PROCEDURE

**E. G.H. De Moura**[1], C.M. Sakai[1], G. L.R. Silva[1], D. T.H. De Moura[2], E. T.H. De Moura[1], A.C. S. Borges[3], M. Passos Galvão Neto[4], P. Sakai[1]

**Contact E-mail Address:** eduardoghdemoura@gmail.com
**Introduction:** The bariatric Duodenal-Jejunal Bypass Sleeve (DJBS) - Endobarrier TM - GI Dynamics, Inc., Lexington MA - is a temporary, endoscopically delivered device that consists of a proximal metallic self-expandable anchor, which is placed in the duodenal bulb, attached to a 60 cm sleeve that acts as a physical barrier to the mucosa up to the proximal jejunum. It constitutes a promising therapy strategy for weight loss as well as metabolic disorders associated with obesity [1–5]. It is, however, associated with a relatively high rate of adverse events, as well as rare but serious complications such as hematemesis, cholecystitis and duodenal perforation [5–7], some of which requiring surgical intervention.
**Aims & Methods:** We present the case of a 58-year-old male, who successfully underwent placement of a DJBS. Patient developed abdominal pain and postprandial fullness after 8 weeks. Endoscopic examination revealed metallic barbs migrated into the lesser curvature of the distal antrum, and a considerable amount of hyperplastic tissue in the duodenal bulb firmly adhered to the proximal metallic end of the DJBS. A two sessions endoscopic approach was then attempted for device removal. First, the pylorus and the proximal end of the device were dilated using a 20 mm hydrostatic balloon, and an over-the-scope fully covered 6 cm metallic stent was placed. Two weeks later, the stent was removed, and the excessive hyperplastic tissue was resected using a polypectomy snare. The proximal end of the plastic liner was then mobilized distally, as to disengage the metallic barbs from the gastric wall, exposing the removal drawstrings in the duodenal lumen.
**Results:** Device removal was then feasible according to the usual removal procedure: traction of one of the drawstrings using a custom grasper, followed by collapse of the metallic barbs into the removal cap, and complete extraction of the whole device. Immediate endoscopic evaluation showed no signs of major complications such as perforation of hemorrhage.
**Conclusion:** This case illustrates a serious complication of the DJBS and an endoscopic treatment technique that successfully prevented an invasive surgical intervention, demonstrating that DJBS removal may be possible even in very difficult scenarios.
**Disclosure of Interest:** M. Passos Galvão Neto: Consulting physician for GI DYNAMICS, Inc., Lexington MA.

## VC05 TUNNEL AND BRIDGE TECHNIQUE: A NOVEL APPROACH TO ENDOSCOPIC SUBMUCOSAL DISSECTION OF GIANT RECTAL POLYPS

K. Kandiah, **S. Subramaniam**, F.J.Q. Chedgy, S. Thayalasekaran, P. Bhandari
*Gastroenterology, Queen Alexandra Hospital, Portsmouth/United Kingdom*

**Contact E-mail Address:** shar811@googlemail.com
**Introduction:** Endoscopic submucosal dissection (ESD) is a safe and effective method for resecting large rectal polyps of over 2 cm. This technique facilitates en bloc dissection and leads to lower recurrence rates. However, ESD of giant laterally spreading tumours can be technically challenging.
**Aims & Methods:** We aim to demonstrate the use of a novel ESD 'tunnel and bridge' technique in the management of giant rectal polyps. A mucosal incision and a small degree of submucosal dissection is performed on the anal side followed by the caecal side of the lesion. This creates a 'polyp bridge'. Once the bridge has been fashioned, the submucosal dissection is extended from the anal side through to the caecal side of the polyp. Patient position change is utilised during the procedure, enabling gravity to hold the bridge up in place. The bridge ends are dissected using a scissor type knife to complete the polyp resection.
**Results:** This technique was demonstrated in a 63-year-old female with a 50 mm lateral spreading tumour – granular type in the rectum. There were no previous resection attempts. The lesion contained Kudo pit pattern IIIS and IIIL. Successful en bloc resection was achieved using the 'tunnel and bridge' technique with no complications. The histology from this lesion confirmed a tubular adenoma with low grade dysplasia. The adenoma was completely excised with no residual lesion present on follow up.
**Conclusion:** The 'tunnel and bridge' technique during endoscopic submucosal dissection of giant rectal polyps is a safe and viable method that enables time efficient resection. Further studies comparing this novel dissection technique to conventional ESD are needed to better understand and refine its role.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## VC06 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) OF A 25MM NEUROENDOCRINE TUMOUR OF THE GASTRIC BODY

**M. Sidhu**[1], D. J. Tate[1], M. J. Bourke[2]

[1]*Gastroenterology And Hepatology, Westmead Hospital Sydney, Westmead, NSW/Australia*

**Contact E-mail Address:** msidhu16@hotmail.com
**Introduction:** Neuroendocrine Tumours (NETs) are neoplasms with predominant neuroendocrine differentiation that extend into the submucosa and sometimes involve the muscularis. Gastric NETs represent approximately 7% of all Gastroenteropancreatic NETs. Endoscopic resection has been shown as an effective method of treatment for Type I and II lesions as opposed to surgical resection. Traditionally endoscopic mucosal resection (EMR) was the preferred modality however this is now being replaced by endoscopic submucosal dissection (ESD) with improved outcomes.
**Aims & Methods:** To discuss the classification and management of Gastric Neuroendocrine tumours and to demonstrate endoscopic resection of a Gastric NET by ESD focusing on management of procedural complication especially major bleeding. This is a video of an ESD of 25 mm, Paris 0-Is, gastric NET (Type I) of the gastric body (greater curve).
**Results:** Complete endoscopic resection with histopathology confirming a well-differentiated Grade 2 Gastric NET.
**Conclusion:** ESD is an effective and safe technique for treatment of Gastric NETs (Type I and II). Major bleeding however can still occur despite prophylactic measures and endoscopistis must be aware of this risk.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Proximal migration of pancreatic stent (PS) is a complication described in patients with PS and its retrieval is a challenging situation considering that all known techniques are ''blind'' and developed for biliary stents(1).
**Aims & Methods:** A 36-year-old female was admitted in the hospital due to complete common bile duct dissection during a laparoscopic cholecystectomy. An ERCP was performed with biliary stent placement. During the procedure the main pancreatic duct was catheterized, so a straight, double-flared per side PS 5fr-7 cm was placed. The patient recovered uneventfully and biliary stent extraction and/or replacement were scheduled 3 months later. During the second ERCP, the biliary stent was identified and replaced but no PS was detected. Abdominal x-ray revealed the complete migration of the PS proximally inside the pancreatic duct. Pancreatic sphincterotomy was performed, followed by guide-wire cannulation of the main pancreatic duct. A biliary dilation balloon was repeatedly introduced over the wire, but failed to extract the stent. A single pigtail PS was then placed alongside the old PS and left for 5 days. An attempt followed to extract both stents at the same time, drifting the old stent while extracting the new one without success. Further attempts to retrieve the PS with biopsy forceps, a biliary stone extraction balloon and again, with biliary dilation balloon, failed as well. Subsequently, direct pancreatoscopy with the Spyglass™ visualization system (Boston Scientific) was performed. The distal end of the stent was visualized, but multiple attempts to grab the stent with the SpyBite™ forceps (Boston Scientific) failed due to the position of the PS and poor SpyBite deployment. In the final procedure, the new Spyglass™ DS (Boston Scientific) was used. The image quality was far superior compared to its predecessor. The distal end of the PS was clearly identified and Spybite was easier to introduce and deploy. Several attempts were done in order to change the stent's tip position. Then the tip was grabbed and successfully removed. No procedure-related complications occurred except for asymptomatic amylasemia and the patient was discharged two days later.
**Results:** Proximally migrated pancreatic stents can be effectively identified grasped and retrieved with the new Spyglass™ DS system.
**Conclusion:** The high image quality, the adequate manoeuvrability and ease of use that the new system offers under direct visualization, enables an alternative safe salvage technique when conventional methods of stent retrieval have failed.

## VC08 ENDOSCOPIC MUCOSAL RESECTION OF GIANT FLAT POLYP EXCLUSIVELY CLOSED WITH A SURGICAL HAEMOSTATIC AGENT

**Introduction:** An asymptomatic 72-year-old man was diagnosed with colonic polyps in the colorectal-cancer-screening program. The biggest polyp was localized in the proximal transverse colon with a diameter of 5 cm and characterized as lateral spread with IIIL/ IV based in Kudós classification, II/ IIa Sano and LST-G IIa+Is under Pariśs classification. The polyp was resected in ''piece meal'' (3 pieces) and fulgurated with Argon plasma coagulation (APC) over the suspicious remains areas and also over the proximal edge. Immediately after finished the resection the scarf was covered with a surgical haemostatic agent (PURASTAT®), No adverse event was presented nor after immediately post-procedure and neither in the follow-up.
**Aims & Methods:** Closing the scarf after mucosectomies reduces significantly secondary events such as immediately bleeding or delay bleeding. However in giant polyps it would be impossible to close with the traditional systems as through-the- scope clips or over-the-scope clips and could develop late stricture. For this reason, we used the PuraStat®, which is a transparent, slightly viscous synthetic peptide solution that is marked as a surgical haemostat agent. Upon contact with blood, the peptide solution instantaneously self-assembles a hydrogel barrier, sealing open blood vessels naturally to accomplish complete haemostasis.
**Results:** The histology of resection pieces were tubule-villous adenoma with high-grade dysplasia (Haggitt 0), with free edge.
**Conclusion:** Thus this case is a unique example exemplifying the safety and efficiency to use of this new method to prevent the bleeding after large mucosectomy and reduces the rate of delay strictures. In addition this report showed a new, easy and fast technique to applied the haemostatic agent.

## VC09 THE INSERTION OF A PERCUATENOUS ENDOSCOPIC SIGMOIDOSTOMY TUBE

**V. Cubas**, O. Adedeji
*General Surgery, University Hospital Birmingham, Birmingham/United Kingdom*

**Contact E-mail Address:** vanessacubas@nhs.net
**Introduction:** We present a video demostration of insertion of a percutaneous endoscopic sigmoidostomy tube and a brief overview of possible problems and after care.
**Aims & Methods:** The main indications are recurrent sigmoid volvulus and chronic pseudo-obstruction. It may also be used for chronic constipation to administer enemas.
**Results:** It is a safe procedure with minimal morbidity for commonly encountered problems often necessitating repeat hospitalisation.
**Conclusion:** Percutaneous endoscopic sigmoidostomy offers an alternative treatment for patients who have tried conventional treatment options without success. Traditional treatment options for sigmoid volvulus and pseudo-obstruction comprise endoscopic decompression and/or open resection. However, these management options have varying success with endoscopic decompression having a recurrence rate of approximately 40% and open resection may be contraindicated for frail, elderly patients or the severly immunocompromised. ## VC10 HIGH MAGNIFICATION DIAGNOSIS AND TREATMENT OF ESOPHAGEAL INTRAEPITHELIAL SQUAMOUS CELL CARCINOMA

**Introduction:** Endoscopic submucosal dissection (ESD) is the standard treatment for intraepithelial esophageal squamous tumors[1]. A high-quality preliminary endoscopy of eligible lesion is essential for a satisfactory outcome. For this purpose, the classification of intrapapillary capillary loop arrangement and the iodine staining characteristics (IPCL)[2] is a reliable predicting tool. We report our experience using a new generation gastroscope for the preliminary assessment and subsequent endoscopic resection of intraepithelial esophageal squamous cell carcinoma.

**Aims & Methods:** A 59-year-old man with a relevant history of alcohol abuse, underwent upper endoscopy. A gastroscope, equipped with 3rd generation Narrow Band Imaging (NBI) and high magnification zooming lever (Olympus H290Z, Japan) was employed. A cylindrical soft hood was employed for both the assessment and resection of the lesion, which was recognized under white light. The iodine staining and IPCL characteristics were employed to determinate the borders and the staging of the lesion. A glycerol solution was employed to lift the lesion border. The dissection was performed using a water-jet assisted dual knife (Olympus, Japan) connected to a manual infusion system (Figure 1a-b). Coagulation forceps and short clips were employed for preventive coagulation of visible vessels

**Results:** The normal iodine staining was lost in the majority of the lesion and partially in the surrounding inflamed mucosa (figure 2b). Therefore, the neoplastic borders were marked according to the IPCL findings (Figure 2a-d). We experienced a satisfactory feasibility by using the same endoscope for ESD, avoiding scope change and easily visualizing vascular structure even in difficult positions by using the zoom lever (figure 2e-g). The ESD procedure duration was 160 minutes. No intra-procedural or short-term adverse events were reported. The length of the stay was 5 days. The histopathology confirmed the R0 endoscopic resection of a mild differentiated intraepithelial esophageal squamous carcinoma (T1a)

**Conclusion:** The new generation zoom endoscope allowed an optimal observation of early squamous cell esophageal neoplasm characteristics and a feasible endoscopic resection in this preliminary experience. The adjustable zoom resulted in a continuous high quality view, which facilitated some procedural steps of the endoscopic resection. For the resection of distal esophageal lesions, a standard "J" endoscope with a major retroflection bending capacity may be preferred.
