<sup>3</sup> Faculty of Chemistry, A. Mickiewicz University, Poznań, Poland

A new series of 16 6-chloro-1,1-dioxo-7-{4-[(4-*R*<sup>1</sup>-phenyl)imino]-4*H*-3,1-benzoxazin-2-yl}-3-(substituted amino)-1,4,2-benzodithiazines **7–22** was prepared in order to evaluate the cytotoxic activity against six human cancer cell lines. The structures of the new compounds were confirmed by IR, <sup>1</sup>H-, and <sup>13</sup>C-NMR, elemental analysis and in the cases of **11** and **31** by X-ray crystal structure analysis. This analysis showed that contrary to our earlier report the structures contain a benzoxazine ring instead of the proposed quinazolinone ring. The bioassay indicated that the benzodithiazine derivatives **7–22** possess cancer cell growth-inhibitory properties. Some compounds showed a high level of selectivity for certain cell lines. The most active compounds **11**, **12**, **16**, **19**, **21**, and **22** exhibited potency higher or comparable to cisplatin. The compounds were particularly effective in LCLC-103H and MCF-7 cell lines with IC<sub>50</sub> values of 0.49–1.60 μM. Quantitative structure activity relationships (QSAR) revealed that a chloro substituent *R*<sup>1</sup> in the phenyl ring as well as the shape of the substituted amino group at *R*<sup>2</sup> (e.g., unsaturation is beneficial) are important for potency.

## Introduction

Aryl and heteroarylsulfonyl sulfonamides are attracting attention as anticancer agents. Our systematic studies on the synthesis of 1,4,2-benzodithiazine-1,1-dioxides and their subsequent transformation into *N*-(azolyl or azinyl)-2-mercaptopbenzenesulfonamides **A** (Fig. 1) have resulted in promising

anticancer agents [1–5] and potent inhibitors of HIV-1 integrase (MBSAs) [6]. We also found that cyclic sulfonamide derivatives of 2-amino-8-chloro-5,5-dioxo[1,2,4]triazolo[2,3-*b*][1,4,2]benzodithiazine (**B**, Fig. 1) [7, 8] or of type **C–D** (Fig. 1) possess interesting *in-vitro* anticancer properties [9–11]. In addition, various 1,3-benzoxazine derivatives have been found to show versatile bioactivities such as antimicrobial, antiviral, antifungal [12], anti-human coronavirus [13], and anticancer activity [14].

In the search for more potent and selective agents against cancer, we report the synthesis of 16 new compounds of type **E** and the results of their *in-vitro* evaluation for cytotoxic activity. The scaffold of this class of compounds consists of

two moieties: 1,1-Dioxo-1,4,2-benzodithiazine and 1,3-benzoxazine. The objective of this drug-design approach was to merge these two moieties to enhance their activity against cancer cells. Our previous studies with this class of compounds showed that electronic character of the benzodithiazine ring system substituent at position-3 was an important factor influencing cytotoxicity [15]. However, in this previous publication we reported that the compounds were quinazolinone derivatives. Based on X-ray crystal structure analysis of two representative compounds we now correct the structures to be benzoxazine derivatives. Herein, the effects of further structural modifications on antitumor activity were explored within two structural domains: The benzodithiazine ring (substituent  $R^2$ ) and substituents of benzoxazine moiety ( $R^1$ -phenyl). A correlation between the structures of these derivatives and the potency to inhibit the growth of cancer cells was investigated by using quantitative structure activity relationship (QSAR) methods.

## Results and discussion

### Chemistry

The previously described methods were employed for the synthesis of 6-chloro-3-methylthio-1,1-dioxo-1,4,2-benzodithiazin-7-carbonyl chloride **1** [16, 17]. The reaction of **1** with the appropriate 2-aminobenzanilide was carried out in boiling toluene in the presence of pyridine and afforded the expected *N*[2-(phenylcarbamoyl)phenyl]-6-chloro-1,1-dioxo-3-methylthio-1,4,2-benzodithiazin-7-carboxamide **2–3** in 80% yield. Treatment of **2–3** with an excess of thionyl chloride under reflux gave rise to the novel 6-chloro-7-[4-( $R^1$ -phenyl)imino]-4*H*-3,1-benzoxazin-2-yl]-3-methylthio-1,4,2-benzodithiazine 1,1-dioxides **4**, **5**, and **6** [15].

The spectroscopic data do not allow straightforward discrimination between the quinazolone structure and alternative benzoxazine. Therefore, X-ray crystallography was undertaken with a previously described compound **31** [15]

as well as with a new one **11** with the goal to establish the more discrete structural features of these compounds. Unexpectedly, X-ray structure analysis showed that compounds are 6-chloro-7-[4-( $R^1$ -phenyl)imino]-4*H*-3,1-benzoxazin-2-yl]-3- $R^2$ -1,4,2-benzodithiazine dioxides (Figs. 2–4), and not the quinazolinone structure we previously reported [15].

The mechanism of the reaction pathway was not investigated but it can be postulated as follows. First, the reaction of carboxamide **2** or **3** with thionyl chloride involves the initial formation of unstable intermediate **A**, which with evolution of the hydrogen chloride giving rise to formation intermediate **B**. In turn, the latter intermediate subsequently undergoes an intramolecular cyclocondensation with evolution molecule of the sulfur dioxide to afford the final products **4–6**. Carboxamides **2** or **3** did not undergo the intramolecular cyclization (Scheme 1) in the presence of dehydrating agents such as phosphorous oxychloride or thionyl chloride to obtain quinazolinone **C** [18–20].

Furthermore, nucleophilic displacement of the 3-methylthiol group of **4–6** by the appropriate amine in boiling methanol proceeded with elimination of methyl mercaptane, leading to the target benzodithiazines **7–22** in 27–78% yields (Scheme 2). All final products were characterized by IR and NMR spectroscopy as detailed in the experimental section. Elemental analyses were in accordance with the proposed structures.

Molecules **11** and **31** [15] with their labeling scheme are shown in Figures 2 and 3. Bonding geometries of the benzoxazin-4-imine and 1,4,2-benzodithiazin-3-amine 1,1-dioxide units are similar to those found in previously reported structures [10, 11],[21–24]. Bond lengths indicate a double bond character at C14–N19 [1.274(2) and 1.254(6) Å] and C16–N24 [1.262(3) and 1.257(6) Å], a relevant degree of single bond for C25–N24 [1.417(3) and 1.426(6) Å] and a strong conjugation in the amidine N3–C3–N31 fragment with the C–N bond lengths in the range 1.299(7) to 1.320(8) Å.

The analogous parts for the two molecules have very similar conformations as shown in Fig. 4, where superposition of the molecular structures of **11** and **31** is presented.

A 1,1-dioxo-1,4,2-dithiazine ring with the lone pairs of electrons on the S atom is known to prefer the boat conformation [25] and this conformation is adopted by this ring in both molecules, leading to their butterfly shape. The central part that comprises a 3,1-benzoxazine system and the fragment of 1,4,2-benzodithiazine unit, consisting of the benzene ring and S substituent atoms, is virtually planar with dihedral angles between the two parts being 3.6 and 6.1° in **11** and **31**, respectively.

### Biology

A microtiter based assay based on the staining of adherent cells with crystal violet was used to quantify the antiprolifer-

**Scheme 1.** Proposed mechanism of the formation of benzoxazines 4–6.

ative potential of the new compounds on human cancer cell lines. Details of this test have been published elsewhere [26, 27]. Primary screening of compounds 7–22 for antiproliferative activity took place on three human cancer cell lines: A-427, DAN-G and LCLC-103. All compounds showed inhibition of cell growth by more than 50% at 20  $\mu\text{M}$  in one or more of the cell lines. Secondary screening to determine potency was performed on a panel of 6 human cancer cell lines: RT-4 (urinary bladder transitional cell cancer), 5637 (urinary bladder cancer), DAN-G (pancreas cancer), LCLC-103H (large cell lung cancer), A-427 (lung cancer), and MCF-7 (breast cancer). Table 1 lists the average  $\text{IC}_{50}$  values calculated from the dose-response data obtained from three independent experiments. The  $\text{IC}_{50}$  is the concentration required to inhibit cell growth by 50% compared to the untreated control over a 96 h treatment period [26].

The present results show that further structural modification of earlier tested benzodithiazine derivatives [15] can

lead to further increases in potency. In the series of derivatives 7–22, the compounds differ in a substituent at the position 3 of the benzodithiazine scaffold and in substitution in the position 4 of the phenyl attached to the benzoxazine moiety (chlorine, hydrogen or methyl group).

Based to the substituent at position 3 ( $R^2$ ), compounds can be divided into three groups: 9–11 possessing an aliphatic chain, 12–22 with a pyridine moiety and 7–8 with the morpholine entity. The cytotoxicity of compounds with the morpholine moiety is much lower than of the other benzodithiazines, although their selectivity towards the 5637 cell line is apparent. The most active group appears to be those with pyridine substituent. However, the mean  $\text{IC}_{50}$  value of the compound 11 with allylamino group is lower comparable to pyridine substituted compounds 12, 16, and 21.

A comparison with activity of anticancer-agent cisplatin indicates that benzodithiazines 7–22 possess very good cell

growth inhibitory properties. The values of the IC<sub>50</sub> were taken from a previously published study [26] conducted in analogous conditions to our assay. In general these results show the greatest similarities in activity of tested benzodithiazines to the alkylating agents like cisplatin and DACH-Pt. The LCLC-103H cell line is the most sensitive of the six cell lines. In this cell line some of the compounds showed similar (16, 19, and 21) or even greater (10–13 and 22) potency compared to cisplatin. Moreover, the RT-4 cell line was susceptible to cell growth inhibition by 12 < 19 < 22 < 11 < 14 < 16, which was similar or greater than cisplatin in the case of compounds 13, 21, and 18.

#### Quantitative structure activity relationship studies

QSAR are frequently used in medicinal chemistry to establish a predictive relationship between structure and potency [28]. In search of possible QSAR with our data, multiple regression analysis was performed with 18 quantitative descriptors for the amines at R<sup>2</sup> and two indicator variables for either a chlorine atom or a methyl group at R<sup>1</sup> (see Table S1, Supplementary Material). The dependent variable was the -log of the IC<sub>50</sub> values. The compounds used in the QSAR analysis included the 16 compounds described in this work as well as 8 compounds, 23–30 (Scheme 2) reported in an earlier study [15]. The range in the IC<sub>50</sub> values for the

24 compounds was ca. 20-fold in the RT-4, DAN-G and the MCF-7 lines, 12-fold in the LCLC-103H line and less than 6-fold in the remaining two lines. Both the IC<sub>50</sub> values for the individual cell lines as well as the average IC<sub>50</sub> values over

identified as having a positive influence while in the three parameter equation the kappa shape index, order 1 (KSI-1) [29] has a positive effect while too large a molar volume (MV) is detrimental.

$$-\log(\text{IC}_{50})_{\text{all lines}} = 0.024(\pm 0.006)\text{USA} + 0.306(\pm 0.091)I_{\text{Cl}} + 4.336(\pm 0.249) \quad (1)$$

$n = 24 \quad r\text{CV}^2 = 0.400 \quad r = 0.768 \quad s = 0.252 \quad F = 15.139$

$$-\log(\text{IC}_{50})_{\text{all lines}} = 0.442(\pm 0.094)\text{KSI-1} - 0.024(\pm 0.008)\text{MV} + 0.367(\pm 0.074)I_{\text{Cl}} + 4.811(\pm 0.175) \quad (2)$$

$n = 24 \quad r\text{CV}^2 = 0.585 \quad r = 0.861 \quad s = 0.282 \quad F = 19.082$

all six lines where included in the analysis.

The best correlations were found with the data from the averaged IC<sub>50</sub> values for all six lines, where the IC<sub>50</sub> values differed by a factor of maximal 24-fold (see Table S1). Significant correlations were also found with three individual cell lines (LCLC-104H, RT-4, and MCF-7). The remaining three cell lines (DAN-G, A-427, and 5637) gave much poorer correlations, which were in many cases no longer significant (data not shown). Cross-validation of the data was performed by the leave-one-out procedure and is reported as the cross-

In the cases of three individual cell lines where significant correlations were found, the unsaturated surface area of the group at R<sup>2</sup> and the presence of a chlorine atom at R<sup>1</sup> were again important determinates for activity. This was particularly apparent when the data was fitted to the two best parameters, as in the cases of Eqs. (3), (5), and (7). In the cases of the cell lines LCLC-104H and RT-4, inclusion of a second indicator variable for the methyl group at R<sup>1</sup> improved the correlation considerably (see Eqs. (4) and (6)). This was not unexpected because the methyl is bioisoteric with Cl.

$$-\text{Llg}(\text{IC}_{50})_{\text{LCLC}} = 0.011(\pm 0.003)\text{USA} + 0.568(\pm 0.135)I_{\text{Cl}} + 5.048(\pm 0.131) \quad (3)$$

validated squared correlation coefficient  $r\text{CV}^2$ .

Equations (1) and (2) show the results of the multiple regression analysis for two and three best variables for the average IC<sub>50</sub> values of all lines. The single most important parameter contributing to good activity is the presence of a chlorine atom at position R<sup>1</sup> of the phenyl ring, as evidence by the indicator variable  $I_{\text{Cl}}$  in both equations. The shape of the substituent at R<sup>2</sup> also appears to influence activity; in the two variable equation the unsaturated surface area (USA) was

In the case of the MCF-7 cell line, the inclusion of the three best parameters in the regression equations still indicated that the shape of the substituent at R<sup>2</sup> is important but now the saturated surface area (SSA) is detrimental while the water accessible surface area (WASA) is beneficial to activity (Eq. (8)). The result that the saturated surface area is detrimental is consistent with the regression equations that showed the unsaturated surface area to be beneficial because the one parameter is the opposite of the other.

$$-\log(\text{IC}_{50})_{\text{MCF7}} = 0.011(\pm 0.003)\text{USA} + 0.370(\pm 0.108)I_{\text{Cl}} + 5.011(\pm 0.105) \quad (7)$$

$n = 24 \quad r\text{CV}^2 = 0.370 \quad r = 0.755 \quad s = 0.287 \quad F = 13.90$

$$-\log(\text{IC}_{50})_{\text{MCF7}} = -0.013(\pm 0.003)\text{SSA} + 0.012(\pm 0.002)\text{WASA} + 0.316(\pm 0.088)I_{\text{Cl}} + 4.925(\pm 0.244) \quad (8)$$

$n = 24 \quad r\text{CV}^2 = 0.610 \quad r = 0.855 \quad s = 0.325 \quad F = 18.10$

## Conclusion

The above data show the usefulness of uniting benzoxazine and benzodithiazine moieties to build a scaffold with good cytotoxic activity. It can be concluded that the shape (e.g., unsaturation) of the substituents R<sup>2</sup> of the benzodithiazine ring system as well as a chlorine or methyl group in the phenyl ring at R<sup>1</sup> positively influence the cytotoxicity potency of the compounds. Further structural modification along the lines of the QSAR may help to further increase the potency of this interesting new class of cytotoxic compounds.

## Experimental

### Chemistry

#### General

Melting points are uncorrected and were determined on a Büchi SMP-20 apparatus (Büchi Labortechnik, Flawil, Switzerland). The IR spectra were recorded on 1600 FTIR Perkin Elmer (Perkin Elmer, Norwalk, CT, USA) spectrometer by using potassium bromide pellets and frequencies were expressed in cm<sup>-1</sup>. The <sup>13</sup>C- and <sup>1</sup>H-NMR spectra were obtained on a Varian Gemini (50 MHz and 200 MHz) or Varian Unity Plus (125 MHz and 500 MHz) spectrometers (Varian Inc., Palo Alto, CA, USA). The chemical shift values  $\delta$  were expressed in ppm relative to the residual solvent signal at 2.50 or 7.26 ppm and 39.5 or 77 ppm, respectively. The analytical results for C, H, and N were within  $\pm 0.4\%$  of the theoretical values and results are reported in Table S2 (Supplementary Material). The starting 6-chloro-3-methylthio-1,1-dioxo-1,4,2-benzodithiazin-7-carboxylic acid [16], 6-chloro-3-methylthio-1,1-dioxo-1,4,2-benzodithiazin-7-carbonyl chloride **1** [17], *N*-[2-(phenylcarbamoyl)phenyl]-6-chloro-1,1-dioxo-3-methylthio-1,4,2-benzodithiazin-7-carboxamide [15], and 6-chloro-1,1-dioxo-3-methylthio-7-[4-(phenylimino)-4*H*-3,1-benzoxazin-2-yl]-1,4,2-benzodithiazine **6** [15] were obtained by the previously described methods.

#### *N*-[2-(*R*<sup>1</sup>-Phenylcarbamoyl)phenyl]-6-chloro-1,1-dioxo-3-methylthio-1,4,2-benzodithiazin-7-carboxamides **2, 3**

To a suspension of compound **1** (3.42 g, 10 mmol) and 2-amino-*N*-(*p*-tolyl or 4-chlorophenyl)benzamide (11 mmol) in anhydrous toluene (120 mL), pyridine (0.8 mL, 10 mmol) in anhydrous toluene (50 mL) was added. The reaction mixture was stirred at reflux for 48 h and then left overnight at room temperature. The precipitate was filtered off, washed with toluene (5 mL), dried and suspended in 0.5% aqueous K<sub>2</sub>CO<sub>3</sub> (200 mL). The mixture was stirred for 1 h, filtered off, washed successively with water (2  $\times$  50 mL), methanol (20 mL), and dried. In this manner, the following compounds were obtained.

#### *N*-[2-(4-methylphenylcarbamoyl)phenyl]-6-chloro-1,1-dioxo-3-methylthio-1,4,2-benzodithiazin-7-carboxamide **2**

Starting from 2-amino-*N*-*p*-tolylbenzamide (2.48 g); yield: 4.5 g (85%); mp 268–270°C. IR (KBr, cm<sup>-1</sup>) 3267 (NH), 1650 (CONH), 1600 (C=N), 1335, 1170 (SO<sub>2</sub>). <sup>1</sup>H-NMR (200 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  2.27 (s, 3H, CH<sub>3</sub>Ph), 2.74 (s, 3H, CH<sub>3</sub>S), 7.13 (d, *J* = 8.4 Hz, 2H, arom.), 7.37 (t, *J* = 7.3 Hz, 1H, arom.), 7.54–7.68 (m, 3H, arom.), 7.79 (d, *J* = 7.3 Hz, 1H, arom.), 8.04 (d, *J* = 8.1 Hz, 1H, arom.), 8.17

(s, 1H, H-5 benzodit.), 8.36 (s, 1H, H-8 benzodit.), 10.40 (s, 1H, NH), 11.09 (s, 1H, NH) ppm.

#### *N*-[2-(4-chlorophenylcarbamoyl)phenyl]-6-chloro-1,1-dioxo-3-methylthio-1,4,2-benzodithiazin-7-carboxamide **3**

Starting from 2-amino-*N*-(4-chlorophenyl)benzamide (2.71 g); yield: 4.4 g (80%); mp 242–244°C. IR (KBr, cm<sup>-1</sup>) 3276 (NH), 1666 (CO), 1628, 1603 (C=N), 1350, 1165 (SO<sub>2</sub>). <sup>1</sup>H-NMR (200 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  2.72 (s, 3H, SCH<sub>3</sub>), 7.28–7.45 (m, 3H, arom.), 7.54–7.82 (m, 4H, arom.), 7.93 (d, *J* = 7.7 Hz, 1H, arom.), 8.15 (s, 1H, H-5 benzodit.), 8.32 (s, 1H, H-8 benzodit.), 10.58 (s, 1H, NH), 10.94 (s, 1H, NH) ppm.

#### 6-Chloro-7-[4-(*R*<sup>1</sup>-phenyl)imino]-4*H*-3,1-benzoxazin-2-yl]-3-methylthio-1,4,2-benzodithiazine 1,1-dioxides **4–5**

A mixture of carboxamide **2** or **3** (10 mmol) and thionyl chloride (50 mL) was refluxed for 30 h. The thionyl chloride was distilled off (80°C) then to the residue toluene was added (2  $\times$  40 mL) and distilled off (111°C). The dry residue was recrystallized from anhydrous toluene (100 mL) to give **4** or **5**.

#### 6-Chloro-1,1-dioxo-7-[4-[(4-methylphenyl)imino]-4*H*-3,1-benzoxazin-2-yl]-3-methylthio-1,4,2-benzodithiazine **4**

Starting from **2** (5.32 g); yield: 1.3 g (25.3%); mp 256–258°C. IR (KBr, cm<sup>-1</sup>) 1670 (N=C), 1630, 1605 (C=N), 1345, 1170 (SO<sub>2</sub>). <sup>1</sup>H-NMR (500 MHz, CDCl<sub>3</sub>):  $\delta$  2.36 (s, 3H, PhCH<sub>3</sub>), 2.74 (s, 3H, SCH<sub>3</sub>), 7.03 (d, *J* = 8 Hz, 2H, PhCH<sub>3</sub>), 7.09 (d, *J* = 8 Hz, 2H, PhCH<sub>3</sub>), 7.48 (s, 1H, H-5 benzodit.), 7.59 (t, *J* = 7.3 Hz, 1H, arom.), 7.64 (d, *J* = 8.3 Hz, 1H, arom.), 7.76 (t, *J* = 7.3 Hz, 1H, arom.), 8.46 (d, *J* = 7.8 Hz, 1H, arom.), 8.66 (s, 1H, H-8 benzodit.) ppm; <sup>13</sup>C-NMR (500 MHz, CDCl<sub>3</sub>):  $\delta$  16.69 (SCH<sub>3</sub>), 20.97 (CH<sub>3</sub>), 119.0, 122.58, 125.86, 127.28, 127.56, 127.64, 128.28, 129.13, 129.47, 129.90 (two overlapping signals), 129.95, 130.51, 131.91, 134.71, 135.45, 138.04, 142.35 (aromat.), 146.97, 152.22 (C=N), 179.91 (N=C) ppm.

#### 6-Chloro-1,1-dioxo-7-[4-[(4-chlorophenyl)imino]-4*H*-3,1-benzoxazin-2-yl]-3-methylthio-1,4,2-benzodithiazine **5**

Starting from **3** (5.52 g); yield: 3.8 g (70%); mp 228–230°C. IR (KBr, cm<sup>-1</sup>) 1670 (N=C), 1630, 1605 (C=N), 1345, 1170 (SO<sub>2</sub>). <sup>1</sup>H-NMR (200 MHz, CDCl<sub>3</sub>):  $\delta$  2.72 (s, 3H, SCH<sub>3</sub>), 7.09 (d, *J* = 8.7 Hz, 2H, PhCl), 7.32 (d, *J* = 8.7 Hz, 2H, PhCl), 7.48 (s, 1H, H-5 benzodit.), 7.52–7.63 (m, 2H, arom.), 7.72 (ddd, *J* = 1.5 Hz, *J* = 8.2 Hz, *J* = 8.5 Hz, 1H, arom.), 8.31 (ddd, *J* = 7.7 Hz, *J* = 8.8 Hz, *J* = 1.2 Hz, 1H, arom.), 8.64 (s, 1H, H-8 benzodit.) ppm. <sup>13</sup>C-NMR (200 MHz, CDCl<sub>3</sub>):  $\delta$  16.94 (SCH<sub>3</sub>), 119.66, 124.14 (two overlapping signals), 127.28, 127.56, 127.88, 129.25, 129.47 (two overlapping signals), 129.83, 130.07, 130.17, 130.27, 134.72, 134.79, 134.96, 138.0, 142.47 (aromat.), 151.57, 152.86 (C=N), 180.07 (N=C) ppm.

#### General procedure for preparation of 6-chloro-1,1-dioxo-7-[4-(*R*<sup>1</sup>-phenyl)imino]-4*H*-3,1-benzoxazin-2-yl]-3-*R*<sup>2</sup>-1,4,2-benzodithiazines **7–22**

A mixture of the corresponding benzodithiazine **4–6** (1 mmol) and the appropriate amine (1.1 mmol) in dry methanol (20 mL) was stirred at room temperature for 10 h and then refluxed until the evolution of MeSH had ceased (20–40 h) [Caution: because of high toxicity, MeSH should be trapped in an aqueous NaOH

solution]. The precipitate was filtered off, washed successively with methanol (5 mL), chloroform (5 mL), and dried. In this manner, the following compounds were obtained:

**6-Chloro-1,1-dioxo-7-{4-[(4-methylphenyl)imino]-4H-3,1-benzoxazin-2-yl}-3-morpholino-1,4,2-benzodithiazine 7**

Starting from **4** (0.51 g) and morpholine (0.096 g); yield: 0.29 g (53%); mp 276–278°C. IR (KBr,  $\text{cm}^{-1}$ ) 1673 (N=C), 1630 (C=N), 1320, 1160 ( $\text{SO}_2$ ).  $^1\text{H-NMR}$  (200 MHz,  $\text{CDCl}_3$ ):  $\delta$  2.33 (s, 3H,  $\text{CH}_3$ ), 3.62–4.05 (m, 8H,  $4 \times \text{CH}_2$ ), 6.95–7.10 (m, 2H,  $\text{PhCH}_3$ ), 7.18–7.31 (m, 2H,  $\text{PhCH}_3$ ), 7.49 (s, 1H, H-5 benzodit.), 7.50–7.80 (m, 3H, arom.), 8.39 (d,  $J = 7.7\text{ Hz}$ , 1H, H-5 arom.), 8.62 (s, 1H, H-8 benzodit.) ppm.

**6-Chloro-1,1-dioxo-7-{4-[(4-chlorophenyl)imino]-4H-3,1-benzoxazin-2-yl}-3-morpholino-1,4,2-benzodithiazine 8**

Starting from **5** (0.53 g) and morpholine (0.096 g); yield: 0.3 g (52.6%); mp 245–247°C. IR (KBr,  $\text{cm}^{-1}$ ) 1665 (N=C), 1625 (C=N), 1310, 1160 ( $\text{SO}_2$ ).  $^1\text{H-NMR}$  (200 MHz,  $\text{CDCl}_3$ ):  $\delta$  3.53–4.1 (m, 8H,  $4 \times \text{CH}_2$ ), 7.11 (d,  $J = 8.5\text{ Hz}$ , 2H,  $\text{PhCl}$ ), 7.31 (d,  $J = 8.5\text{ Hz}$ , 2H,  $\text{PhCl}$ ), 7.52 (s, 1H, H-5 benzodit.), 7.47–7.62 (m, 2H, arom.), 7.67–7.76 (m, 1H, arom.), 8.33 (d,  $J = 7.7\text{ Hz}$ , 1H, arom.), 8.61 (s, 1H, H-8 benzodit.) ppm.

**6-Chloro-1,1-dioxo-7-{4-[(4-chlorophenyl)imino]-4H-3,1-benzoxazin-2-yl}-3-isopropylamino-1,4,2-benzodithiazine 9**

Starting from **5** (0.53 g) and 2-aminopropane (0.11 g, 18 mmol); yield: 0.22 g (40%); mp 284–285°C. IR (KBr,  $\text{cm}^{-1}$ ) 3240 (NH), 1675 (N=C), 1625 (C=N), 1305, 1150 ( $\text{SO}_2$ ).  $^1\text{H-NMR}$  (200 MHz,  $\text{DMSO-}d_6$ ):  $\delta$  1.18 (d,  $J = 6.6\text{ Hz}$ , 6H,  $2 \times \text{CH}_3$ ), 4.04–4.21 (m, 1H, CH), 7.23 (d,  $J = 8.5\text{ Hz}$ , 2H,  $\text{PhCl}$ ), 7.36 (d,  $J = 8.5\text{ Hz}$ , 2H,  $\text{PhCl}$ ), 7.56–7.68 (m, 2H, arom.), 7.76–7.86 (m, 1H, arom.), 8.07 (s, 1H, H-5 benzodit.), 8.23 (d,  $J = 7.9\text{ Hz}$ , 1H, arom.), 8.39 (s, 1H, H-8 benzodit.), 9.77 (s, 1H, NH) ppm.  $^{13}\text{C-NMR}$  (50 MHz,  $\text{DMSO-}d_6$ ):  $\delta$  21.71 ( $2\text{C}, 2 \times \text{CH}_3$ ), 46.45 (CH), 119.26, 124.29 (two overlapping signals), 126.43, 127.23, 127.51, 128.32, 128.94 (two overlapping signals), 129.80, 130.09, 130.52, 131.78, 133.87, 134.75, 135.29, 142.16, 144.33 (18C, arom.), 146.19, 152.51 (C=N), 160.67 (N=C) ppm.

**6-Chloro-1,1-dioxo-7-{4-[(4-chlorophenyl)imino]-4H-3,1-benzoxazin-2-yl}-3-(3-hydroxypropylamino)-1,4,2-benzodithiazine 10**

Starting from **5** (0.53 g) and 3-amino-1-propanol (0.083 g); yield: 0.15 g (27%); mp 210–211°C. **X-ray crystal structure analysis**

The diffraction data for single crystals of compounds **11** and the previous described **31** [15] were collected at 130 K with a KumaCCD diffractometer using graphite monochromated  $\text{Mo K}\alpha$  radiation. The intensity data were collected and processed using Oxford Diffraction CrysAlis Software [30]. The structures were solved by direct methods with the program SHELXS-97 [22] and refined by full-matrix least-squares method on  $F^2$  with SHELXL-97 [31].

Crystal data for **11**:  $\text{C}_{24}\text{H}_{16}\text{Cl}_2\text{N}_4\text{O}_3\text{S}_2 \cdot \text{C}_2\text{H}_6\text{OS}$ , triclinic, space group P-1,  $a = 6.7802(4)$ ,  $b = 10.3058(7)$ ,  $c = 19.8403(9)$  Å,  $\alpha = 98.845(5)$ ,  $\beta = 97.206(4)$ ,  $\gamma = 100.563(6)^\circ$ ,  $V = 1329.70(13)$  Å<sup>3</sup>,  $Z = 2$ ,  $d_x = 1.552$  g  $\text{cm}^{-3}$ ,  $\mu(\text{Mo K}\alpha) = 0.522$  mm<sup>-1</sup>, 19 305 data were collected up to  $2\theta_{\text{max}} = 52.74^\circ$  for a crystal with dimensions  $0.6 \times 0.04 \times 0.02$  mm<sup>3</sup> ( $R_{\text{int}} = 0.0380$ ,  $R_\sigma = 0.0753$ ). Final  $R$  indices for 3374 reflections with  $I > 2\sigma(I)$  and 360 refined parameters are:  $R_1 = 0.0309$ ,  $wR_2 = 0.0629$  ( $R_1 = 0.0649$ ,  $wR_2 = 0.0723$  for all 5402 data). The allyl group shows a minor disorder.

Crystal data for **31**:  $\text{C}_{29}\text{H}_{21}\text{ClN}_4\text{O}_3\text{S}_2 \cdot \text{C}_3\text{H}_8\text{O}$ , monoclinic, space group  $\text{P}2_1/c$ ,  $a = 21.0555(8)$ ,  $b = 10.3818(4)$ ,  $c = 13.8548(6)$  Å,  $\beta = 93.378(4)^\circ$ ,  $V = 3023.3(2)$  Å<sup>3</sup>,  $Z = 4$ ,  $d_x = 1.391$  g  $\text{cm}^{-3}$ ,  $\mu(\text{Mo K}\alpha) = 0.309$  mm<sup>-1</sup>, 25 149 data were collected up to  $2\theta_{\text{max}} = 50^\circ$  for a crystal with dimensions  $0.6 \times 0.4 \times 0.01$  mm<sup>3</sup> ( $R_{\text{int}} = 0.0748$ ,  $R_\sigma = 0.0977$ ). Final  $R$  indices for 2718 reflections with  $I > 2\sigma(I)$  and 372 refined parameters are:  $R_1 = 0.0687$ ,  $wR_2 = 0.1830$  ( $R_1 = 0.1352$ ,  $wR_2 = 0.2174$  for all 5319 data). The phenylethylene fragment of the molecule is disordered over two orientations with the occupancy factors equal to 0.69 and 0.31. The disordered fragment was refined isotropically with common isotropic displacement parameter for each orientation and restraints imposed on its geometry.

Crystallographic data for compounds **11** and **31** have been deposited with the Cambridge Crystallographic Data Centre, with the deposition Nos CCDC 768913 & 768914.

**In-vitro cytotoxicity studies**

The microtiter plate method used for cytotoxicity testing is based on crystal violet staining of cells and has been described in detail elsewhere [26, 27]. All the cells were obtained from the German Collection of Microorganisms and Cell Cultures (DSMZ) (Braunschweig, FRG). Stock solutions of compounds were prepared in DMSO and diluted 1000-fold with cell culture medium (RPMI medium + 10% fetal calf serum) for testing. For  $\text{IC}_{50}$  determinations, all substances were tested at 5 serially diluted concentrations. The corrected  $T/C$  values ( $T/C_{\text{corr}}$ ) for each concentration were calculated with the following equation:

$$(T/C)_{\text{corr}}(\%) = (\text{O.D.}_T - \text{O.D.}_{C,0}) / (\text{O.D.}_C - \text{O.D.}_{C,0A}) \times 100$$

where  $T$  is the optical density at  $\lambda = 570$  nm ( $\text{OD}_{570}$ ) of the treated cells at after a 96 h treatment time,  $C$  is the  $\text{OD}_{570}$  of the untreated cells after 96 h of growth without substance,  $C_0$  is the  $\text{OD}_{570}$  of the cells on at the time of treatment (i.e. 96 h before  $T$  and  $C$ ). Linear regression analysis of the log concentration versus the  $T/C_{\text{corr}}$  plots was used to estimate the concentration of substance that caused a  $T/C_{\text{corr}} = 50\%$  ( $\text{IC}_{50}$ ). At least three independent experiments were done to determine the  $\text{IC}_{50}$  values.

**Descriptor calculations**

Molecular models of the amines  $\text{R}^2$  were constructed and minimized with the software PCModel (Serena Software, Bloomington, IN, USA, ver 8.50). The MMX force field of PCModel was used in the calculation of the following descriptors: the saturated surface area (SSA), the unsaturated surface area (USA), the polar surface area (PSA), the molecular volume (molvol) and the molar volume (Mvol) of each fragment. The structures were imported into the program CAChe (Fujitsu Biosystems Group, Beaverton, OR, USA, ver 7.5.0.85) and the following descriptors were calculated with the PM5 semi-empirical method at the PM5 minimum: Dipole moment (DM), HOMO and LUMO energies, molecular refractivity (MR), polarizability (P), heat of formation (HF), water assessable surface area (WASA) and ionization potential (IP). Further descriptors calculated by CAChe were: Molecular weight (MW),  $\log P$ , and the kappa shape indexes, orders 1, 2 and 3 (KSI-1, KSI-2, KSI-3).

**Correlation analysis**

Initial multiple regression analysis was performed with the CAChe ProjectLeader software. The dependent variable used in

the calculations was the negative  $\log(\text{IC}_{50})$ . The independent variables included the descriptors described above as well as two indicator variables,  $I_{\text{Cl}}$  and  $I_{\text{CH}_3}$ , which were set to 1 when  $R^1$  was a chlorine or methyl group, respectively, or set to 0 when  $R^1$  was hydrogen. The program was used to identify the QSAR equations with the data best fitted to one, two and three variables from all possibilities. Multiple regression analysis of the best-fitted equations with two and three variables was repeated with MS-Excel (ANOVA analysis). Leave-one-out cross-validation was performed with the cross-validated squared correlation coefficient  $r_{\text{CV}}^2$ , correlation with the Pearson correlation coefficient  $r$ , and significance was determined by the  $F$ -test.

We wish to thank the EU for Erasmus scholarships to AK.

The authors have declared no conflict of interest.
