## ARTICLE INFO

## Keywords:

Yoga  
Cancer survivors  
Symptom management  
Health-related outcomes  
Systematic review  
Meta-analysis

## ABSTRACT

**Objective:** To evaluate the effects of yoga on health-related outcomes [i.e., physical function, mental health, and overall quality of life (QOL)] of cancer survivors via a systematic review and meta-analysis of randomized controlled trials (RCTs) over the past 5 years across cancer types.

**Methods:** An updated systematic review and meta-analysis was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses. RCTs published from January 1, 2018, to February 23, 2023, were searched in five English databases (PubMed, The Cochrane Library, ISI, PsycINFO, and CINAHL), three Chinese databases (Wan Fang, China National Knowledge Infrastructure, and Chinese Biomedical Literature Database), and three English clinical trials registry platforms (International Clinical Trials Registry Platform, [ClinicalTrials.gov](http://ClinicalTrials.gov), and EU Clinical Trials Register).

**Results:** A total of 34 RCTs were included in this updated review. Yoga benefited the physical function, mental health, and overall QOL of cancer survivors. The effect size of yoga for most physical and mental health-related outcomes was relatively small, but that for the QOL was generally large. The impact of yoga on the QOL of cancer survivors ranged from moderate to high.

**Conclusions:** Yoga has health benefits for cancer survivors and could therefore be used as an optional supportive intervention for cancer-related symptom management.

## Introduction

Although cancer is a leading cause of death globally, advances in cancer treatment continue to improve survival rates.<sup>1</sup> The overall 5-year relative survival rate for all types of cancer combined is 68%,<sup>1</sup> resulting in a steady increase in the number of cancer survivors. After active cancer treatment, cancer survivors often experience numerous adverse disease- and treatment-related outcomes, including pain, fatigue, insomnia, anxiety, and depression, which substantially affect their quality of life (QOL).<sup>2,3</sup> Evidence suggests that yoga effectively reduces some physical and psycho-emotional symptoms and improves the QOL of cancer survivors.<sup>4,5</sup>

Yoga was originally developed in Indian philosophy approximately 4000 years ago and has become a popular exercise for promoting physical and mental well-being in the general population.<sup>5,6</sup> It is practiced as a

mind-body therapy or an exercise that involves a combination of spiritual practices, physical activities, breathing, and meditation.<sup>5,6</sup> Yoga practitioners focus their minds on specific postures with inner awareness and a meditative focus. The health benefits of yoga include improvements not only in physical function but also in mental health.<sup>4,5</sup> The mechanism proposed to explain the health benefits of yoga involves a decrease in dysregulation within the sympathetic nervous system and the hypothalamic-pituitary-adrenal axis through the body's stress response.<sup>7-9</sup> Yoga can enhance the activity of the parasympathetic nervous system and consequently reduce the level of the stress hormone cortisol.<sup>10</sup> This effect helps restore the existing autonomic nervous system imbalance and reduce the allostatic load within stress response systems to recover optimal homeostasis among yoga practitioners.<sup>8,10</sup> Hence, cancer survivors are recommended to undertake yoga as a regular exercise for improving their health.<sup>11,12</sup>

Although a number of systematic reviews summarizing the available evidence on the effects of yoga among cancer survivors exist, most randomized controlled trials (RCTs) on yoga included in a recently published systematic review were conducted in or before 2019.<sup>5,13-16</sup> The results showed that there is still a lack of strong evidence on the benefits of yoga on symptoms (e.g., pain), physical functions (e.g., exercise capacity), and physiological changes (e.g., immune responses) in cancer survivors.<sup>13-16</sup> In recent years, more research has further explored these benefits of yoga in more types of cancer survivors. An updated systematic review and meta-analysis are needed to combine previous and current evidence from comprehensive evaluations of yoga for cancer.

Therefore, this study aimed to evaluate the effects of yoga on health-related outcomes including physical function, mental health, and overall QOL of cancer survivors through an updated systematic review and meta-analysis of RCTs over the past 5 years across cancer types.

**Methods**

This study was performed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA).<sup>17</sup> The PRISMA flow diagram of study selection is shown in Fig. 1.

*Search strategy*

Parallel electronic searches for RCTs on yoga in adults with cancer published from January 1, 2018, to February 23, 2023, were conducted in five English databases (PubMed, The Cochrane Library, ISI, PsycINFO, and CINAHL), three English clinical trials registry platforms (International Clinical Trials Registry Platform, [ClinicalTrials.gov](http://ClinicalTrials.gov), and EU Clinical Trials Register), and three Chinese databases (Wan Fang, China National Knowledge Infrastructure, and Chinese Biomedical Literature

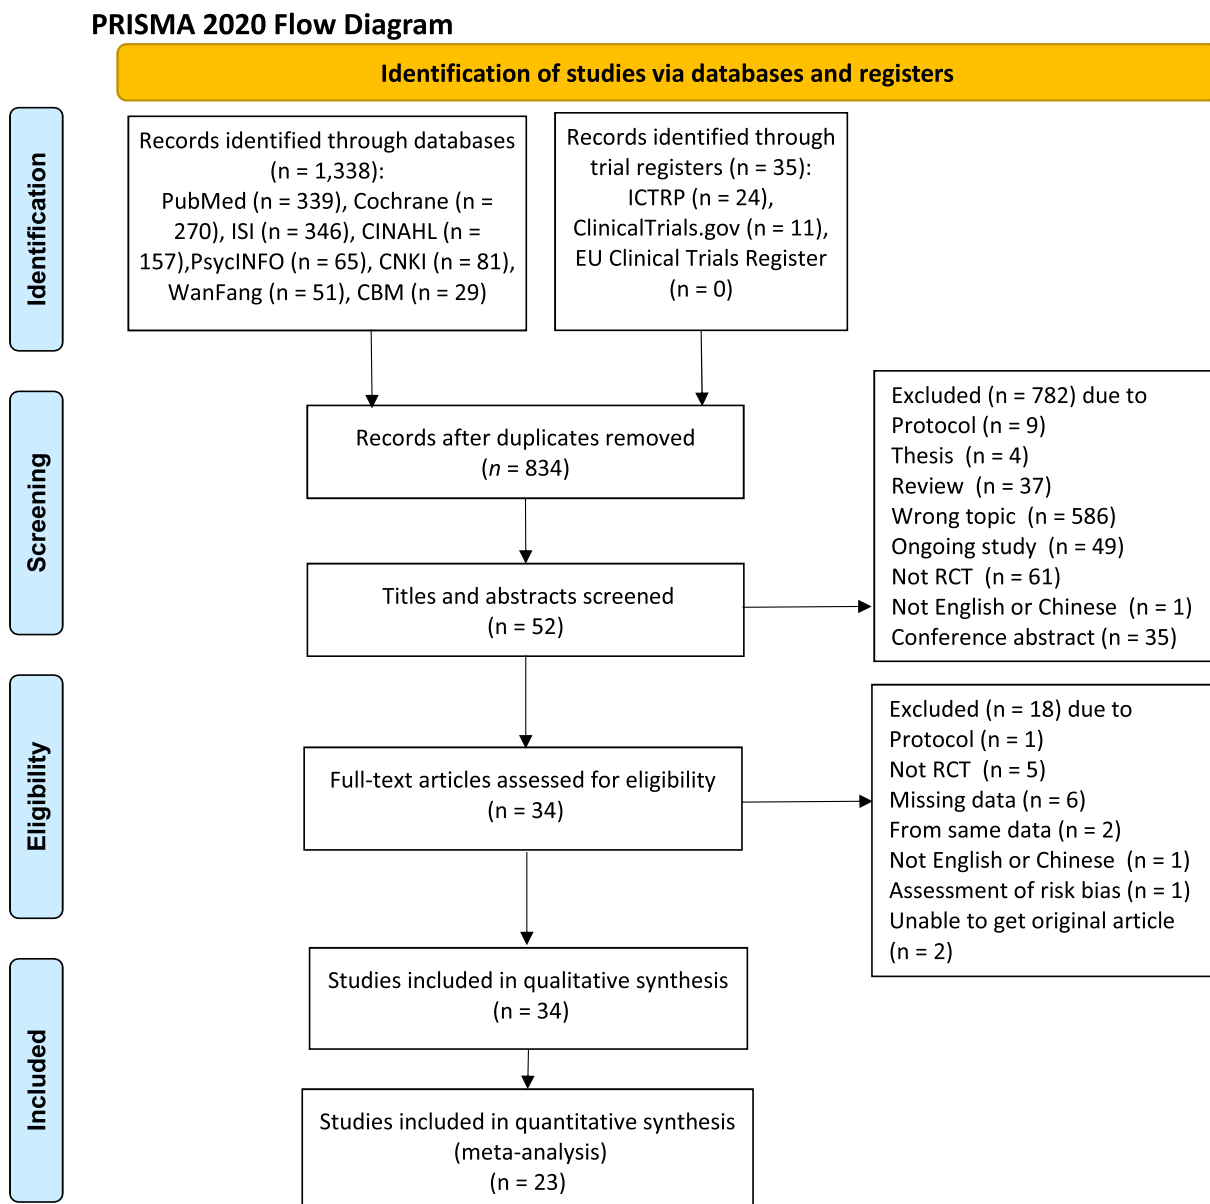

Fig. 1. Flow diagram of study selection. PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses; RCT, randomized controlled trial.

Database). The keywords and terms used in various combinations during the search included “neoplasms\*,” “cancer\*,” “tumor\*,” “malignan\*,” “carcino\*,” “lymphoma\*,” “adenocarcinoma\*,” and “yoga.” The detailed search strategy or search history is shown in [Appendix 1](#).

### Inclusion and exclusion criteria

The inclusion criteria were as follows: (1) participants: adult (age > 18 years) survivors of any type of cancer; (2) group: at least two: experimental (yoga) group, which received any type of yoga as an intervention or yoga plus other combined intervention, and control group, which received usual care or the same intervention as the combined intervention in the yoga group; (3) primary outcomes: physical function (e.g., exercise capacity), biological indicators [e.g., serum anti-inflammatory factor tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) level], cancer-related symptoms (e.g., pain, sleep disturbances, and fatigue), and mental health-related outcomes (e.g., anxiety and depression); secondary outcome: overall QOL; (4) design: RCT; and (5) publication language: English or Chinese. The exclusion criteria were duplicate publications, study protocols, theses, reviews, ongoing studies, and conference abstracts.

### Data extraction and quality assessment

The following data were independently extracted from eligible studies by two reviewers (NN and RH) in accordance with the eligibility criteria: author/s, publication year, cancer type, sample size, intervention-related information, physical and mental health-related outcomes assessed, and assessment time. The risk of bias was judged by two reviewers (NN and JZ) using the Cochrane Collaboration's tool for risk of bias assessment.<sup>18</sup> The Joanna Briggs Institute (JBI) Levels of Evidence and Grades of Recommendation tool was used to assess the quality of evidence. In the JBI evidence grading system, the evidence level is divided into five levels from high to low: level 1 to level 5.<sup>19</sup> Any discrepancy was resolved through discussion with a third author (JZ or YZ).

### Data analysis

Review Manager version 5.4 (Cochrane Collaboration) was used to generate pooled estimates of the effect size.<sup>20</sup> Standardized mean differences (SMDs) and mean differences (MDs) with their corresponding 95% confidence intervals (CIs) were used for comparisons. SMDs of < 0.4, 0.4–0.7, and > 0.7 reflect small, moderate, and large effect sizes, respectively.<sup>20</sup> Heterogeneity among the trials was assessed using the Higgins  $I^2$  statistic and Q test.  $I^2$  values of  $\geq 50\%$  and  $P$  values of < 0.1 were considered to indicate high heterogeneity of evidence, and the random-effects model was used to evaluate the effects of the intervention conservatively. Conversely,  $I^2$  values of < 50% and  $P$  values of > 0.1 were considered to indicate low-to-moderate heterogeneity, and the fixed-effects model was used. A sensitivity analysis was conducted to explore the potential sources of heterogeneity.  $P$  values of < 0.05 were considered statistically significant. Potential publication bias was not evaluated, as fewer than 10 studies were included in the meta-analysis. Individual study results that could not be pooled in the meta-analysis were summarized qualitatively.

## Results

A total of 1373 records were identified through electronic searches. After exclusion of duplicates, 834 records remained. A preliminary screening of titles and abstracts was then conducted in accordance with the inclusion and exclusion criteria, yielding 52 remaining records. After further evaluation of the full-text articles, 34 studies were finally included ([Fig. 1](#)).

### Characteristics of the included studies and levels of evidence

A total of 2552 cancer survivors were included in this review. The sample size of each study varied from 20 to 358 participants. The duration of the interventions ranged from 5 days to 48 weeks. [Table 1](#) shows the characteristics of the included studies. The JBI evidence grading system was used to assess the level of evidence. Overall, the level of evidence among the studies was relatively high. [Table 2](#) details the levels of evidence.

### Methodological quality of the included studies

The evaluation of methodological quality revealed that all studies had a medium risk of bias. Owing to the nature of yoga, it was difficult to achieve blinding of patients and interveners. Therefore, all performance biases in the included studies were considered high risk. Furthermore, the sources of the risk of bias were associated with insufficient reports of randomization, allocation concealment, or evaluator blinding. [Fig. 2](#) shows the results of the risk of bias assessment of the included studies.

### Effects of yoga on pain

Three studies<sup>21–23</sup> reported the effects of yoga on pain 12 weeks after the intervention. The heterogeneity among these studies was high ( $P = 0.08$ ,  $I^2 = 61\%$ ), so a random-effects model was applied. The results showed no significant difference between the two groups ( $n = 144$ ; SMD =  $-0.32$ ; 95% CI =  $-0.86, 0.22$ ) [[Fig. 3\(a\)](#)]. However, the sensitivity analysis suggested that the study by Porter et al.<sup>23</sup> had a large effect on the heterogeneity. No heterogeneity was observed when this study was removed ( $P = 0.46$ ,  $I^2 = 0\%$ ). There was a significant difference between the two groups ( $n = 89$ ; SMD =  $-0.58$ ; 95% CI =  $-1.01, -0.15$ ;  $P = 0.008$ ) [[Fig. 3\(b\)](#)]. The results were not stable, so the effects of yoga on pain among cancer survivors after 12 weeks of intervention must be verified by more studies. The results of three studies<sup>22,24,25</sup> were reported qualitatively. Yang et al.<sup>24</sup> observed that yoga relieved pain symptoms significantly after 1 week of intervention. For the long-term effects, Huberty et al.<sup>22</sup> showed that yoga had moderate effects on reducing pain at 16 weeks. Carson et al.<sup>25</sup> demonstrated that practice sessions of longer duration were related to lower daily pain levels within the yoga group.

### Effects of yoga on sleep quality

Two studies<sup>26,27</sup> reported the effects of yoga on sleep 4 weeks after the intervention. No heterogeneity among these studies was found ( $P = 0.67$ ,  $I^2 = 0\%$ ). The results revealed that yoga significantly improved the sleep quality in cancer survivors 4 weeks after the intervention compared with the control intervention ( $n = 399$ ; SMD =  $-0.2$ ; 95% CI =  $-0.4, -0.01$ ;  $P = 0.04$ ) [[Fig. 4\(a\)](#)]. Six studies<sup>22,23,27–30</sup> reported the effects of yoga on sleep 8 weeks after the intervention. There was no heterogeneity among these studies ( $P = 0.87$ ,  $I^2 = 0\%$ ). The meta-analysis showed that yoga significantly improved sleep compared with the control intervention ( $n = 251$ ; SMD =  $-0.29$ ; 95% CI =  $-0.55, -0.04$ ;  $P = 0.02$ ) [[Fig. 4\(b\)](#)]. Four studies<sup>22,23,27,31</sup> reported the effects of yoga on sleep 12 weeks after the intervention. The heterogeneity among these studies was high ( $P = 0.003$ ,  $I^2 = 78\%$ ), so a random-effects model was used. The results showed no significant difference between the two groups ( $n = 303$ ; SMD =  $-0.00$ ; 95% CI =  $-0.55, 0.54$ ;  $P = 0.99$ ) [[Fig. 4\(c\)](#)].

### Effects of yoga on fatigue

Three studies<sup>26,27,32</sup> reported the effects of yoga on fatigue 4 weeks after the intervention. The heterogeneity was high among these studies

**Table 1**  
Characteristics of included studies.

Author, year	Participants		Intervention		Measurements	Main outcomes	Assessment time
	Cancer type	Sample size	YG	CG			
Jain et al, 2023	Breast cancer	YG: 42 CG: 40	Yoga, 30 min/session, 5 days/week, 48 weeks	Usual care	EORTC QLQ-C30; Serum cytokines and oxidative stress markers	Yoga significantly improved QOL ( $P < 0.001$ ) and reduced IFN- $\gamma$ , TNF- $\alpha$ and MDA levels ( $P < 0.05$ ).	Baseline, 16, 32, and 48 weeks
Lu et al, 2023	Lung cancer	YG: 36 CG: 34	Yoga breathing exercises, 20 min/session, twice a day, 9–14 days	Usual care	BS; 6MWT; HADS; Thoracic closed drainage time	Significant difference for dyspnea and anxiety ( $P < 0.05$ ) were found in yoga group when compared to the control group.	Admission, the day before surgery, and discharge
Zhang et al, 2023	Lung cancer	YG: 40 CG: 40	Yoga, 30 min/session, 2 days/week, 8 weeks	Usual care	PSS; SAS; SDS; PPQ	Yoga group reported lower PSS, SAS and SDS scores and higher PPQ scores than control group ( $P < 0.05$ ).	Baseline, 8 weeks
Greaney et al, 2022	Breast cancer	YG: 13 CG: 13	Yoga, 30 min/session, 3 times/week, the end of treatment (12–20 weeks)	Usual care	Weight change; FACT-G; Serum cytokines	Control group increased weight while yoga group lost weight ( $P < 0.05$ ). There was no significance in QOL, TNF- $\alpha$ and CRP between two groups.	Baseline and the end of treatment
Kaushik et al, 2022	Prostate cancer	YG: 12 CG: 14	Yoga, 60 min/session, 2 times/week, 12 weeks (6 weeks preoperatively and postoperatively)	Usual care	FACT-G; FACT-P; FACIT-F; EPIC; Serum cytokines and immune cell levels	Yoga significantly increased Fc receptor III and IFN- $\gamma$ expression and decreased G-CSF and MCP-1 levels ( $P < 0.05$ ).	Baseline (6 weeks preoperatively), immediately before surgery, and 6 weeks postoperatively
Knoerl et al, 2022	Breast, gastrointestinal, and gynecological cancer	YG: 23 CG: 14	Yoga, 45 min/session, 8 weeks	Usual care	BPI; PROMIS (pain interference, sleep-related impairment, anxiety, fatigue, depression and physical function); QLQ-CIPN20	When compared to control group, yoga showed significant improvements in fatigue and depression ( $P < 0.05$ ).	Baseline, 8 weeks
Liu et al, 2022	Breast cancer	YG: 68 CG: 68	Yoga, 90 min/week, 8 weeks	Usual care	HADS; PFS; BPI; FACT-B	Significant difference for anxiety, depression and QOL were reported in yoga group when compared to the control group ( $P < 0.05$ ).	Baseline, 8 and 20 weeks
Naderi et al, 2022	Breast cancer	YG: 10 CG: 10	Yoga plus a high dose of vitamin D, 60–90 min/session, 2 times/week, 12 weeks	A high dose of vitamin D	Height, weight, and body fat measurements; Handgrip strength tests; EORTC QLQ-C30; Serum cytokines	Yoga group demonstrated significant improvements in body fat percentage, handgrip strength and QOL ( $P < 0.05$ ). The level of IL-10 was increased, while IL-6 expression level declined in yoga group.	Baseline, 12 weeks
Sohl et al, 2022	Gastrointestinal cancer	YG: 23 CG: 21	Yoga, four 30 min sessions, practice daily, 14 weeks	Usual care	PROMIS (fatigue, depression, sleep disturbances); PSS; Serum cytokines	Yoga found a larger reduction in fatigue, depression and sleep disturbances than control group. Serum IL-6, sTNF-R1 levels were lower than control group.	Baseline, 8, 10 and 14 weeks
Xing et al, 2022	Cervical cancer	YG: 46 CG: 46	Yoga plus Clean intermittent catheterization, 8 weeks	Clean intermittent catheterization	Bladder function assessment; QLICP-CE	Significant difference for recovery time of self-urination, duration of indwelling catheter, residual urine volume, bladder neck mobility and QLICP-CE ( $P < 0.0001$ ) were reported in yoga group when compared to control group.	Baseline, 8 weeks
Carson et al, 2021	Breast cancer	YG: 30 CG: 18	Yoga, 15–30 min/day, 5–6 times/week, 8 weeks	Usual care	Self-made pain scale	There were no different treatment effects between 2 groups. More practice durations were related to the lower pain within yoga group.	Baseline, daily assessment on alternate weeks
D'Cunha et al, 2021	Cervical cancer	YG: 24 CG: 24	Yoga, 23 min/session, 5 times/week, 5 weeks	Usual care	Self-made stress scale	Yoga revealed less stress than the control groups ( $P < 0.001$ ).	Baseline, 5 weeks

Author, year	Participants		Intervention		Measurements	Main outcomes	Assessment time
	Cancer type	Sample size	YG	CG			
Eyigör et al, 2021	Breast cancer	YG: 15 CG: 16	Yoga, 60 min/session, 2 times/week, 10 weeks	Usual care	Phase angle; EORTC QLQ-C30; Arm volume; BMI	The comparisons between the 2 groups showed no significant differences.	Baseline, 10 weeks
Khedmati et al, 2021	Breast cancer	YG: 10 CG: 10	Yoga plus a high dose of vitamin D, 60–90 min/session, 2 times/week, 12 weeks	A high dose of vitamin D	RWT; Shoulder flexibility; BAI; Serum cytokines	Yoga group found significant improvements in RWT, shoulder flexibility and anxiety ( $P < 0.05$ ). The expression of blood leukocyte P53 and Bcl2 level was higher than control group ( $P < 0.05$ ).	Baseline, 12 weeks
Zetzi et al, 2021	Unlimited type	YG: 69 CG: 67	Yoga, 60 min/session, 1 times/week, 8 weeks	Usual care	EORTC QLQ-FA12; PHQ-9; EORTC QLQ-C15-PAL	When compared to control group, yoga revealed significant improvements in fatigue, depression and QOL ( $P < 0.05$ ).	Baseline, 10 weeks
Zhi et al, 2021	Breast and gynecological cancer	YG: 21 CG: 20	Yoga, 60 min/session, every day, 8 weeks	Usual care	HADS; BFI; ISI; TES	Yoga relieved anxiety significantly when compared to control group ( $P < 0.05$ ).	Baseline, 4, 8 and 12 weeks
Chen et al, 2021	Unlimited type	YG: 57 CG: 61	Yoga, 20 min/session, 3 to 6 times/week, 8 weeks	Usual care	NRS; FACT-G; PSQI	Yoga group significantly improved QOL, sleep quality ( $P < 0.05$ ), and reduced fatigue ( $P < 0.01$ ) when compared to control group.	Baseline, 8 weeks
Bao et al, 2020	Breast and gynecological cancer	YG: 21 CG: 20	Yoga, 60 min/session, every day, 8 weeks	Usual care	NRS (pain, numbness, and tingling); FACT/GOG-Ntx subscale; Functional reach test; Chair to stand; Number of falls; 4-Meter walk speed	Yoga group found significant improvements in pain, neurotoxicity, functional reach test and chair to stand test when compared to control group ( $P < 0.05$ ).	Baseline, 4, 8 and 12 weeks
Prakash et al, 2020	Breast cancer	YG: 48 CG: 52	Yoga, 2 times/day, 15 weeks	Usual care	EORTC QLQ-C30	Yoga revealed significant advantages on increasing QOL ( $P < 0.05$ ).	Baseline, 3, 6, 9, 12 and 15 weeks
Li et al, 2020	Lung cancer	YG: 70 CG: 69	Yoga breathing exercises, 16 min/session, every day, 4 weeks	Usual care	EORTC QLQ-C30; 6MWT; SpO <sub>2</sub> ; Pulse; BS	Significant improvements of 6MWT were reported in yoga when compared to control group ( $P < 0.05$ ).	Baseline, 4 weeks
Yang et al, 2020	Unlimited type	YG: 57 CG: 57	Yogic meditation, 30 min/session, twice a day, 1 week	Usual care	BPI	Yoga relieved pain symptom significantly when compared to control group ( $P < 0.05$ ).	Baseline, 1 week
Huberty et al, 2019	Myeloproliferative neoplasm	YG: 27 CG: 21	Yoga, 60 min/week, 12 weeks	Usual care	SAF; PROMIS (anxiety, depression, pain, sleep disturbance, sexual function, global health, and quality of life); Serum cytokines	Yoga showed small effects on anxiety, sleep and pain, and a moderate effect on depression. TNF- $\alpha$ in yoga group was found a decline from baseline to 12 weeks.	Baseline, 7, 12, and 16 weeks
Kothari et al, 2019	Unlimited type	YG: 50 CG: 50	Yoga plus standard antiemetic therapy, 60 min/session, 5 days	Standard antiemetic therapy	Nausea and vomiting	Yoga reduced vomiting significantly when compared to control group ( $P < 0.05$ ).	3 days post-chemotherapy
Lin et al, 2019	Unlimited type	YG: 177 CG: 181	Yoga, 75 min/session, 2 days/week, 4 weeks	Usual care	MFSI; PSQI	Significant improvements of fatigue and sleep were observed in yoga when compared to control ( $P < 0.01$ ).	Baseline, 4 weeks
Milbury et al, 2019	Glioma	YG: 10 CG: 10	Yoga, 45 min/session, 2 or 3 times/week, through radiotherapy	Usual care	MDASI-BT; CES-D; BFI; SF-36	Yoga performed significant effects on improving cancer-related symptoms, depression and mental QOL when compared to control group.	Baseline, the last day of radiotherapy
Milbury et al, 2019	Lung or esophageal cancer	YG: 13 CG: 13	Yoga, 60 min/session, 2 or 3 times/week, 6 weeks	Usual care	SF-36; CES-D; 6MWT		Baseline, the last day of radiotherapy, 12 weeks

**Table 2**  
Evidence certainty of outcomes.

No.	Outcomes	Evidence certainty
1	Yoga on fatigue at 4, 8, 10 weeks after intervention	Level 1a
2	Yoga on fatigue at 16, 24 weeks after intervention	Level 1c
3	Yoga on anxiety at 8, 12 weeks after intervention	Level 1a
4	Yoga on anxiety before surgery and at discharge	Level 1c
5	Yoga on anxiety at 16, 24 weeks after intervention	Level 1c
6	Yoga on depression at 8, 10, 12 weeks after intervention	Level 1a
7	Yoga on depression at 16, 24 weeks after intervention	Level 1c
8	Yoga on pain at 12 weeks after intervention	Level 1a
9	Yoga on pain at 1, 16 weeks after intervention	Level 1c
10	Yoga on sleep at 4, 8, 12 weeks after intervention	Level 1a
11	Yoga on QOL at 8 weeks after intervention	Level 1a
12	Yoga on global health, function and symptom of EORTC QLQ-C30 at 12 weeks after intervention	Level 1a
13	Yoga on 6MWT at 4 weeks after intervention	Level 1c
14	Yoga on 6MWT at 12 weeks after intervention	Level 1a
15	Yoga on heart rate and SpO <sub>2</sub> after 1 week of intervention	Level 1c
16	Yoga on body fat percentage, handgrip strength, Rockport walk test, shoulder flexibility, functional reach test and chair to stand test at 12 weeks after intervention	Level 1c
17	Yoga on serum TNF- $\alpha$ , IL-6, IFN- $\gamma$ , G-CSF, MCP-1, MDA, IL-10, P53 and Bcl2 levels	Level 1c
18	Yoga on neurotoxicity, nausea and vomiting, cancer-related symptom, stress, psychological capital and urinary function of patients	Level 1c

QOL, Quality of life; EORTC QLQ-C30, European organization for research and treatment of cancer quality of life questionnaire-core 30; 6MWT, 6-min walk test; TNF- $\alpha$ , Tumor necrosis factor- $\alpha$ ; IL-6, Interleukin-6; IFN- $\gamma$ , Interferon- $\gamma$ ; G-CSF, Granulocyte colony stimulating factor; MCP-1, Monocyte chemoattractant protein-1; MDA, Malondialdehyde.

( $P = 0.05$ ,  $I^2 = 67\%$ ), so a random-effects model was applied. The results showed no significant difference between the two groups ( $n = 489$ ;  $SMD = -0.09$ ;  $95\% \text{ CI} = -0.49, 0.3$ ;  $P = 0.64$ ) [Fig. 5(a)]. However, the sensitivity analysis suggested that the study by Zhi et al.<sup>27</sup> had a large effect on the heterogeneity. No heterogeneity was observed when this study was removed ( $P = 0.62$ ,  $I^2 = 0\%$ ). There was a significant difference between the two groups ( $n = 448$ ;  $SMD = -0.29$ ;  $95\% \text{ CI} = -0.48, -0.11$ ;  $P = 0.002$ ). The meta-analysis results were unstable, indicating the need for further exploration.

Nine studies<sup>22,23,27-30,32-34</sup> reported the effects of yoga on fatigue 8 weeks after the intervention. The heterogeneity among these studies was low ( $P = 0.28$ ,  $I^2 = 18\%$ ). The results showed no significant difference between the two groups ( $n = 547$ ;  $SMD = -0.06$ ;  $95\% \text{ CI} = -0.23, 0.11$ ;  $P = 0.48$ ) [Fig. 5(b)]. Two studies<sup>29,35</sup> reported the effects of yoga on fatigue 10 weeks after the intervention. No heterogeneity was detected among these studies ( $P = 0.78$ ,  $I^2 = 0\%$ ). The results indicated that yoga significantly improved fatigue in cancer survivors 10 weeks after the intervention ( $n = 180$ ;  $SMD = -0.63$ ;  $95\% \text{ CI} = -0.93, -0.33$ ;  $P < 0.01$ ) [Fig. 5(c)]. The results of two studies<sup>22,23</sup> could not be pooled, so a qualitative description was adopted. For the long-term effects, Huberty et al.<sup>22</sup> found that yoga was more effective in reducing fatigue than the control intervention at 16 weeks, and Porter et al.<sup>23</sup> confirmed this positive effect at 24 weeks.

*Effects of yoga on exercise capacity*

Three studies<sup>23,36,37</sup> reported the effects of yoga on the 6-min walk test (6MWT) distance 12 weeks after the intervention. The heterogeneity among these studies was high ( $P = 0.05$ ,  $I^2 = 66\%$ ), so a random-effects model was used. The results showed no significant difference between the two groups ( $n = 117$ ;  $MD = 6.31$ ;  $95\% \text{ CI} = -42.99, 55.61$ ;  $P = 0.80$ ) [Fig. 6(a)]. The results of five studies<sup>21,38-41</sup> were reported qualitatively. Barassi et al.<sup>38</sup> found that yoga significantly improved the heart rate and SpO<sub>2</sub> after 1 week of intervention compared with the control intervention. Li et al.<sup>39</sup> observed that yoga significantly improved the 6MWT distance 4 weeks after the intervention. Some studies demonstrated the physical benefits of yoga 12 weeks after the intervention. Naderi et al.<sup>40</sup> showed the advantages of yoga in improving body fat percentage and handgrip strength. Khedmati et al.<sup>41</sup> reported that patients in the yoga group performed better on the Rockport walk test and shoulder flexibility test. Bao et al.<sup>21</sup> found significant effects on the functional reach test and chair-stand test results.

*Effects of yoga on serum cytokine level*

Owing to insufficient data for the pooled analysis, only descriptive analyses were performed. Five studies<sup>22,29,40,42,43</sup> reported the

relationship between the serum level of the anti-inflammatory factor TNF- $\alpha$  and yoga. Jain et al.<sup>42</sup> found that the decline in the TNF- $\alpha$  level in the yoga group was better than that in the control group at 48 weeks of

follow-up. Huberty et al.<sup>22</sup> showed a significant decrease in the TNF- $\alpha$  level within the yoga group at 12 weeks of follow-up. However, Greaney et al.,<sup>43</sup> Naderi et al.,<sup>40</sup> and Sohl et al.<sup>29</sup> reported non-significant changes. For the serum level of the anti-inflammatory factor interleukin (IL)-6, Naderi et al.,<sup>40</sup> Huberty et al.,<sup>22</sup> and Sohl et al.<sup>29</sup> all found a significant decline in the yoga group. For the serum level of interferon- $\gamma$ , Jain et al.<sup>42</sup> showed a significant decrease in the yoga group, but Kaushik et al.<sup>44</sup> noted the opposite. In addition, the yoga group showed significant increases in the serum granulocyte colony-stimulating factor,<sup>44</sup> monocyte chemoattractant protein-1,<sup>44</sup> and malondialdehyde levels,<sup>42</sup> and significant decreases in the serum IL-10,<sup>40</sup> anti-apoptotic gene P53,<sup>41</sup> and anti-apoptotic gene Bcl2 levels.<sup>41</sup>

Effects of yoga on anxiety

Five studies<sup>23,28,33,34,45</sup> reported the effects of yoga on anxiety 8 weeks after the intervention. The heterogeneity was high among these studies ( $P = 0.04, I^2 = 59\%$ ), so a random-effects model was applied. The results showed that yoga significantly improved anxiety in cancer survivors 8 weeks after the intervention ( $n = 378$ ; SMD =  $-0.53$ ; 95% CI =  $-0.87, -0.19$ ;  $P = 0.002$ ) [Fig. 7(a)]. Five studies<sup>22,23,27,41,46</sup> reported the effects of yoga on anxiety 12 weeks after the intervention. The heterogeneity among these studies was low ( $P = 0.15, I^2 = 40\%$ ). The meta-analysis revealed that yoga significantly reduced anxiety compared with the control intervention ( $n = 247$ ; SMD =  $-0.67$ ; 95% CI =  $-0.93, -0.41$ ;  $P < 0.01$ ) [Fig. 7(b)]. Three studies<sup>22,23,47</sup> were reported qualitatively. Lu et al.<sup>47</sup> found that yoga breathing training after admission and at discharge significantly improved anxiety among lung cancer survivors. Concerning long-term effects, Huberty et al.<sup>22</sup> found that yoga had small effects on reducing anxiety at 16 weeks. Porter et al.<sup>23</sup> discovered that yoga yielded modest improvements in anxiety at 24 weeks.

Effects of yoga on depression

Eight studies<sup>23,27-30,33,34,45</sup> reported the effects of yoga on depression 8 weeks after the intervention. There was no heterogeneity among these studies ( $P = 0.81, I^2 = 0\%$ ). The meta-analysis showed that yoga significantly reduced depression compared with the control intervention ( $n = 489$ ; SMD =  $-0.36$ ; 95% CI =  $-0.54, -0.18$ ;  $P < 0.01$ ) [Fig. 8(a)]. Three studies<sup>29,35,36</sup> reported the effects of yoga on depression 10 weeks after the intervention. No heterogeneity among these studies was found ( $P = 0.63, I^2 = 0\%$ ). There was a significant difference between the two groups ( $n = 216$ ; SMD =  $-0.41$ ; 95% CI =  $-0.68, -0.14$ ;  $P < 0.01$ ), which indicated that yoga significantly improved depression in cancer survivors 10 weeks after the intervention [Fig. 8(b)]. Five studies<sup>22,23,27,37,46</sup> reported the effects of yoga on depression 12 weeks after the intervention. The heterogeneity was high among these studies ( $P = 0.07, I^2 = 54\%$ ), so a random-effects model was applied. The results revealed that yoga significantly reduced depression in cancer survivors 12 weeks after the intervention compared with the control intervention ( $n = 253$ ; SMD =  $-0.47$ ; 95% CI =  $-0.86, -0.09$ ;  $P = 0.02$ ) [Fig. 8(c)]. The results of two studies<sup>22,23</sup> were reported qualitatively. For the long-term effects, Huberty et al.<sup>22</sup> showed that yoga had moderate effects on reducing depression at 16 weeks. Porter et al.<sup>23</sup> discovered that yoga yielded improvements in depression at 24 weeks compared with the control intervention.

Effects of yoga on QOL

Four studies<sup>34,35,48,49</sup> reported the effects of yoga on the QOL 8 weeks after the intervention. These studies showed high heterogeneity ( $P = 0.006, I^2 = 76\%$ ), so a random-effects model was used. The meta-analysis showed that yoga significantly improved the QOL compared with the control intervention ( $n = 482$ ; SMD =  $0.65$ ; 95% CI =  $0.27, 1.02$ ;  $P = 0.001$ ) [Fig. 9(a)]. Five studies<sup>36,40,46,50,51</sup> reported

a. Mean changes of pain from baseline to 12 weeks after intervention

b. Mean changes of pain from baseline to 12 weeks after intervention by sensitivity analysis

Fig. 3. (a) Mean changes of pain from baseline to 12 weeks after intervention; (b) Mean changes of pain from baseline to 12 weeks after intervention by sensitivity analysis.

a. Sleep at 4 weeks after intervention;

b. Mean changes of sleep from baseline to 8 weeks after intervention

c. Mean changes of sleep from baseline to 12 weeks after intervention

Fig. 4. (a) Sleep at 4 weeks after intervention; (b) Mean changes of sleep from baseline to 8 weeks after intervention; (c) Mean changes of sleep from baseline to 12 weeks after intervention.

the effects of yoga on the global health subdomain of the EORTC QLQ-C30 12 weeks after the intervention. The heterogeneity among these studies was low ( $P = 0.29$ ,  $I^2 = 20\%$ ). Yoga had significant advantages in improving global health ( $n = 270$ ; MD = 9.58; 95% CI = 6.27, 12.89;  $P < 0.01$ ) [Fig. 9(b)]. Three studies<sup>36,40,50</sup> reported the effects of yoga on the functional subdomain of the EORTC QLQ-C30 12

weeks after the intervention. The heterogeneity was high among these studies ( $P = 0.005$ ,  $I^2 = 81\%$ ). No significant difference was found between the two groups ( $n = 87$ ; MD = 6.96; 95% CI = -5.99, 19.91;  $P = 0.29$ ) [Fig. 9(c)].

Three studies<sup>36,40,50</sup> reported the effects of yoga on the symptom subdomain of the EORTC QLQ-C30 12 weeks after the intervention.

a. Fatigue at 4 weeks after intervention;

b. Mean changes of fatigue from baseline to 8 weeks after intervention

c. Fatigue at 10 weeks after intervention.

Fig. 5. (a) Fatigue at 4 weeks after intervention; (b) Mean changes of fatigue from baseline to 8 weeks after intervention; (c) Fatigue at 10 weeks after intervention.

a. Mean changes of 6MWT from baseline to 12 weeks after intervention

Fig. 6. (a) Mean changes of 6MWT from baseline to 12 weeks after intervention.

These studies showed high heterogeneity ( $P < 0.1$ ,  $I^2 = 93\%$ ). No significant differences were found between two of the groups ( $n = 87$ ; MD = -3.36; 95% CI = -20.97, 14.25;  $P = 0.71$ ) [Fig. 9(d)]. However, the sensitivity analysis suggested that the study by Naderi et al.<sup>40</sup> had a large effect on the heterogeneity. No heterogeneity was observed when this study was removed ( $P = 0.91$ ,  $I^2 = 0\%$ ). The pooled analysis of the remaining studies suggested that yoga had advantages over the control intervention in reducing symptoms ( $n = 67$ ; MD = 6.61; 95% CI = 1.37, 11.84;  $P = 0.01$ ). The meta-analysis results were unstable, indicating the need for further studies.

Others

Finally, the results of seven studies<sup>21,45,46,49,52-54</sup> could not be included in the meta-analysis because the analysis focused on particular outcomes for which the available number of studies was insufficient. Bao et al.<sup>21</sup> found that the yoga group performed better in reducing neurotoxicity at 12 weeks of follow-up. Kothari et al.<sup>52</sup> found that the yoga group reported less nausea and vomiting than did the control group 3 days after chemotherapy; this positive effect was also demonstrated by Jong et al.<sup>46</sup> at 24 weeks of follow-up. Additionally, the yoga group demonstrated

significant improvements in cancer-related symptoms,<sup>53</sup> stress,<sup>54</sup> yoga capital,<sup>45</sup> and urinary function<sup>49</sup> compared with the control group.

Discussion

This updated systematic review and meta-analysis included 34 recent RCTs to determine the effects of yoga on cancer survivors. Consistent with previous reports,<sup>13-16</sup> the findings of this study suggested that yoga improved physical function, mental health, and overall QOL. However, for physical function, there is still a lack of strong evidence on the benefits of yoga on exercise capacity. Further research is needed on this topic. For mental health, previous studies<sup>13,16</sup> reported the effects of yoga on reducing anxiety and depression in the short term.

Consistent with most previous studies,<sup>13</sup> this updated review showed a moderate-to-high impact of yoga on the overall QOL of cancer survivors in the short term. For cancer-related symptoms, the updated review found that the effects of yoga on pain and fatigue were not consistent, indicating the need for more exploratory studies. In addition, Cramer et al.<sup>5</sup> reported that yoga reduced sleep disturbances in the short term, which was also confirmed in this review. Overall, the methodological quality of the studies showed a moderate-to-low risk of

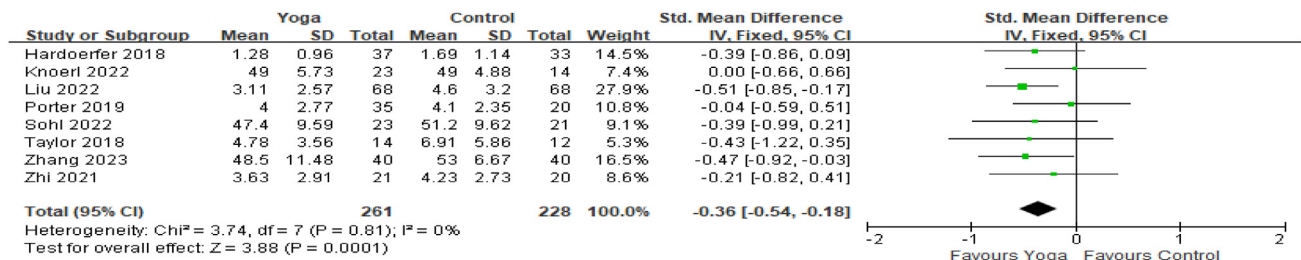

a. Anxiety at 8 weeks after intervention;

bias. Owing to the nature of the study interventions, it was difficult to achieve blinding of participants and interveners. Some included studies lacked clear descriptions of the procedures of randomization and allocation concealment,<sup>27,36,39,42,45</sup> resulting in potential selection bias. Accordingly, further rigorous and high-quality RCTs are needed to confirm the effects of yoga on health-related outcomes of cancer survivors.

In traditional Chinese medicine, it is believed that the pathogenesis of cancer is closely linked to imbalances in the body, including pathogenic disorders and positive bodily states. When mood fluctuates, the liver controls the free flow of Qi; Qi stagnation leads to phlegm and blood stasis, eventually producing a congealed mass. Conversely, the spleen is the source of Qi and blood generation. When patients ruminate, their diet may become irregular, causing damage to the spleen; since Qi and blood are not easily generated, a deficiency of Qi and blood gradually results. The loss of healthy Qi results in the invasion of evil Qi, causing the onset of cancers.<sup>7-10</sup> Within this traditional framework, the significant reductions in symptoms of anxiety and depression and the improvements in mood achieved suggest that yoga enhances the generation of healthy Qi while dispelling evil Qi. In addition, yoga improves physical and mental health- and QOL-related outcomes, which may be attributed to neuroendocrine regulation. Yoga may also enhance the immune function of cancer survivors by interrupting the inflammatory process and reducing the activity of T-cells and NK cells.<sup>42,55</sup>

Limitations

While the effect sizes of yoga for the QOL were generally large, the effect sizes for most physical and mental health-related outcomes were relatively small among the studies included in this review. This finding may be attributed to the heterogeneity of cancer survivors. Future exploration of the moderators of yoga's physical and mental health benefits for cancer survivors should utilize large samples. In addition, some studies included in this updated systematic review and meta-analysis evaluated multiple health-related outcomes, which can potentially lead to underestimation of the benefits of yoga. Finally, this updated study included articles published in Chinese or English only, and given yoga's Indian roots, some important articles may have been excluded.

Implications for practice

Despite the abovementioned limitations, the findings of this updated systematic review and meta-analysis have the following important implications. Yoga benefits the physical and mental health-related outcomes and overall QOL of cancer survivors and could therefore be used as an optional supportive intervention for people with cancer. Since most participants in the included studies were current cancer survivors and short-term cancer survivors, future research should explore yoga's health benefits for long-term cancer survivors. Cognitive impairment is a crucial

problem for cancer survivors.<sup>56</sup> Future research should also examine the effects of yoga on the cognitive function of long-term survivors. Because most studies included in this updated study lacked allocation concealment with a short-term follow-up assessment of study outcomes, more rigorous RCTs are needed to assess the longer-term effects of yoga and enhance the health benefits for people with cancer.

## Conclusions

This updated systematic review and meta-analysis offers available evidence on the effects of yoga on the physical function, mental health, and QOL of cancer survivors. Since most included studies employed relatively small sample sizes, more large-scale, multi-center, high-quality RCTs are needed to further verify yoga's health benefits for cancer survivors.
