SARS-CoV-2

Virus diseases

## SUMMARY

**Background & aims:** There are some studies indicating the effects of probiotic-containing foods or supplements on viral diseases. We aimed to conduct a rapid review of probiotics with specific emphasis on their potential for early administration in patients at greater risk of SARS-CoV-2 infection.

**Methods:** We searched on PubMed, EMBASE, Google Scholar, Science Direct, Scopus and Web of Science up to February 2021 to identify interventional and observational studies documenting the effects of probiotics strains on interleukins, virus titers, and antibody production with a focus on probiotic-containing foods (PROSPERO Registration ID: CRD42020181453)

**Results:** From a total of 163 records, 21 studies were classified into three domains based on the efficacy of probiotics on 1) the level of interleukins (n = 7), 2) virus titers (n = 2), and 3) interferon (IFN) and antibody production (n = 12). The suppression of pro-inflammatory interleukins and type I INF production seemed to be the main anti-viral effect of probiotics. Nine studies also indicated the beneficial effects of probiotics and fermented foods on viral diseases.

**Conclusion:** Based on evidence, some probiotic strains may be useful in viral infections; randomized trials are needed to confirm these findings.

## 1. Introduction

Severe Acute Respiratory Coronavirus 2 (SARS-CoV-2) is a new public health crisis threatening the humanity [1,2]. SARS-CoV-2 attaches to Angiotensin Converting Enzyme 2 (ACE2) receptor with 10–20 folds higher affinity than SARS-CoV [3]. Practically, antibiotic therapy results in more susceptibility to subsequent infections in severe COVID-19 patients [4]; one of the most irritating complication is antibiotic-associated diarrhea [5].

Probiotics are live microorganisms which when administered in adequate amounts confer a health benefit to the host [6]. Clinical evidence shows that certain probiotics may help treat and prevent viral infections [7,8] due to the proven immunomodulatory activity and ability to stimulate interferon (INF) production [9]. Based on evidence, the gut–lung axis explains the possible relationship between respiratory disorders and gut microbiome [10]. It was indicated that some probiotic strains activate the innate and the acquired immune system, resulting in an anti-viral protection [11–13].

Recently, some COVID-19 patients showed microbial dysbiosis with decreased *Lactobacillus* and *Bifidobacterium* [14]. In addition, gut microbiota diversity is reduced in elder peoples, who are vulnerable to severe forms of COVID-19 [15]. There are limited data on the effects of probiotics in COVID-19. Several different probiotics, including *Lactobacillus acidophilus*, *Bifidobacterium* and *Saccharomyces boulardii*, along with minerals and vitamins were given to a COVID-19 case; this type of nutritional support lowered the complications of massive antibiotic therapy (antibiotic-associated diarrhea and recurrent *Clostridioides Difficile* infections) [16]. Furthermore, another author suggested the concurrent use of probiotics in COVID-19 patients to decrease the risk for *Candida albicans* (caused by prophylaxis with azithromycin) [17].

In another report, COVID-19-like symptoms disappeared after two days administration of oral probiotic in a 9 years-old boy [18]. Results of a case series - consists of 62 SARS-CoV2 infected patients in Zhejiang province - was interesting. In this research, probiotics were administered as adjunct and the authors reported that only two patients (3%) developed shortness of breath on admission. Moreover, only one was admitted to an intensive care unit [19]. Other reports showed a significant effect of probiotics; compared to patients with non-severe disease, patients with severe disease were more likely to be treated by probiotics therapy (87.5% vs 40.4%,  $p = 0.037$ ) [20].

According to recent data, more than ten clinical trials have been registered regarding the probiotics supplementation in COVID-19 patients [21], however, more information is needed for designing future research protocols. We aimed to summarize the effects of probiotic supplementation on interleukins, viral titers, interferons, and antibody production in viral infections especially SARS-CoV-2.

## 2. Methods

### 2.1. Protocol registration

The protocol of this systematic review has been registered on PROSPERO website ([www.crd.york.ac.uk/PROSPERO](http://www.crd.york.ac.uk/PROSPERO)) developed based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement guidelines [22]. The selected studies did not provide sufficient data for quantitative analysis, therefore, all studies were just systematically reviewed.

### 2.2. Search strategy

A comprehensive search of the literature was conducted in the following databases up to June 30, 2020: PubMed, EMBASE, Google

Scholar, Science Direct, Scopus, and Web of Science. All citations were imported into a bibliographic database (EndNote X8.1; Thomson Reuters) and duplicates were removed. The search strategy was handled independently by two authors.

The used search string - based on suitable MESH and non-MESH keywords - were: ((“COVID-19” OR “SARS-CoV-2” OR “Severe Acute Respiratory Coronavirus 2” OR “Coronavirus” OR “Virus Disease” OR “Viral Infection” OR “Virus”) AND (“Virus Titers” OR “Titers” OR “Interleukin” OR “IL-6” OR “IL-17” OR “Antibody” OR “IgG” OR “IgA” OR “Interferon” OR “INF”) AND (“Synbiotics” OR “Probiotics” OR “Prebiotics” OR “Probiotic Milk” OR “Probiotic Yoghurt” OR “Probiotic Honey” OR “Probiotic Food” OR “Fermented Foods”). Moreover, bibliographies of all published reviews and studies were assessed for additional relevant papers.

### 2.3. Study selection criteria, data extraction and quality assessment

Title, abstract, and full-text of all articles were screened to select and extract studies that investigated the effect of probiotics on viral infections (with emphasis on SARS-CoV-2) in English language (all research types with both human and animal origin). We excluded HIV papers, due to not being directly related to respiratory viral infections. Data extraction from primary articles was performed by one author by using a standardized form. A second author checked the accuracy of the data extracted. Data collected from the studies included authors' family name, type of study, probiotic strains and dose, sample size, and overall outcomes. The cochrane collaboration criteria for assessing risk of bias were applied to assess the quality of the studies included in the review [23].

### 2.4. Risk of bias assessment

The included studies were evaluated for bias by using the Cochrane Risk-Of-Bias. Each included study was evaluated for the following biases: random sequence generation (selection bias), allocation concealment (selection bias), blinding of participant and personnel (performance bias), blinding of outcome assessment (detection bias), incomplete outcome data (attrition bias), selective reporting (reporting bias) and other bias. The reviewers' judgment was classified as “Low risk,” “High risk” or “Unclear risk” of bias.

## 3. Results

A diagram showed the details of included studies (Fig. 1). 163 records were identified initially from selected databases. After excluding duplicates and articles that did not meet the inclusion criteria, we obtained 58 papers with full-texts, which were read for further evaluation. Another 28 papers were excluded due to insufficient data and duplication. In general, we included 30 articles for qualitative analysis; 21 studies were classified into three domains based on the efficacy of probiotics on 1) the level of interleukins ( $n = 7$ ), 2) virus titers ( $n = 2$ ), and 3) interferon and antibody production ( $n = 12$ ). Another nine papers evaluated the efficacy of probiotics-containing and fermented foods on viral diseases.

### 3.1. Risk of bias report

Risk of bias was low in the following domains: selection bias (random sequence generation and allocation concealment, eight and twelve studies, respectively), performance bias (nine studies), detection bias (thirteen studies), attrition bias (two studies), and reporting bias (four studies). In overall state, thirteen studies had low risk of bias, three studies seemed to be at a high risk of attrition bias. Moreover, five studies had unclear risk of bias.

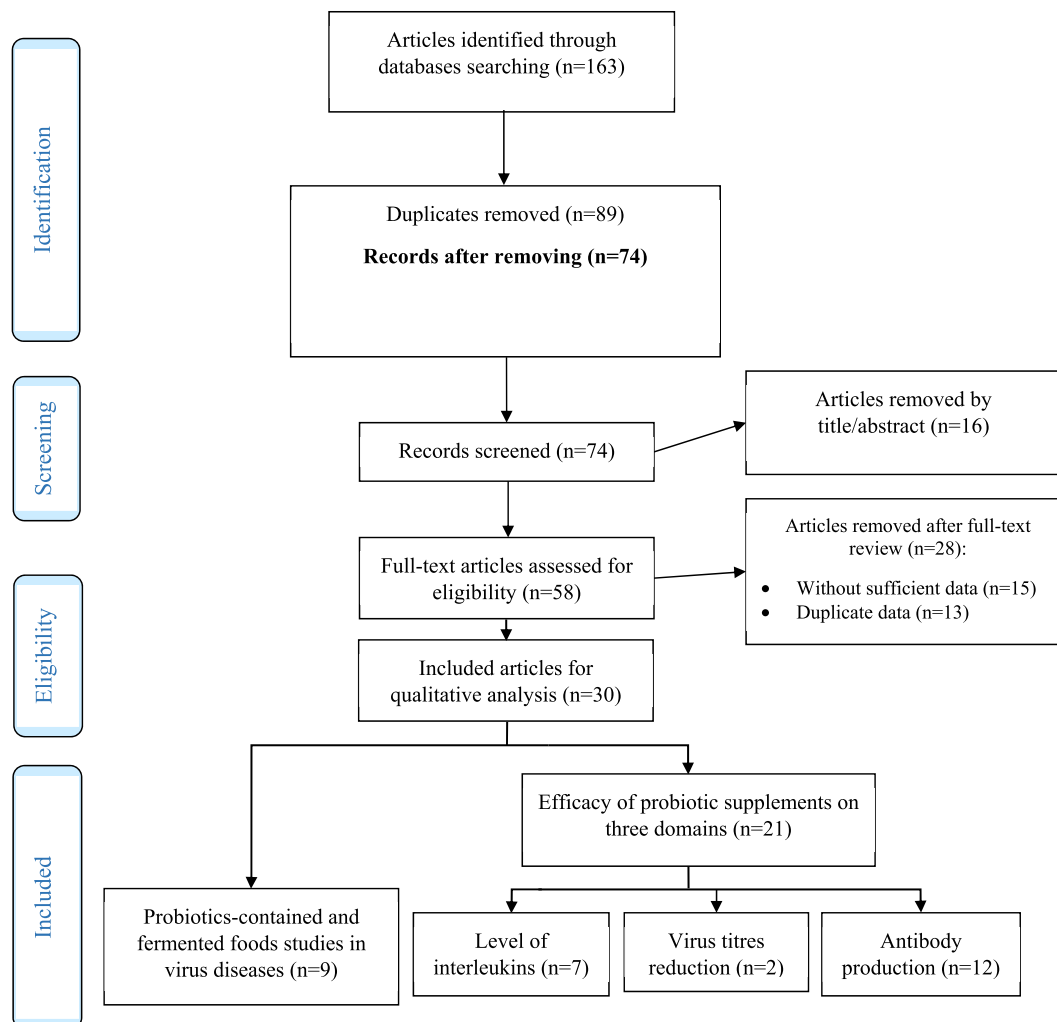

Fig. 1. Flow diagram of the different phases of systematic review.

### 3.2. Major effects of probiotics in viral infections

The effects of probiotics supplementation on interleukins, viral titers and antibody production were briefly displayed in Fig. 2. Moreover, clinical evidence for the role of probiotics in COVID-19 - up to June 2021 - was summarized in Fig. 3.

#### 3.2.1. Effects on levels of interleukins

Jiang et al. [24] administered an oral *Lactobacillus casei* ATCC 39392 vaccine against anti-transmissible gastroenteritis virus (TGEV) in piglets. This vaccine polarized Th2 cell immunity, stimulated Interleukin (IL)-17 expression, and induced an anti-TGEV infection Th17 pathway. However, Bozkurt et al. [25] reported that the *Bifidobacterium animalis* strain may be effective in preventing colorectal cancer through non-stimulatory effects on Th17 (and IL-17) cells, and a promoting effect on Th1 cells. In another study, the strain 'heat-killed *Lactobacillus plantarum* L-137' was introduced as an IL-12 inducer in mice [26].

In a trial conducted by Kimmel et al. [27], ten healthy Subjects consumed one capsule/day of *Bacillus coagulans* GBI-30 6086 (GanedenBC<sup>30</sup>) for 28 days and returned for post-treatment immunological markers evaluation; IL-6, IL-8, and Tumor Necrosis Factor-alpha (TNF- $\alpha$ ) levels were increased after exposure to a

strain of adenovirus (AdenoVI) and influenza A (H3N2 Texas strain; FluTex). IL-1beta levels also increased after exposure to AdenoVI but were reduced after ex vivo exposure to FluTex.

Abt et al. [28] described the antiviral activity of *Streptococcus salivarius* K12. Some hypotheses indicated that oral administration of the *S. salivarius* K12, through a still not perfectly clear molecular anti-inflammatory mechanism, reduced IL-8 plasma concentrations and increased salivary INF- $\gamma$ . These modulations may also realistically account for anti-inflammatory and antiviral activity, which would then be added to the antibacterial action of the K12 strain [29]. However, it seems that not all *S. salivarius* strains elicit similar immune responses, since *S. salivarius* ATCC 25975 was reported to upregulate IL-6, IL-8 and TNF- $\alpha$  gene expression [30].

Coronaviruses may also be vulnerable to probiotics. Chi et al. [31] noted that pretreating swine testicular cells with *Enterococcus faecium* NCIMB 10415, which is approved as a feed additive in the European Union, led to protective effects against the enteropathogenic coronavirus transmissible gastroenteritis virus (TGEV). A stimulated cellular defense was suggested as the underlying mechanism because of increased cellular production of nitric oxide and IL-6 and IL-8 expression. Although *E. faecium* NCIMB 10415 reduced all viral structural proteins, this strain significantly increased the production of pro-inflammatory factors IL-6 and IL-8

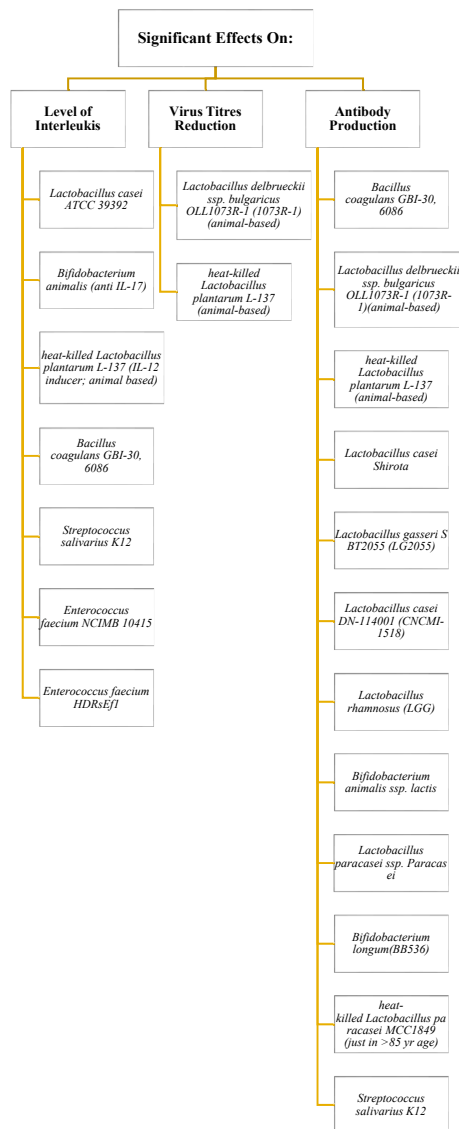

Fig. 2. Evidence-based efficacy of some probiotic strains on interleukins, virus titers and antibody production in viral infections.

Fig. 3. The probiotics strains that have been reported in the context of COVID-19.

in TGEV-infected ST cells. In contrast, Tian et al. [32] claimed that *E. faecium* HDRsEf1 can significantly downregulate the mRNA level of pro-inflammatory factors IL-1 $\beta$ , IL-6, IL-8, IL-12, IL-17, and TNF- $\alpha$ .

### 3.2.2. Effects on viral titers

In an animal study, the administration of yogurt fermented with *Lactobacillus delbrueckii* ssp. *bulgaricus* OLL1073R-1 (1073R-1) for 21 days significantly decreased influenza virus titers in infected mice [33].

Results of another animal study, conducted by Maeda et al. [34], showed that heat-killed *Lactobacillus plantarum* L-137 can lower the viral titers of influenza virus A/FM/1/47 (H1N1, a mouse-adapted strain) in infected mice, however, researchers demonstrated this effect on humans [35]. Contrary, the strain “heat-treated *Enterococcus faecalis* FK-23” during 6–36 months administration for 39 adult HCV-positive subjects could reduce Alanine Aminotransferase (ALT) and Aspartate Transaminase (AST) with no significant effect on viral load [36].

### 3.2.3. Effects on interferon and antibody production

IgA and type 1 Interferons (IFNs) production are direct mediators of protection against viral infections especially in SARS-CoV-2 [37]. Based on previous findings, the consumption of one capsule/day *Bacillus coagulans* GBI-30 6086 (GanedenBC<sup>30</sup>) for 28 days increased CD3<sup>+</sup>CD69<sup>+</sup> cells and IFN-gamma levels [27]. Moreover, Nagai et al. [33] reported that *Lactobacillus delbrueckii* ssp. *bulgaricus* OLL1073R-1 (1073R-1) increases anti-influenza virus (A/PR/8/34 (H1N1)) antibodies (IgA, IgG1) in an animal model. Interestingly, heat-killed *Lactobacillus plantarum* L-137 can act as an IFN- $\beta$  inducer [34].

*Lactobacillus casei* Shirota, another potential probiotic, was capable to reduce plasma antibody titers in cytomegalovirus and Epstein–Barr virus infected people through modulation the activity of Natural Killer (NK) cells [38]; but it did not have any therapeutic effect on norovirus-induced gastroenteritis [39].

Oral administration of yogurt containing *Lactobacillus gasseri* SBT2055 (LG2055) in healthy adult subjects potentiated vaccine-specific antibody production against A/H1N1 and B influenza viruses [40]. In another trial, titers against the influenza B strain increased significantly in group receiving *Lactobacillus casei* DN-114 001 (CNCMI-1518) for 13 weeks [41].

Another strain, *Lactobacillus rhamnosus* GG (LGG), when administered for 4 weeks to children with gastroenteritis, who were positive for either rotavirus or *Cryptosporidium* species in stool, caused a significant increase in serum Immunoglobulin (Ig) G levels [42]. According to evidence, the titers of vaccine-specific IgG, IgG1, and IgG3 in plasma as well as that of vaccine-specific secretory IgA in saliva were significantly greater in those who received both probiotics “*B. animalis* ssp. *lactis* and *Lactobacillus paracasei* ssp. *Paracasei* (10<sup>9</sup> CFU for 6 weeks)” [43]. Furthermore, 172 full-term infants who were fed probiotic formula 10<sup>6</sup> CFU/g *B. animalis* subspecies *lactis* (Bb12), had more anti-poliovirus-specific IgA in the feces sample, but not anti-rotavirus-specific IgA [44].

Akatsu et al. [45] highlighted a significant association between *Bifidobacterium* and increased immune function and intestinal microbiota in the elderly; administration of *Bifidobacterium longum* (BB536) for 5 weeks resulted in an increase of serum IgA. BB536 did not significantly affect hemagglutination inhibition in response to influenza vaccine. NK cell activity did not also decrease significantly in probiotic group.

Interestingly, Receiving a jelly containing 10 billion heat-killed *Lactobacillus paracasei* MCC189 cells for 6 weeks could improve the antibody responses to the A/H1N1 and B antigens in  $\geq 85$  years of age subgroup (n = 27), however, the overall results were not significant in comparison with placebo group [46].

### 3.3. Major effects of probiotic-containing and fermented foods on viral infections

Probiotic milk, yoghurt and honey are the most common probiotics-containing foods worldwide. There are some reports indicating the beneficial effects of these foods on viral diseases. Human milk is the main source of Lactic Acid Bacteria (LAB); LAB indicated a protective effect against rotavirus and TGEV [47]. Moreover, two strains *Lactocaseibacillus rhamnosus* LHL6 and LHL7 have significant probiotic property in breast milk [48]. Administration of *L. rhamnosus* showed a beneficial effects on the protection against enteric viruses in vivo [49].

Kimchi, a traditional Korean fermented vegetable food, has a variety of probiotic strains [50] which may induce the immune response against the viral infections. In 2018, researchers demonstrated that a new *Lactobacillus plantarum* strain (LRCC5310) - derived from kimchi-inhibits the adherence and proliferation of rotavirus in vivo and in vitro [51]. Shin et al. [52] also reported that LRCC5310 inhibit viral proliferation in human rotavirus-induced gastroenteritis.

Evidence showed that dietary intake of fermented dairy products reduces the risk of infectious diseases and enhances immune cell activity [53–55]. The administration of *Lactobacillus plantarum* JLK0142 isolated from fermented dairy tofu significantly improved phagocytic activity of macrophages and the secretion of NO in cyclophosphamide-induced immunosuppressed mice [56]. Another study showed that oral administration of milk fermented with *Lactococcus lactis* subsp. *cremoris* FC protects mice against influenza viral infection [57]. In 2019, Rigo-Adrover et al. [58] reported that a fermented milk, made by *Bifidobacterium breve* C50 (BbC50), *Streptococcus thermophilus* 065 (St065), and prebiotic mixture short chain galactooligosaccharides/long chain fructooligosaccharides, prevents from rotavirus diarrhea in suckling rats. Although there are positive findings about the antiviral effects of fermented milk [33,59,60], future research is needed to make a robust conclusion.

In a trial, the dietary intake of yogurt fermented with *Lactobacillus delbrueckii* ssp. *bulgaricus* OLL1073R-1 did not show a significant preventive effect against influenza or a significant enhancement in NK cell activity. However, intake of this yogurt showed an increase in IFN- $\gamma$  production [61]. Previous investigations also revealed that the consumption of yoghurt fermented with *L. bulgaricus* OLL1073R-1 increases NK cell activity and reduces the risk of common cold occurrence in elderly individuals [62].

However, it is notable that fermented food may interact with other probiotic-based products. Hishiki et al. [63] indicated that a probiotic strain of LAB, *Pediococcus acidilactici* K15, has a beneficial effect on the prevention of respiratory tract infections just for children who eat less than two fermented food or yogurt items per week. According to findings, probiotic-based and fermented foods are beneficial for the prevention and treatment of viral diseases, however, these effects should be investigated in SARS-CoV2 infection [64].

## 4. Discussion

Here we reviewed clinical trials on single probiotic or probiotic-containing foods, which potentially affected viral diseases. Probiotic strains like *Lactobacillus plantarum*, *Lactobacillus casei*, *B. animalis*, *Bacillus coagulans*, *S. salivarius*, and *E. faecium* had inhibitory effects on pro-inflammatory interleukins. Moreover, several conventional probiotics (*Lactobacillus gasseri*, *Lactobacillus rhamnosus*, *B. longum*) potentially increased the level of antibodies in viral infections.

According to recent evidence, gut dysbiosis occurs in COVID-19; gut–lung axis greatly affects the severity of the pulmonary complications [65,66]. D'Ettorre et al. [67] observed that the administration of probiotic mixture (*L.brevis* DSM27961, *L. acidophilus* DSM32241, *L. helveticus* DSM32242, *L. paracasei* DSM32243, *L. plantarum* DSM32244, *S. thermophilus* DSM32245, *Bifidobacterium lactis* DSM32246, and *B. lactis* DSM32247) for 2 weeks at  $2.4 \times 10^{12}$  CFU/day have beneficial effect on diarrhea and respiratory failure in COVID-19 patients, however, they did not conducted an initial gut microbiome screening before intervention. Altered intestinal microbiomes have been detected in COVID-19 patients [68–71], therefore, nutritional interventions such as probiotics and prebiotics may be beneficial as a fundamental therapeutic technique [72,73].

Coronaviruses (CoVs) involve a large family of surrounded, positive-stranded RNA viruses that infect a wide range of animal hosts as well as humans. The most recognized coronavirus, the Middle East respiratory syndrome virus, was found in Africa and Asia [74]. The currently available antiviral agents for management of CoV-induced infections does not take into consideration the effect of other factors on the treatment process including intestinal microbiota. *Lactobacilli* and *Bifidobacteria* are two conventional probiotics that can really tip the balance of a diverse gut ecosystem in combating COVID-19 [14].

There are some mechanisms explaining the antiviral impacts of probiotics. Some authors claimed that high-single dose endoscopic administration of *Bifidobacterium Infantis* (BB-12), as a potential probiotic, or bacterial lipopolysaccharide membrane in vaccine production can result in more therapeutic and preventive effects in CoV-infected patients especially in individuals with gastrointestinal symptoms (diarrhea, abdomen pain, vomiting) [75–77]. Moreover, *B. animalis* theoretically can inhibit the replication of CoVs by reducing endoplasmic reticulum stress-related autophagy, especially through the Inositol-Requiring Enzyme 1 (IRE1) pathway, over its anti interleukin-17 effect [25]. Apparently, the main pathogenic mechanism in the viral infection-induced pneumonia seems to be a “cytokine storm”; IL-6 is the main pro-inflammatory marker in the infectious diseases [78]. Coomes et al. [79] in a meta-analysis concluded that inhibition of IL-6 may be a novel target for therapeutic goals in patients with COVID-19. The current state of knowledge on the immunomodulatory effects of probiotics has recently advanced [80].

Some probiotics have potency to induce the IFN production pathways. *L. lactis* JCM5805 can activate human plasmacytoid Dendritic Cells (pDCs) in vitro; pDCs play a crucial role in antiviral immunity as proficient type I IFN producing cells (IPCs) [81,82] and mucosal T cell independent IgA production [83]. pDC-derived type I IFNs can indirectly inhibit viral replication and spread [84], and activation of NK cells [83]. Two distinct types of Toll-Like Receptors (TLR7 and TLR9) - expressed by pDCs - have some molecular role [85]; TLR7 recognizes the microbial RNA of virus [86,87], and TLR9 senses the ssDNA containing CpG motifs [88,89]. Upon sensing the viral nucleic acid, Interferon Regulatory Factor 7 (IRF7) is activated, phosphorylated, and translocated into the nucleus to begin the transcription of type I IFNs [90]. In conclusion, this strain had many important roles in both innate immunity and adaptive immunity. In addition, several human-based trials confirmed this observation (influenza virus as main target) [91–93]. Furthermore, some probiotic strains such as *E. faecium* HDRsEf1 could significantly downregulate the mRNA level of TLR4, TLR5, TLR7, and TLR8 [32].

As discussed earlier, there have also been negative reports against probiotics. According to scRNA-Seq analysis, Feng et al. found that the SARS-Cov-2 receptor, ACE2, could be elevated in the presence of both invasive bacteria *Salmonella Enterica* and its counterpart, *Segmented Filamentous Bacteria* as probiotics in the

mouse small intestine [94] and human enterocytes [95], in another study *Lactobacillus acidophilus* and *Bacillus clausii* also failed to decrease the coronavirus receptors expression in the murine small intestine compared to control and post *Salmonella* infection [96].

In total, the US Food and Drug Administration classifies probiotics as Generally Recognized As Safe (GRAS) organisms, meaning that the risks of probiotics administration seem to be low, however, the amount and type of probiotic strains are also considerable [97–99]. Notably, unconfirmed prescription of conventional probiotics for COVID-19 is not recommended until further investigations regarding the pathogenesis of SARS-CoV-2 and their effect on gut microbiota were published.

A few limitations of this review shall be highlighted. The systematic review table was not designed due to inconsistent data of relevant studies. Moreover, meta-analysis has not been performed due to heterogeneity of studies, especially in relation to published data for SARS-CoV-2. In addition, we excluded a large number of research on supplementation of different nutrients, which were related to immune function. However, the main strength of the current study was that we performed an exclusive investigation for diseases of the same origin i.e. viral diseases, especially COVID-19.

## 5. Conclusion

We described the efficacy of probiotics for the prevention or treatment of viral-based infectious diseases; more than twenty strains improved the anti-inflammatory interleukins and anti-body production against viruses. Moreover, virus titers were lowered after probiotics supplementation. Probiotic-containing foods and fermented food products also showed significant effect on prevention and treatment of viral diseases. The large number of viral species and their subtypes as well as the high mutation rate of viruses do not allow scientists to discover appropriate vaccines and antiviral drugs, therefore, the administration of pro/prebiotics - as immune function modulators and antibiotic-related side effects removers - is recommended. Although further detailed research is necessary, the authors recommend researchers/physicians/dietitians to use probiotics as more rational adjunctive option in COVID-19 pandemic, especially in mechanically ventilated patients.
