Background: Reducing the need for hospitalisation in patients with chronic obstructive pulmonary disease (COPD) is an important goal in COPD management. The aim of this study was to evaluate re-hospitalisation, treatment, comorbidities and mortality in patients with COPD who were hospitalised for the first time due to a COPD exacerbation.

Methods: This was a retrospective, population-based observational cohort study of Swedish patients using linked data from three mandatory national health registries to assess re-hospitalisation rates, medication use and mortality. Rate of hospitalisation was calculated using the number of events divided by the number of person-years at risk; risk of all-cause and COPD-related mortality were assessed using Cox proportional hazard models.

Results: In total, 51,247 patients were identified over 10 years; 35% of patients were not using inhaled corticosteroid, long-acting muscarinic antagonist or long-acting β_2 -agonist treatment prior to hospitalisation, 38% of whom continued without treatment after being discharged. Re-hospitalisation due to a second severe exacerbation occurred in 11.5%, 17.8% and 24% of the patients within 30, 90 and 365 days, respectively. Furthermore, 24% died during the first year following hospitalisation and risk of all-cause and COPD-related mortality increased with every subsequent re-hospitalisation. Comorbidities, including ischaemic heart disease, heart failure and pneumonia, were more common amongst patients who were re-hospitalised than those who were not.

Conclusion: Following hospitalisation for first severe COPD exacerbation, many patients did not collect the treatment recommended by current guidelines. Risk of mortality increased with every subsequent re-hospitalisation. Patients with concurrent comorbidities had an increased risk of being re-hospitalised.

Keywords: COPD, re-hospitalisation, management, mortality

Introduction

Chronic obstructive pulmonary disease (COPD) is a heterogeneous and progressive disease characterised by chronic airflow limitation.^{1,2} Patients typically endure intermittent exacerbations of varying frequency that are characterised by acute deterioration in symptoms of chronic breathlessness, cough and sputum production.^{3,4} Severe exacerbations that result in hospitalisation are resource demanding³ and re-hospitalisation is common following discharge.⁴ In addition, hospitalisation is associated with a high risk of mortality following discharge.⁵ Therefore, reducing the risk of hospitalisations is an important goal in COPD management.²

The GOLD 2020 guidelines recommended treating COPD with either monotherapy or combination therapy comprising bronchodilators (long-acting muscarinic antagonists [LAMAs] or long-acting β_2 -agonists [LABAs]) and inhaled corticosteroids (ICS).² The exact treatment is based on the nature and severity of an individual's disease and may be escalated in the event of a deterioration in disease status.² For patients with exacerbations, ICS/LABA or LAMA/LABA combinations form a vital part of the treatment regimen, with a more aggressive approach required for severe exacerbations, particularly in the event of acute respiratory failure.^{2,6} Suboptimal treatment may contribute to worse outcomes and increased healthcare burden for the society and the individual patient.

The aim of this study was to evaluate re-hospitalisation, treatment, comorbidities and mortality in patients with COPD who were hospitalised for the first time due to a COPD exacerbation and to identify risk factors for re-hospitalisation and mortality.

Methods

Study Design and Data Sources

This was a population-based observational study in Sweden using data from three mandatory national health registries: The National Patient Register (NPR), covering all hospital admissions since 1987 and outpatient specialist visits since 2001;⁷ the Prescribed Drug Registry, covering all collected outpatient drug prescriptions since July 2005 using Anatomical Therapeutic Chemical (ATC) codes;⁸ and the Cause of Death Register, covering data on cause of death from all people registered in Sweden.⁹ Individual patient data were linked by the Swedish National Board of Health and Welfare using each individual's unique personal identification number. Exacerbations were defined as either

pharmacy collection of oral corticosteroids (OCS) or respiratory antibiotics (tetracyclines or penicillin with extended spectrum), or emergency visits and/or hospitalisations due to COPD. The study protocol was approved by the Stockholm Regional Ethics Committee (registration number 2017/4:2).

Study Population and Follow-Up

The study population included all patients aged ≥ 40 years hospitalised with a first severe COPD exacerbation as a main diagnosis (International Classification of Diseases-10 diagnosis [ICD-10]¹⁰ code J44: [COPD¹¹]) in inpatient secondary care during the observation period between 1 January 2006 and 31 December 2015. The index date was the date of the first hospitalisation with COPD as a primary diagnosis; baseline was the 12-month period pre-index. Patients were followed prospectively from index until date of death, emigration or end of follow-up (up to 11 years), whichever occurred first (Figure 1). Medications were assessed during the 4 months prior to index and for 4 months after. Exclusion criteria included inpatient hospital visits with a diagnosis of COPD between 1 January 1997 and 1 January 2006 and immigration to Sweden < 5 years prior to index.

Assessments and Characterisations

Data were collected as follows: demographics (age, sex), mortality (all-cause mortality and COPD-related mortality), healthcare resource utilisation, hospital admissions, hospital outpatient visits and drugs dispensed from pharmacies, comorbidity (respiratory-related conditions [eg, chronic lower respiratory diseases and pneumonia] and other relevant conditions [eg, cancer, diabetes, cardiovascular diseases, rheumatoid arthritis and osteoporosis/fractures] according to ICD-10 codes) and treatment patterns

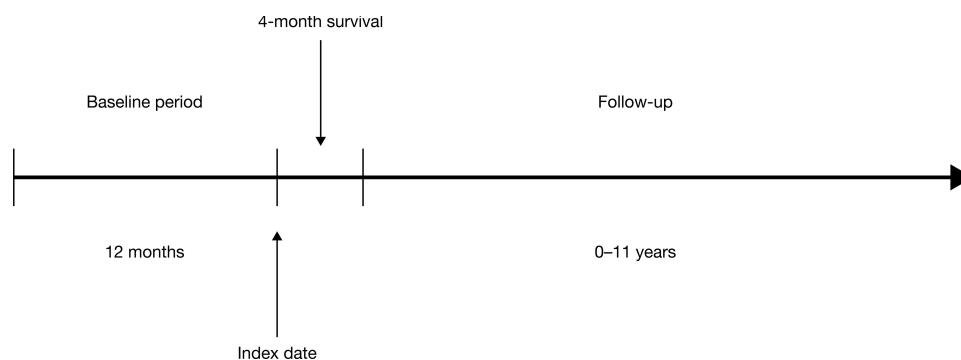

Figure 1 Study timeline. The index date was date of the first hospitalisation with COPD as a primary diagnosis; baseline was the 12-month period pre-index. Patients had to have survived for ≥ 4 months post-index and were followed prospectively from index until date of death, emigration or end of follow-up (up to 11 years).

(prescription of drugs for obstructive airway diseases [eg, ICS, LAMA, LABA and short-acting β_2 -agonists] and relevant concomitant medication [eg, antibiotics, antiviral, anti-allergy, antihistamines and antidepressants] according to ATC codes).

Statistical Analyses

Baseline characteristics were described as mean (standard deviation [SD]) for continuous variables and absolute and relative frequencies for categorical variables. Rate of hospitalisation was calculated using the number of events divided by the number of person-years at risk. Confidence intervals (95% CI) for rates were derived by approximating the Poisson distribution by a normal distribution.

Risk factors for re-hospitalisation within 30, 90 and 365 days were explored by odds ratios (OR) with 95% CI using logistic regression models. Among patients followed for ≥ 12 months, risk of all-cause and COPD-related mortality by post-index re-hospitalisations was assessed by hazard ratios (HR) with 95% CI using Cox proportional hazard models. Estimates adjusted for sex, index age, baseline comorbidities and baseline COPD treatment were calculated. Change in medication before and after the first hospitalisation was calculated for patients who were not re-hospitalised during up to 4 months of follow-up.

Results

In total, 51,247 patients were included in this study; 54.8% were female, mean age was 74.6 years and 39.3% had experienced moderate exacerbations during the 12 months preceding hospitalisation (the baseline period; [Table 1](#)). Of these, 18,167 (35.4%) patients had no previous maintenance treatment with ICS or long-acting bronchodilators, whereas 27.7% were collecting ICS, LAMA and LABA combined as triple therapy. Hypertension (20.7%), heart failure (15.4%) and ischaemic heart disease (14.2%) were the most common comorbidities ([Table 1](#)). Concomitant treatment for any cardiovascular-related comorbidities was also common (77.4%) and 42.1% of patients were collecting beta-blockers (online [supplementary Table 1](#)). More than a quarter of patients (27.2%) were collecting concomitant antidepressants.

Treatment Patterns

Of the total patient population, 39,181 patients had ≥ 12 months of follow-up. Of these, there was an increase in the

Rate (95% CI) per 100 PY	25.2 (24.7–25.7)	53.4 (52.6–54.1)

Notes: Patients with ≥ 12 months of follow-up were included (n=39,181). COPD treatments were collected during a 4-month period pre-index and post-index for the baseline and follow-up period, respectively.

Abbreviations: CI, confidence interval; COPD, chronic obstructive pulmonary disease; ICS, inhaled corticosteroid; LABA, long-acting β_2 -agonist; LAMA, long-acting muscarinic antagonist; N/A, not applicable; PD4, phosphodiesterase-4; PY, patient-years; SABA, short-acting β_2 -agonist.

LABA during follow-up, but less than half (42.5%) switched to an ICS-containing treatment regimen (online [supplementary Table 2](#)).

Among patients without maintenance treatment during the baseline period and without any hospitalisation during the first 4 months of follow-up (n=10,008), those that continued without treatment following hospitalisation (n=3239) were older and had more comorbidities (Table 3).

Outpatient Visits

Among the 39,181 patients with ≥ 12 months of follow-up, there was an increase in the number of COPD-related outpatient visits during follow-up compared with baseline from 25.2 to 53.4 visits per 100 patient-years (PY) (Table

2); however, 70.8% did not have an outpatient hospital visit due to COPD within the first year post-discharge.

Re-Hospitalisations

Of the 39,181 patients followed for ≥ 12 months, re-hospitalisation due to a second severe exacerbation occurred in 23.9% of patients (Table 2). Among these patients, there was a higher incidence of ≥ 1 moderate exacerbation during baseline versus patients who were not re-hospitalised (49.4% versus 36.0%). Comorbidities, including ischaemic heart disease (12.0% versus 14.6%), heart failure (11.3% versus 14.4%) and pneumonia (9.7% versus 14.5%), were more common among patients who were re-hospitalised than those who were not. Anxiety and depression disorder, along with osteoporosis/fractures also occurred more frequently among re-hospitalised patients. Differences in sex and age were minimal (Table 4).

Re-hospitalisation due to a second severe exacerbation within 30 (n=48,461) and 90 (n=45,608) days was seen in 11.5% (n=5563) and 17.8% (n=8120) of the patients, respectively (Table 5). Female gender, higher age, comorbidities and previous exacerbations were independently associated with re-hospitalisation at both 30 days, 90 days and 12 months (Table 5).

Mortality

Overall, patients were followed on average for 3.2 years (range, 0 to 11 years). The 1-, 5- and 8-year mortality rate was 23.5%, 61.1%, and 75.9%, respectively. Corresponding mortality rates for the 39,181 patients alive and still under observation after 12 months of follow-up were 15.7% at 1 year and 56.7% at 5 years. The risk of both all-cause mortality and COPD-related mortality increased with each subsequent re-hospitalisation (Figure 3).

Discussion

In this nationwide observational study of patients in Sweden experiencing their first hospitalisation due to a severe COPD exacerbation, more than one-third of patients did not collect any inhaled ICS or long-acting bronchodilator treatment prior to hospitalisation. Moreover, despite an increase in the proportion of patients collecting maintenance LAMA, LABA or ICS treatment and an increase in the number of outpatient visits, more than one-third of these patients still did not collect the recommended maintenance treatment after 12 months of follow-up. This group of patients were older and had more

Figure 2 ICS, LAMA and LABA treatment after hospitalisation for severe COPD exacerbation in patients without COPD treatment during baseline period. *Neither LAMA, LABA or ICS. COPD treatments were collected during a 4-month period pre-index and post-index. All patients (n=18,167) were included irrespective of follow-up time. COPD, chronic obstructive pulmonary disease; ICS, inhaled corticosteroid; LABA, long-acting β_2 -agonist; LAMA, long-acting muscarinic antagonist.

comorbidities than the patients who started using treatment after their first hospitalisation. Each subsequent re-hospitalisation was associated with an increased risk of both all-cause and COPD-related mortality.

In the present study, we found that patients who continued without appropriate respiratory treatment after their first COPD-related hospitalisation were older and had more comorbidities than patients collecting medications following hospitalization. We can only speculate that this is related to fewer prescriptions from the physicians or non-collection of prescribed medications by the patients, as only data on the collection of drugs are available in our study. It cannot be ruled out that age and comorbidities may affect the behaviour identified.

Guidelines recommend a follow-up appointment takes place within 1 month after discharge following hospitalisation due to COPD² but, in the present study, only 29% of patients received this care from a hospital-based specialist. Importantly, we found that almost one-quarter of patients had a readmission due to a severe COPD exacerbation within 1 year and almost one-quarter of patients died within 1 year. In common with previous studies,^{5,12–14} we found that, for patients hospitalised as a result of a severe COPD exacerbation, the risk of mortality increased with every new re-hospitalisation, for both all-cause death and COPD-related death. In addition, in a prospective study in France, 1824 patients hospitalised with a severe exacerbation, the mortality rate during the 4-year follow-up was similar to the rate found in our study (45%).¹⁵

In a European dataset of prospectively collected data for patients with severe COPD exacerbations resulting in

hospitalisation (European COPD Audit), readmitted patients were found to have a higher mortality than non-readmitted patients and a logistic regression analysis identified patient-related variables such as age, comorbidities and previous admissions as factors that increased the risk of readmission.¹⁶ Furthermore, Wang et al described an association between hospitalisation due to a severe COPD exacerbation and an increased risk of cardiovascular events in patients from a Taiwanese healthcare insurance database, providing further confirmation of the urgent need to ensure appropriate treatment of severe COPD exacerbations.¹⁷

In the present study, 12% were re-hospitalised within 30 days, 18% within 90 days and 24% of patients were re-hospitalised within one year. Although this was lower than findings from the European COPD Audit, where approximately one-third of patients were re-hospitalised within 90 days,^{14,16,18} clearly there is room for further improvement. In the US, a policy was created with the aim of improving outcomes by imposing penalties in the event of higher than expected all-cause 30-day readmission rates following hospitalisation for COPD. However, evidence to support specific interventions was found to be inadequate, suggesting that re-hospitalisation may not be preventable in all patients.^{19,20} Indeed, patients recovering from any form of exacerbation require an array of specific interventions to promote self-management, address existing comorbidities, and coordinate ongoing community care.¹⁹

In line with other studies, comorbidities were common among patients who were hospitalised for severe COPD exacerbations.^{4,14,21–24} Patients with concurrent asthma had a higher risk of re-hospitalisation, a finding that is in

accordance with many other studies showing that patients with concomitant asthma and COPD have a higher morbidity than those with COPD alone.^{25–27} Of note, anxiety and depression disorder was also associated with re-hospitalisation, further supporting the findings from previous studies.^{18,28,29} It has been suggested that physicians may underestimate the psychological impact of exacerbations on patients³⁰ and only a small proportion of patients with anxiety or depression are offered effective treatment for their comorbidity, which is likely to have a negative impact on their COPD.²³ Apart from comorbidities, the

risk of re-hospitalisation was also increased for women and older patients compared with men and younger patients, respectively.

The main strengths of this study were the nationwide setting, with high-quality study registers covering all patients with COPD-related inpatient visits in Sweden during the study period. Furthermore, the large sample size with long follow-up strengthened the statistical power of the analysis. In terms of study weaknesses, a lack of information about primary care visits will have led to an underestimate of the observed healthcare utilisation, particularly as some of

Note: ^aIf not otherwise specified.

Abbreviations: OR, odds ratio; CI, confidence interval.

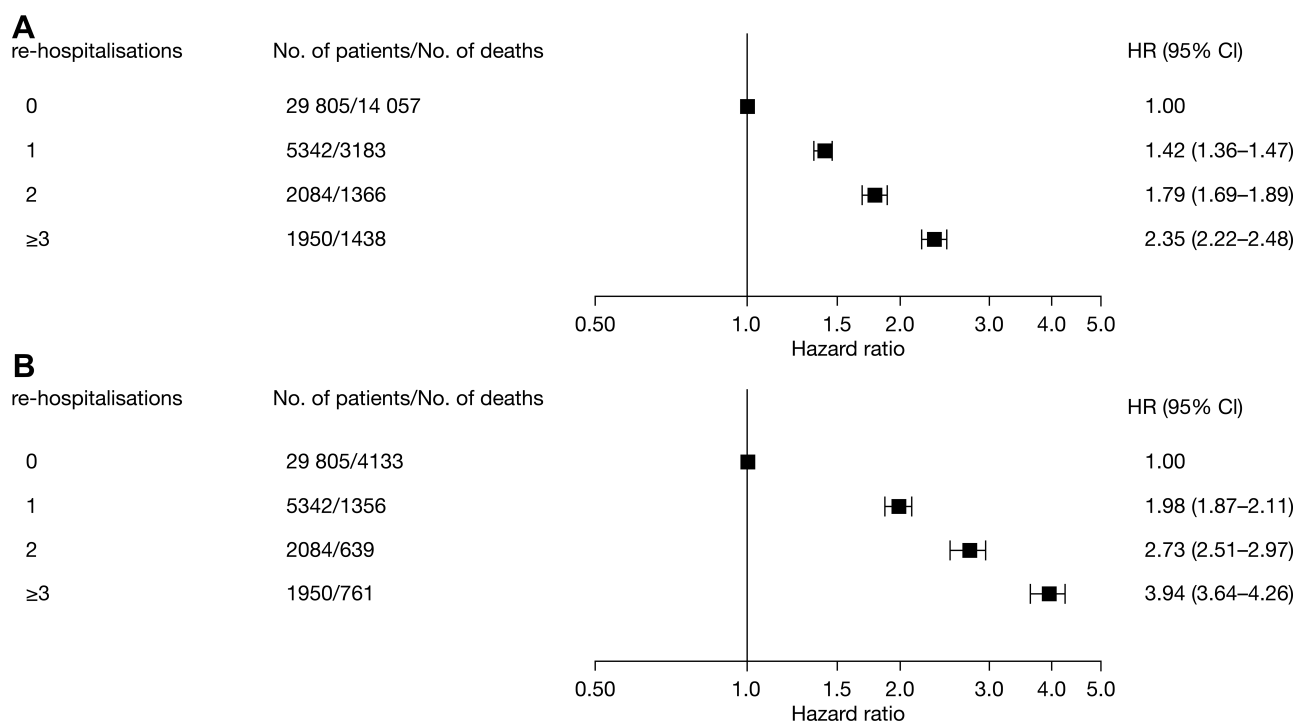

Figure 3 Risk of (A) all-cause death and (B) COPD-related death by history of severe exacerbations during 1-year follow-up. Adjusted for gender, index age, Charlson comorbidity index and COPD treatment. CI, confidence interval; COPD, chronic obstructive pulmonary disease; HR, hazard ratio.

the patients not seen in hospital-based outpatient care will likely have been followed-up in primary care. In addition, clinical measurements, such as lung function, smoking and cough, are not captured in the registries used in this study. Treatments reported in this study are based on claims from pharmacy, medications provided during hospital admissions could not be captured due to limitations in the registry infrastructure. Finally, patients who died during follow-up may not have survived long enough to have a second COPD-related hospitalisation, which may have reduced the calculated re-hospitalisation rate.

In conclusion, we found that following a first hospitalisation due to severe COPD exacerbation, many patients did not collect the treatment recommended by current guidelines.² Patients with concurrent ischaemic heart disease, heart failure and pneumonia had an increased risk of being re-hospitalised and risk of mortality increased with every subsequent re-hospitalisation. Hospital admission should provide an opportunity for clinicians to identify at-risk patients and provide them with closer follow-up and the best available preventive treatment to improve outcomes.

Data Sharing Statement

The dataset supporting the conclusions of this article can be available upon request.

Ethics Approval and Consent to Participate

This study was performed in accordance with the Declaration of Helsinki, the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use Good Clinical Practices, Good Pharmacoepidemiology Practice and the applicable legislation on non-interventional studies and/or observational Studies. All data accessed complied with relevant data protection and privacy regulations. The study protocol was approved by the Stockholm Regional Ethics Committee (registration number 2017/4:2).

Consent for Publication

All authors made a significant contribution to the work reported, whether that is in the conception, study design, execution, acquisition of data, analysis and interpretation, or in all these areas; took part in drafting, revising or critically reviewing the article; gave final approval of the version to be published; have agreed on the journal to which the article has been submitted; and agree to be accountable for all aspects of the work.

Acknowledgments

Editorial support, under the direction of the authors, was provided by Richard Knight, PhD, CMC Connect,

McCann Health Medical Communications, and funded by AstraZeneca in accordance with Good Publication Practice (GPP3) guidelines.³¹

Funding

This study was sponsored by AstraZeneca.

Disclosure

CJ has received payments for educational activities from AstraZeneca, Boehringer Ingelheim, Chiesi, Novartis, and Teva, and has served on advisory boards arranged by AstraZeneca, Boehringer Ingelheim, Chiesi, GlaxoSmithKline, Novartis, and Teva. GT is an employee by AstraZeneca. FW is an employee at Statisticon for which AstraZeneca is a client. The authors report no other conflicts of interest in this work.

International Journal of Chronic Obstructive Pulmonary Disease

Dovepress

Publish your work in this journal

The International Journal of COPD is an international, peer-reviewed journal of therapeutics and pharmacology focusing on concise rapid reporting of clinical studies and reviews in COPD. Special focus is given to the pathophysiological processes underlying the disease, intervention programs, patient focused education, and self management

protocols. This journal is indexed on PubMed Central, MedLine and CAS. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
