

Efficacy of Intraoperative Recurrent Laryngeal Nerve Monitoring During Thoracoscopic Esophagectomy for Esophageal Cancer: A Systematic Review and Meta-Analysis

Xinxin Wang, Haixie Guo, Quanteng Hu, Yongquan Ying and Baofu Chen*

Department of Thoracic and Cardiovascular Surgery, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou, China

Background: Recurrent laryngeal nerve paralysis (RLNP), a severe complication of mini-invasive esophagectomy, usually occurs during lymphadenectomy adjacent to recurrent laryngeal nerve. This systematic review and meta-analysis aimed to evaluate the efficacy of intraoperative nerve monitoring (IONM) in reducing RLNP incidence during mini-invasive esophagectomy.

Methods: Systematic literature search of PubMed, EMBASE, EBSCO, Web of Knowledge, and Cochrane Library until June 4, 2021 was performed using the terms “(nerve monitoring) OR neuromonitoring OR neural monitoring OR recurrent laryngeal nerve AND (esophagectomy OR esophageal).” Primary outcome was postoperative RLNP incidence. Secondary outcomes were sensitivity, specificity, and positive and negative predictive values for IONM; complications after esophagectomy; number of dissected lymph nodes; operation time; and length of hospital stay.

Results: Among 2,330 studies, five studies comprising 509 patients were eligible for final analysis. The RLNP incidence was significantly lower (odds ratio [OR] 0.33, 95% confidence interval [CI] 0.12–0.88, $p < 0.05$), the number of dissected mediastinal lymph nodes was significantly higher (mean difference 4.30, 95%CI 2.75–5.85, $p < 0.001$), and the rate of hoarseness was significantly lower (OR 0.14, 95%CI 0.03–0.63, $p = 0.01$) in the IONM group than in the non-IONM group. The rates of aspiration (OR 0.31, 95%CI 0.06–1.64, $p = 0.17$), pneumonia (OR 1.08, 95%CI 0.70–1.67, $p = 0.71$), and operation time (mean difference 7.68, 95%CI –23.60–38.95, $p = 0.63$) were not significantly different between the two groups. The mean sensitivity, specificity, and positive and negative predictive values for IONM were 53.2% (0–66.7%), 93.7% (54.8–100%), 71.4% (0–100%), and 87.1% (68.0–96.6%), respectively.

Conclusion: IONM was a feasible and effective approach to minimize RLNP, improve lymphadenectomy, and reduce hoarseness after thoracoscopic esophagectomy for esophageal cancer, although IONM did not provide significant benefit in reducing aspiration, pneumonia, operation time, and length of hospital stay.

INTRODUCTION

Thoracoscopic radical esophagectomy is an important surgical approach in esophageal cancer, and lymphadenectomy during esophagectomy is necessary because lymph node metastasis is common in patients with esophageal cancer. Lymph nodes along the recurrent laryngeal nerve (RLN) is a common site of metastasis, and radical dissection of lymph nodes along bilateral RLNs is important for improving patient prognosis (1–6). However, injury to RLN, which usually occurs during lymphadenectomy, can lead to RLN paralysis (RLNP), a cause of hoarseness and a risk factor for aspiration and pneumonia after surgery (7). The various causes of RLNP include thermal damage, compression, ischemia, and towing among the various causes of RLNP. The reported rate of RLNP during esophagectomy ranges from 14.0 to 76.2% (8–11). Protection of the RLN during surgery is important in preventing complications and aiding in patient recovery. Intra-operative nerve monitoring (IONM), which can identify nerves and is widely utilized in thyroid surgery, has been demonstrated as a good approach for protecting RLN (12–15). Recent studies examining the utility of IONM in esophagectomy reported its feasibility and efficacy in protecting the RLN (16–20). However, studies focusing on the utility of IONM as a method are limited and the number of patients included in these studies remains low. Therefore, we performed a systematic review and meta-analysis to elucidate the impact of IONM on protecting the RLN during thoracoscopic esophagectomy for esophageal cancer.

MATERIALS AND METHODS

Search Strategy

A literature search of PubMed, EMBASE, EBSCO, Web of Knowledge, and Cochrane Library until June 4, 2021 was conducted using the terms “(nerve monitoring OR neuromonitoring OR neural monitoring OR recurrent laryngeal nerve) AND (esophagectomy OR esophageal).” **Patients who were diagnosed with esophagus cancer and underwent thoracoscopic esophagectomy were included for study. The outcome of RLNP were compared in the IONM and non-IONM group. Studies must be retrospective or prospective case control studies.**

The inclusion criteria were studies which included patients who underwent thoracoscopic esophagectomy for esophageal cancer and compared patients evaluated with IONM (IONM group) to those not evaluated with IONM (non-IONM group) and reported the outcome of RLNP. Following were the exclusion criteria: (1) articles using duplicated data from the same study, (2) studies that did not directly compare between IONM and non-IONM, (3) articles with only an abstract and no full text, and (4) articles not in English. Relevant articles were also identified through the reference lists of relevant review articles.

Data Extraction

Data were independently retrieved from the identified studies by two authors (XW and HG). Consensus was reached by discussion in cases of disagreement. The following data were retrieved

from the studies: first author; country; publication year; study design; number of patients; sex; smoking history; location of tumor; pathological type; prior therapy; cancer stage according to the American Joint Committee on Cancer guidelines; incidence of RLNP; complications including aspiration, pneumonia, and hoarseness; number of dissected lymph nodes; operation time; time of thoracic procedure; and length of hospital stay.

Quality Assessment

The quality of included studies were assessed using the Newcastle–Ottawa scale, and a Newcastle–Ottawa scale score of >6 were used to define high-quality studies. The assessment was independently performed by two authors (QH and YY), and a third author (BC) was consulted to settle disagreements if necessary.

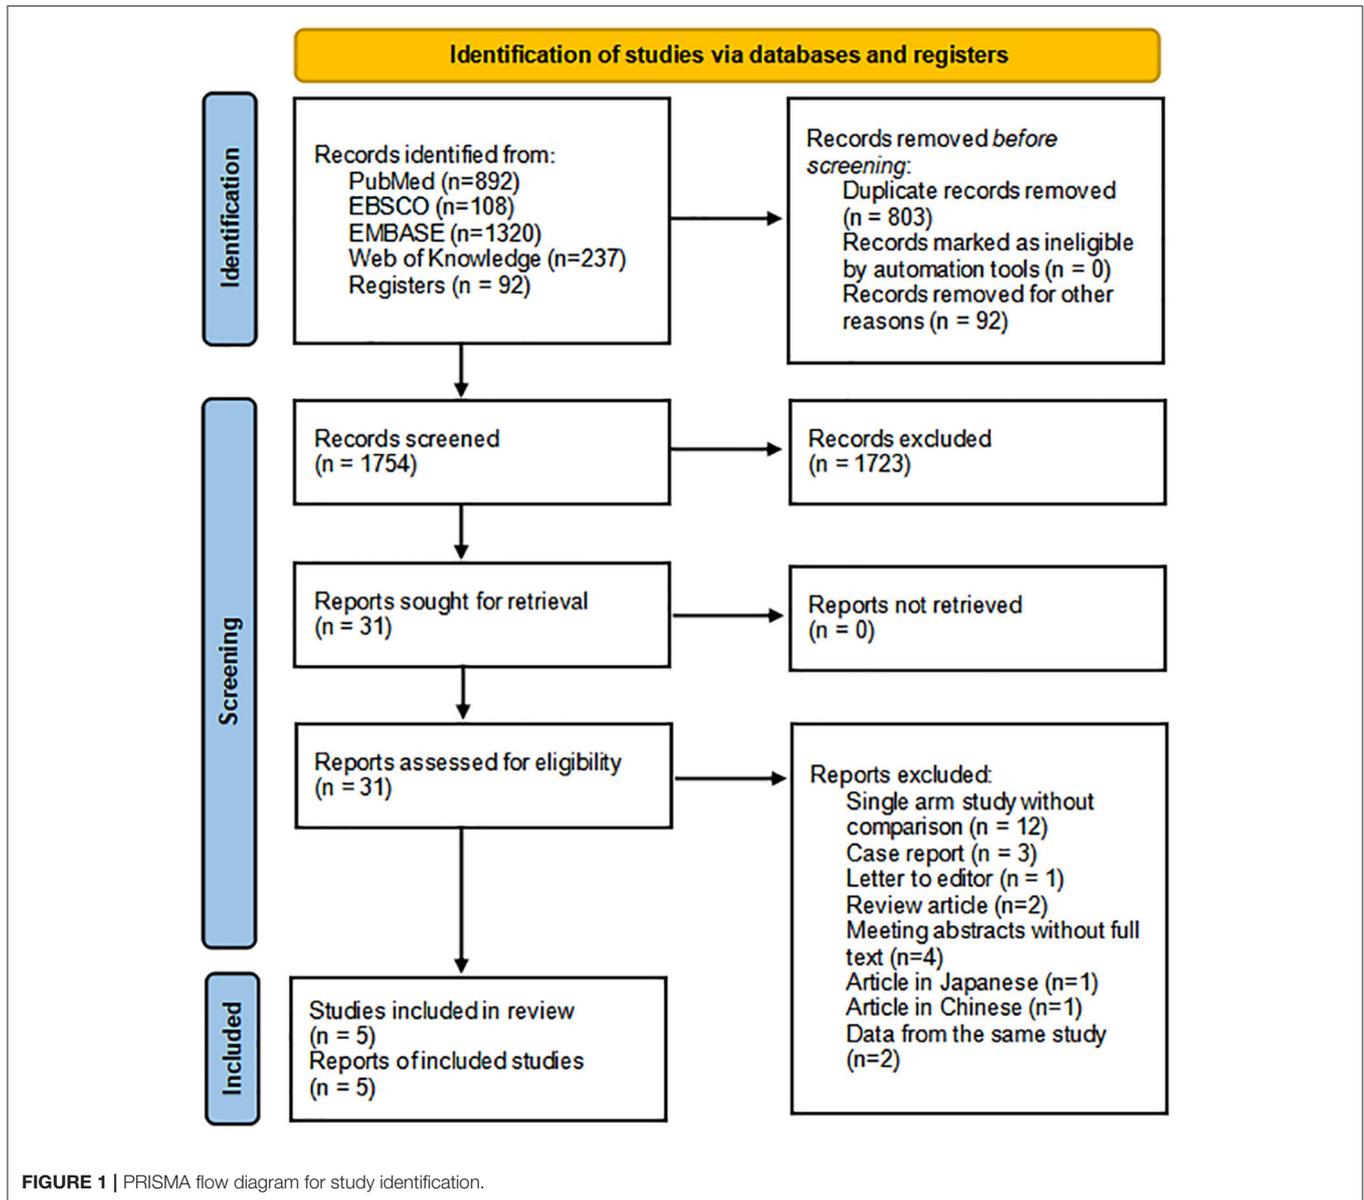

Statistical Analysis

All statistical analyses were performed using the Review manager software (version 5.3). Between-study heterogeneity was calculated using Higgins’ I^2 statistics (21). Pooled results with an $I^2 > 50\%$ were considered to exhibit a high degree of heterogeneity, and the random-effects model was used to estimate. A fixed-effects model was used in studies with a low degree of heterogeneity. Sensitivity analysis was performed in the presence of a high degree of heterogeneity. Pooled odds ratios (ORs) and the corresponding 95% confidence intervals (CIs) were estimated for dichotomous outcomes, and mean differences were estimated for continuous outcomes. The Mantel–Haenszel and inverse variance methods were used for the analysis of dichotomous and continuous outcomes, respectively. Publication bias was qualitatively estimated using funnel plots. Mean and standard deviation of samples were estimated using sample sizes, medians, ranges, and/or interquartile ranges, as described by Wan et al. (22). The overall effect was considered statistically significant with a two-sided $p < 0.05$.

RESULTS

Search Results

The literature search of the five electronic databases included in the study identified a total of 2,649 studies fulfilling the inclusion criteria. After preliminary screening, 31 studies were retrieved to assess eligibility. Of these, 12 studies which did not compare IONM with non-IONM (23–34). Three case reports on IONM (35–37), one letter to the editor (38), and two reviews (39, 40) were excluded. Additionally, four meeting abstracts lacking full texts (41–44), two studies which utilized data from the same study (45, 46), and two studies which were not in English (47, 48) were excluded. Finally, a total of five studies, including three retrospective cohort studies and two prospective cohort studies, comprising a total of 509 patients undergoing thoracoscopic esophagectomy for esophageal cancer were identified (16–20). In total, there were 240 and 269 patients who underwent surgery with and without IONM, respectively. The PRISMA flow diagram of study identification is presented in **Figure 1**.

Patient Characteristics

The detailed baseline information of patients is summarized in **Table 1**. Briefly, the mean patient age ranged from 58.9 to 69.5 years in the non-IONM group and from 59.9 to 67.7 years in the IONM group. All studies reported tumor location, and most tumors were located in middle and lower esophagus. All but one of the studies reported the pathological tumor type, and the majority were squamous cell cancer. The percentage of patients who received therapy prior to surgery was not significantly different between the IONM and non-IONM groups in four of the five studies which reported that patients received therapy prior to surgery. All studies reported the cancer stage of patients according to the American Joint Committee on Cancer guidelines, and the cancer stage did not significantly differ between the IONM and non-IONM group.

Outcome of RLNP

All studies reported RLNP as a surgical outcome. RLNP occurred in both the IONM and non-IONM groups in four studies, except for the study by Zhong et al. The detailed results of IONM are presented in **Table 2**. The rate of RLNP ranged from 0 to 46.3% in the IONM group and from 9.8 to 53.3% in the non-IONM group. The pooled analysis showed that IONM was associated with a significant reduction in the rate of RLNP after thoroscopic esophagectomy (OR 0.33, 95%CI 0.12–0.88, $p < 0.05$, **Figure 2**). Three studies reported the correlation between signal loss and postoperative RLNP in the IONM group. The ranges of sensitivity, specificity, positive predictive value, and negative predictive value were 0–66.7%, 54.8–100%, 0–100%, and 68.0–96.6%, respectively.

Lymph Node Dissection and Surgical Outcomes

All studies reported the number of dissected mediastinal lymph nodes during surgery. The detailed information of lymph node dissection and surgical outcomes are presented in **Table 3**. Briefly, the mean number of dissected mediastinal lymph nodes ranged from 16.0 to 25.8 in the non-IONM group and from 20.6 to 27.9 in the IONM group. The pooled analysis revealed

that there were significantly more dissected mediastinal lymph nodes in the IONM group than in the non-IONM group (mean difference 4.30, 95%CI 2.75–5.85, $p < 0.001$, **Figure 3**). Two studies reported the total number of dissected lymph nodes, including the mediastinal and abdominal lymph nodes. The pooled analysis showed that number of dissected lymph nodes was higher in the IONM group than in the non-IONM group (mean difference 5.61, 95%CI 3.07–8.15, $p < 0.001$, **Figure 4**).

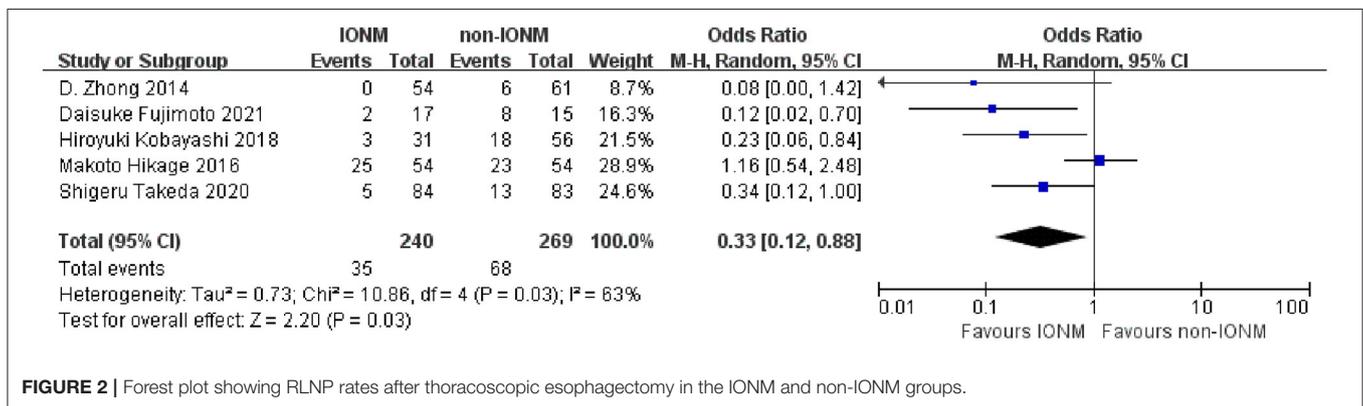

FIGURE 2 | Forest plot showing RLNP rates after thoracoscopic esophagectomy in the IONM and non-IONM groups.

All studies reported the mean operation time, which ranged from 237.8 to 665.3 min in the IONM group and from 251.1 to 596.7 min in the non-IONM group. The pooled analysis showed that there was no significant difference in the operating time between the IONM and non-IONM groups (mean difference 7.68, 95%CI -23.60-38.95, $p = 0.63$, **Figure 5**). The mean length of hospital stay, which was reported in three studies, ranged from 12.5 to 37.3 days in the IONM group and from 16.1 to 60.9 days in the non-IONM group. The pooled analysis of the mean length of hospital stay revealed that there was no significant difference between the IONM and non-IONM groups (mean difference -10.87, 95%CI, -24.57-2.83, $p = 0.12$, **Figure 6**).

Complications

All studies reported the rate of pneumonia after surgery, which ranged from 7.4 to 40% in the non-IONM group and from 13.0 to 25.0% in the IONM group. The pooled analysis of pneumonia revealed no significant difference in the rate of pneumonia between the IONM and non-IONM groups (OR 1.08, 95%CI 0.70-1.67, $p = 0.71$, **Figure 7**). Four studies reported the rate of aspiration after surgery, which ranged from 9.8 to 46.7% in the non-IONM group and from 0 to 44.4% in IONM group. The pooled analysis showed that there was no significant difference in

the rate of aspiration after surgery between the IONM and non-IONM groups (OR 0.31, 95%CI 0.06-1.64, $p = 0.17$, **Figure 8**). Two studies reported the rate of hoarseness after surgery, which ranged from 9.8 to 40% in the non-IONM group and from 0 to 11.8% in the IONM group. The pooled analysis showed that the rate of hoarseness was significantly lower in the IONM group than in the non-IONM group (OR 0.14, 95%CI 0.03-0.63, $p < 0.05$, **Figure 9**).

Heterogeneity and Sensitivity Analysis

We observed significant heterogeneity in the data on rates of RLNP, aspiration, operation time, and length of hospital stay (I^2 , 63, 78, 88, and 77%, respectively). Therefore, we performed sensitivity analysis by excluding each study and recalculated pooled ORs with 95%CI. After excluding the study by Hikage et al., the ORs for RLNP and aspiration were in favor of IONM (OR 0.23, 95%CI 0.11-0.48, $I^2 = 0%$, and OR 0.15, 95%CI, 0.05-0.44, $I^2 = 0$, respectively). The rate of operation time did not exhibit a significant difference after excluding each study. However, after excluding the study by Kobayashi et al., the OR for length of hospital stay was in favor of IONM (mean difference -3.65, 95%CI, -7.06--0.25, $p < 0.05$, $I^2 = 0%$).

Publication Bias

The funnel plot for RLNP (Figure 1) revealed that the studies exhibited an almost symmetrical distribution on each side, and an obvious publication bias was not observed.

Quality Assessment

The quality assessment of the studies is shown in Table 4. Briefly, all studies had a Newcastle–Ottawa scale score of nine, which indicated good methodological quality. No study was excluded because of low quality.

DISCUSSION

To our knowledge, this is the first systematic review and meta-analysis examining the relationship between IONM and RLNP, which revealed that IONM could significantly reduce the rate of RLNP, improve lymphadenectomy, and reduce hoarseness after thoracoscopic esophagectomy for esophageal cancer. But we did not observe significant differences in operation time, aspiration, pneumonia, and length of hospital stay between the patients evaluated with IONM and those who were not evaluated by IONM during surgery.

The rate of RLNP was significantly lower in the IONM group than in the non-IONM group, although there was a decent degree of heterogeneity. After excluding the study by Hikage et al. (19), the rate of RLNP remained significantly lower in the IONM group without heterogeneity among the studies, which might be explained by the low sensitivity of IONM. In the study by Hikage et al., the surgeon was not familiar with the manipulation of the nerve monitoring system in the first 10 cases and IONM was

discontinued in almost 30% of all patients in the IONM group for a variety of reasons, which might be associated with the lack of reduction in RLNP rate in that study.

The number of dissected mediastinal lymph nodes and all dissected lymph nodes, including mediastinal and abdominal lymph nodes, were significantly higher in the IONM group compared with the non-IONM group. IONM during surgery facilitated the radical dissection of lymph nodes along bilateral RLNs without high risk of injury to the RLN. The ratio of positive total dissected lymph nodes was significantly higher in the IONM group in the study by Zhong et al. (17). Lymph node metastasis is a risk factor for survival (49, 50); therefore, radical lymphadenectomy is necessary for accurate cancer staging and improving survival, which was demonstrated in the study.

In the present meta-analysis, the incidence of aspiration was not significantly lower in the IONM group compared with the non-IONM group. Studies previously reported the association of aspiration with RLNP after surgery for esophageal cancer (7, 10, 51). The reduction in the rate of RLNP after surgery in patients receiving IONM might be partially responsible for the reduced rate of aspiration. Conversely, there was also no significant difference in the rate of pneumonia between the IONM and non-IONM groups. In the study by Zhong et al. (17), the rate of postoperative pneumonia was significantly lower in the IONM group compared with the non-IONM group, which might have been due to the higher percentage of patients with smoking history in the non-IONM group; history of smoking is a proven risk factor for postoperative pneumonia (52). Therefore, large-scale studies are warranted to clarify the association between IONM and postoperative pneumonia.

TABLE 4 | Quality assessment of the nonrandomized studies using the Newcastle-Ottawa scale.

Publication year	Study	Selection			Comparability (Based on design and analysis)		Outcome		
		Representativeness of exposed	Selection of non-exposed	Ascertainment of exposure	Outcome of interest absent at	Assessment outcome	Follow-up long enough for outcomes to occur	Adequacy of follow-up	Total score
2016	Hikage et al.	1	1	1	1	2	1	1	9
2021	Fujimoto et al.	1	1	1	1	2	1	1	9
2014	Zhong et al.	1	1	1	1	2	1	1	9
2018	Kobayashi et al.	1	1	1	1	2	1	1	9
2020	Takeda et al.	1	1	1	1	2	1	1	9

The operation time was not significantly different between the IONM and non-IONM groups, which might be due to radical lymphadenectomy and nerve identification using electrodes during both the thoracic and cervical procedures.

The survival rates of patients in the IONM and non-IONM groups were present only in the study by Zhong et al., in which the Kaplan–Meier analysis indicated that survival was significantly better in the IONM group. This outcome might be associated with the use of radical and complete lymphadenectomy in the IONM group; this approach can identify the metastasis lymph nodes and allows for accurate clinical staging. Of course, additional studies are warranted to elucidate the association between IONM and survival.

To our knowledge, this is the first systematic review and meta-analysis focusing on the impact of IONM on protecting RLN during thoracoscopic esophagectomy for esophageal cancer. However, the present study has several limitations that should be acknowledged. First, none of the studies included in the analysis were randomized. Second, only studies published in English were included and studies reported in other language might have been missed. Third, the small number of studies and patients included in the meta-analysis might not be an accurate representation to assess the impact of IONM on RLNP. Fourth, there was a decent degree of heterogeneity in the current study results, which should be interpreted with caution. Finally, other factors such as ethnicity, **prior therapy** and surgical technique might also have an impact on RLNP.

In conclusion, the results of the present systematic review and meta-analysis suggested that IONM was associated with lower rates of RLNP and hoarseness and more effective lymphadenectomy after thoracoscopic esophagectomy for esophageal cancer. However, IONM was not associated with a significant benefit in preventing pneumonia and aspiration or reducing operation time and length of hospital stay.
