India

ABSTRACT

India is one among the most affected countries in the COVID-19 pandemic. The increasing number of cases in India and the fear of COVID-19 infection is causing fear and anxiety. Fear and anxiety related to COVID-19 the community dwellers are less studied. This study was conducted to assess the fear and anxiety related to COVID-19 among the people seeking COVID-19 screening test. The cross-sectional study was conducted on a sample of 398 participants aged 18 years and above who attended the screening clinic of a tertiary care hospital of eastern India. Participants were assessed using Coronavirus Anxiety Scale (CAS) and Fear of COVID-19 scale which are validated screening scales. Result showed that 20.4 % of the participants were having anxiety due to COVID-19. The mean fear score was 17.87 ± 4.48 . Females, Middle aged, housewives, less educated, symptomatic, comorbid and people under institutional quarantine were having more fear. People with COVID-19 related anxiety faced more fear. These findings suggest the need for screening anxiety in COVID-19 screening clinics. People with high levels of COVID related anxiety and fear are at risk for developing psychiatric disorders hence need targeted approach to address their mental health.

1. Introduction

Coronavirus Disease (COVID-19) was declared as public health emergency of international concern on 30th January 2020 (World Health Organization, 2020a) and a pandemic on 11th March 2020 by World Health Organization (World Health Organization, 2020b). As on 18th December, the world has witnessed over 72 million confirmed cases and approximately 1.6 million deaths due to COVID-19. During the same period, India has 9.9 million confirmed cases and more than 0.14 million deaths (Ministry of Health and Family Welfare Government of India, 2020).

As the cases are rising and similarly the hardship, the general population is experiencing fear and anxiety related to COVID-19 (Varshney et al., 2020). More than half of the people reported fear and anxiety in China during the ongoing pandemic (Zhang and Ma, 2020).

Fear is usually an emotional state that is triggered by a real or perceived threat that is accompanied by autonomic arousal or thought of

immediate danger or any escape behaviour, whereas, anxiety reflects generalized anticipation of future threat (American Psychiatric Association, 2013). Many people adapt to the threats of a pandemic and become less afraid and anxious, but a significant number of individuals will not adjust and will develop fear and anxiety (Taylor, 2019).

Fear and anxiety during a pandemic are mostly due to the uncertainty related to the disease spread, infodemics and mis-infodemics (Sahoo et al., 2020), probable contact with confirmed or suspected cases of COVID-19, contagion by the virus (Xiang et al., 2020). The stigma associated with the disease is also adding to the anxiety and fear (Dubey et al., 2020).

There is limited literature which has addressed anxiety and fear among the general population during COVID-19 pandemic. To the authors' knowledge, there is no data reported from India which has assessed COVID-19 related fear and anxiety in the general population. We did this study to estimate fear and anxiety related to COVID-19 and factors associated with it among community-dwelling population

Abbreviations: CAS, Coronavirus Anxiety Scale; OPD, Out Patient Department.

visiting COVID-19 screening centre of a tertiary care hospital in eastern India using Coronavirus Anxiety Scale (CAS) and Fear of COVID-19 scale.

2. Material and methods

2.1. Study design and study participants

A cross-sectional study was conducted during August-September 2020 among community-dwelling population visiting COVID-19 screening centre of All India Institute of Medical Sciences, Bhubaneswar a tertiary care hospital in Odisha, Eastern part of India. On average, 200 patients attend the screening clinic daily. The purpose of the clinic was to screen for symptoms suggestive of COVID-19 among the attendees and also perform COVID-19 test whenever required. Along with this, a major portion was the cancer patients who attended the screening clinic to get tested as it was mandatory to undergo testing before any procedure like chemotherapy and radiotherapy.

All the patients aged 18 years or more visiting COVID-19 screening centre of the hospital were included in the study. Health Care Workers and those not willing to participate or having any diagnosed mental disorders were excluded from the study. Assuming 37.3% prevalence of anxiety among general population during COVID-19 (Islam et al., 2020), considering absolute precision of 5% and a significance level of 95%, the sample size was calculated to be 356. Considering 10% of non-response rate, the final sample size was calculated to be 395. The first 20 visitors to screening centre of the day were recruited consecutively and written informed consent was obtained prior to the interview. Ethical approval was obtained from the institutional ethics committee prior to the commencement of the study.

2.2. Data collection and analysis

The study tool was divided into three parts. The first part consisted of demographic variables, COVID-19 risk status, symptoms of COVID-19, quarantine status, and the reason for visiting the screening centre. The second and third part consists of the Coronavirus Anxiety Scale and the Fear of COVID-19 scale.

Coronavirus Anxiety Scale: Coronavirus Anxiety Scale (CAS) is a good screener to screen individuals with anxiety related to coronavirus and also validated in the Indian context (Chandu et al., 2020). The five items scale consists of somatic symptoms of fear and anxiety triggered by thoughts or information of Coronavirus. The responses were recorded in a 4-points Likert scale ("not at all" (0 point), "rare, less than a day or two" (1 point), "several days" (2 points), "more than 7 days" (3 points), "nearly every day over the last 2 weeks" (4 points). A score of 9 was taken as cut off for the corona anxiety score.

Fear of COVID-19 Scale: The validated 7 item fear of COVID-19 scale is useful to assess the fear generated by the coronavirus (Ahorsu et al., 2020). The participants indicated their level of agreement using a five-item Likert scale ("strongly disagree", (1 point) "disagree", (2 points) "neutral", (3 points) "agree", (4 points) "strongly agree", (5 points).

Coronavirus Anxiety Scale was developed to capture cognitive, behavioural, emotional and physiological aspects of anxiety related to coronavirus. Whereas Fear of COVID scale was based on Hospital Anxiety and Depression Scale and Perceived Vulnerability to Disease Scale. Hence Fear of COVID scale measures psychological fear, anxiety, depression and hypochondriasis related to COVID (Ahorsu et al., 2020). To measure adverse psychological reactions including anxiety, fear, depression, stress and hypochondriasis we used both the scales in this study.

Data collection was performed by trained doctors using Epicollect mobile application. Data was kept anonymous and confidentiality was maintained. Data analysis was conducted using Statistical Package for Social Sciences Version 20. Categorical variables were presented as

proportion and continuous variables were presented as mean and standard deviation. Chi-square test was applied for the level of significance for the two or more group for categorical variables. P value of less than 0.05 was considered as significant.

3. Results

A total of 424 beneficiaries were approached and 26 of them were excluded from the study as they were healthcare workers. A total of 398 participants of age between 18 and 85 years, (38.76 ± 13.90 years) participated in the study and two-third (66.3%) were male. Descriptive characteristics of study participants are given in Table 1. 119 (29.9%) participants had one or more symptoms during the visit. Among those having symptoms, fever (58.8%) was the most common presenting symptoms followed by cough (56.3%). Among the study participants, 160 (40.2%) were having one or more underlying health condition. Malignancy was the commonest co-morbidity found among 99 (61.8%) followed by immunocompromised condition among 27 (16.8%) of the participants having any of the co-morbidities.

History of travel to other state or country was present in only 36 (9.0%) of the participants. Similarly, a history of contact with COVID-19 positive patient was seen among 119 (29.9%) participants. However, 47 (11.8%) of the participants did not know about their contact status. Only 54 (13.6%) participants were in quarantine and among them, 46 (85.2%) were in home quarantine. The screening Out Patient Department (OPD) attendees came to OPD for various reasons. The most common reason as cited by 146 (36.7%) attendees was a doctor's suggestion to get tested, followed by having symptoms 99 (24.8%) and having high-risk contacts with COVID positive patients 91 (22.8%).

The mean score for fear was 17.87 ± 4.48 with a maximum and minimum score of 7 and 32, respectively. Mean Fear score for Corona was found to be higher among females than the males, but the difference was not statistically significant. Fear was more among the participants of age 41–50 years (18.73 ± 5.29), followed by 31–40 years (18.47 ± 4.26) and more than 50 years (17.60 ± 4.11). The least fear was among the 18–31 years age group (17.18 ± 4.29). Least fear was observed among the illiterate participants and higher fear was observed among primary and high school educated participants. Housewives were having the highest fear among the participants and those not working were having the least fear. Participants having symptoms reported more fear than the participants not having any symptoms. The mean fear score of the symptomatic individuals was 19.13 ± 4.05 and that of asymptomatic was 17.33 ± 4.56 . History of travel had no impact on fear perception. Similarly, no difference was observed for those having any underlying medical condition to that of not having any. Those who did not know about any contact with any COVID-19 positive patients were more fearful than those who knew their contact status. No statistical difference was observed between the participants in quarantine and those not in quarantine. The higher mean fear score was obtained from those who had anxiety score of 9 or more and it was statistically significant than that of anxiety score of less than 9 [Table 1].

As many as 81 (20.4%) participants were found to have anxiety during the assessment. The mean Corona Anxiety score was 3.91 ± 4.14 and the minimum and maximum score were 0 and 16, respectively. Anxiety was experienced more among females in comparison to male participations having mean anxiety score of 4.87 ± 4.54 and 3.42 ± 3.84 respectively, and the difference was found to be statistically significant. Study participants with a history of contact with confirmed COVID-19 positive patient had experienced more anxiety in comparison to who didn't have any contacts (21.0% vs 12.1%). Age of the participant, occupation, quarantine status, history of travel to other state or country, presence of any symptoms and presence of any underlying disease did not have any association with anxiety experience [Table 2].

Table 2
Association of Anxiety and demographic variables.

		Corona Anxiety score <9	Corona anxiety score ≥9	P value	Mean CAS score	P value
Gender	Male	222 (84.1)	42 (15.9)	0.002	3.42 ± 3.84	0.001
	Female	95 (70.9)	39 (29.1)		4.87 ± 4.54	
Age group	18–30 years	117 (79.6)	30 (20.4)	0.995	3.68 ± 4.20	0.476
	31–40 years	78 (80.4)	19 (19.6)		4.20 ± 3.93	
	41–50 years	59 (79.7)	15 (20.3)		4.38 ± 4.25	
	>50 years	63 (78.8)	81 (20.4)		3.54 ± 4.18	
	Illiterate	20 (87.0)	3 (13.0)		2.78 ± 3.37	
Education	Primary school	11 (91.7)	1 (8.3)	<0.001	3.75 ± 3.27	0.001
	Middle school	37 (75.5)	12 (24.5)		4.04 ± 4.24	
	High school	44 (60.3)	29 (39.7)		5.73 ± 4.93	
	Intermediate	81 (81.8)	18 (18.2)		3.91 ± 3.85	
	Graduate	101 (86.3)	16 (13.7)		3.03 ± 3.78	
	Post graduate	23 (92.0)	2 (8.0)		3.56 ± 3.82	
	Agriculture	18 (72.0)	7 (28.0)		5.16 ± 3.95	
	Housewife	58 (67.4)	28 (32.6)		5.14 ± 4.48	
	Manual worker	68 (82.9)	14 (17.1)		3.70 ± 3.88	
	Not working	25 (80.6)	6 (19.4)		2.77 ± 4.08	
Occupation	Office worker	74 (85.1)	13 (14.9)	0.029	3.11 ± 3.95	0.008
	Professional	38 (92.7)	3 (7.3)		3.05 ± 3.76	
	Shopkeeper	18 (81.8)	4 (18.2)		3.68 ± 3.64	
	Student	18 (75.0)	6 (25.0)		4.92 ± 4.65	
	Yes	94 (79.0)	25 (21.0)		4.05 ± 4.13	
	No	204 (87.9)	28 (12.1)		2.92 ± 3.53	
	Don't know	19 (40.4)	28 (59.6)		8.43 ± 3.99	
History of contact with any confirmed COVID positive case	Yes	47 (87.0)	7 (13.0)	0.147	3.44 ± 3.64	0.378
	No	270 (78.5)	74 (21.5)		3.98 ± 4.21	
In quarantine during the visit	Yes	32 (88.9)	4 (11.1)	0.149	3.03 ± 3.59	0.182
	No	285 (78.7)	77 (21.3)		3.99 ± 4.19	
History of travel to other state or country	Yes	32 (26.9)	87 (73.1)	0.041	4.29 ± 4.18	0.234
	No	49 (17.6)	230 (82.4)		3.75 ± 4.12	
Presence of any symptoms	Yes	38 (23.8)	122 (76.2)	0.204	4.23 ± 4.41	0.210
	No	43 (18.1)	195 (81.9)		3.69 ± 3.94	

novelty and uncertainties associated with the disease (Asmundson and Taylor, 2020). A study based on newspaper reports also reported COVID-19 related fear leading to increased incidence of suicide (Dsouza et al., 2020).

In our study, 20.4 % of the participants were having COVID-19 related anxiety. A multi-national study by Chew et al. reported 15.7 % prevalence of anxiety among health care workers (Chew et al., 2020). A population-based online survey conducted in China reported 31.6 % prevalence of anxiety among the general population (Shi et al., 2020). China had an earlier peak and higher mortality hence the prevalence of anxiety was higher in the aforementioned period. In our study, COVID-19 related fear was associated with age, educational qualification, symptom status, history of contact and type of quarantine. COVID-19 related anxiety was found to be associated with age in other similar studies (Ahmed et al., 2020; Shi et al., 2020). Another study conducted in India showed an association of gender and age with fear of COVID-19 (Doshi et al., 2020). Females and middle-aged participants reported having more fear than males and the elderly. The result is similar to our findings.

In our study, an individual who was under institutional quarantine faced more fear than that of home quarantine. But no difference was seen for the individuals under quarantine to that who were not under quarantine. A similar result was observed by Lee et al. where no difference was observed for anxiety among individual under quarantine and without quarantine (Lee et al., 2020). Social isolation and being away from family could be the major reasons for the same (Upadhyay et al., 2020). Our study also reported a significant difference in Corona Anxiety Score when tested against gender, level of education, occupation, history of contact with COVID-19 patients, and symptom status. We could not find any study that evaluated anxiety among the symptomatic and asymptomatic general population. However, one multi-national study conducted among healthcare workers reported similar results (Chew et al., 2020). The higher prevalence of anxiety among the symptomatic individuals could be due to the chance of transmission to

their family members. Housewives were facing more anxiety and fear for COVID than any other groups. This could be due to the infodemics generated by the mass media and social media. No difference in anxiety and fear was observed for those having any underlying medical conditions to that of having no underlying medical condition. This could be because the fear of COVID-19 in itself is very high and is experienced similarly by those having or not having an underlying medical condition. COVID-19 fear seems to have affected everyone equally across the world.

4.1. Strength and limitations

This is the first study from India which has reported on the psychological experience of anxiety and fear among people who are seeking testing of COVID-19. We could achieve the sample size and used validated instruments to measure anxiety and fear due to coronavirus. However, there are a few limitations to the study. The study population were selected in a non-random manner, which may hamper the generalizability of the study. However, the proportion of the participants in each age group was similar to the screening attendees of the eligible age group. The study was conducted among the screening clinic beneficiaries. A comparator group in the general population could have provided a better comparison of the results obtained.

5. Conclusion

The present study revealed the anxiety and fear related to COVID-19 among the screening clinic beneficiaries. Age, educational status, type of quarantine, history of contact with COVID-19 positive cases were the major determinants for the COVID-19 related fear and anxiety. These are the people who are at high risk of developing clinical psychiatric disorders and hence should be targeted for regular follow up for psychiatric evaluation and management.
