### Antimicrobial susceptibility testing – EUCAST and beyond

#### P671 Adjusting EUCAST zone diameter breakpoints for *Haemophilus influenzae* on the Mueller-Hinton Fastidious media

J. Åhman\*, E. Matuschek, P.R. Rhomberg, R.N. Jones, G. Kahlmeter (Växjö, SE; North Liberty, US)

**Objectives:** The European Committee on Antimicrobial Susceptibility Testing (EUCAST) has published clinical MIC and zone diameter breakpoints for *Haemophilus influenzae* (HI). Zone diameter breakpoints were developed for the new Mueller-Hinton Fastidious media (MH-F) and have been tentative since 2010. The objective of this study was to optimise zone diameter breakpoints for HI using broth microdilution (BMD) as reference.

**Methods:** A total of 150 clinical isolates of HI were selected from the SENTRY collection (JMI Laboratories, USA). The collection was biased towards beta-lactam-resistant strains, including beta-lactamase positive and negative strains as well as strains with PBP changes (i.e. BLNAR). Disk diffusion was performed at the EUCAST Laboratory according to EUCAST methodology on Mueller-Hinton agar with 5% defibrinated horse blood and 20 mg/L beta-NAD (MH-F), using agar from two manufacturers. MIC values were determined by BMD, in Mueller-Hinton broth with 5% lysed horse blood and 20 mg/L beta-NAD (MH-F broth), at JMI Laboratories. BMD was performed on custom panels (TREK Diagnostics/Thermo Fisher Scientific) and the horse blood was lysed by repeated freezing and thawing. Data were analysed by EUCAST for antibiotic agents with both MIC and zone diameter breakpoints in EUCAST tables. Very major, major and minor errors (VME, ME and mE) were calculated.

**Results:** Correlation of inhibition zones and MIC values resulted in an adjustment of zone diameter breakpoints for HI as presented in Table 1. Several zone diameter breakpoints were increased by 1–5 mm to reduce

VMEs. New zone diameter breakpoints resulted in error rates (%) as follows (rates for old breakpoints in parenthesis): VME 1.9 (2.7), ME 1.4 (0.8) and mE 0.9 (1.4). Amoxicillin-clavulanate was not analysed due to suggested changes in both MIC breakpoints and disk potency. EUCAST has proposed revised MIC breakpoints for chloramphenicol and rifampicin, which would lower the total VME to 1.5%. The selection towards BLNAR isolates in this collection resulted in high error rates for some beta-lactam antibiotics, but the occurrence of such strains is rare among clinical isolates.

**Conclusions:** An analysis of the MIC/zone diameter correlates for *H. influenzae* resulted in adjusted zone diameter breakpoints for several antibiotics. Revised zone diameter breakpoints for HI will be published in the EUCAST Clinical Breakpoint Table v. 2.0 (January 2012).

#### P672 A comparison of MIC-based screening tests for betalactamase-negative ampicillin-resistant *Haemophilus influenzae*

E. Witherden\*, S. Tristram (Launceston, AU)

**Objectives:** Most B-lactamase negative ampicillin (AMP) resistant *H. influenzae* (BLNAR) have an N526K substitution in penicillin binding protein 3 (PBP3). Their detection is problematic because MICs cluster near the breakpoints (BPs), there is no consensus on BPs and there is poor correlation between MIC and disc diffusion (DD) zones. By strict CLSI criteria, BLNAR strains have AMP MICs  $\geq 4$  mg/L although most use the non-susceptible BP of  $\geq 2$ , consistent with the EUCAST resistant BP of  $>1$ . CLSI DD uses a 10  $\mu$ g disc even though Karpanoja (2004) showed poor correlation of zones sizes and MIC near the BP with these discs and recommended using a 2  $\mu$ g disc with better correlation, which is the disc strength used by EUCAST. Many of these problems are compounded in strains with both altered PBP3 and B-lactamase. Given that strains with altered PBP3 have reduced susceptibility to AMP, amoxicillin-clavulanate (AMC) and cephalosporins, a paradigm shift away from AMP MIC as a basis for detection is warranted. Here we compare the use of a cefotaxime (CTX) screen against current methods for the detection of strains with altered PBP3.

**Methods:** A collection of strains with and without N526K PBP3 substitutions and B-lactamase were tested by broth dilution and DD using CLSI and EUCAST methods to determine the performance of various substrates and BPs. Performance was determined using susceptibility or resistance from MIC and DD methods against the presence of N526 or N526K as the reference for genotypically defined susceptibility or resistance respectively.

Antimicrobial agent	MIC breakpoint (mg/L)		Disk content ( $\mu$ g)	Zone diameter breakpoint (mm)	
	S $\leq$	R $>$		S $\geq$	R $<$
Ampicillin	1	1	2	16	16
Cefepime	0.25	0.25	30	27 (25)	27 (25)
Cefixime	0.12	0.12	5	25 (22)	25 (22)
Cefotaxime	0.12	0.12	5	26 (22)	26 (22)
Cefpodoxime	0.25	0.5	10	26 (24)	23 (21)
Ceftibuten	1	1	30	25 (24)	25 (24)
Ceftriaxone	0.12	0.12	30	30 (27)	30 (27)
Cefuroxime	1	2	30	26 (25)	25 (22)
Cefuroxime axetil	0.12	1	30	50	26 (25)
Doripenem	1	1	10	20	20
Ertapenem	0.5	0.5	10	20	20
Imipenem	2	2	10	20 (16)	20 (16)
Meropenem (non-meningitis)	2	2	10	20	20
Ciprofloxacin	0.5	0.5	5	26 (23)	26 (23)
Levofloxacin	1	1	5	26 (21)	26 (21)
Moxifloxacin	0.5	0.5	5	25 (23)	25 (23)
Ofloxacin	0.5	0.5	5	23 (21)	23 (21)
Erythromycin	0.5	16	15	50	10 (12)

Chloramphenicol	1*	2	30	28	25
Rifampicin	0.5*	0.5*	5	18	18
Trimethoprim-sulfamethoxazole	0.5	1	1.25-23.75	23	20

\* Currently under consultation. Suggested new MIC breakpoints:  
Chloramphenicol S  $\leq 2$  mg/L  
Rifampicin S  $\leq 1$ , R  $> 1$  mg/L

Organisms	Antibiotic	Breakpoint	SN	SP	FN	FP
N526K (n=57)	AMP	CLSI / EUCAST $\geq 2 / > 1$ mg/L	32	97	42	1
	CTX	Proposed $\geq 0.06$ mg/L	67	86	20	5
versus	AMP 2ug	CLSI Karpanoja $< 16$ mm	30	97	43	1
	AMP 2ug	EUCAST $< 16$ mm	21	97	48	1
N526 (n=36)	AMP 10ug	CLSI $< 21$ mm	11	100	55	0
	CTX 0.5ug	Proposed $< 26$ mm	88	75	8	10
N526K (n=57)	AMC	CLSI $\geq 8$ mg/L	13	100	46	0
N526K# (n=10)	AMC	EUCAST $> 1$ mg/L	81	63	10	17
	CTX	Proposed $\geq 0.06$ mg/L	63	92	20	4
versus	AMC 30ug	CLSI / EUCAST $\leq 19 / < 20$ mm	0	100	53	0
	AMC 3ug	CLSI Karpanoja $< 16$ mm	51	100	26	0
N526 (n=36)	CTX 0.5ug	Proposed $< 26$ mm	90	76	6	11
N526# (n=23)						

SN = sensitivity: % of N526K strains showing resistance on test over all N526K strains.  
SP = specificity: % of N526 strains showing susceptibility on test over all N526 strains.  
FN = false negative: % of N526K strains showing susceptibility over all strains tested.  
FP = false positive: % of N526 strains showing resistance over all strains tested.  
# = strains also B-lactamase positive.

**Results:** In strains without B-lactamase, AMP MICs performed poorly in detecting N526K strains and as expected the AMP 10 µg disc performed significantly worse than the 2 µg disc even though they are calibrated to the same MIC BP. When strains with B-lactamase were included, there was a significant difference between the performance of EUCAST and CLSI AMC susceptibility because they use different BPs, and again the use of a low potency disc as recommended by Karpanoja improved performance. The proposed CTX based methods showed superior performance.

**Conclusions:** A screen using CTX as a substrate and BPs of  $\geq 0.06$  mg/L or  $\leq 26$  mm with a 0.5 µg disc, gives the best overall performance in detecting strains with N526K and is not influenced by the presence of B-lactamase. Strains with a positive screen could be reported as having “reduced B-lactam susceptibility” or further tested, depending on the requirements of individual laboratories.

#### P673 PCR screening for beta-lactamase-negative ampicillin-resistant strains of *Haemophilus influenzae*

E. Witherden\*, S. Tristram (Launceston, AU)

**Objectives:** Problems with MIC based methods and breakpoints, has prompted a move to genotypic definition and detection of B-lactamase negative ampicillin resistant (BLNAR) *H. influenzae*. Almost all BLNAR strains have an N526K substitution in penicillin binding protein 3 (PBP3) and single nucleotide specific (snp) PCR methods have been developed to interrogate the *ftsI* gene relevant to that substitution. In published methods, the design of specific reverse primers was based on the AAT (N) to AAG (K) mutation at the 1576–1578 codon seen in BLNAR strains sequenced at that time. There is relatively little published data on the evaluation of these primers, and their performance is in question as it is now recognised that in many BLNAR strains the N526K may be associated with AAA. This study aims to evaluate existing and new snp PCR primers for detecting N526K BLNAR *H. influenzae*.

**Methods:** Nineteen B-lactamase negative ampicillin susceptible (BLNAS-AAT) and 25 BLNAR (11-AAA, 14-AAG) strains were used to evaluate various primer sets on a real time PCR platform to differentiate BLNAR from BLNAS strains. Performance calculations are based on designation of an isolate as BLNAR (either by amplification or non-amplification depending on the assay) being considered a positive, with true positive status based on known genotype.

**Results:** Hasagawa’s PBP3-S PCR, designed to amplify normal BLNAS (AAT) was 100% sensitive and specific in BLNAR detection (Table 1), as all strains with AAT at position 1576–1578 of the *ftsI* gene amplified, and all those with the N526K substitution irrespective of how it was coded did not amplify. By comparison, Hasagawa’s PBP3-BLN and Nakamura’s PBP3-INT PCR assays, designed to amplify BLNAR strains, were relatively non-specific and amplified many BLNAS strains. When different Ct gates were applied, specificity was improved with corresponding loss of sensitivity due to an inability of the primers to differentiate AAT and AAA strains. However, the PBP3-BLNAR PCR of this study, used a degenerate reverse primer targeting both AAA and AAG BLNAR strains and was 100% sensitive and specific.

Author <sup>a</sup>	Primer Set	TP (n)	FN (n)	TN (n)	FP (n)	Sensitivity (%)	Specificity (%)
Hasegawa et al.	PBP3-S <sup>b</sup>	25	0	19	0	100	100
	PBP3-BLN <sup>b</sup>	21	4	5	14	84	26
Nakamura et al.	PBP3-INT <sup>b</sup>	24	1	5	14	96	26
Designed this study	PBP3-BLNAR <sup>c</sup>	25	0	19	0	100	100

<sup>a</sup> Hasegawa et al., 2003; Nakamura et al., 2009.

<sup>b</sup> These assays gated at 30 cycles consistent with original publications.

<sup>c</sup> PBP3-BLNAR assay set is gated at 20 cycles. All BLNARs amplify before 20 cycles.

TP; True positives, FN; false negatives, TN; true negatives, FP, false positives

**Conclusion:** Hasegawa’s PBP3-S or the PBP3-BLNAR PCR of this study can be reliably used to screen for N526K BLNAR strains (AAG or AAA) depending on whether amplification or non-amplification is seen as a better indicator. The other assays evaluated are unreliable due to difficulty in differentiating BLNAS strains from AAA type BLNAR strains resulting from poor primer design.

#### P674 Phenotypic detection of clinical isolates of *Haemophilus influenzae* with altered penicillin-binding protein

I.C. Perez del Molino\*, C. Garcia de la Fuente, M.C. Sanjuan, J. Agüero, L. Martinez-Martinez (Santander, ES)

**Objectives:** Resistance due to penicillin-binding protein (PBP) three alterations are difficult to demonstrate, because sequencing of the *ftsI* gene is usually impractical. We have evaluated several combinations of culture media, testing methodologies and antibiotics for detection of *Haemophilus influenzae* (H.i) with mutations in the *ftsI* gene.

**Methods:** We have studied 77 H.i in which the *ftsI* gene has been amplified by PCR sequenced: 12 strains with wild-type *ftsI* (six producing and six not producing beta-lactamase) and 65 with different mutation profiles [54 B-lactamase negative ampicillin-resistant (BLNAR) and 11 B-lactamase positive amoxicillin-clavulanate resistant (BLPACR)]. Twenty mutation patterns were observed [the two most prevalent: D350N+A502T+N526K (22%) and 350N+M377I+A502V+ N526K (18%)]. Ampicillin (AMP; 2 µg), amoxicillin-clavulanate (AMC; 20/10 µg), cefaclor (CC; 30 µg) and cephalotin (CF; 30 µg) were tested by disk-diffusion on Mueller-Hinton agar with lysed horse blood and NAD (MHF), *Haemophilus* test medium agar (HTM), and Chocolate agar (CHO). MICs of AMP, amoxicillin (AMX) and AMC were determined by E-test. Plates were incubated in 5% CO<sub>2</sub> and read at 20 and 44 hour. H.i ATCC 49766, 1021 (BLNAS) and 49247 (BLNAR) were used as control. Results were interpreted according to EUCAST or (for CF) the CA-SFM.

**Results:** MHF, HTM and CHO allowed growth at 20 hour of 76/77 (99%), 53/77 (69%) and 77/77 (100%) strains, respectively; for another 7 (9%) isolates HTM could be read at 44 hour. Similar inhibition zones and MICs were observed in MHF and CHO at 20 and 44 hour. Clinical categories for strains with wild-type *ftsI* were correct by both disk diffusion and Etest in the three media. For BLPACR with mutation *ftsI* resistance to AMC was detected by Etest for 10/11 strains in all media, and by disk diffusion in 2/11 (CHO), 1/11 (MHF) and 0/11 (HTM). For the remaining 54 strains with mutated *ftsI* the highest percentages of resistance at 20 hour were for CF-disc/CHO (81%) and CC-disc/CHO (80%). Higher resistance rates were obtained at 44 hour for CC-disc/CHO (91%), CF-disc/CHO (83%), AMX-Etest/CHO (82%), and AMX-Etest/MHF (81%). A CC-disc/CHO plus an AMX-Etest/CHO at 48 identified 93% of the isolates.

**Conclusions:** HTM does not allow adequate growth at 20 hour of a relevant number of *H. influenzae*. Detection of isolates with a mutated *ftsI* after a 20 hour incubation is best achieved using chocolate agar and CF or CC discs. Testing of AMX Etest plus CC discs in CHO agar with reading at 44 hour allows optimal detection of these isolates.

#### P675 Contemporary doxycycline and tetracycline susceptibility testing using CLSI and EUCAST criteria for Gram-positive pathogens: results from SENTRY programme

R. Jones\*, M. Stilwell (North Liberty, US)

**Objectives:** To assess the potency and intermethod agreement for doxycycline (DOXY) and tetracycline (TETRA) susceptibility (S) testing breakpoints when tested against SENTRY Antimicrobial Surveillance Program isolates of Gram-positive species (13 188 isolates) collected worldwide.

**Methods:** All organisms were cultured in 2010 with S testing by CLSI M07-A9 (2009) methods and results interpreted by CLSI M100-S11 (2011) and EUCAST (2011) criteria for TETRA and DOXY. A total of 9012 *S. aureus* (SA; 44.9% MRSA); 2325 *S. pneumoniae* (SPN); and

1851 beta-haemolytic streptococci (BHS; 42.8% *S. pyogenes* [SPYO]) were analyzed for S and cross-S rates by the two international breakpoint sets. The tetracycline's S breakpoint MIC (mg/L) criteria differ (CLSI/EUCAST, respectively) as follows: for SA ( $\leq 4/\leq 1$ ), for SPN ( $\leq 2/\leq 1$ ) and for BHS ( $\leq 2/\leq 1$ ). All quality control tests were within published CLSI ranges.

**Results:** S rates for DOXY were consistently greater than TETRA for each interpretive criteria used and for each pathogen group analyzed. The CLSI DOXY/TETRA S rates (EUCAST rates) were as follows: 99.2/94.2 (96.7/93.2)% for MSSA; 96.2/91.2 (93.5/88.1)% for MRSA; 75.3/73.2 (73.8/73.0)% for SPN; 81.2/80.3 (80.2/79.6)% for SPYO; and 15.7/14.6 (15.4/14.6)% for *S. agalactiae* (SAGA). DOXY (MIC90, 0.5 mg/L) was generally two- to four-fold more potent than TETRA (MIC90, 2 mg/L) vs. MRSA. Use of TETRA-S results to predict DOXY-S was excellent (>99.9–100.0%) for SA regardless of breakpoints used, as were predicted for SPN (99.8–100.0%), SPYO (99.6–99.9%) and SAGA (100.0%); errors usually higher applying the lower EUCAST breakpoints. Concerns persist that strains of staphylococci and streptococci having TET-R mechanisms could be categorized by CLSI as S (MICs at 2 or 4 mg/L) by current breakpoints e.g. 2.7% of MRSA tested against DOXY.

Organism/Antimicrobial (no. tested)	Tetracycline (no. isolates)					
	CLSI category <sup>a</sup>			EUCAST category <sup>b</sup>		
	Susceptible	Intermediate	Resistant	Susceptible	Intermediate	Resistant
<b>Doxycycline</b>						
MSSA (4,966)						
Susceptible	4,677	41	208	4,630	18	155
Intermediate	0	0	33	1	1	84
Resistant	0	0	7	0	0	77
<b>MRSA (4,046)</b>						
Susceptible	3,689	32	172	3,564	117	103
Intermediate	0	0	128	0	1	38
Resistant	0	0	25	1	0	222

a. CLSI (2011) criteria for tetracyclines: susceptible at  $\leq 4$  mg/L, and resistant at  $\geq 16$  mg/L. b. EUCAST (2011) criteria for tetracyclines: susceptible at  $\leq 1$  mg/L, and resistant at  $> 2$  ( $\geq 4$ ) mg/L.

**Conclusions:** CLSI and EUCAST interpretive criteria for tetracyclines (TETRA and DOXY) remain discordant, but each determines DOXY to have wider spectrum against four Gram-positive pathogen species and that TETRA-S can accurately predict DOXY-S (99.93–99.86% across 13 188 isolates). Moreover, molecular test-confirmed mechanisms appear highly probably among CLSI-susceptible (MICs, 2 or 4 mg/L) strains requiring international harmonization, to also include other tetracycline or-like agents and systematically applying pharmacodynamic principles.

#### P676 Antimicrobial susceptibility testing of *Listeria monocytogenes* with EUCAST breakpoints: a multi-laboratory study

K. Bowker, J. Åhman, O. Natås, I. Nissan, P. Littauer, E. Matuschek\* (Bristol, UK; Växjö, SE; Stavanger, NO; Jerusalem, IL; Copenhagen, DK)

**Objectives:** The European Committee on Antimicrobial Susceptibility Testing (EUCAST) has recently proposed clinical MIC breakpoints based on epidemiological cut-off (ECOFF) values for *Listeria monocytogenes*. The objective of this study was to establish corresponding zone diameter breakpoints based on the EUCAST Mueller-Hinton Fastidious medium (MH-F) in a multi-laboratory study and to validate the use of a gradient test for MIC determination using broth microdilution (BMD) as reference.

**Methods:** A total of 129 clinical isolates of *L. monocytogenes* were collected from five sites (Denmark, Israel, Norway, Sweden and UK) and antimicrobial susceptibility testing was performed against ampicillin, benzylpenicillin, erythromycin, meropenem and trimethoprim-sulfamethoxazole. Disk diffusion was performed at all sites on Mueller-Hinton agar with 5% defibrinated horse blood and 20 mg/L beta-NAD (MH-F) according to EUCAST methodology. Media and disks from different manufacturers were used at the various sites, and both commercial and in-house prepared MH-F plates were tested. MIC determination was performed with BMD (TREK

Diagnostics/Thermo Fischer Scientific) and Etest (bioMérieux) at Southmead Hospital, Bristol, UK. BMD was performed on custom panels containing MH broth with 5% lysed horse blood (by repeated freezing and thawing) and 20 mg/L beta-NAD (MH-F broth) and Etest was performed on MH-F media. All data were analysed by EUCAST.

**Results:** All *L. monocytogenes* isolates grew well on the MH-F medium. The correlation between BMD and Etest MICs was excellent, with 99.4% of Etest values within  $\pm 1$  dilution of the BMD values. Zone diameter breakpoints were established (Table 1) in such a way that the MIC ECOFF corresponded to the zone diameter distribution ECOFF. Slightly different inhibition zones were obtained at the sites, depending on differences between manufacturers of media and disks.

#### EUCAST Clinical MIC breakpoints for *Listeria monocytogenes* and corresponding zone diameter breakpoints.

Antibiotic agent	MIC breakpoint (mg/L)		Disk content ( $\mu$ g)	Zone diameter breakpoint (mm)	
	S $\leq$	R $>$		S $\geq$	R $<$
Ampicillin	1	1	2	16	16
Benzylpenicillin	1	1	1 unit	13	13
Erythromycin	1	1	15	25	25
Meropenem	0.25	0.25	10	26	26
Trimethoprim-sulfamethoxazole	0.03	0.03	1.25-23.75	29	29

**Conclusion:** MH-F is a suitable medium for antimicrobial susceptibility testing of *L. monocytogenes* for both gradient tests and disk diffusion. As a result of a multi-laboratory study, we present zone diameter correlates to currently proposed EUCAST clinical MIC breakpoints.

#### P677 Susceptibility testing of ten antibiotics against *Corynebacterium* spp. determined by broth microdilution, Etest and EUCAST disc diffusion methods

C. Salas\*, C. Karlsson, A. Akerlund, C. Rodríguez-Mirones, E. Matuschek, L. Martínez-Martínez, G. Kahlmeter (Santander, ES; Växjö, Linköping, SE)

**Objective:** EUCAST has not yet defined breakpoints for clinical categories of clinically relevant antibiotics for *Corynebacterium*. In this study, the performance of three methods for susceptibility testing of five *Corynebacterium* species has been evaluated.

**Methods:** The activity of Penicillin G (PNG), ciprofloxacin (CIP), moxifloxacin (MOX), gentamicin (GEN), vancomycin (VAN), clindamycin (CLI), tetracycline (TET), linezolid (LIN), rifampin (RIF) and cotrimoxazole (SXT) against 60 *Corynebacterium* spp. (12 isolates from each of the following species: *C. striatum*, *C. amycolatum*, *C. jeikeium*, *C. urealyticum* and *C. pseudodiphtheriticum*) were determined using BMD (broth microdilution with cation-adjusted Mueller-Hinton broth with 3% laked horse blood), or on solid medium (Mueller-Hinton agar with 5% defibrinated horse blood and 20 mg  $\beta$ -NAD/L) by Etest and disk diffusion (disk contents as defined by EUCAST). BMD was performed in one lab in Spain, Etest in one lab in Sweden and disk diffusion in three labs (one in Spain, two in Sweden). Plates were incubated at 35°C in air (microdilution) or 5% CO<sub>2</sub> (agar media) and read after 16–20 hour or, in case of insufficient growth, after another 24 hour.

**Results:** Microdilution results could be read after 16–20 hour incubation for all species but *C. pseudodiphtheriticum*. Etest MICs and inhibition zones could be determined at 16–20 hour for all 12 *C. striatum*, but incubation for 40–44 hour was needed to a varying degree for the other species.

Essential agreement (EA, that in  $\pm 1$  dilution) between microdilution and Etest was: PNG and VAN (96.7%), GEN (91.7%), RIF (88.3%), LINZ (81.7%), CIP (76.7%), MOX (71.7%), CLI (66.7%); TET (65%), and SXT (55.0%). For species, EA were: *C. urealyticum* (95.8%), *C. jeikeium* (85.8%), *C. striatum* (80.8%), *C. jeikeium* (73.3%) and *C. pseudodiphtheriticum* (66.6%).

Correlation between BMD MICs and inhibition zones was good, i.e. isolates with high MICs had small inhibition zones and vice versa. Correlation between inhibition zones from three labs was over all good, even when zones had to be read after another 24 hour.

**Conclusions:** Growth of *Corynebacterium* spp. on MH-F differs between species and it is sometimes necessary to incubate plates for longer than the standard 16–20 hour. There is a good correlation between BMD and Etest for penicillin G, vancomycin and gentamicin. More studies on MIC/zone correlation on species-identified *Corynebacterium* must be performed before breakpoints (or ECOFFs) can be established.

#### **P678** Antimicrobial resistance of *Corynebacterium ulcerans* and *C. pseudotuberculosis*

A. Berger\*, J. Trcek, M. Hogardt, S. Hörmansdorfer, J. Rau, A. Sing (Oberschleißheim, DE; Stockholm, SE; Stuttgart, DE)

**Background:** Zoonotic *Corynebacterium ulcerans* and *C. pseudotuberculosis* strains are increasingly recognized as causative agents for human infections presenting as classical or cutaneous diphtheria. Besides prompt diphtheria antitoxin therapy in cases showing classical signs of pharyngeal diphtheria, they require specific antibiotic treatment both to eradicate the pathogens in patients and to prevent infection among contacts. Benzyl penicillin and erythromycin are recommended for specific antibiotic treatment, although only very few antimicrobial susceptibility data are available.

**Methods:** In this study, 74 isolates of toxigenic and non-toxicogenic clinical isolates of *C. pseudotuberculosis* (n = 49) and *C. ulcerans* (n = 25) from humans and animals collected in the National Consiliary Laboratory for Diphtheria from 2001 to 2011 were tested. Minimal inhibitory concentration (MIC) of benzyl penicillin, ceftriaxone, erythromycin, tetracycline, clindamycin, and ciprofloxacin were determined using the Etest system (McFarland standard 0.5; Mueller Hinton blood agar supplemented with 5% sheep blood). In the absence of standardized breakpoints, antibiotic susceptibility was determined by using the CLSI criteria for broth microbouillon dilution susceptibility testing for *Corynebacterium* species.

**Results:** Benzyl penicillin, erythromycin and ciprofloxacin seem to be highly active substances in both potentially toxigenic *Corynebacterium* species. All *C. pseudotuberculosis* strains were completely susceptible to all examined antibiotics. All tested *C. ulcerans* strains were susceptible to penicillin and ceftriaxone, while 80% of the *C. ulcerans* strains were resistant against clindamycin. Moreover, one tox-positive *C. ulcerans* strain isolated from a 56-year-old patient with diphtheria like disease was multi-resistant to erythromycin, clindamycin and tetracycline, but susceptible to penicillin.

**Conclusions:** In Germany penicillin and erythromycin can still be recommended for specific antibiotic treatment of diphtheria caused by *C. ulcerans* or *C. pseudotuberculosis*. Antibiotic resistance against first line drugs may occur, but multi-drug resistant strains are rarely observed. Although clindamycin is not a first-line drug for diphtheria therapy, it should be noted that *C. ulcerans* is not surely covered by this antibiotic. Our data emphasize the necessity of accurate species identification and susceptibility testing of potentially toxigenic *Corynebacterium*.

#### **P679** Comparison of the *Clostridium difficile* agar and Brucella agar for the antimicrobial susceptibility testing of *Clostridium difficile*

J.O. Kang\*, H. Pai, J. Kim, J.H. Hwang, T.Y. Choi (Guri, Seoul, KR)

**Background:** As the name *Clostridium difficile* implies, culture of this pathogen is not easy, and the isolation rate could be affected by specimen treatment method, culture media, or quality of anaerobic condition, etc. Active growth is especially critical when rapid and abundant growth of the microorganism is highly needed, such as antimicrobial susceptibility testing. At a preliminary study, the growth

speed and size of colonies were better in *C. difficile* (CD) agar than on the Brucella agar, so we compared the two media for the antimicrobial susceptibility testing (AST) of *C. difficile* isolates.

**Methods:** The two media used were supplemented (Hemin + VitK1) Brucella agar containing 5% sheep blood, and CD agar (*Clostridium difficile* Agar Base, Oxoid, UK) containing taurocholate (0.1%) and 7% horse blood. The six antibiotics (clindamycin, metronidazole, moxifloxacin, piperacillin-tazobactam, rifaximin, and vancomycin) were added to CD and Brucella media to make AST agar plates containing various concentrations of antibiotics. We used inoculums of 1 McFarland turbidity standard instead of 0.5 standard for the ordinary AST. A total of 171 isolates of *C. difficile* were inoculated with 36-pin replicator to the AST agar plates and incubated in anaerobic chamber for 48 hours.

**Results:** Table 1.

Antimicrobials	Media & number	MIC (ug/ml)			% Resistance		
		Range	MIC50	MIC90	S	I	R
Clindamycin	CD(138)	1.5–256	≥256	≥256	11.6	21.0	67.4
	B(139)	1–256	≥256	≥256	10.8	20.9	68.3
Metronidazole	CD(117)	0.06–8	0.5	4	100.0	0.0	0.0
	B(117)	0.25–4	1	2	100.0	0.0	0.0
Moxifloxacin	CD(164)	0.5–128	16	32	42.1	0.6	57.3
	B(160)	0.5–128	16	64	42.5	0.6	56.9
Piperacillin-Tazobactam	CD(169)	4–64	16	32	99.4	0.6	0
	B(165)	1–64	16	16	99.4	0.6	0
Rifaximin	CD(159)	0.0015–8	0.015	> 8	No standardized breakpoint		
	B(150)	0.0007–8	0.007	> 8	No standardized breakpoint		
Vancomycin	CD(171)	1–8	4	8	100	0	0
	B(165)	0.125–4	1	2	100	0	0

**Conclusion:** Though the growth speed was faster and size of the *C. difficile* colonies was bigger on the enriched *C. difficile* media than the Brucella media, the antimicrobial susceptibility testing results by % resistance were not significantly different by the media themselves. Also the MIC distributions of the six antibiotics were not significantly affected by the media, but MIC50 and MIC90 of the vancomycin was two fold higher in the CD media.

#### **P680** The Brucella blood agar for disc diffusion antimicrobial susceptibility testing – reproducibility results for *Clostridium difficile* ATCC 700057

U.S. Justesen, L.T. Erikstrup\*, T.K. Danielsen, E. Matuschek, G. Kahlmeter (Odense, Aarhus, DK; Växjö, SE)

**Objectives:** The EUCAST disk diffusion antimicrobial susceptibility testing method for fastidious organisms is based on the Mueller-Hinton fastidious agar (MH-F). In a pilot study, most anaerobic bacteria did not grow well enough on MH-F to permit antimicrobial susceptibility testing. We decided to investigate whether or not the Brucella Blood Agar supplemented with hemin and vitamin K (BBA), recommended for antimicrobial susceptibility testing of anaerobic bacteria with gradient strips, might also be suited for disk diffusion testing of *C. difficile*.

**Methods:** *C. difficile* ATCC 700057 was tested with Etest (bioMérieux, Craaponne, France) gradient strips (piperacillin/tazobactam, meropenem, metronidazole, clindamycin, penicillin G, vancomycin, moxifloxacin and tigecycline) on BBA (Becton Dickinson, Heidelberg, Germany) according to the manufacturer's instructions. The corresponding disk (EUCAST disk strength) was included on each plate (Oxoid, Basingstoke, UK). All tests were repeated twelve times. I.e. twelve plates were incubated day 1 at 37°C in an anaerobe environment (10% CO<sub>2</sub>, 10% H<sub>2</sub> and 80% N<sub>2</sub>) for 24 hours with each antimicrobial agent to assess intra-day variability. This was repeated day 2 to assess inter-day variability. Etest results were compared with the acceptable ranges for ATCC 700057 (reference

Antimicrobial agent	Inhibition zone diameters (mm) for <i>Clostridium difficile</i> ATCC 70007		
	Day 1 and 2 at 37°C		35°C
	(10% CO <sub>2</sub> , 10% H <sub>2</sub> and 80% N <sub>2</sub> )		(10% CO <sub>2</sub> , 10% H <sub>2</sub> and 80% N <sub>2</sub> )
Piperacillin-tazobactam (30.6 microg)	27.5 (25.7-28.3)	26.9 (25.2-28.3)	26.5 (25.7-27.3)
Meropenem (10 microg)	29.7 (28.7-30.1)	31.4 (30.5-32.1)	31.5 (30.9-31.8)
Metronidazole (5 microg)	38.7 (37.4-40.0)	38.6 (37.6-39.7)	38.9 (38.2-40.0)
Clindamycin (2 microg)	10.3 (9.6-10.8)	10.8 (10.4-11.1)	11.8 (10.8-12.3)
Penicillin G (1 U)	6.0 (5.0) NO ZONE	8.3 (5.9-9.0)	6.4 (5.0-8.2)
Vancomycin (5 microg)	23.1 (22.5-23.3)	23.0 (22.6-23.7)	23.5 (23.1-24.3)
Moxifloxacin (5 microg)	25.5 (24.5-26.3)	25.4 (24.9-25.8)	25.1 (24.4-25.9)
Tigecycline (15 microg)	34.5 (34.0-34.9)	34.5 (33.4-35.1)	35.5 (34.7-36.2)

agar dilution testing, CLSI guideline M11-A7). Twelve plates with disks only were also incubated at 5% CO<sub>2</sub> (10% H<sub>2</sub> and 85% N<sub>2</sub>) at 37°C and another twelve plates at 35°C with 10% CO<sub>2</sub>, 10% H<sub>2</sub> and 80% N<sub>2</sub>.

**Results:** All Etest results were within acceptable ranges and the intra- and inter-day variability was ≤1 dilution step. Zone diameter mean values and ranges are shown in the table.

The greatest difference between two mean values was 3.2 mm and the greatest range was 3.3 mm. There were small effects of the changes in CO<sub>2</sub> levels and temperature on the inhibition zone diameters.

**Conclusion:** Both intra- and inter-day reproducibility was excellent with disk diffusion on BBA with the eight tested antimicrobial agents. Studies to decide whether this can be repeated with clinical isolates and whether disk diffusion can distinguish resistant isolates from wild type *C. difficile* are in progress.

#### P681 Disc diffusion antimicrobial susceptibility testing of *Clostridium difficile*

L.T. Erikstrup\*, T.K. Danielsen, V. Hall, K. Fuursted, G. Kahlmeter, U.S. Justesen (Aarhus, Odense, DK; Cardiff, UK; Växjö, SE)

**Objectives:** The clinical significance of *Clostridium difficile* and the emergence of decreased susceptibility, especially towards metronidazole, have highlighted the importance of antimicrobial susceptibility testing of *C. difficile* and the importance of having a simple testing method for the routine laboratory. The aim of our study was to evaluate disk diffusion for antimicrobial susceptibility testing of *C. difficile* by comparing disk diffusion results with Etest gradient strips.

**Methods:** Consecutive clinical and toxigenic isolates of *C. difficile* (n = 211) were collected from patients with diarrhoea hospitalised at Aarhus University Hospital (n = 110) in 2008 and from Odense University Hospital (n = 101) in 2010. Furthermore, ten clinical isolates of *C. difficile* from the University Hospital of Wales with reduced susceptibility to either metronidazole or vancomycin, were included. The isolates were tested with Etests (metronidazole, vancomycin, clindamycin, and moxifloxacin) (bioMérieux, Craponne, France) and the following corresponding disks (microgram) were used: metronidazole (5), vancomycin (5), clindamycin (2), and moxifloxacin (5) (Oxoid, Basingstoke, UK). All tests were performed on Brucella Blood Agar supplemented with hemin and vitamin K (Becton Dickinson, Heidelberg, Germany). The plates were incubated at 37°C

Antimicrobial agent	Disk diffusion zone diameter (mm)		Etest MIC (mg/L)		ECOFF ≤
	Median (range) Danish isolates	Median (range) Welsh isolates	Median (range) Danish isolates	Median (range) Welsh isolates	
Metronidazole	37 (23-45)	12 (9-14) <sup>1</sup>	0.094 (0.023-1)	2 (1.5-3) <sup>1</sup>	2
Vancomycin	23 (19-28)	18 (15-19) <sup>1</sup>	0.5 (0.25-1.5)	2 (1.5-3) <sup>1</sup>	2
Clindamycin	11 (6-17)		3 (0.38-256)		16
Moxifloxacin	24 (6-28)		0.75 (0.38-32)		4

1. n=4 for isolates with reduced susceptibility towards metronidazole 2. n=6 for isolates with reduced susceptibility towards vancomycin.

in an anaerobe environment (10% CO<sub>2</sub>, 10% H<sub>2</sub> and 80% N<sub>2</sub>) for 24 hours. The zone diameter was read at 100% inhibition.

**Results:** Zone diameter (median and range) and MIC (median and range) for the Danish and the Welsh isolates are shown in the table. The majority of the Danish isolates had MICs below the ECOFF (i.e. MICs representative of the wild type), whereas the Welsh isolates were selected because of known reduced susceptibility to metronidazole or vancomycin. For each MIC value, the inhibition zones varied from 1 to 9 mm (the majority exhibiting 5–6 mm variation).

**Conclusion:** There was a good agreement between MIC values and zone diameters for the antimicrobial agents tested. Disk diffusion was able to detect reduced susceptibility towards metronidazole and vancomycin. Disk diffusion is an option for antimicrobial susceptibility testing of *C. difficile*. Zone diameter breakpoints can now be established by EUCAST.

#### P682 EUCAST standardised disc diffusion methodology for *Campylobacter jejuni* and *C. coli*

E. Matuschek\*, K. Veldman, A. Hakanen, S. Bengtsson, M. Lehtopolku, D. Mevius, G. Kahlmeter (Växjö, SE; Lelystad, NL; Turku, FI)

**Objectives:** Antimicrobial susceptibility of *Campylobacter* spp. is often performed with disk diffusion at clinical microbiological laboratories, even though standardised methodologies and interpretive criteria are lacking to various extents. The European Committee on Antimicrobial Susceptibility Testing (EUCAST) is in the process of establishing clinical MIC breakpoints for *Campylobacter* spp. The objective of this study was to investigate if EUCAST methodology can be used as a reproducible disk diffusion test for *C. jejuni* and *C. coli*. **Methods:** Disk diffusion according to EUCAST methodology was performed at three sites (FI, NL and SE). Preliminary testing was performed on 15 *C. jejuni* and 15 *C. coli* from NL with known MIC values (broth microdilution, ISO 20776-1:2006), including isolates with and without phenotypic resistances. Additional testing was performed on 17 *C. jejuni* and 12 *C. coli* from FI. All isolates were tested in triplicate for ciprofloxacin 5 µg, erythromycin 15 µg and tetracycline 30 µg. Preliminary testing included different media (unsupplemented MH agar vs. MH agar with 5% defibrinated horse blood and 20 mg/L beta-NAD, MH-F), incubation temperatures (35, 37, 39 vs. 41°C) and length of incubation (24 vs. 44 hour). A McFarland 0.5 inoculum and incubation in plastic containers (microaerobic environment) were used. Because of the inhibition zone halo effect obtained when tilting plates, inhibition zones were recorded as the smallest and largest appearing zone.

**Results:** The proposed disk diffusion methodology is presented in Table 1. Both *C. jejuni* and *C. coli* grew best on MH-F plates at 41°C. Swarming was avoided by drying plates before inoculation. *C. jejuni* grew well after 24 hour of incubation whereas some *C. coli* required 44 hour before inhibition zones could be read. All isolates with MICs above the epidemiological cut off (ECOFF) were identified as non-wild type also with the disk diffusion test, irrespective of whether the smallest or largest inhibition zone was used. The results were reproducible within and between the sites.

#### EUCAST proposed disk diffusion methodology for *Campylobacter jejuni* and *Campylobacter coli*.

Medium	Mueller-Hinton agar with 5% defibrinated horse blood and 20 mg/L β-NAD (MH-F) (Plates should be dried before incubation to avoid swarming, either at room temperature (20-22°C) over night or at 35°C for 1-2 hours.)
Inoculum	McFarland 0.5
Incubation	Microaerobic environment 41°C 24 hours ± 30 minutes ( <i>C. coli</i> with non-sufficient growth after 24 h incubation are re-incubated immediately and read after totally 40-48 h incubation.)
Reading of zones	EUCAST standard reading instructions: Read MH-F plates from the front with the lid removed illuminated with reflected light. Zone edges should be read at the point of complete inhibition as judged by the unaided eye.

**Conclusion:** Disk diffusion testing of *C. jejuni* and *C. coli* on the EUCAST MH-F media at three sites resulted in reproducible inhibition

zones, separating wild-type isolates from those with MICs above ECOFF. Further evaluation of the methodology is currently performed at several laboratories in Europe.

### P683 Development of an agar dilution susceptibility testing method for *Actinomyces* species

M. Wootton\*, V. Hall, V.E. Daniel, R. A. Howe (Cardiff, UK)

**Objectives:** Actinomycosis is a chronic disease characterized by abscess formation, tissue fibrosis and draining sinuses, caused by *Actinomyces* species. These bacteria are normal colonising organisms of the oropharynx, gastrointestinal tract and female genital tract, requiring a break in the mucous membranes to invade deeper body structures and cause illness. Infections often develop in tissue adjacent to mucous membranes; oral and cervicofacial infections are most common but any body-site can be infected and, rarely, disseminated spread can occur. Susceptibility testing of anaerobes in general, and in actinomycetes in particular, is problematic due to growth requirements and slow growth. Currently, only CLSI have described an anaerobe susceptibility testing method. This study aims to compare combinations of media, inoculum size, blood and additives on growth & quality of MIC cut off to inform the development of a EUCAST method.

**Methods:** Forty-five *Actinomyces* species of varied morphology were used; *A. israelii*, *A. gerencseriae*, *A. graevenitzi*, *A. meyeri*, *A. naeslundii*, *A. odontolyticus*, *A. urogenitalis*, *A. turicensis*, *A. cardiffensis*, *A. funkei*, *A. europaeus*. Agar dilution (AD) (CLSI) with Penicillin was performed using McFarland 1, 2 and 4 inoculum densities. Combinations of media, blood and additives used were: Brucella agar (BA) + 5% laked sheep blood (LSB) + haemin (h) + vitamin K (vk) (CLSI), Mueller Hinton agar (MHA) + 5% defibrinated horse blood (DHB) + NAD (EUCAST-F), plus CLSI and EUCAST method variants; 1- BA + DHB + h + vk, 2- BA + 5% LSB + NAD + h + vk, 3- BA + 5% DHB + h + vk, 4- MHA + LSB + NAD + H + vk, 5- MHA + DHB + NAD + h + vk. Quality of growth and cut off were compared. MICs for each combination were compared to CLSI method.

**Results:** Quality of growth and cut offs were compared (Table 1). Growth and cut off quality was good to poor when using MHA but good to excellent for BA. It was considered that CLSI method resulted in accurate MICs. Percentage agreement to CLSI MICs was best (98%) in combination 3 and worst in EUCAST-F (66%).

	Quality of growth	Quality of cut off	% MIC agreement with CLSI	% MIC disagreement with CLSI
CLSI	Excellent	Excellent	N/A	N/A
EUCAST	Good	Fair	66	34
1	Good	Good	96	4
2	Good	Good	97.8	2.2
3	Very good	Very good	98	2
4	Poor	Very poor	90.1	9.1
5	Poor	Poor	74	26

**Conclusions:** The CLSI method using Brucella agar and 5% laked sheep blood gives the best quality growth and cut offs for *Actinomyces* species using penicillin. However DHB can be substituted with little loss to growth and cut off quality or MIC accuracy.

### P684 Comparison of neo-sensitabs (ROSCO) tablets with paper discs (OXOID) for antimicrobial susceptibility testing of Gram-negative clinical isolates according to the EUCAST recommendations

H. Rodriguez-Villalobos\*, A. Boeras (Brussels, BE)

**Objectives:** The EUCAST disk diffusion method was developed using 6 mm paper disc but Neo-sensitabs (ROSCO) have 9 mm diameter: Are

Neo-sensitabs tablets equivalent for the proposed by the EUCAST? The aim of this study was to validate the complete exchangeability between neo-sensitabs and paper discs among clinical Gram-negative microorganisms.

**Methods:** One hundred and seventy-five clinical Gram-negative isolates were included: 150 Enterobacteriaceae (including ESBLs and AmpC isolates) and 25 Gram negative non fermenters (including multi-resistant *P. aeruginosa*). Strains were tested in parallel for 18 antimicrobial drugs (paper discs and neo-sensitabs) According to the EUCAST disk diffusion method for antimicrobial susceptibility testing (V 1.1 2010). MICs were determined by microdilution (BD Phoenix System). Four quality control test were included: *P. aeruginosa* (ATCC27853), *E. coli* (ATCC25922), *E. coli* (ATCC35218), *K. pneumoniae* (ATCC 700603). To minimize the inoculum effect, paper discs and tables were tested into the same plate. Plates were read by the SIRscan system (i2a). To allow comparison, zones around OXOID disks with diameters below 9 mm were read as 9 mm. Results were analysed by Passing-Bablok regression and Pearson's correlation.

**Result:** No differences were observed in the inhibition diameter zone between neo-sensitabs and oxoid paper discs (see table 1). Overall percentage of 0.14% of minor error and 0.14% of major error was observed. Good correlation between the diameter of inhibition zones and MIC values were observed with both discs (<3% of discrepancies).

antimicrobial	PB (95% CI)		PC	discrepancies (%)
	intercept	slope		
ampicillin 10 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,999	0
amoxicillin-clavulanic acid 20-10 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,999	0
giperacillin-hydrocloridam 30-6µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,999	0
cefazolin 30 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,999	0
Cefazone 30µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,992	0
Cefazone 15µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,999	0
Ceftriaxone 30 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,992	0
cefepime 30µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,999	0
Achroman 30 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,992	0
Moxiparam 15µg	3,299 (0,999 to 5,393)	1,000 (0,999 to 1,000)	0,997	0
ertapenem 10 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,979	0
gentamicin 10 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,979	0
Tobramycin 10 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,991	3 minor, 1 major
Amikacin 30 µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,962	0
retifurankan 150µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,993	1 very major
co-trimoxazole 1:15-23:75	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,995	0
Levofloxacin 5µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,992	0
Ciprofloxacin 5µg	0,999 (0,999 to 0,999)	1,000 (1,000 to 1,000)	0,995	0

PB: Passing-Bablok test; PC: Pearson's correlation.

**Conclusion:** Our results showed excellent correlation between ROSCO neosensitabs and OXOID paper disk for Enterobacteriaceae antimicrobial sensitivity testing (EUCAST method) for all antibiotics tested. Overall percentage of 0.29% of error was observed. The majority of discrepancies concerning tobramycin.

### P685 Effect of manganese in test media on in vitro tigecycline susceptibility of *Enterobacteriaceae* and *Acinetobacter baumannii*

J. Veenemans\*, J.A.J.W. Kluytmans, J.W. Mouton, P. van Keulen (Breda, Nijmegen, NL)

**Objectives:** Several studies reported that in vitro bacterial susceptibility to tigecycline varies by test media and test conditions. This variability may be due to differences in manganese (Mn) concentration between test media, resulting in falsely elevated MICs when using standard media. We assessed the effect of Mn concentration in test media on MICs of tigecycline, using of five species of Enterobacteriaceae and *Acinetobacter baumannii*.

**Methods:** For each species, antimicrobial susceptibility was tested for five strains and an ATCC control strain, and MICs were determined by broth microdilution (BMD) and by Etest on freshly prepared media. We used two commercial test media with standardised low Mn concentration (Synthetic Amino Acid Medium (0 mg/L Mn) or Isosensitest agar (2 mg/L Mn), supplemented with increasing quantities of MnCl<sub>2</sub>, resulting in medium Mn concentrations ranging

(with two-fold incremental steps) between 0.001 and 1.024 mg/L and between 2 and 1.024 mg/L, for broth BMD and Etests, respectively.

**Results:** For both BMD and Etests, the effect of manganese on MICs was negligible for medium concentrations below 8 mg/L. MIC values increased substantially, however, when medium manganese concentrations exceeded 64 mg/L (figure). Compared to values measured on a Mn free medium, MICs were doubled at medium Mn concentrations of 220, 240, 200, 230 and 136 mg/L for *E. coli*, *K. pneumoniae*, *C. freundii*, *E. cloacae* and *A. baumannii*, respectively (BMD). For *P. mirabilis*, this effect seemed less pronounced (figure). Independent of Mn concentrations, MICs determined by Etest were higher than those determined by BMD (geometric mean difference 0.8 doubling dilution [95% CI: 0.7–0.9]).

**Conclusions:** In vitro bacterial susceptibility to tigecycline is influenced by manganese concentrations in the test medium. Susceptibility testing should be performed on a medium with standardised low manganese content (<8 mg/L). Due to poor reproducibility of its mineral content, the Mueller-Hinton medium may be unsuitable for this purpose. Because Mn concentrations in human serum (0.8–1.3 µg/L) are substantially lower than those found in standard susceptibility test media, Mn is unlikely to interfere with tigecycline antibacterial activity under physiological conditions. Lastly, the effect of medium Mn concentration could not explain the differences in MICs observed with Etest and broth microdilution, and further studies should clarify the causal factors involved.

**P686** New EUCAST breakpoint for detection of antimicrobial susceptibility in *Helicobacter pylori*

T. Alarcon\*, A. Somodevilla, M. Espinola, M. Lopez-Brea (Madrid, ES)

**Background:** CLSI had breakpoints for *H. pylori* since 1999 but only for clarithromycin. Other breakpoints proposed by previous studies, by BSAC or breakpoint for other bacteria are used for studying antimicrobial activity of other antimicrobial agents. EUCAST group from ESCMID (European Committee on Antimicrobial Susceptibility Testing) has proposed in March–April 2011 breakpoint for all antimicrobials used to treat *H. pylori*.

The aim of this study was to determine the resistance percentage in *H. pylori* clinical isolates using EUCAST breakpoint.

**Methods:** Susceptibility to amoxicillin (Amx), tetracycline (Te), metronidazole (Met), clarithromycin (Cla), rifampicin (Rif) and levofloxacin (Lev) in 300 *H. pylori* clinical isolates from 1 March 2009 to 30 October 2011. Biopsies were cultured in selective and non

selective media. Strains identified by colony and Gram stain morphology, and urease, oxidase and catalase positive test. Antimicrobial susceptibility was performed by E-test and EUCAST breakpoint. According to previously used Breakpoints resistance to Amx was considered when >2 mg/L, to Met when ≥8 mg/L, to Cla when >0.5 mg/L, to Rif when >32 mg/L, and to Te and Lev when >4 mg/L. According to EUCAST Breakpoint resistance to Amx was considered when >0.12 mg/L, to Met when >8 mg/L, to Cla when >0.5 mg/L and to Te, Rif and Lev when >1 mg/L.

**Results:** The percentage of strains susceptible, intermediate or resistant with each breakpoint used is in the table.

		Amx	Cla	Rif	Lev	Te	Met
With old breakpoint	S %	93,6	45,5	97,6	93,3	100	63,9
	I %	0,7	1,3	0,4			
	R %	5,7	53,2	2	6,7		36,1
With EUCAST breakpoint	S %	87	45,5	70	93,3	99,7	64,6
	I %		0,7				
	R %	13	53,8	30	6,7	0,3	35,4

**Conclusions:** Levofloxacin resistance did not change with the use of the new breakpoint. Clarithromycin, metronidazole and tetracycline susceptibility changed only in a few strains. However, new breakpoint affected seriously amoxicillin and rifampicin resistance, with 13.6% of the strains being resistant to amoxicillin and 30.3% to rifampicin.

**P687** Susceptibility of *Actinomyces* species to potential therapeutic antimicrobials

M. Wootton\*, V. Hall, V.E. Daniel, R.A. Howe (Cardiff, UK)

**Objectives:** Actinomycosis is a chronic disease characterized by abscess formation, tissue fibrosis and draining sinuses, caused by *Actinomyces* species. These bacteria are normal colonising organisms of the oropharynx, gastrointestinal tract and female genital tract, requiring a break in the mucous membranes to invade deeper body structures and cause illness. Infections often develop in tissue adjacent to mucous membranes; oral and cervicofacial infections are most common but any body-site can be infected and, rarely, disseminated spread can occur. Current treatment of actinomycosis is penicillin or amoxicillin. However, these infections are usually polymicrobial requiring treatment which covers all organisms. This study aims to determine the susceptibilities of *Actinomyces* species to 11 antimicrobials thought to offer alternative therapies.

**Methods:** Two hundred and eighty-seven *Actinomyces* species of varied morphology were used; *A. israelii*, *A. gerencseriae*, *A. graevenitzi*, *A. meyeri*, *A. naeslundii*, *A. odontolyticus*, *A. urogenitalis*, *A. turicensis*, *A. cardiffensis*, *A. funkei*, *A. europaeus*, *A. georgiae*, *A. neuii*, *A. timonensis*, *A. oricola*, *A. hominis*, *A. johnsonii*, *A. oris*, *A. radingae*, *A. honkongensis*. MICs were determined for penicillin (P), amoxicillin (A), ceftriaxone (CX), erythromycin (E), clindamycin (CD), clarithromycin (CM), meropenem (M), rifampicin (R), tetracycline (T), doxycycline (D) and ciprofloxacin (CP) using agar dilution (CLSI).

**Results:** MIC50, MIC90, MIC range, percentage resistance, percentage susceptibility are shown in table 1. R was most active with MIC50 and MIC90 of 0.004 and 0.008 respectively. Only a few isolates of *A. neuii*, *A. radingae*, *A. turicensis* and *A. funkei* had MICs

	MIC Range	MIC50	MIC90	% R
P	0.015-1	0.06	0.25	6.6%
A	0.008-2	0.25	0.5	0%
CX	0.015-4	0.12	0.5	N/A
E	0.008->64	0.06	0.25	N/A
CD	0.008->64	0.12	0.5	4.2%
CM	0.004->64	0.03	>64	N/A
M	<0.002-0.5	0.008	0.12	0%
R	<0.002-0.12	0.004	0.008	N/A
D	0.03-32	0.5	1	N/A
T	0.12-64	0.5	2	N/A
CP	0.25-128	16	32	N/A

>0.03. M was very active against all species, exhibiting MIC50/MIC90 of 0.008/0.12. P, A, CX, E, CD, D, T were all active against most species. All isolates of *A. urogenitalis* exhibited  $\geq$ MIC90 MICs to all antimicrobials except R, M and CX. All 10 *A. funkei* showed A MICs  $\geq$ 0.25. CP & CM were least active against all species. Using EUCAST BPs, no resistance was found to occur with A & M, whilst 6.6% and 4.2% resistance was found in penicillin & clindamycin respectively.

**Conclusions:** Rifampicin and meropenem were most active, with meropenem showing efficacy against all species. Some species showed association with resistance to certain antimicrobials therefore species determination is important when choosing therapy.

## Community-acquired infections

### P688 Time trends in length of hospital stay, post-discharge mortality, and risk of readmission among patients hospitalised for community-acquired bacteraemia in Denmark, 1995–2006

M. Sogaard\*, M. Nørgaard, R.W. Thomsen, H.C. Schönheyder (Aalborg, DK)

**Objective:** During the past decades the length of hospital stay for patients with bacteraemia has declined substantially. The continuing decline raises concerns that increasing numbers of patients may be discharged prematurely before their condition has been fully stabilized, leading to more adverse events in the period early after discharge. We examined changing trends over calendar time in length of stay, post-discharge mortality, and hospital readmission among patients discharged alive after a hospitalization with community-acquired bacteraemia.

**Methods:** Population-based cohort study of patients who were discharged alive after hospitalization with community-acquired bacteraemia, 1995–2006. Outcome measures were length of stay, 30-day post-discharge mortality and all-cause 30-day readmission. We used Cox regression analysis to examine changes in hazard ratios (HRs) for 30-day post-discharge mortality and readmission over four 3-year calendar periods, adjusting for age, sex, and comorbidity.

**Results:** Of the 4492 patients who were hospitalized with community-acquired bacteremia between 1995 and 2006, 597 (13.3%) died during hospitalization and 3895 (86.7%) were discharged alive. The mean length of hospital stay with community-acquired bacteremia decreased from 18.5 days in 1995 to 15.5 days in 2006, corresponding to a 16% relative reduction over this period. There was a slight decline in 30-day post-discharge mortality from 7.1% in the reference period 1995–1997 to 6.0% in 2004–2006. Adjusted 30-day post-discharge mortality HRs were 0.71 (95% CI 0.49–1.04) in 1998–2000, 0.88 (95% CI 0.63–1.25) in 2001–2003, and 0.84 (95% CI 0.59–1.19) in 2004–2006, when compared with 1995–1997. The proportion of patients who were readmitted to hospital within 30 days of discharge was 16.4% in 1995–1997, 17.9% in 1998–2000, 19.8% in 2001–2003, and 19.1% in 2004–2006, corresponding to adjusted HRs of readmission of 1.10 (95% CI 0.89–1.38) in 1998–2000, 1.21 (95% CI 0.98–1.50) in 2001–2003, and 1.17 (95% CI 0.95–1.45) in 2004–2006, compared with 1995–1997.

**Conclusion:** We found a decrease in length of stay for patients hospitalized with community-acquired bacteraemia between 1995 and 2006, and an increase over time in the proportion of patients who were

readmitted within 30 days after discharge. However, 30-day post-discharge mortality tended to decrease over time

### P689 Current management of patients hospitalised with complicated skin and soft tissue infections across Europe (2010–2011): assessment of clinical practice patterns and real-life effectiveness of antibiotics (REACH study)

J. Garau\*, F. Blasi, J. Medina, M. Ávila, K. McBride, H. Ostermann on behalf of the REACH study group

**Objectives:** Data on the management of hospitalised complicated skin and soft tissue infections (cSSTIs) are limited. REACH (NCT01293435) was a retrospective, observational cohort study aiming to provide data on current clinical management of moderate to severe cSSTIs in European hospitals.

**Methods:** Data were collected from 129 sites in ten European countries. The population comprised patients  $\geq$ 18 years, hospitalised between March 2010 and February 2011 with a cSSTI requiring intravenous antibiotic treatment. Variables were collected via an electronic Case Report Form.

**Results:** The total population included 1996 patients; mean age 60.6 years; 57.8% male, 1154 from university hospitals, 842 from non-university hospitals. Based on information in the patient records, 78.0% (n = 1557) of patients reported  $\geq$ 1 co-morbidity or receiving relevant medications in the 3 months prior to hospitalisation (64.3%; n = 1284); 29.9% (n = 596) had received antibacterials/antivirals. One-quarter of infections (25.6%; n = 510) were recurrences and 10% (n = 199) were nosocomial. Microbiological diagnosis was available for 51.1% (n = 1020) of patients, revealing Gram-positive cocci in 68.9% (n = 703) (9.9% [n = 101] methicillin-resistant *Staphylococcus aureus*, 26.9% [n = 274] methicillin-sensitive *S. aureus*) and Gram-negative bacilli in 33.6% (n = 343) of patients. Once hospitalised, patients were usually treated on Day 1 (81.6% [n = 1629] empirically and 17.3% [n = 346] with a specific therapy). The most common antibiotic agent used, alone or in combination, was amoxicillin-clavulanate (29.9%; n = 596) followed by piperacillin-tazobactam (18.2%; n = 364). Treatment failure (defined as a need for antibiotic change) was reported in 46.6% (n = 930) of patients (mortality rate 3.4%). Failure of initial therapy was more common in patients with co-morbidities vs those without (49.3%; n = 767 vs 37.1%; n = 163), in university vs non-university hospitals (49.7%; n = 573 vs 42.4%; n = 357) and in patients with nosocomial vs non-nosocomial cSSTI (53.3%; n = 106 vs 45.9%; n = 824). Surgery was required by 37% (n = 739) of patients. Initial treatment with piperacillin-tazobactam was associated with a failure rate of 49.6% vs 31.7% for amoxicillin-clavulanate. Outcomes varied by country; treatment failure varied between 55.6% in Italy and 33.8% in the Netherlands.

**Conclusions:** These data give a current view of management of cSSTIs in European hospitals in 2011 and provide evidence of a high failure rate of initial antibiotic therapy.

### P690 Health economic analysis of current clinical management of patients hospitalised with complicated skin and soft tissue infections across Europe (2010–2011) (REACH study): use of resources and consequences of treatment failure

H. Ostermann\*, F. Blasi, J. Medina, E. Pascual, K. McBride, J. Garau on behalf of the REACH study group

**Objectives:** Data describing the economic burden of hospitalised complicated skin and soft tissue infections (cSSTIs) in Europe are limited. REACH (NCT01293435) was a large, retrospective, observational study collecting empirical data on current management strategies and economic burden of cSSTI in European hospitals.

**Methods:** Data collected from 129 sites in ten European countries between March 2010 and February 2011 were recorded using an

Resource	Treatment failure		
	cSSTI N=1996*	With n=930*	Without n=1066*
Length of hospitalisation, days, mean (SD; median)	19.3 (22.0; 13.0) (n=1944)	24.5 (24.6; 16.0) (n=910)	14.7 (18.3; 10.0) (n=1034)
Admitted to ICU at any time, n (%)	130 (6.5)	91 (9.8)	39 (3.7)
Time in ICU, days, mean (SD; median)	9.7 (13.5; 4.5) (n=118)	11.4 (15.2; 5.0) (n=79)	6.2 (8.6; 3.0) (n=39)
Surgical intervention after cSSTI diagnosis, n (%)	739 (37.0)	387 (41.6)	352 (33.0)
Blood pressure support during hospitalisation, n (%)			
Fluid resuscitation	217 (10.9)	152 (16.3)	65 (6.1)
Vasopressors	75 (3.8)	68 (7.3)	7 (0.7)
Invasive procedures	13 (0.7)	7 (0.8)	6 (0.6)
Isolation required, n (%)	106 (5.3)	71 (7.6)	35 (3.3)
Parenteral nutrition, n (%)	89 (4.5)	68 (7.3)	21 (2.0)
Duration of parenteral nutrition, days, mean (SD; median)	14.8 (33.6; 7.0) (n=88)	17.0 (38.2; 7.0) (n=67)	7.5 (4.7; 6.0) (n=21)
Acute renal failure necessitating renal replacement therapy, n (%)	41 (2.1)	34 (3.7)	7 (0.7)
Duration of renal failure, days, mean (SD; median)	12.1 (32.5; 4.0) (n=37)	13.4 (34.8; 4.5) (n=32)	3.6 (3.7; 2.0) (n=5)
Complications during hospitalisation, n (%)			
Septic shock	55 (2.8)	51 (5.5)	4 (0.4)
Home-based care, n (%)	282 (14.1)	162 (17.4)	120 (11.3)

\*Patient numbers refer to patients for whom data on the variable(s) in question were available.

electronic Case Report Form. Patients were aged  $\geq 18$  years and hospitalised with a cSSTI requiring IV antibiotics.

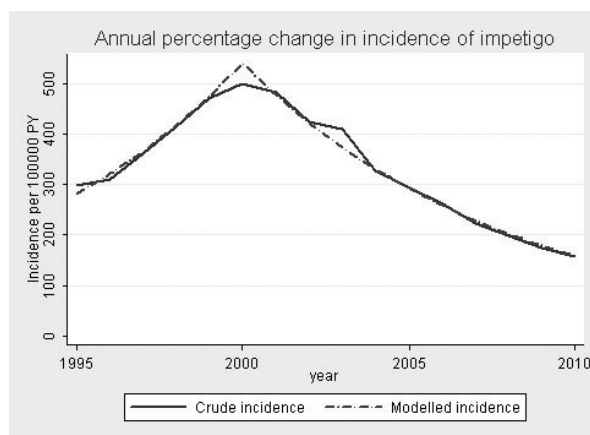

**Results:** The analysis population comprised 1996 patients (mean age: 60.6 years). Patients had a mean duration of initial hospital stay of 18.0 days. The most common types of lesion were abscess (23.1%) or fasciitis (21.6%), surgical intervention was required by 37% (n = 739) of patients and 6.5% (n = 130) were admitted to the intensive care unit (ICU), where the mean duration of stay was 9.7 days. Treatment failure, defined as a need for antibiotic change, occurred in 46.6% of patients (n = 930). An analysis of resource use in patients with vs without treatment failure is shown in Table 1. Notable differences between the two groups were: overall duration of hospitalisation (>9 days longer in patients with failure), admission to ICU (9.8% vs 3.7%), requirement for surgical intervention (41.6% vs 33.0%), parenteral nutrition (7.3% vs 2.0%) and home-based care after discharge (17.4% vs 11.3%). Patients hospitalised again after initial discharge (recurrence) (8.6%; n = 172) remained in hospital longer compared with patients with an initial infection (36.1 vs 17.3 days), and were more likely to be admitted to ICU (9.3% vs 5.1%), to require surgical intervention (52.9% vs 34.6%) and to require home-based care after discharge (24.4% vs 14.7%). Patients developing complications (septic shock) during treatment (2.8%; n = 55) had longer overall hospitalisation (37.9 vs 18.8 days), and were more likely to be admitted to ICU (63.6% vs 4.9%), require parenteral nutrition (36.4% vs 3.6%) and develop acute renal failure necessitating renal replacement therapy (23.6% vs 1.4%) than patients without complications. Overall mortality was 3.4% (n = 68).

**Conclusions:** The REACH study revealed that resource utilisation was increased in patients with cSSTIs who experienced treatment failure compared with those patients who did not.

#### P691 A hidden epidemic of impetigo – trends from the THIN database of primary care consultations

L.J.F. Shallcross\*, A.C. Hayward, A.M. Johnson, I. Petersen (London, UK)

**Objectives:** Outbreaks of impetigo have been described in Northern Europe but information on the incidence and natural history of disease in the general population is limited. Impetigo is primarily a disease of childhood caused by infection with either staphylococci or Group A streptococci. To investigate the burden of disease in primary care we examine time trends in the incidence of impetigo over the past two decades using data from the Health Improvement Network (THIN) primary care database.

**Methods:** We included patients registered with 419 General Practices between 1995 and 2010, equivalent to 30 400 person years of follow-up. Time trends in the incidence of impetigo were estimated adjusted for gender, age and deprivation score. We used segmented regression analysis (<http://surveillance.cancer.gov/joinpoint/>) to quantify change in the annual incidence of infection.

**Results:** Ninety five thousand six hundred and seventy-eight people had at least one recorded episode of impetigo. The annual incidence of infection increased from 299 (95% CI 284, 316) per 100 000 PY in 1995 to 498 (95% CI 488–509) per 100 000 PY in 2000 and then steadily decreased to 156 (95% CI 149, 163) per 100 000 PY in 2010. Two distinct time trends were identified with an annual percent change (APC) in incidence of +13.9% (95% CI: 9.9, 18.1) between 1995 and 2000, and –11.6% (95% CI: –10.8, –12.3) between 2000 and 2010.

**Conclusions:** We have identified a previously un-described epidemic of impetigo in the UK which peaked in 2000 and was followed by a rapid and unexplained decline over the following 10 years. Population based studies from Norway and Denmark report similar trends, suggesting an epidemic of impetigo may have spread across Europe between 2000 and 2004. Factors driving this surge and subsequent decline in impetigo are unclear and are likely to reflect changes in the pathogenicity of the causative organism, host factors or antibiotic prescribing practices.

Surveillance systems based on primary care patient records have potential to identify otherwise hidden epidemics. More routine use should be made of such data to facilitate timely investigation of epidemic trends and guide public health action.

#### P692 Multiplex PCR for the rapid diagnosis of skin/soft tissue and bloodstream infections

L. Novak-Frazer\*, R. Rautema-Richardson, D. Denning, P. Bowyer (Manchester, UK)

**Objectives:** To assess the diagnostic performance of the SeptiFast multiplex PCR tool (Roche Diagnostics) for organism detection and identification in skin/soft tissue and bloodstream infections as compared to standard current diagnostic practice. In addition, qualitative factors such as the ease of use, throughput and hands-on time were assessed.

**Methods:** Patients with features of acute (<72 hours) skin/soft tissue infection (n = 8) or suspected sepsis (n = 9) were enrolled in this exploratory diagnostic study. Parallel samples (wound swabs or 1.5 mL whole blood) were taken for PCR and conventional culture. Samples for PCR were processed immediately after sampling while conventional cultures were run in parallel. The time from patient sampling to final result was recorded.

**Results:** There was good correlation of results between the SeptiFast kit and skin swab cultures for 7/9 patients but generally PCR detected more species compared to culture. In two other cases, the PCR and swab culture results disagreed. In one case, PCR results indicated

coagulase-negative *Staphylococcus* spp. while culture indicated *Staphylococcus aureus* and in the other case, PCR indicated *Enterococcus faecalis* while culture indicated mixed coliforms. The predominant bacterial species detected were coagulase-negative *Staphylococcus* spp. (4/9), *Proteus mirabilis* (3/9) and *Enterococcus faecalis* (3/9). In addition, the fungi *Candida albicans* (2/9), *C. glabrata* (1/9) and *Aspergillus fumigatus* (3/9) were detected. Anaerobes detected by culture in one sample were not detected by PCR due to kit limitations. Of the patients with suspected sepsis, all were found to be negative by both PCR and 48 hour blood culture. The time from the start of sample processing to final report was between 5–7 hour for PCR as compared to conventional blood/swab culture which was 24–48 hour.

**Conclusions:** The agreement between the PCR and the standard wound swab cultures was generally good. Despite the identification profile of the PCR technique being limited to 25 bacterial and fungal species, more organisms were identified in skin/soft tissue samples by PCR than by culture. The multiplex PCR and blood culture results agreed fully, with the added benefit that the PCR results were available within a few hours of sampling. This multiplex PCR technique is a more rapid approach to identification of sepsis than blood culture although some development is required to extend its use for the diagnosis of other infection

**P693** Assessment of two early-response outcome measures in a phase 2 clinical trial of the pleuromutilin BC-3781 in acute bacterial skin and skin structure infections

W. Prince, F. Obermayr, C. Lell, A. Das, G. Talbot\* (Vienna, AT; San Francisco, Anna Maria, US)

**Background:** Clinical trials must use validated outcome measures that are relevant to patients and physicians but also to regulators worldwide. A Phase 2 trial of BC-3781, a novel IV and orally administered pleuromutilin, in acute bacterial skin and skin structure infections (ABSSSI) allowed an assessment of three different measures of clinical success: (i) FDA's proposed Early Response outcome measure (success: no increase in area, length or width of skin lesion erythema vs. baseline with a temperature  $\leq 37.6^{\circ}\text{C}$  at Study Day 3); (ii) the Foundation for the National Institutes of Health (FNIH) proposed Early Response outcome measure (success:  $\geq 20\%$  decrease in skin lesion erythema vs. baseline); and (iii) the traditional test-of-cure (TOC) clinical response (i.e., success being complete resolution of ABSSSI or improvement such that no additional therapy needed).

**Methods:** This randomized, double-blind trial compared 100 mg BC-3781 (BC-100) vs. 150 mg BC-3781 (BC-150) vs. 1 g vancomycin (VA), each given IV q12h for 5–14 days, for treatment of ABSSSI caused by a gram-positive pathogen. Eligibility required the presence of burn or surgical site/traumatic wound infection, cellulitis, or abscess with cellulitis. Also required were  $\geq 2$  signs of systemic inflammation (e.g., fever, elevated WBC count) or the presence of a significant

		Treatment Group		
		BC-100	BC-150	VA
Outcome Measure	Analysis Population			
Early Response - FDA (Day 3)	ITT	85.7% (60/70)	83.1% (59/71)	80.3% (53/66)
	CE	88.3% (53/60)	88.9% (48/54)	86.3% (44/51)
Early Response FNIH (Day 3)	ITT	74.3% (52/70)	70.4% (50/71)	71.2% (47/66)
	CE	76.7% (46/60)	75.9% (41/54)	76.5% (39/51)
Clinical Response (TOC)	ITT	85.7% (60/70)	83.1% (59/71)	81.8% (54/66)
	CE	90.0% (54/60)	88.9% (48/54)	92.2% (47/51)

systemic or local co-morbidity (e.g., diabetes mellitus). Early Response success or failure was determined programmatically using erythema length/width and temperature as recorded daily during the study. Clinical response was determined at TOC. Analyses were conducted in the ITT and Clinically Evaluable (CE) populations.

**Results:** The success rates for each outcome measure are shown in the Table. Early Response success rates were numerically lower than TOC success rates. Some patients who met Early Response criteria for "success" were a Clinical Response failure at TOC; notably, depending on the definition of Early Response, greater or lesser numbers of Early Response "failures" were a success at TOC (data not shown).

**Conclusions:** An Early Response analysis can be useful to clinicians and regulators in determining the rapidity of response of ABSSSI to antibacterial therapies; however, in this study a change in the definition of the Early Response measure had a substantial impact on the observed response rate with resultant implications for study sample size as well as for correlation with the outcome assessed at TOC.

**P694** Safety and efficacy of PTK 0796 (omadacycline) as treatment of complicated skin and soft tissue infection

G.J. Noel\*, M. Draper, H. Hait, S.K. Tanaka (Boston, US)

**Background:** Having completed phase 1 and 2 clinical programs, PTK 0796, an aminomethylcycline, broad-spectrum antibacterial agent active against all the leading causes of complicated skin and soft tissue infection (cSSTI) including methicillin-resistant *Staphylococcus aureus* (MRSA), has begun assessment in phase 3 trials.

**Methods:** A randomized (1:1), controlled, evaluator-blind, stratified by infection type, trial comparing PTK 0796 (100 mg iv; 300 mg po QD) to linezolid (LZD; 600 mg iv/po BID) was designed to establish non-inferiority between treatment arms regarding efficacy based on clinical assessment immediately after (EOT), and 10–17 days after (TOC) completing therapy in the intent-to-treat (ITT) and clinically evaluable (CE) populations. Subjects were given iv therapy initially with an option to transition to oral formulations of either PTK 0796 or LZD. Moxifloxacin (400 mg QD) was added to LZD treatment if infection due to Gram-negative bacteria was suspected.

**Results:** The trial was administratively stopped to address alignment with a new FDA guidance on ABSSSI, after 143 of the planned 790 subjects were enrolled. Subjects enrolled at six sites with 140 and 127 qualifying for the ITT and CE populations, respectively. A total of 44 (65%) PTK 0796 and 48 (67%) LZD subjects had cellulitis and 14 (21%) PTK 0796 subjects and 14 (19%) LZD subjects (19%) had wound infections. The mean and median duration of therapy were 10.1 and 10.0 days for PTK 0796 and 9.9 and 9.5 days for LZD subjects. Clinical success in each treatment arm is shown in the table.

MRSA was the most frequently isolated pathogen and success in the CE population occurred in 96.2% (25/26) with PTK 0796 and 93.5% (29/31) with LZD treatment. There were comparable numbers of treatment emergent adverse events (56;82.4% in PTK 0796 and 58;80.6% in LZD) and study-drug related adverse events (41;60.3% in PTK 0796 and 41;56.9% in LZD) across treatment arms. The most common adverse events reported involved the gastrointestinal system and the most common of these was nausea, reported by 18 PTK 0796 and 19 LZD treated subjects.

	PTK 0796	LZD	Difference (95% CI)
	success/total (%)	success/total (%)	
Intent-to-treat (ITT) population			
EOT	61/68 (89.7%)	66/72 (91.7%)	-2.0% (-12.4, 8.5)
TOC	58/68 (85.3%)	64/72 (88.9%)	-3.6% (-15.5, 8.3)
Clinically Evaluable (CE) population			
EOT	59/60 (98.3%)	64/67 (95.5%)	2.8% (-4.0, 9.6)
TOC	58/60 (96.7%)	64/67 (95.5%)	1.1% (-6.5, 8.8)

**Conclusions:** Results of this phase 3 trial experience are consistent with those of the phase 2 clinical program that also involved patients with cSSTI and showed comparable efficacy and overall safety/tolerability between PTK 0796 and LZD. Although stopped before meeting planned enrolment goals, results in the CE population met the

protocol-defined criteria of a 10% margin to conclude non-inferiority between treatments.

**P695** **The burden of community-acquired gastroenteritis in hospitalised adults at a London teaching hospital: a retrospective analysis**

M. Mirfenderesky\*, H. Wilkin-Crowe, T. Planche, A. Breathnach (London, UK)

**Objectives:** Acute gastroenteritis is a common condition affecting approximately one in five adults over a year period. A small minority subsequently require hospitalisation however these cases are not well defined. We wish to characterise the burden of community acquired gastroenteritis (CAG) requiring hospitalisation at our institution.

**Methods:** We performed a retrospective analysis of all adult (16≥) positive stool samples received between February 2008 and February 2009 at a 950 bed teaching hospital in South London. Results of positive stool samples, patient demographics and admission details were gathered from electronic patient record systems. Samples received within 3 days of admission were classified as community acquired. All stools samples were processed for the presence of Salmonella, Shigella, Campylobacter and *E. coli* 0157 according to standard laboratory procedures. Samples from patients aged >65 were processed for *C. difficile* using an ELIZA toxin test (Premier®) and confirmed with a latex agglutination (Microgen®) and a cytotoxicity assay. Subsequent tests for Vibrios, Aeromonas, Yersinia, *C. difficile*, ova & parasites were performed where appropriate. All samples excluding those from GPs were processed for norovirus using RT-PCR (Cepheid®). Investigations for other viruses were not routinely performed.

**Results:** During the 13 month period 816 enteric pathogens were isolated of which 77% (631) were community acquired. Thirty percent of these community cases (190) were admitted. In decreasing order of frequency these were norovirus (32%), *C. difficile* (29%), *Campylobacter* (24%), *Salmonella* (9%), *Giardia lamblia* (3%) and *Shigella* (2%). The average age of admitted cases was 56 compared with 43 in those that were not admitted. The average length of stay was 9 days with a loss of 1612 bed days over the 13 month period. Individuals with *C. difficile* and norovirus comprised 1169 bed days between them.

**Conclusion:** One hundred and ninety patients were admitted with pathogen confirmed CAG. Patients with norovirus and *C. difficile* comprised 61% of all admitted CAG. These patients were older with more prolonged admissions than other causes of CAG. Between them they comprised a 72% share of the total number of bed days occupied by cases of CAG. This has important infection control implications as without sufficient isolation facilities and stringent infection control practices these infections can result in nosocomial outbreaks with devastating consequences for hospitals.

**P696** **Comparison of risk factors for Campylobacter jejuni, Campylobacter coli and Campylobacter foetus isolated in France**

E. Bessede\*, L. Labadie, S. Bakiri, P. Lehours, F. Megraud (Bordeaux, FR)

**Objective:** *Campylobacter* spp. are recognized as the leading cause of bacterial enteric infections worldwide but little information is known on the risk factors of the main two species found: *Campylobacter jejuni* and *Campylobacter coli*.

**Material and Methods:** Our laboratory is the National Reference Center for Campylobacters in France and receives isolates from a network of laboratories from all over the country. The epidemiological data obtained from 2003 to 2010 were used to compare the characteristics of these infections. During this period all isolates were identified by using both phenotypic methods and molecular methods

except in 2010 when MALDI-TOF mass spectrometry was used. A univariate and a multivariate analysis were performed on the characteristics of the main species found. All statistical analyses were performed using SPSS V 11.5.

**Results:** In total, 22 245 isolates were identified; 7138 isolated from hospital laboratories and 16 842 from private laboratories. The repartition for the main species was *C. jejuni* (17 575, 79.3%), *C. coli* (3382, 15.2%) and *Campylobacter fetus* (873, 3.9%). Eight other species represented only 1.5% of the cases. Globally, Campylobacter infection had a sex ratio of 1.2, was observed at all ages but predominated in children 0–10 years, and was more common during summertime. Concerning the thermotolerant Campylobacters, the results of the multivariate analysis showed that *C. jejuni* was associated with summertime (May–September) while *C. coli* was associated with an occurrence at higher age (mean age 7 year older) and with a trip abroad ( $p < 0.01$ ). In comparison to thermotolerant Campylobacters, *C. fetus* was associated with an occurrence at a higher age, with specimens other than stools, partly blood culture and with a more frequent hospitalization.

**Conclusion:** Comparison of the characteristics of *C. jejuni* and *C. coli* infection on a large number of strains allowed us to show that the epidemiology of these two closely related enteropathogens are not strictly superposed, while the well known characteristics of *C. fetus* infection were observed.

**P697** **Travel-related outbreak of multi-resistant Shigella sonnei among Dutch water polo players**

J.E. Stalenhoeef\*, D.W.L. Scoop, E.C.J. Claas, I. van Disseldorp, F.P. Kroon, E.J. Kuijper (Leiden, NL)

**Objectives:** *Shigella sonnei* is an uncommon cause of foodborne outbreak of gastro-enteritis in The Netherlands. Empirical treatment, if necessary, consists of trimethoprim-sulfamethoxazole or ciprofloxacin. We report a travel related outbreak of multiresistant *S. sonnei* in water polo players who returned from Tblisi, Georgia.

**Methods:** In September 2011 a dutch male water polo team joined a European tournament in Tblisi, Georgia. During their 5 day stay, 14 out of 15 team members and support staff (mean age 30, range 18–57) had acute onset of fever and gastrointestinal symptoms with watery diarrhea and abdominal cramps (attack rate 93%). Three players were hospitalized in Georgia, where they were empirically treated with ciprofloxacin and IV fluids for 2 days. The other patients did not receive antibiotics. Faecal specimens were submitted for conventional cultures of enteropathogens and for molecular testing of 15 common gastrointestinal pathogens by multiplex PCR (xTag GPP, Luminex Molecular Diagnostics). *S. sonnei* strains were biochemically identified using API 20E and agglutination (Remel Europe Ltd., Dartford, UK). The Georgian National Center for Disease Control investigated the source of the outbreak. No cases were reported among hotel staff or other guests and no food contamination could be documented as source. Further spread of disease was prevented by advice on personal hygiene. No secondary cases were found among household contacts.

**Results:** Stool samples from 11 patients revealed the presence of *S. sonnei*, which was also found by multiplex PCR performed on seven available stool samples. PCR also identified the presence of heat-labile enterotoxin producing (LT) *Escherichia coli* in three of seven samples investigated and *G. lamblia* in one sample. Three cases had negative stool cultures, but the specimens were obtained 3 weeks later, after recovery of symptoms. Antibiotic sensitivity testing revealed that all isolates were resistant to trimethoprim-sulfamethoxazole, nalidixic acid, tetracycline, norfloxacin, ciprofloxacin and erythromycin and sensitive to amoxicillin and 3rd and 4th generation cephalosporins.

**Conclusion:** We report an outbreak of severe gastroenteritis caused by multidrug resistant *S. sonnei*, concomitant with LT-producing *E. coli*. Secondary cases were not found and a source could not be identified.

**P698 National enteric pathogens laboratory-based surveillance network (UEPLA) in Turkey, July 2007–June 2011**

B. Levent\*, R. Gulesen, H. Kalaycioglu, F. Sezen, A. Gozalan on behalf of the UEPLA Participants

**Objectives:** The National Enteric Pathogens Laboratory-based Surveillance Network (UEPLA) was established in Turkey in 2007. The general aim of the network was to convey a laboratory based surveillance to promote sharing of information between participating laboratories and the reference laboratory, Refik Saydam National Public Health Agency, to facilitate typing of selected gastrointestinal pathogens and their antimicrobial resistance.

The aim of this study is to describe the isolates sent by the participating laboratories to national reference laboratory in the framework of UEPLA in Turkey between July 2007 and June 2011.

**Methods:** The UEPLA includes 34 laboratories nationwide. The selected microorganisms were *Salmonella*, *Shigella*, *Campylobacter* and verotoxigenic *Escherichia coli* (VTEC). Isolates were confirmed by using biochemical methods, serotyped, and screened for antimicrobial resistance using disc diffusion test. Data was collected by Open-Office 3.0 programme and analyzed by SPSS 15.0 software package, CHICAGO, IL, RSHMB 9887381.

**Results:** Totally 2526 isolates were analyzed between July 2007 and June 2011. The distribution of confirmed microorganisms by years are given in Figure 1.

Among the 1676 *Salmonella* isolates, 1101 (65.7%) were *Salmonella enteritidis*; 102 (6.1%) *S. typhimurium* and 96 (5.7%) *S. paratyphi* B. The most common *Shigella* serogroup was *Shigella sonnei* (n = 420, 68.3%). Of the 231 isolates of *Campylobacter* 160 (69.3%) were *C. jejuni* and 65 (28.1%) were *C. coli*. *Salmonella* isolates were resistant to nalidixic acid (n = 200, 11.9%) and ampicillin (n = 160, 9.6%). *Shigella* isolates were resistant to streptomycin (n = 436, 70.9%), tetracycline (n = 241, 39.2%), trimethoprim/sulfamethoxazole (n = 236, 38.4%), and ampicillin (n = 206, 33.5%). None of the *E. coli* strains were verotoxigenic.

**Conclusions:** UEPLA results demonstrate that the *S. enteritidis*, *S. sonnei* and *C. jejuni* are most prevalent gastrointestinal pathogens in Turkey. Highest resistance percentages were observed to nalidixic acid in *Salmonella*, and streptomycin in *Shigella*. The number of participating laboratories and the interested pathogens are expected to increase in years. The UEPLA will strengthen the collaboration between participating laboratories and the reference laboratory.

**P699 Detection of *Vibrio cholerae* and *Acanthamoeba* species from same natural water samples collected from different cholera endemic areas in Sudan**

S. Shanani\*, H. Abd, I. Hedenström, A. Saeed, G. Sandström (Huddinge, SE)

**Background:** *Vibrio cholerae* O1 and *V. cholerae* O139 infect humans, causing the diarrheal and waterborne disease cholera, which is a worldwide health problem. *V. cholerae* and the free-living amoebae *Acanthamoeba* species are present in aquatic environments, including drinking water and it has shown that *Acanthamoebae* support bacterial

growth and survival. Recently it has shown that *Acanthamoeba* species enhanced growth and survival of *V. cholerae* O1 and O139. Four hundred Water samples from different cholera endemic areas in Sudan were collected during cholera outbreak and 48 were collected during no cholera outbreak from the same areas with the aim to detect both *V. cholerae* and *Acanthamoeba* species from same natural water samples by polymerase chain reaction (PCR).

**Methods:** samples were examined by PCR to detect *Vibrio cholerae* toxin gene (toxA) and *Acanthamoeba* 18S RNA gene.

**Result:** For the first time both *V. cholerae* and *Acanthamoeba* species were detected in same natural water samples collected from different cholera endemic areas in Sudan. Eighty-nine percent of detected *V. cholerae* was found with *Acanthamoeba* in same water samples. Other samples during no cholera outbreak showed that 11 (13%) water samples contained *Acanthamoeba* only and no *V. cholerae* detected.

**Conclusions:** The current findings disclose *Acanthamoebae* as a biological factor enhancing survival of *V. cholerae* in nature.

**P700 Cross-sectional survey on seroprevalence of leptospirosis in Austria**

W. Poeppl\*, M. Orola, S. Tobudic, A. Faas, G. Mooseder, P. Winter, H. Burgmann (Vienna, AT)

**Study design:** Explorative nationwide cross-sectional seroprevalence survey.

**Objective:** To assess the prevalence of infections with *Leptospira* in Austria and the occupational exposure of military personnel. In addition, information on possible risk factors for exposure to *Leptospira* was obtained

**Methods: Setting:** Serum samples and demographical data were obtained from adults volunteering for international military employments between April and June 2009 at the Military Hospital Vienna.

**Participants:** Four hundred healthy adults from all federal states of Austria between 18 and 57 years were included.

**Variables:** Antibody titres against *Leptospira* were determined by microscopic agglutination test using a panel of cultures with 14 different serovars. Samples with titres  $\geq 1:100$  were considered positive. Variables surveyed included professional soldier or civilian, previous foreign military assignments, residential area, occupational animal contact and regular outdoor activities

**Statistical Methods:** Differences in proportions were tested using Fisher's exact test. A two-sided p value  $< 0.05$  was considered statistically significant.

**Results: Participants:** Eighteen participants were excluded from the statistical analysis because of impurities in the serum. The remaining 382 participants consisted of 166 professional soldiers and 216 civilians.

**Main results:** Overall, 88 (23%) individuals tested positive in serologic screening. The proportion of seropositive samples was

Serovars	Frequency	Percentage (%)
Canicola	63	71.6
Hardjo	45	51.1
Copenhageni	19	21.6
Bratislava	11	12.5
Tarassovi	10	11.4
Pyrogenes	4	4.5
Saxkoebing	2	2.3
Pomona	1	1.1
Grippotyphosa	1	1.1
Bataviae	1	1.1
Wolfii	0	0
Australis ballico	0	0
Hebdomadis	0	0
Autumnalis Aka	0	0

significantly lower among professional soldiers (15.7) than among civilians (28.7) ( $p = 0.003$ ). There were no significant differences between seroprevalence of *Leptospira* and any of the remaining variables surveyed. Subject sera were most commonly reacting with organisms of the serogroup Canicola (71%) and Hardjo (51%).

**Conclusions:** Our data demonstrate serologic evidence of *Leptospira* infection among the Austrian population. No increased risk of exposure to *Leptospira* could be detected for military personnel.

**P701 A mathematical model predicting the rate of early onset GBS disease**

G. Avital\*, R. Drai-Hassid, D. Engelstein, T. Bdolah-Abram, E. Persitz, D. Hochner-Celnickier, A.E Moses (Jerusalem, Beit Shemesh, IL)

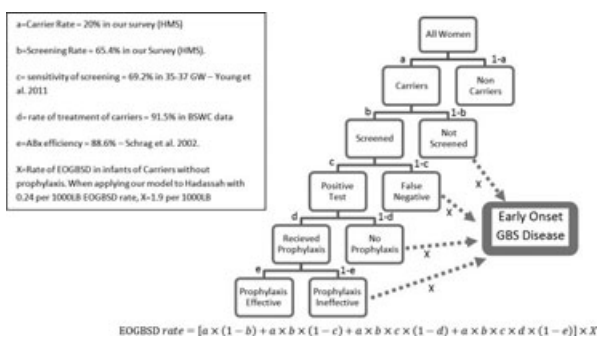

**Objectives:** Providing a tool for evaluating the effect of the pre-natal screening rate and method on the predicted morbidity in early onset group B streptococcal disease (EOGBSD), as universal GBS screening at 35–37 GW, formally adopted and applied in the USA, is still under dispute in other countries, including Israel, which has a low rate of EOGBSD (0.37 per 1000 live births [LB]).

**Methods:** A mathematical model was developed, describing the probability of EOGBSD as a product of the probabilities of predisposing events. Screening sensitivity and effectiveness of antibiotic prophylaxis were obtained from existing literature. Carriage during labor and pre-partum screening rates were surveyed in 80 women giving birth during January to April 2009 in Hadassah Hospital Mount Scopus (HMS) delivery unit. All women treated in Beit-Shemesh Women's Health Centre (BSWC) who gave birth at Hadassah hospitals (2006–2008) were reviewed for the rate of prophylaxis administration to known carriers of GBS.

**Results:** We found a 20% (95%CI: 11.9–30.4%) carriage rate and a 65.4% (95%CI: 53.8–75.8%) screening rate. 91.5% (43/47) of the BSWC GBS carriers who gave birth at Hadassah were treated during labour.

Given the rate of EOGBSD in Hadassah Hospitals (0.24 per 1000 LB), our model (Fig. 1) calculated the probability of neonatal disease from a GBS colonised mother without prophylaxis to be 1.9 per 1000 LB.

Using our model with the national EOGBSD rate and the screening rate as a variable, we conclude that there is a very low screening rate in Israel. Furthermore, 100% screening is expected to decrease morbidity to 0.17 per 1000 LB.

**Conclusion:** We developed a model which calculates the probability of GBS infection in a neonate considering screening, carriage and prophylaxis rates. Using our data we can calculate the effect of trends in prophylaxis on morbidity rate. Our model's main weakness is the lack of extensive national data regarding rates of screening, carriage and prophylaxis. Such data will enable our model to assess effects on EOGBSD rate, assisting policy makers to decide about the need for GBS prophylaxis.

**P702 Pneumococcal conjunctivitis in young children in Gipuzkoa, northern Spain, 2001–2010: non-encapsulated genotypes and influence of conjugate vaccines**

M. Ercibengoa, M. Alonso, J.M. Marimon\*, J.M. García-Arenzana, E. Pérez-Trallero (Donostia-San Sebastian, ES)

**Background:** Acute conjunctivitis (AC) is the most frequent ophthalmic infection being *Streptococcus pneumoniae* a significant aetiological agent. Non-typeable pneumococci have been associated to AC but little is known about the serotype prevalence of other pneumococci causing AC. The 7-valent pneumococcal conjugate vaccine (PCV7) was introduced in Spain in June 2001.

**Aim:** Analyze the serotype distribution of pneumococci causing AC in children aged <5 years old after PCV7 (2001–2010) in the University Hospital Donostia, north Spain and characterise non-encapsulated isolates.

**Methods:** Serotypes were determined using the Pneumoarray or multiplex PCR and confirmed by the Quellung reaction. Capsule absence in non-typeable isolates was confirmed by a negative result in a specific PCR of the capsular *cpsA* gene. Molecular characterization was done by PFGE and MLST and antimicrobial susceptibility testing by the broth microdilution method. Statistical analysis was done by the Chi square test.

**Results:** During the study period 519 episodes of pneumococcal AC in 496 children were included (mean age 1.05 years). Non-encapsulated isolates were responsible for 169 (32.6%) episodes. Of encapsulated isolates, the most prevalent serotypes were 19A (10%), 15B/C (4.6%), 6A y 23F (3.9% each) and 19F (3.5%). A decreasing trend for PCV7 serotypes causing conjunctivitis was observed ( $p < 0.01$ ). The rate of PCV7 serotypes fall from 37.5% in 2001 to 2% in 2010 ( $p < 0.01$ ). Conjunctivitis caused by serotypes 19F and 23F showed a decreasing trend ( $p < 0.05$ ). Contrarily, rates of serotypes 15B/C increased ( $p < 0.05$ ).

Non-encapsulated isolates were more resistant than encapsulated to oral-penicillin and co-trimoxazole: 47.3% vs 18.6% ( $p < 0.01$ ) and 58.6% vs 28.6% ( $p < 0.05$ ), respectively.

95/169 non-encapsulated isolates characterized by PFGE gave 26 different patterns (similarity >80%). MLST of representative isolates of the most common PFGE patterns showed CC941 (32.6%) and ST448 (25.3%) to be the most prevalent among non-encapsulated isolates. This distribution was not homogeneous: between 2004 and 2006 more than 50% of the non-encapsulated conjunctivitis were caused by CC941 while in 2009–2010 more than 50% were due to ST448.

**Conclusions:** Non-encapsulated pneumococci are an important cause of conjunctivitis, but genotype distribution showed changes in the distribution of clones throughout time. The decrease in PCV7 serotypes causing conjunctivitis can be attributed to the herd effect of PCV7 on carriage.

**P703 Bartonella quintana in Ethiopian head lice**

S. Cutler\* (London, UK)

**Objectives:** To further characterise the head lice vectors of *Bartonella quintana* in Ethiopia.

We have recently reported the finding of *B. quintana* among both head lice and clothing lice collected from Ethiopia. We now report the characterisation of the lice vectors using amplification and sequencing of the mitochondrial gene cytochrome B (cytB).

**Methods:** Lice from Ethiopia were collected and pooled by patient (each pool <20 lice) from the inhabitants of Jimma, Ethiopia and its surrounds during summer 2010. A total of 98 pools were collected of which 65 were of head lice and 33 clothing lice. These were screened using a PCR specific for the intragenic transcribed spacer ITS. To further characterise the genetic background of the vector of those lice found to be positive for *Bartonella*, we sequenced the cytochrome b gene comparing this with available data from GenBank.

**Results:** Of the 98 lice pools screened, one of 33 of the clothing lice pools and 6 of 65 of head lice pools were infected with *B. quintana*. Sequence analysis of the louse vector was undertaken for both clothing and head lice, and compared with those found to be infected with *Bartonella*. Sequencing of *cytB* divided lice into two deeply rooted clades, both of which contained sequences of Ethiopian clothing lice. Interestingly, all head lice analysed fell into the second clade, whether infected with *B. quintana* or not.

**Conclusion:** The finding of *B. quintana* among head lice is important given the frequency of infestations seen among humans, especially children, around the globe. The perception among the general public is that head lice do not carry pathogens, a belief that should now be rectified. Whether all genetic lineages of head lice are equally competent for this pathogen under natural circumstances remains to be elucidated by comprehensive studies of head lice from diverse locations.

## Community-acquired respiratory tract infections

### P704 The viral aetiology of an influenza-like illness during the 2009 pandemic

S.D. Thiberville, L. Ninove, V. Vu Hai, E. Botelho-Nevers, C. Gazin, L. Thirion, N. Salez, X. de Lamballerie, R.N. Charrel\*, P. Brouqui (Marseille, FR)

Many viruses can cause influenza-like illness; however, in nearly 50% of cases, the etiologic agent remains unknown. The distribution of viruses in patients with influenza-like illness was investigated during the 2009 A/H1N1 influenza pandemic (A/H1N1p). From June 2009 to January 2010, 660 patients with suspected influenza infection were questioned and examined, and nasal swabs were collected. All patient samples were tested for influenza virus, and 286 negative nasal swabs were further tested for 18 other respiratory viruses using real-time RT-PCR. Two waves of influenza-like illness were observed in the epidemic curve (weeks 35–42 and weeks 42–49). At least eight viruses co-circulated during this period: human rhinovirus (HRV) (58), parainfluenza 1–4 viruses (PIV) (9), human Coronavirus (hCoV) OC43 (9), enterovirus (EV) (5), adenovirus (AdV) (4) and human metapneumovirus (hMPV) (2); however, 204 samples remained negative for all tested viruses. Influenza-like illness symptoms, according to the CDC definition, were reported in 75% of the cases. These patients had positive swabs for A/H1N1p, HRV, hCoV-OC43, PIV, AdV and hMPV without significant difference with non-influenza-like illness patients. This study showed that many respiratory viruses circulated during this period and that the A/H1N1p did not impact on the kinetics of other respiratory viruses. The proportion of non-documented cases remains high. Influenza-like illness was not efficient to distinguish A/H1N1p infection from that due to other respiratory viruses. However, in multivariate analysis, cough, chills, conjunctive hyperemia and dyspnea were significantly associated with influenza virus vs. other respiratory viruses.

### P705 Epidemiology and clinical features of severe influenza in adults: 7 years of surveillance in Toronto, Canada

K. Hassan\*, R. Devlin, J. Downey, S. Drews, K. Green, J. Gubbay, K. Katz, D. Low, C. Ma, T. Mazzulli, M. Muller, A. Plevneshi, J. Powis, W. Rudnick, A. Sarabia, A. Simor, A. McGeer on behalf of the Toronto Invasive Bacterial Diseases Network

**Background:** The epidemiology of influenza requiring ICU admission in adults has not been well studied.

**Methods:** Population-based surveillance for laboratory confirmed influenza in adults (>15 years) requiring ICU admission (LCI-ICU) in Toronto/Peel (pop 4M) was performed from 12/04 to 5/11; Consenting patients with a positive direct test (antigen or PCR) or culture for influenza were enrolled. From the 2006/7 to the 2010/11 season, active

surveillance for influenza was conducted in 6 of 19 ICUs in the surveillance area. Influenza A isolates were subtyped from 2007/8 season on.

**Results:** From 1/12/04 to 31/5/11, 576 adults with LCI-ICU were identified: 198 with 2009pH1N1 and 378 with seasonal influenza (158 AH3N2, 143 A-notsubtyped/able, 11 sH1N1, 77 B). Median annual incidence was 2.2/100000 (range 0.38–4.3). Patient median age was 68.5 years (range 17–101); 297 (52%) were male. Four hundred and seventy-two (92%) had at least one chronic condition qualifying them for seasonal influenza vaccine (but only 59% of those with seasonal influenza had been vaccinated); the median Charlson score was 4 (range 0–13); 57 (10%) were residents of long term care facilities (LTCF). The median admission APACHEII score was 15 (range 2–42). Forty-two (7%) patients had an admitting diagnosis of influenza; 189 (33%) had an admitting diagnosis of pneumonia, 134 (23%) another respiratory condition, 96 (17%) a cardiac condition; 115 (20%) another diagnosis. Thirty-four (5.9%) had a concomitant bacteremia (14 *S. aureus*, 14 *S. pneumoniae*, 3 *E. coli*, 1 each GAS, *H. influenzae*, *S. marcescens*). Four hundred and ninety-two (85%) patients received antibacterials at admission; 380 (66%) received antivirals (378 oseltamivir; 2 zanamivir). The median ICU LOS was 6 days (range 1–>100); 317 (55%) patients required mechanical ventilation for a median of 8 days (range 1–>100). One hundred and eleven patients (19.3%) died within 15 days of admission; these included 60/380 (16%) patients treated with antivirals and 50/1195 (26%) others ( $p = 0.005$ ). In multivariable analysis, APACHEII score (OR/10 points 3.5, 95%CI (2.5, 4.8) residence in long term care (OR 2.0, 95% CI 1.0, 4.0) and failure to treat with oseltamivir (OR 2.7 95%CI .1.6–14.9) were risk factors for mortality.

**Conclusions:** Influenza is an important cause of respiratory illness requiring ICU admission during the winter season, particularly in unvaccinated, at-risk adults. *S. aureus* is the most common complicating bacterial infection. Treatment with oseltamivir was associated with a significant reduction in mortality

### P706 Retrospective comparison of PCR confirmed influenza H1N1 infections and PCR-negative influenza-like illnesses in South East Austria: a case-control study

M. Hoenigl\*, J. Prattes, M. Drescher, K. Tovilo, H. Kessler, K. Vander, R. Raggam, T. Valentin, K. Seeber, I. Zollner-Schwetz, R. Krause, H. Flick (Graz, AT)

**Objectives:** Pandemic 2009 influenza A (H1N1) virus has spread rapidly resulting in millions of laboratory confirmed cases and over 18 000 deaths worldwide. Compared to previous non-pandemic influenza seasons epidemiology of the H1N1 pandemic in 2009–2010 differed significantly. As sensitivity of currently available rapid antigen tests has shown to be low, PCR is the recommended test for diagnosis and confirmation of infection. PCR results may, however, are usually not rapidly available. Development of a clinical score for H1N1 influenza may facilitate clinical diagnosis of H1N1 infection and consecutively help to improve outcome and reduce health care related costs.

**Methods:** We retrospectively analyzed case files from patients in South East Austria with PCR confirmed H1N1 influenza in the 2009/2010 season regarding clinical, laboratory findings, and outcome. In a second step the same data collection was performed in a group of PCR-negative patients, which were tested during the influenza season 2009/2010 for influenza-like illness. The data from the PCR-positive group were compared to the data from the PCR-negative group.

PCR confirmed 624 cases of H1N1 influenza during the surveillance period from Oct 2009 until Jan 2010. Data were obtained from 222/624 (36%) of patients who presented to participating hospitals. No data was available of the other 402 patients as these patients presented to family doctors only. Results were compared to data obtained in 117 patients with negative PCR result.

**Results:** Clinical characteristics of patients collective with PCR confirmed Influenza H1N1 infection ( $n = 222$ ) and of patients

	PCR positive group (n=222)	PCR negative group (n=117)

Normal ranges, where applicable: Creatinine protein, 0-0.8 mg/dl; Creatinine, 0.7-1.3 mg/dl; gST 0-35 U/L; AST 0-35 U/L; ALT 0-40 U/L; Creatinikinas, 0-170 U/L; Lactate dehydrogenase 120-240 U/L

collective with clinical suspicion of H1N1 infection in which PCR turned out negative (n = 117) are depicted in table 1.

**Conclusion:** Occurrence of a prodrome before fever onset and body temperature below 38°C, measured at home and at presentation were significantly associated with negative H1N1 PCR result. Cough and general weakness, on the other hand, were predictors of positive H1N1 PCR result. Total white blood cell count, relative eosinophil count, and thrombocyte count seemed to be lower in patients with confirmed H1N1 infection, while creatinine kinase values seemed to be higher. For the first time we found an correlation between eosinopenia, elevated creatinine kinase values and Influenza H1N1 infection. Presented data may help to implement a clinical score for H1N1 infection.

### P707 A 2-year retrospective study of H1N1 influenza pandemic: experience from a teaching hospital in northwestern England

S. Suranjana\*, A. Guleri (Blackpool, UK)

**Background:** H1N1 virus, a subtype of influenza A was responsible for the global pandemic outbreak as termed by the World Health Organization (WHO) in 2009. This strain also called as swine flu affected more than 70% of young and middle aged with pre existing immunity. As per health protection agency (HPA) report more than 1000 patients succumbed to this illness in 2 years. Also the seasonal flu activity in 2010/11 was higher than last winter and that H1N1 "swine" flu was the dominant strain.

**Aim:** To compare the pandemic over 2 years, study the demographics, clinical characteristics, complications and mortality rate in patients who were screened for H1N1 influenza.

**Methods:** The medical records of all patients (n-91) who were prescribed with Oseltamivir between January 2009–December 2010 were retrospectively reviewed. Patient demographics, symptoms, mode of screening, clinical outcome, complications and mortality rate were analysed.

**Results:** Ninety-one patients (males-30, females-61) were included in the study. During 2009/2010 and 2010/11, 24 and 67 patients respectively were screened; male to female ratio was 1:2 and 1:3; The median age at presentation in males was 43 (range 0–91) and in

Total number of H1N1 Influenza cases	n-37	
Clinical Characteristics	Number	Percent
Fever >38°C	25/37	67.5%
Cough	30/37	81%
Headache	28/37	75.6%
Rhynorrhoea	24/37	64.8%
Myalgia	18/37	48.6%
Vomiting	5/37	13.5%
Diarrhea	4/37	10.8%
Contact with Confirmed Cases	4/37	10.8%
Chest x-ray abnormalities	15/37	40.5%
Hospital Admission	34/37	91.8%
ITU Admissions	2/37 (2009) 2/37 (2010)	5.4% 5.4%
Prior Vaccination	2/37	5.4%
Outcome (Mortality)	2/37 (2009-1, 2010-1)	5.4%
<b>Complications</b>	<b>n-12</b>	<b>32%</b>
Type-1 Respiratory Failure	5	
ARDS	1	
Pleural Effusion	1	
Pneumonia	2	
Multiorgan Failure	1	
Death	2	5.4%

females 38 (range 0–94). The predominant symptoms were fever, cough, headache, rhynorrhoea, myalgia, vomiting and diarrhoea (Table 1a). There was an increase in the number of patients who were screened during December 2010 (n-57). Eighty-nine patients were screened with a nasopharyngeal swab and 2 had a bronchoalveolar lavage. The reasons for screening included clinical suspicion of H1N1 influenza, clinical symptoms disproportionate to their diagnosis, severe disease process or recent exposure to H1N1 contacts.

37/91 patients (41%) were found positive for H1N1 with PCR technique and had the full course of Oseltamivir for 5 days. Six patients were positive for H1N1 in 2009 and 31 patients in 2010. Twenty-five patients had an uneventful recovery and 12 (32%) patients had complications (Table 1b). The mortality rate from our hospital was 5.4% (n-2).

**Conclusions:** Over a period of 2 years, we encountered 37 cases of H1N1 Influenza. Majority of the patients were females with no previous cardio respiratory illness and with no significant co-morbidities as reflected by the HPA data. Influenza is a preventable illness and vaccination is the best way to protect against any infection. A concerted effort must be made by the healthcare professionals to encourage vaccination.

### P708 Pandemic 2009 (H1N1) influenza A infection in the elderly requiring ICU admission: clinical characteristics and risk factors for mortality

A. Gutiérrez\*, J. Garnacho, J. Márquez, R. Zaragoza, R. Granada, S. Ruiz, J. Rello, A. Rodríguez (Seville, Valencia, Barcelona, Gran Canaria, Tarragona, ES)

**Objective:** Little information is available regarding the clinical characteristics, presentation and prognosis of elderly patients infected with influenza virus A (H1N1) 2009 and admitted to the intensive care units (ICUs). Our aims are to examine epidemiological and clinical data of patients over 64 years old and to identify independent predictors of mortality in this cohort.

**Methods:** This was a prospective, observational, multicenter study conducted in 148 Spanish ICUs, with patients infected with influenza

virus A (H1N1) 2009 confirmed by RT-PCR (Real Time Polymerase Chain Reaction) from April 2009 to July 2011. Patients over 64 years were compared with the rest with a bivariate analysis. Logistic regression analysis was carried out to determine independent predictors of mortality in patients over 64 years.

**Results:** A total of 1485 patients were included, of whom 188 (12.7%) were over 64 years, with a higher proportion of men (68.6% vs. 31.4%,  $p < 0.005$ ). Severity of illness assessed by Acute Physiology and Chronic Health Evaluation (APACHE) II and Sequential Organ Failure Assessment (SOFA) were significantly higher in elderly patients. Prevalence of chronic diseases (diabetes, chronic renal disease, hematologic disease, chronic pulmonary obstructive disease and cardiac insufficiency) was more common in patients over 64 than in the rest. Viral pneumonitis was more frequent in patients younger than 65 years (72.4% vs. 55.9%,  $p < 0.001$ ) although incidence of co-infection was similar in both groups. Presence of leukocytosis and renal dysfunction at admission was higher in the elderly group. Non-invasive mechanical ventilation was more often used in patients over 64 years (37.5% vs. 28.6,  $p < 0.05$ ). ICU mortality was greater in patients over 64 years (29.1% vs. 19.3%;  $p < 0.005$ ). In these patients, APACHE II score (OR = 1.14; 95% CI, 1.13–1.24;  $p = 0.001$ ), oseltamivir therapy initiated after 48 hours (OR = 3.3; 95% CI, 1.02–10.5;  $p < 0.05$ ), and use of corticosteroids (OR = 1.60; 95% CI, 1.12–6.7;  $p < 0.05$ ) were identified as independent variables associated with mortality.

**Conclusions:** Patients over 64 years infected with influenza A (H1N1) 2009, admitted to the ICU have a higher incidence of underlying diseases and differences in clinical presentation compared to younger patients. Elderly patients should receive prompt treatment with oseltamivir and the use of corticosteroids is discouraged.

#### **P709** A retrospective cohort study: can we predict a diagnosis of H1N1 pneumonia?

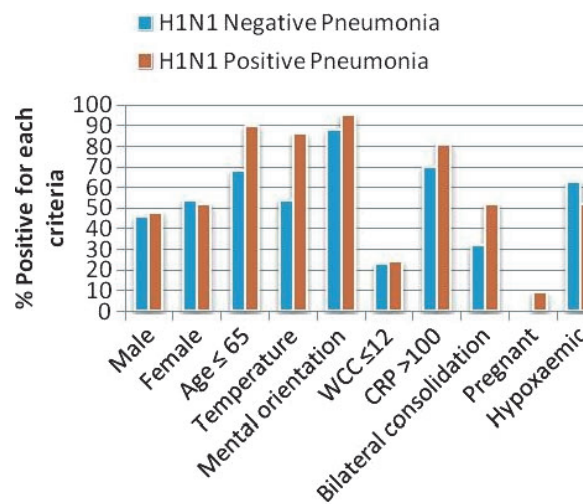

*J.E.K. Sherman\*, R. Thompson, C.M.E. Edwards (London, UK)*

**Objectives:** Prior to the h1n1 epidemic in the winter of 2010 a communication from the Department of Health suggested that five indicators could determine whether or not someone with pneumonia was likely to have h1n1. These were age  $\leq 65$ , temperature  $\geq 38^\circ$ , white cell count  $\leq 12$ , preserved mental orientation and chest x-ray showing bilateral consolidation. The aim of this study was to retrospectively evaluate the effectiveness of this clinical scoring system in diagnosis of H1N1 pneumonia.

**Methods:** The clinical details of all patients tested for H1N1 between November 2010 and February 2011 were obtained from the microbiology department. Age, sex, temperature on admission, WCC, CRP, CXR findings and hypoxaemia were for each patient. Each patient was assigned a score out of five based on the five clinical variables; age  $\leq 65$ , temperature  $\geq 38^\circ$ , WCC  $\leq 12$ , preserved mental orientation and CXR showing bilateral consolidation. The distribution of scores and of the five clinical variables within H1N1 pneumonia and community acquired pneumonia cohorts were compared. Sensitivity, specificity, negative predictive value (NPV) and positive predictive values (PPV) of the clinical scoring system were calculated.

**Results:** One hundred and seventy-nine patients were analysed. Sixty-two patients tested positive for h1n1, 21 were also treated for pneumonia. One hundred and seventeen patients tested negative for h1n1, 57 were also treated CAP. As illustrated in the figure there was little difference in any criterion between the two groups. The greatest difference between H1N1 positive and negative was with a score of 4/5 (38% of the H1N1 positive group, 16% H1N1 negative). For a score of 4/5 the PPV was 47%, NPV 78%, sensitivity 38% and specificity 34%, P was not significant.

Age  $\leq 65$ , temperature  $\geq 38^\circ\text{C}$  and bilateral consolidation on CXR showed the biggest difference in distribution between the H1N1 pneumonia and CAP cohorts. PPV and NPV for a score of  $\geq 3/5$  was calculated, where the three variables had to include age, temperature and bilateral consolidation. There was no significant difference between

the groups, PPV 45%, NPV 75%, sensitivity 24% and specificity 89%,  $p$  was not significant.

**Conclusion:** The use of the five clinical criteria identified as being predictive of h1n1 pneumonia is unhelpful as an aid in the diagnosis of h1n1 pneumonia. We would contest that a thorough clinical history and examination and appropriate investigations are paramount when determining a diagnosis of h1n1 pneumonia.

#### **P710** Did the 2009 influenza pandemic change influenza prevention, diagnosis and management? Evidence from surveillance for influenza-associated hospitalisation in Canada

*A. McGeer\*, R. Devlin, J. Downey, S. Drews, K. Green, J. Gubbay, K. Hassan, K. Katz, T. Mazzulli, M. Muller, A. Plevneshi, J. Powis, W. Rudnick, A. Sarabia, A. Simor, D.E. Low on behalf of the Toronto Invasive Bacterial Diseases Network*

**Background:** The 2009 influenza (flu) pandemic changed attitudes and practice. In Ontario, recommendations were written for testing and treatment, but seasonal flu vaccination rates decreased post-pandemic.

**Objectives:** To compare epidemiology, clinical features and management of adults with laboratory-confirmed seasonal flu requiring hospitalization (LCSI-H) pre- and post-pandemic in Toronto.

**Methods:** Population-based surveillance for LCSI-H has been performed in Toronto (popn~4M) since 2004. LCSI-H is defined as illness requiring admission with positive direct test (antigen or PCR) or culture for flu. From 2006/7 season onward, ICUS in 6/19 hosps conducted active surveillance for LCSI-H. FluA subtyping started in 2006. This analysis compares LCSI-H in the 2004/5–2007/8 seasons (pre-pandemic) and the 2010/11 season (post). Subgroup analysis was performed for flu sub/types.

**Results:** The incidence of LCSI-H was 7.7/100 000 pop pre- and 26.4/100 000 post-pandemic. Flu B comprised 336 (20%) infections pre v 96 (8.7%) post; among subtyped flu A, (H3N2) comprised 78% (222/284) pre v 89% (832/934) post. Comparing pre and post cases, there was no difference in median age (78 year pre vs 76.5 year post), percent male (566.49% vs 531.48% post), proportion with chronic conditions creating a risk of complicated flu (906.79% vs 881.80%), Charlson score  $> 2$  (895.77% vs 860.78%) median admission APACHEII score (12 vs. 12), proportion with admitting diagnosis of pneumonia/flu (453.39% vs. 406.37%), or proportion receiving antibiotics (82% vs. 84%) or admitted to ICU (213.19% vs. 209.19%). Post-pandemic cases were less likely to be nursing home residents (137.12% vs. 185.16%,  $p = 0.02$ ), to be nosocomial (97.9% vs. 161, 14%,  $p = 0.001$ ), and to be vaccinated against flu (633.64% vs. 495.56%,  $p < 0.001$ ), but more likely to be treated with antivirals (468.41% vs. 792.73%,  $p < 0.001$ ). Pre-pandemic

cases were more likely to be diagnosed in hospitals with active ICU surveillance (577.50% vs. 420.41%,  $p < 0.001$ ), and somewhat more likely to die (7.8% at 15 days vs. 6.4%,  $p = 0.22$ ). Analysis by subtype did not change results. In multivariable analysis, infection pre vs post pandemic was not associated with mortality, but antiviral use was associated with decreased mortality (OR 0.51, 95% CI 0.35, 0.71).

**Conclusion:** The post-pandemic increase in LCSI-H post-pandemic appears associated with increased testing and reduced pop'n vaccination rates, but clinical and epi features are unchanged. Increasing use of antivirals may have improved outcomes.

#### **P711** Influenza outbreak 2010/2011 – significant burden on hospital resources

C. McBrearty\*, B. Hanahoe, C. Fleming (Galway, IE)

**Objectives:** To describe the clinical and epidemiological features of influenza in patients hospitalized at Galway University Hospital (GUH) during the 2010/2011 influenza season, 1 year after the H1N1 pandemic.

**Methods:** All adult patients (>15 years) admitted to GUH with a positive Influenza RNA PCR between 01/09/2010 and 01/05/2011 were included. Medical records were reviewed.

**Results:** Sixty patients were admitted to GUH with laboratory confirmed Influenza from 21/12/2010 to 04/03/2011. The mean age of patients was  $49.6 \pm 18.8$  (range 16–88). Twelve (20%) were <25 years old, 49 (82%) <65 years. Seventy-seven percent were confirmed Influenza A (H1N1); 23% Influenza B.

The average duration of symptoms on admission was 4.3 days. Forty-two (70%) had at least one co-morbidity; chronic lung disease in 43%. Sixty-eight percent had a normal chest X-ray.

Ten patients (17%) required ICU admission. Compared to non ICU admissions, those admitted to ICU had a longer mean duration of symptoms at presentation (+3.1 days; CI 6.2, 0.1;  $p = 0.0467$ ) and a longer mean number of days from onset of symptoms to commencement of Oseltamivir (+3.8 days; CI 7.0, 0.5;  $p = 0.0236$ ). Seven patients (12%) required mechanical ventilation. Total ICU bed days was 130 with mean length of stay of 13 days (range 1–40).

The mean length of stay for community acquired Influenza was 8.6 days. Mean length of stay was longer in those with co-morbid lung disease, by 9.8 days ( $p = 0.0487$ ), but not with any other co-morbidity. Three patients (5%) died from Influenza, all of whom had significant co-morbidities. The date of onset of symptoms peaked on 02/01/2011. Nine influenza admissions (15% of total) occurred on 1 day (07/01/2011). Between 4th and 14th January, 52% of all admissions and 70% of ICU admissions occurred. For 7 days in a row in January, 7 ICU beds were occupied by patients with influenza, which equates to 78% of ICU capacity.

**Discussion:** A high number of Influenza H1N1 cases required admission to hospital over a short period of time, with those affected being relatively young. There was a high ICU utilisation rate and this accounted for 78% of ICU capacity for a 7 days period. The EpiCurve is consistent with an epidemic, with the peak of onset of symptoms and peak of admissions illustrating a very short warning period for the hospital to prepare. It is likely that this pattern will be repeated in the coming influenza season.

#### **P712** Clinical features of adult community-acquired pneumonia caused by Gram-negative bacilli: comparison with pneumococcal pneumonia

H. Kim\*, H. Chang, S. Kim, J. Lee, S. Cha, H. Ki, H. Jung, K. Yoo, S. Ryu, K. Kwon, B. Lee, S. Park, J. Oh, C. Kang, D. Chung, K. Peck, J. Song, G. Suh, T. Shim, D. Kim, E. Choo, Y. Kim, H. Lee, C. Moon, K. Park, N. Yun, S. Yoon, K. Shon, K. Jung (Daegu, Seoul, Ilsan, Bucheon, Wonju, Busan, Kwangju, Daejeon, KR)

**Objectives:** Despite *Streptococcus pneumoniae* is the most common pathogen causing community-acquired pneumonia (CAP), and gram-

negative bacilli (GNB) have also been reported as an important pathogen in Korea. The aim of this study is to evaluate clinical features and risk factors of adult community-acquired pneumonia by GNB requiring admission by comparison with those of pneumococcal pneumonia (PP).

**Methods:** We have conducted nationwide multicenter prospective observational study of adult CAP in 14 teaching hospitals in Korea since October 2009. During the study period from October 2009 to September 2011, eighty nine cases were enrolled in the group of CAP by GNB, which were diagnosed by sputum and blood culture and receiving inpatient treatment, and clinical features of them were compared with those of eighty cases of PP, which were diagnosed by serologic test and culture methods, and also receiving inpatient treatment.

**Results:** In the group of CAP by GNB, *K. pneumoniae* was the most common etiologic microorganism (37 cases, 41.6%), followed by *P. aeruginosa* (17, 19.1%), *E. coli* (7, 7.9%), *Enterobacter cloacae* (6, 6.7%), *H. influenzae* (5, 5.6%), etc. No difference was detected among the baseline characteristics such as age, gender distribution, status of residence, site of admission, functional status of patients between the groups of CAP by GNB and PP. Diabetes mellitus (31.5% vs. 10.0%,  $p = 0.002$ ) and a recent exposure to immunosuppressants (3.4% vs. 0%,  $p = 0.002$ ) were observed as the significant risk factor of the CAP by GNB. Among the clinical manifestations of CAP, arthralgia (3.4% vs. 0%,  $p = 0.002$ ), skin rash (2.2% vs. 1.3%,  $p = 0.019$ ), crackle (76.4% vs. 52.5%,  $p = 0.002$ ) and purulent sputum (68.5% vs. 56.3%,  $p = 0.038$ ) were more frequently observed in the group of CAP by GNB. But the pneumonia severity scores such as PSI and CURB-65 and other laboratory findings were not different between the two groups. There was no difference observed in the incidence of acute respiratory distress syndrome, the need and duration of mechanical ventilation, the duration of antimicrobial treatment, and clinical outcomes between the two groups.

**Conclusion:** Data from this study showed that diabetes mellitus and the recent exposure to immunosuppressant treatment were the significant risk factors of the CAP by GNB, and some clinical manifestations were more frequent in the CAP by GNB, comparing with PP. But the analysis of clinical outcomes didn't show any significant difference.

#### **P713** Burden of community-acquired pneumonia in older adults in the new EU countries of the Central Europe

A. Tichopad\*, C. Roberts, A. Skoczynska, I. Gembula, K. Jahnz-Rozyk (Prague, CZ; New York, US; Warsaw, PL; Bratislava, SK)

**Objectives:** Older adults are in an increased risk of respiratory infections including community acquired pneumonia (CAP). The former socialistic countries of the Central Europe form a unique region with specific health care and epidemiology characteristics, yet with rather scarce local underlying epidemiology figures. The objective was to estimate incidence and case fatality rate (CFR) of CAP in adults 50+ years of age in the Czech Republic (CR), Hungary (HU), Poland (PL) and Slovakia (SK).

**Methods:** The incidence and the CFR for hospitalised CAP were estimated using the national surveillance systems (PL, CR, SK) and national insurance records (HU). National retrospective patient chart reviews (CZ, SK) were used to estimate the non-hospitalised CAP incidence as a portion of the hospitalised CAP. In PL we used national surveillance data and in HU the national insurance fund records to estimate outpatient CAP incidence.

**Results:** Hospitalised CAP incidence per 100 000 person years was 457 in CR, 879 in HU, 879, 364 in PL, and 524 in SK. The CFR per 100 cases of hospitalised CAP was estimated as 21 in CR; 20 in SK; and 18 both in PL and HU. Non-hospitalised CAP incidence per 100 000 person years was 710 in CR, 3551 in HU, 316 in PL, and 598 in SK. Compared with adults 50–64 years of age, the incidence of hospitalised CAP were 2.3-fold higher in those 65–74, 5.2-fold higher in 75–84 and 10.8-fold higher in those 85+, manifesting an exponential trend seen

also in mortality. By contrast, the incidence of non-hospitalised CAP was generally flat or declining with age, reflecting a higher likelihood of hospitalisation with increasing age. The total number of hospitalisations in the 65+ group and deaths in CR, HU, PL, and SK were 17 473 and 3686; 23 652 and 4796; 35 895 and 7325; 6321 and 1497, respectively) In PL, for instance, adults over 65 represent 14% of the study population, while accounting for 80% of deaths from CAP.

**Conclusion:** The morbidity and mortality of hospitalised CAP increases sharply with advancing age, signalling a likely increasing public health problem as the population ages over time. In HU, where the primary incidence data were provided by the national insurance fund, substantially larger incidence was calculated in both types of CAP with strikingly high number of outpatient CAP cases. This may be mainly due to different coding practice. Nevertheless, CAP poses a significant burden in all four countries among adults 50+ years of age.

**P714** **Has the incidence of invasive pneumococcal disease been influenced by the 2009 influenza A (H1N1) pandemic? Prospective multicentre study in Barcelona, Spain**

M.L. Pedro-Botet\*, V. Falcó, M. Luján, M. Gimenez, J. Rello, D. Fontanals, C. Ardanuy, L. Mateu, R. Núñez-Aragón, I. Casas, M. Sabrià (Badalona, Barcelona, Sabadell, ES)

**Background:** The incidence of Invasive Pneumococcal Disease (IPD) seems to be associated with viral respiratory illnesses, such as influenza. We therefore analyzed: (i) changes in the incidence of IPD in adults during the Influenza A (H1N1) Pandemic (IAP), (ii) changes in clinical characteristics of IPD episodes and, (iii) trends in serotype (ST) distribution.

**Methods:** A prospective multicenter study on IPD from January to December 2009 in an area of Barcelona of 1 483 781 adult inhabitants was performed. Serotyping was made by Quellung. The incidence of IPD and ST distribution in 2009 were compared with 2008 data.

**Results:** Two hundred and three cases of IPD were detected, 62% being males with a mean age of 61.2 year (18–98). 15.8% were healthcare or hospital-related, 69.9% had comorbidity. 76.3% had pneumonia. Mortality was 16.2%. IAP was confirmed in 4/53 (7.5%) cases. The most frequent serotypes in 2008 were 1 (20.4%), 7F (10.2%), 3 (9.6%), 19A (9%) and 14 (7.2%) whereas the most frequent in 2009 were 3 (9.1%), 7F (7.4%), 16F (7.4%), 9V (6.8%), and 13 (5.7%), 19A (5.7%). An increase (85.5% vs. 89.7%) in non-7pneumococcal conjugate vaccine ST (PCV7ST) was noted in 2009 compared to 2008. The annual incidence of IPD in 2008 and 2009 was 147.2 and 164.2, respectively per 100 000 inhabitants and year. Monthly incidence of IPD in adults of this series according to 2008 vs. 2009 and monthly incidence of IAP in Spain is shown in the graph.

**Conclusions:** Compared to 2008, the annual rate of IPD increased by 10% in 2009. IAP was associated with peaks in the incidence of IPD in adults in June, October and November 2009. Non-PCV7ST tended to increase in 2009 and some changes in demographic and clinical data were noted in patients with IPD during the 2009 IAP.

**P715** **Incidence and distribution of *Streptococcus pneumoniae* serotypes in adults in Catalonia, Spain**

P. Ciruela\*, S. Hernández, C. Izquierdo, C. Muñoz-Almagro on behalf of the working group of Microbiological Reporting System of Catalonia

**Objectives:** *Streptococcus pneumoniae* is an important public health problem because of its high morbidity and mortality in children and adults. In Spain, the 23 valent pneumococcal polysaccharide vaccine (PCV23) was introduced in 1999 in adults  $\geq 65$  years. The effectiveness of PCV23 is controversial while conjugate vaccines have been proven to be safe, immunogenic and effective in preventing pneumococcal disease caused by vaccine included serotypes in children. In Catalonia, 7-valent conjugate vaccine (PCV7) has not been introduced into the routine vaccination schedule. The main goal of this study is to know the incidence of invasive pneumococcal disease (IPD), clinical syndrome and serotype distribution in adults  $\geq 50$  years after the licensing of PCV7 in Catalonia.

**Methods:** We conducted a prospective study based on notifications to the Microbiological Reporting System of Catalonia with an active surveillance. Patients studied were adults  $\geq 50$  years old with confirmed IPD by culture during 2005 and 2009. Age groups analyzed were: 50–54, 55–59, 60–64, 65–69, 70–74, 75–79 and  $\geq 80$  years. The incidence rate was calculated from data obtained of Statistical Institute of Catalonia. To assess association of variables, Chi-square test was used. Significance level was set at 0.05.

**Results:** During the study period, 3085 IPD cases were identified: 3078 (99.8%) were confirmed by culture. Annual incidence was 25.6/100 000 persons-year. Incidence rate in 2009 (28.7/100 000 hour) was higher than 2005 (17.2/100 000 hour) (OR = 44.8;  $p < 0.01$ ). Annual incidence (100 000 hour persons-year) per age groups was: 11.5, 15.7, 21.2, 26.7, 26.9, 36.3 and 51.1 for 50–54, 55–59, 60–64, 65–69, 70–74, 75–79 and  $\geq 80$  years, respectively. Clinical presentation was: 72% bacteremic pneumonia (5.6% empyema), 15.2% bacteremia without focus, 6% meningitis, 1.9% peritonitis, 0.6% arthritis and 0.03% cellulitis. A total of 2125 (68.9%) cases were serotyped. There were identified 64 different serotypes. The most prevalent serotypes were: serotype 3 (7.4%), serotype 1 (6.8%), serotype 19A (6.3%), serotype 14 (5.4%) and serotype 7F (5.2%). Percentage cases due to PCV7, PCV10, PCV13 and PCV23 serotypes were: 19.4%, 39.5%, 63.3% and 73.7%, respectively.

**Conclusion:** The incidence of IPD in adults is high mainly in  $\geq 80$  years old. Great variability of serotypes was observed in adults. Serotype 3 and serotype 1 were the most prevalent serotypes. PCV13 and PCV23 offers a good coverage against IPD in adults.

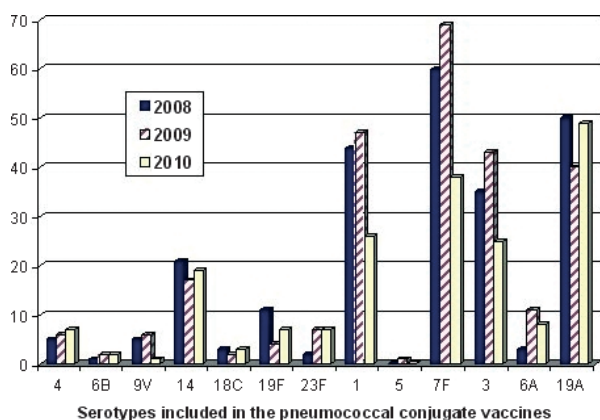

**P716** **Invasive pneumococcal disease in the Comunidad Valenciana, Spain, 2008–2010**

A. Gil-Brusola\*, A. Rosingh, A. Irazzo, J. Guitian, E. Cantón, J. López Hontangas, F. González Moran (Valencia, ES)

The emergence of complicated pneumococcal disease is a fact in many geographical areas. In the Comunidad Valenciana (CV), Spain, invasive pneumococcal disease (IPD) is a mandatory reportable disease since 2007. In this community, vaccination with the pneumococcal polysaccharide vaccine (PPV-23) is recommended in adults more than 65 years old. In children, the pneumococcal conjugate vaccine (PCV) is also recommended, but not included in the childhood immunization schedule (CIS), and subsidized by the Health Service only in case of high risk of IPD.

**Objectives:** To describe the epidemiology and serotype distribution of the *Streptococcus pneumoniae* isolates causing IPD in children and adults in the CV, between the years 2008 and 2010.

**Methods:** Retrospective study including all reported cases of patients with culture-proved IPD admitted to 24 medical centers in the CV, between 2008 and 2010. Epidemiological data were retrieved from the microbiology surveillance network of the CV (RedMIVA). Serotyping

of the strains of *S. pneumoniae* received at the Microbiology Department of the University Hospital La Fe was done through slide agglutination test (Denka Seiken, Tokyo, Japan). Some pneumococci were also sent to the National Reference Laboratory for serotyping and confirmation.

**Results:** In the period of study, 1577 cases of IPD were reported in the CV – 591 in 2008, 566 in 2009 and 420 in 2010. Regarding sex and age of the patients, 58.1% were men, 12.4% were children <5 years old and 40.9% were adults 65 years and older. Pneumonia was the clinical presentation in 59.4% of the patients, followed in frequency by sepsis (16.2%), meningitis (9.6%) and empyema (7%). A total of 967 (61.3%) strains of *S. pneumoniae* were serotyped – 339 (57.3%) in 2008, 354 (62.5%) in 2009 and 274 (65.2%) in 2010- and 47 different serotypes were found. The distribution of the serotypes included in the PCVs is shown in Chart 1. These accounted to more than 70% of the serotyped strains. Frequent serotypes not included in this chart were 22, 23F, 11A and 8, all in the PPV-23.

**Conclusions:** The incidence of IPD has diminished in the CV. Young children and elderly were the most affected groups of population. Pneumonia was the most frequent clinical presentation. Serotypes 7F, 19A, 1, 3 and 14 were predominant, with data similar to that observed in the rest of Spain. The introduction of the PCV in the CIS could reduce the incidence of IPD in our community.

#### P717 Serotypes causing invasive pneumococcal disease in adults (≥18 years) in Spain, 2010–2011: a multicentre hospital-based study

A. Fenoll, C. Ardanuy\*, E. Cercenado, F. Marco, A. Fleites, B. Buendia, M.C. Zúñiga, B. Palop, C. Mendez and the ODIN Study Group

**Objectives:** To explore serotypes (Sts) causing invasive pneumococcal disease (IPD) in adults in order to determine coverage by PCV13.

**Methods:** A prospective, active, hospital-based surveillance of all culture-confirmed IPDs in adults (≥18 years) was performed in seven Spanish hospitals (August 2010-June 2011). IPD was considered isolation of *S. pneumoniae* in normally sterile fluids (blood, cerebrospinal fluid, pleural fluid...). Clinical presentations were classified as complicated pneumonia -CP- (pneumonia with pleural effusion, and/or empyema and/or multilobar presentation), non-complicated pneumonia (N-CP), meningitis (M), primary bacteremia (PB), sepsis (S), peritonitis (P) and others (O). Serotyping was performed by the Quellung reaction or dot blot assay. Sts 6A, 6B, 19A and 19F were identified by real-time PCR.

**Results:** One hundred and ninety-one cases (mean age 62.2 ± 17.8 years) were identified. The table shows by clinical presentation the number of cases and percentages of Sts accounting for >5% in total population.

	CP	N-CP	M	PB	S	P	O	Total
n	70	66	19	14	9	8	5	191
<b>PCV13 Sts (%):</b>								
3	15.7	13.6	5.3	0.0	0.0	12.5	0.0	11.5
19A	8.6	10.6	10.5	0.0	22.2	12.5	0.0	9.4
7F	8.6	13.6	0.0	0.0	0.0	12.5	0.0	8.4
1	10.0	6.1	5.3	0.0	0.0	0.0	0.0	6.3
14	5.7	7.6	0.0	0.0	11.1	12.5	0.0	5.8
Others*	17.1	6.1	5.3	7.1	0.0	25.0	40.0	11.5
<b>Non-PCV13 Sts (%):</b>								
PPV23 non PCV13	18.6	16.7	5.3	7.1	33.3	25.0	60.0	18.3
6C	2.9	7.6	10.5	14.3	0.0	0.0	0.0	5.8
Others	12.9	18.2	57.9	71.4	33.3	0.0	0.0	23.0
<b>PCV13 coverage</b>	<b>65.7</b>	<b>57.6</b>	<b>26.4</b>	<b>7.1</b>	<b>33.3</b>	<b>75.0</b>	<b>40.0</b>	<b>52.9</b>

\*including Sts 4, 19F, 6A, 6B, 9V, 23F and 18C (no cases by St 5)

By age group, PCV13 serotypes accounted for 57.4% of cases in ≥18 – ≤49 year; 58% in ≥50–≤64 year; 57.7% in ≥65–≤74 year and 42.6% in ≥75 year; PPV23 non PCV13: 20.4%, 20%, 11.5% and 18%, respectively; and serotype 6C: 7.4%, 6.0%, 3.8%, 4.9%, respectively.

**Conclusion:** More than 20% of cases were due to 19A and 3 with a PCV13 coverage depending on the age group and clinical presentation. The highest coverage was for adults younger than 75 years of age. For pneumonia, that represented the most frequent presentation accounting for 71.2% IPDs, the PCV13 coverage was 61.7%.

#### P718 Early detection of community outbreaks of respiratory tract infections from house-call visits in the metropolitan area of Athens, Greece

A. Spanos, G. Theocharis, D. Karageorgopoulos\*, G. Peppas, D. Fouskakis, M. Falagas (Athens, GR)

**Objectives:** The traditional Serfling-type approach for influenza-like illness surveillance requires long historical time-series. We retrospectively evaluated the use of recent, short, historical time-series for recognizing the onset of community outbreaks of respiratory tract infections (RTIs).

**Methods:** The data used referred to the ratio of diagnoses for upper or lower RTIs to total diagnoses for house-call visits, performed by a private network of medical specialists (SOS Doctors) in the metropolitan area of Athens, Greece, between 01/01/2000 and 10/12/2008. The reference standard classification of the observations was obtained by generating epidemic thresholds after analyzing the full 9-year period. We evaluated two different alert generating methods [simple regression and cumulative sum (CUSUM), respectively], under a range of input parameters, using data for the previous running 4–6 week period. These methods were applied if the previous weeks contained non-aberrant observations.

**Results:** We found that the CUSUM model with a specific set of parameters performed marginally better than simple regression for both groups. The best results (sensitivity, specificity) for simple regression and CUSUM models for upper RTIs were (1.00, 0.82) and (1.00, 0.90) respectively. Corresponding results for lower RTIs were (1.00, 0.80) and (1.00, 0.86) respectively.

**Conclusions:** Short-term data for house-call visits can be used rather reliably to identify respiratory tract outbreaks in the community using simple regression and CUSUM methods. Such surveillance models could be particularly useful when a large historical database is either unavailable or inaccurate and, thus, traditional methods are not optimal.

#### P719 A randomised, double-blind, multicentre study to evaluate the efficacy and safety of oral solithromycin (CEM-101) compared to oral levofloxacin in the treatment of patients with community-acquired bacterial pneumonia

D. Oldach\*, K. Clark, J. Schranz, A. Das, C. Craft, D. Scott, B. Jamieson, P. Fernandes (Chapel Hill, San Francisco, US)

**Trial Design:** This was a multi-center, Phase 2, double-blind, randomized, efficacy and safety study to evaluate oral solithromycin

vs. oral levofloxacin in the treatment of adults with moderate to moderately severe community-acquired bacterial pneumonia (CABP). [Clinical Trials registration NCT01168713]

**Methods:** Patients with CABP were enrolled and randomized (1:1) to either: solithromycin 800 mg orally (PO) on Day 1 followed by 400 mg PO daily on Days 2–5 or levofloxacin 750 mg PO daily on Days 1–5. Randomization was stratified by age (<50 or ≥50 years) and pneumonia severity index (PORT) score. Co-primary efficacy outcome measures were Investigator's assessment of clinical success at test-of-cure (TOC; 4–11 days after the last dose of study drug) in the Intent-to-Treat (ITT) and Clinically Evaluable (CE) populations. Early response success (at Day 3) was defined as improvement in at least two cardinal symptoms (cough, sputum production, chest pain, or dyspnea) without worsening in any.

**Results:** The 132 patients randomized were primarily (95%) from US sites, 50.7% male, and 82.6% Caucasian, with a mean age of 55. Randomized patients had PORT scores of II (73%), III (20%), or IV (5%). Clinical success rates, presented in the table below, were comparable across the analysis populations, at both early response (Day 3) and TOC visits, as well as among subgroups with a baseline elevated procalcitonin (PCT) and with an identified pneumococcal infection. More levofloxacin recipients experienced one or more treatment-emergent adverse events (TEAEs) during the study (45.6%) than did solithromycin recipients (29.7%). The majority of TEAEs were gastrointestinal, were of mild or moderate intensity, and included nausea (1.6% solithromycin; 10.3% levofloxacin), diarrhea (7.8% solithromycin; 5.9% levofloxacin), and vomiting (0% solithromycin; 4.4% levofloxacin). Six patients, all receiving levofloxacin, discontinued study drug due to an AE. There was one death in the trial, attributed to a pulmonary embolism, in a levofloxacin recipient.

Clinical Success Rates Visit: Population	Solithromycin	Levofloxacin
	n/N (%)	n/N (%)
TOC: ITT (co-primary efficacy outcome)	55/65 (84.6)	58/67 (86.6)
CE (co-primary efficacy outcome)	46/55 (83.6)	54/58 (93.1)
microITT	14/18 (77.8)	10/14 (71.4)
ME	12/15 (80.0)	10/13 (76.9)
TOC: ITT, Baseline Plasma PCT ≥ 0.2 ng/mL	22/25 (88.0)	24/27 (88.9)
TOC: ITT, Baseline Plasma PCT < 0.5 ng/mL	14/15 (93.3)	12/13 (92.3)
TOC: <i>Streptococcus pneumoniae</i> diagnosis	5/7 (71.4)*	2/3 (66.7)
Day 3: ITT	47/65 (72.3)	48/67 (71.6)

\* includes one patient who missed EOT visit, but was considered a success when evaluated at TOC.

Notes: n/N (%): n=number of patients in the specific category; N=number of patients with an assessment of the specified parameter; percentages=100 x (n/N). PCT=procalcitonin. *S. pneumoniae* diagnoses were established by blood or sputum culture, or by detection of streptococcal capsular antigen in urine (BINAX assay). Success at Day 3 was defined as improvement in at least two cardinal symptoms (cough, sputum production, chest pain, or dyspnea) without worsening in any.

**Conclusions:** Solithromycin demonstrated efficacy comparable to levofloxacin and a favorable safety and tolerability profile, with a lower incidence of treatment-emergent adverse events than levofloxacin. These findings strongly support the further study of solithromycin in Phase 3 clinical trials for the treatment of CABP.

**Funding:** Cemptra Pharmaceuticals.

## P720 Macrolides quinolones for community-acquired pneumonia: systematic review and meta-analysis of randomised controlled trials

D. Yahav\*, K. Skalsky, A. Lador, N. Eliakim-Raz, L. Leibovici, M. Paul (Petah-Tikva, IL)

**Objectives:** We sought to compare the efficacy and safety of macrolides vs. quinolones in the treatment of community-acquired pneumonia (CAP).

**Methods: Design:** Systematic review and meta-analysis. Data sources: PubMed, Central, LILACS databases, references of included studies, relevant conference proceedings, trial registries and new drug application documents. Eligibility criteria: We included randomized controlled trials comparing any macrolide vs. any quinolone, as monotherapy or both in combination with a beta-lactam, for the treatment of CAP among inpatients or outpatients. We did not limit inclusion by age, pneumonia severity, publication status, language or

date of publication. The primary outcomes assessed were 30-day all-cause mortality and a treatment failure. Two authors independently extracted the data. Fixed effect meta-analysis of risk ratios (RR) with 95% confidence intervals was performed.

**Results:** Sixteen trials (4989 patients) were included, mostly assessing outpatients with mild to moderate CAP. All-cause mortality was not significantly different for macrolides vs. quinolones, RR 1.03 (0.63–1.68, seven trials), with a low event rate (2%). Treatment failure was significantly lower with quinolones, RR 0.78 (0.67–0.91, 16 trials) (figure). The definition of success (and failure) used in the primary studies was not clearly representative of patients' benefit. Microbiological failure was lower with quinolones, RR 0.63, (0.49–0.81, 13 trials). All adverse events, adverse events requiring discontinuation and any premature antibiotic discontinuation were significantly more frequent with macrolides, mainly on account of gastrointestinal adverse events. Resistance development was not assessed in the trials.

**Conclusions:** Randomized controlled trials show an advantage to quinolones in the treatment of CAP with regard to clinical cure without need for antibiotic modification and adverse events. The clinical significance of this advantage is unclear.

## P721 Assessment of outcomes at an early time point may identify a differential effect of macrolide therapy on community-acquired pneumonia due to atypical pathogens

T. File Jr.\*, P. Eckburg, D. Low, G. Talbot, L. Llorens, H.D. Friedland (Akron, Oakland, US; Toronto, CA; Anna Maria, US)

**Objectives:** Controversy exists regarding the need to include empiric therapy for atypical pathogens for optimal treatment of patients with CAP. Several CAP studies failed to show a clinical benefit of adding coverage for atypicals. Two recent global, randomised, double-blind, multicentre trials (FOCUS 1 and FOCUS 2) assessed the efficacy and safety of ceftriaxone (CPT) fosamil vs ceftriaxone (CRO) in CAP. The trials were identical except for a 24-hour course of clarithromycin (CLR) on Day 1 in FOCUS 1. This difference in design offers a unique opportunity to assess the effect of a macrolide on the outcome of CAP caused by ≥1 atypical pathogens.

**Methods:** FOCUS 1 and FOCUS 2 trials included hospitalised (non-ICU) moderate to severe CAP patients (PORT risk class III or IV) requiring intravenous therapy. Patients were randomised to CPT fosamil 600 mg q12h or CRO 1 g q24h for 5–7 day. FOCUS one patients also received oral CLR 500 mg q12h for 1 day. Primary

Subjects with:	FOCUS Day 4 S&S Response and Investigator Determined Clinical Response at Specified Timepoint n/N (%)			
	FOCUS 1 (macrolide)		FOCUS 2 (No macrolide)	
	S&S Day 4	TOC (Investigator Assessment)	S&S Day 4	TOC (Investigator Assessment)
Typical pathogens (mMITTE)	105/155 (67.7)	126/155 (81.3)	114/178 (64.0)	138/178 (77.5)
Atypical pathogen only (includes <i>M. pneumoniae</i> , <i>C. pneumoniae</i> , <i>L. pneumophila</i> ) (MITTE)	49/64 (76.6)	57/64 (89.1)	38/66 (57.6)	58/66 (87.9)
<i>L. pneumophila</i> only (MITTE)	8/12 (66.7)	12/12 (100)	12/19 (63.2)	14/19 (73.7)
<i>M. pneumoniae</i> and/or <i>C. pneumoniae</i> only (MITTE)	38/49 (77.6)	42/49 (85.7)	24/43 (55.8)	41/43 (95.3)

CAP = community-acquired pneumonia; FOCUS = cePtarOline Community acquired pneumonia trial versus ceftriaxone in hospitalized patients; MITTE = subjects with PORT score III/IV; mMITTE = subset of MITTE who had  $\geq 1$  typical pathogen with or without an atypical pathogen; PORT = Pneumonia Patient Outcomes Research Team; S&S=clinical stability and symptom improvement; TOC = test of cure; US FDA = United States Food and Drug Administration.

endpoint was clinical response at TOC visit (8–15 day after end of therapy). Also, a US FDA-specified endpoint of clinical stability and symptom improvement on Day 4 was assessed post hoc. Patients with an atypical pathogen only (65 *Mycoplasma pneumoniae*, 21 *Chlamydia pneumoniae*, 31 *Legionella pneumophila*, 13 mixed atypicals) were summarized separately.

**Results:** Compared with the overall study population, patients with only an atypical pathogen were younger (mean age 50.3 years in CPT fosamil group and 55.9 years in CRO group vs 60.8 years and 61.6 years, respectively) and had less severe infections (proportion with PORT IV CAP: 28.6% in CPT fosamil group; 23.2% in CRO group vs 37.9% and 38.4%, respectively).

**Conclusions:** A differential clinical benefit was observed at Day 4 in patients with CAP due to an atypical pathogen only, specifically *M. pneumoniae* and/or *C. pneumoniae*, and who received 1 day of CLR (76.6% vs 57.6%). No difference was seen at the TOC visit, perhaps due to the self-limited course of many atypical pneumonias. The addition of macrolide made no difference for typical pathogens, either at day 4 or TOC. In patients with *L. pneumophila* only, a difference was not seen early, but a numerical difference favouring the CLR-group occurred at TOC. Although not a randomised comparison, our observations suggest that outcome assessment at an early time point may better identify differential effects of two treatments than a later evaluation and that empiric atypical coverage may impact early clinical response. Additional study is warranted.

#### **P722** Increased reports of *Mycoplasma pneumoniae* from laboratories in Scotland in 2010 and 2011

N.J. Gadsby\*, A. Reynolds, J. McMenamin, W.F. Carman, S. McDonagh, P.J. Molyneaux, D.L. Yirrell, K.E. Templeton (Edinburgh, Glasgow, Inverness, Aberdeen, Dundee, UK)

**Objectives:** An increased incidence of *Mycoplasma pneumoniae* was noted in several countries in Europe in 2010. In Edinburgh during the winter of 2010/11, higher than expected *M. pneumoniae* report frequency was found from patients at the Royal Hospital for Sick Children, and this continued through 2011. This local experience prompted a national review of *M. pneumoniae* reporting data for Scotland.

**Methods:** Health Protection Scotland captures nationwide laboratory reports of *M. pneumoniae* through the Electronic Communication of Surveillance in Scotland (ECOSS) reporting system. Reports from 01/01/2008 until 20/09/2011 were analysed in this study. Multiple samples from the same patient and infection episode (defined as 56 days) were excluded, and data were anonymised.

**Results:** There were a total of 716 *M. pneumoniae* reports in Scotland during the period studied. There were 76 reports in 2008, 124 in 2009, 254 in 2010 and 262 to week 37 in 2011. Reports of *M. pneumoniae* were highest in the autumn/winter period 2010/11, peaking in week 50 of 2010 and week 4 of 2011. Reporting frequency declined through the spring and early summer of 2011, but rose to high levels again after week 27. In 2010 and 2011, the mean age of patients was 21.6 years (SD  $\pm$  19.5 years; range <1 month to 89 years), however, the mode age was <1 year. The majority (78.9%) of reports were generated by PCR testing of respiratory specimens (of these, 94.3% were from the upper respiratory tract), 20.3% by serology and 0.8% were not stated. However, 48.1% of reports from respiratory specimens were in children <10 years old, compared to 24.5% of serology specimens.

**Conclusion:** *M. pneumoniae* reports have increased in frequency in Scotland since autumn/winter 2010, compared to previous years, and this has been sustained in 2011. Most reports were from children, particularly those <2 years of age, and were mainly diagnosed through PCR testing of upper respiratory tract specimens. Testing methods differed between laboratories, however those using PCR reported more positives from younger patients than those using serology, reflecting the greater acceptability of PCR for the diagnosis of *M. pneumoniae* in young children. Denominator testing data is not currently available, thus a prospective surveillance programme for *M. pneumoniae* incidence would be of benefit in optimising future antibiotic policy for pneumonia. Use of molecular testing is resulting in a change in the epidemiology of this infection.

#### **P723** Was winter 2010/11 a *Mycoplasma pneumoniae* epidemic season in Germany?

N. Wellinghausen, U. Weber, O. Bätz, J. Kramer, M. Böttcher\* (Ravensburg, Geesthacht, Wedel, DE)

**Objectives:** *Mycoplasma pneumoniae* (Mp) epidemics occur every 4–6 years. In late summer 2010 reports of an incipient epidemic arrived from Denmark. The epidemic situation in north and south Germany was then analysed in a retrospective survey.

**Methods:** Frequency of Mp infections was analysed from laboratory data in four successive autumn-winter periods (AWPs) from 2007 to 2011 (Sept. to Feb.). Sera from 14 279 patients (2760–4234 patients per season, age 1–95 years), of whom 61% were children and adolescents (1–20 years) were tested for IgG, IgA and IgM antibodies (Ab) using Mp-ELISA medac. Acute infection (AI) was defined as IgM- and IgA- or IgG-positive, and current/persistent or past infection (CPI) as IgG- and IgA- or single IgG-positive. In 818 patients from south Germany respiratory specimens (throat swabs, secretions) were also tested for Mp-DNA.

**Results:** Over the four AWPs Ab prevalences for IgG, IgA and IgM in the entire study population were: 28% to 31%, 8% to 9% and 6% to 15% respectively. The 15% positive IgM cases were recorded in winter 2010/11. In AWP 2010/11 AI reached their highest level with a mean of 11%. In parallel, the percentage of CPI at 17% was comparable to that in previous years. The percentage of Mp-DNA-positive samples in winter 2010/11 at 10.0% was also markedly higher than in the two previous observation periods (0.6% and 2.1%). In terms of seasonal variations, most AI were noted between November and January (14%), with a minimum (7%) in September. In children and adolescents the mean percentage of AI was found to be 15% in all years. The 6–10-year age group was prominent with 22%. In December 2010 and January 2011 values of 29% and 27% respectively were even recorded in this age group. In north Germany AI were recorded earlier and in marginally greater numbers than in south Germany.

**Conclusions:** AWP 2010/11 was characterised by a high percentage of acute Mp infections. Children between 6 and 10 years old were

predominantly affected. The peak time for infection was from December to January. Serological and PCR data point to an Mp epidemic in winter 2010/11 in Germany.

#### **P724** Macrolide resistant *Mycoplasma pneumoniae* in England and Wales

V.J. Chalker\*, T. Stocki, M. Mentasti, A. Harnden, K. Wang, T.G. Harrison (London, Oxford, UK)

**Objectives:** *Mycoplasma pneumoniae* is a common cause of pneumonia in humans. Reports of macrolide resistant *M. pneumoniae* have been increasingly reported globally. Other than a limited study in winter 2010 no studies have been performed in the UK to assess the level of macrolide resistance. We sought to determine if known genetic markers of macrolide resistance were present in clinical strains isolated in England and Wales from 1965 to 2005 and in DNA extracted from clinical samples known to be PCR positive from 1991 to October 2011.

**Methods:** Erythromycin sensitive phenotype was confirmed by microbroth dilution on the first 37 freeze dried strains, the remaining 33 isolates and 117 clinical samples were tested by molecular methods only. DNA was extracted from 70 stored strains (46 freeze dried, 24 frozen) and 117 clinical isolates using the Qiasymphony and Magnapure compact respectively. Samples were analysed by PCR for *M. pneumoniae* (Pitcher et al., 2006). A 600 bp fragment of the 23srRNA sequence was obtained from positive samples by PCR and sequencing. For 17 stored DNA extracts amplification did not occur and subsequent qPCR indicated a reduction in MPN DNA indicative of sample degradation. The remaining 100 samples gave adequate sequence data that were analysed for known mutations conferring macrolide resistance (2063 A-G/C, 2064 A-G/C, 2067 A-G, 2167 C-A/G). The % resistant detected by sequencing was calculated in all samples tested from 2008 to October 2011.

**Results:** Macrolide resistance markers were not found in clinical strains from England and Wales isolated from 1960 to 2005. In clinical samples screened from 1991 to October 2011 a single mutation was detected in one sample only from 2008 (2063 A-G). The % resistant detected by sequencing was calculated from 2008 to October 2011 2.2% (95%CI 0.01–12.6) 1/45.

**Conclusion:** Macrolide resistance markers were not found in 70 clinical isolates in England and Wales prior to 2005, and erythromycin resistant phenotype was not detected prior to 1996. In 100 clinical samples from 1991 to 2011 a single case of macrolide resistance was detected in 2008. Although limited by the number of positive cases available for testing, macrolide resistance was not detected in England and Wales prior to 2008 and was detected in *M. pneumoniae* in England and Wales at a low level (2.2% (95%CI 0.01–12.6) from October 2008–2011).

#### **P725** Macrolide resistance in *Mycoplasma pneumoniae* during two successive years with epidemic in Denmark

C. Wiid Svarrer\*, J. Skov Jensen, S. Uldum (Copenhagen, DK)

**Objectives:** Cases of *Mycoplasma pneumoniae* (M. pn.) infections occur throughout the year, with the highest incidence during autumn and winter. The highest prevalence is seen in children and younger adults. At Statens Serum Institut (SSI) the rate of PCR positive samples is calculated each week, and a rise from approximately 5% to at least 15% over a few weeks is considered indicative of an M. pn. epidemic. During the autumn/early winter of 2010, a relatively small epidemic was seen in Denmark (DK). This autumn (2011) it appears that we are heading for another epidemic. During an M. pn. epidemic the consumption of macrolides increases considerably. In theory this could lead to an increase in macrolide resistance in M. pn., especially in a situation where the epidemic seems to cover two seasons.

**Methods:** PCR is used as a routine diagnostic test for M.pn. infections at SSI. Several local clinical microbiology laboratories in DK also use this method as a routine test for M. pn. In this study, only cases

diagnosed by PCR at SSI were included. A selection of PCR positive samples from the two epidemics (242 in 2010 and >250 for 2011) were examined by a pyrosequencing method which detects mutations associated with macrolide resistance (domain V of the 23S rRNA gene).

**Results:** The duration of the 2010 epidemic was from August to January 2011. The second epidemic (2011) also had its onset in August and is still ongoing. At the beginning of the 2010 epidemic, we found 1.4% (2 of 140) macrolide resistant samples, and at the end of the epidemic 2.8% (3 of 108) had mutations detected (not significant). Macrolide resistance data for the 2011 epidemic is still pending.

**Discussion:** M. pn. epidemics have a high impact on the community, and a laboratory-based system for the surveillance of this disease is recommended. According to our knowledge, Denmark is the only country with a continuous PCR-based surveillance system for M. pn. based on routine samples. Macrolide resistance in M. pn. is an increasing problem worldwide. In Denmark, low frequencies of resistant samples have been seen, but continuous surveillance is important.

#### **P726** Community-acquired *Legionella pneumophila* pneumonia: single-centre experience with 214 hospitalised cases over 15 years

D. Viasus, C. Garcia-Vidal\*, S. Di Yacovo, J. Adamuz, R. Verdaguer, J. Dorca, F. Gudiol, J. Carratalà (Vandellòs i l'Hospitalet, ES)

**Objective:** *Legionella pneumophila* has been increasingly recognized as a cause of community-acquired pneumonia (CAP). We aimed to determine the epidemiology, diagnosis, clinical features, treatment and outcomes of sporadic cases of community-acquired *L. pneumophila* pneumonia (LP) requiring hospitalization over a 15-year period.

**Methods:** Observational analysis of prospective cohort of hospitalized adults with CAP at a tertiary teaching hospital in Spain (1995–2010).

**Results:** Of the 3933 hospitalized patients with CAP during the study period, 214 (5.4%) patients had LP. While the diagnosis of LP by urinary antigen test remained stable over the years ( $p = 0.42$ ), the use of seroconversion and culture decreased ( $p < 0.001$  and  $p = 0.001$  respectively). The median age of patients with LP was 58.2 years (SD 13.8) and 76.4% were males. Comorbid conditions were present in 119 (55.6%) patients, mainly chronic heart disease, diabetes mellitus and chronic pulmonary disease. The frequency of older patients and comorbidities among patients with LP increased over years ( $p = 0.06$  and  $p = 0.02$  respectively). In addition, 100 (46.9%) patients were classified into groups IV-V according to the PSI. Twenty-four (11.2%) patients received inappropriate empirical antibiotic therapy at hospital admission. The number of patients who received macrolides decreased over years, whereas the number of patients who were given levofloxacin increased significantly. Compared with macrolide use, levofloxacin therapy was associated with a trend to shorter time to reach clinical stability (median 3 vs 5 days;  $p = 0.09$ ) and a shorter length of stay (median 7 vs 10 days;  $p < 0.001$ ). Regarding outcomes, 38 (17.8%) patients required ICU admission and 8 (3.7%) patients died. There has been a trend to lower frequency of mechanical ventilation ( $p = 0.10$ ) and overall mortality ( $p = 0.04$ ) over the study years.

**Conclusion:** *L. pneumophila* is a relatively frequent causative pathogen among hospitalized patients with CAP. During the 15-year period study period, the annually number of LP cases has remained stable over years and they are associated with high morbidity. Similarly, significant changes have occurred in diagnosis, treatment and prognosis of LP.

#### **P727** Detection of atypical pneumoniae with the BD MAXTM-instrument compared with BioRad CFX96

P. Silvestre\*, S. Barhdadi, G. Babini, R. Close (Sart-Tilman, Buccinasco, BE)

**Introduction and Objectives:** *Mycoplasma pneumoniae* (Mpn), *Chlamydia pneumoniae* (Cpn) and *Legionella pneumophila* (Lpn)

are the organisms responsible for most atypical pneumonia. Atypical pneumonia due to these bacteria causes mild forms of pneumonia and is characterized by a more protracted course of symptoms unlike other forms of pneumonia which can progress more quickly with more severe early symptoms. The BD MAXTM is a fully automated instrument for molecular diagnostics. The nucleic acid extraction and subsequent PCR is done by adding the appropriate reagent cartridges and the test tubes. Further intervention is not necessary (walk-away system). Performance comparison between classical extraction method with subsequent PCR and walk-away BD MAX allowed us to prove possible the transfer of classical assays to the BD MAXTM-instrument.

**Material and methods:** QCMD 2010 MCpn EQA Panel and QCMD 2010 Lpn EQA Panel were used on both systems to compare performance. This includes 12 MCpn samples (three Mpn cores, three Cpn cores, two Mpn positives, three Cpn positives and one negative) and 10 Lpn samples (four cores, three positives, and three negatives).

**Classical assay:** Four hundred microlitre of QCMD sample and 10 mL of Internal Control (IC) were extracted with QIAamp DNA Mini Handbook and eluted in 60 mL. Subsequent PCR was performed in 25 mL on BioRad CFX96.

**BD MAX assay:** 500 mL of QCMD sample and 10 mL of IC were extracted with DNA extraction kit DNA-3. PCR was performed automatically after sample preparation by BD MAXTM. Primers and probes were by Diagenode (Dia-MCpn-050 and Dia-Lpn-050). Master Mix was by BD.

**Results:** All positive Mpn samples but one (MCpn 08 – low positive) were correctly detected as such by BD Max (sensitivity 80%). All positive Cpn samples but one (MCpn 03 – low positive) were correctly detected as such by BD Max (sensitivity 83%). All positive Lpn samples but one (Lpn 09 – core) were correctly detected as such by BD Max (sensitivity 86%). All negative samples were detected as such; specificity was of 100% for all three parameters. Classical assay had a specificity of 100% for all three parameters and sensitivity of 80%, 100%, and 93% for Mpn, Cpn, and Lpn respectively (Fig. 1).

**Conclusions:** All samples were correctly detected, except low positive ones. Transfer from classical PCR systems to the BD MAXTM was easy. Sensitivity was overall the same on BD MAXTM and on CFX96. BD MAX is a true walk-away system that saves time in a routine molecular diagnostic laboratory.

**P728** **Elevated red cell distribution width predicts poor outcome in adult patients with community-acquired pneumonia: a cohort study**

*E. Braun\*, J. Kheir, Z.S. Azzam (Haifa, IL)*

**Objectives:** Community acquired pneumonia (CAP) is a major cause of morbidity and mortality. We recently demonstrated that among young patients (<60 years old) with CAP, elevated red blood cell distribution width (RDW) levels on admission was associated with significant higher rates of mortality and severe morbidity. We aimed to investigate the prognostic predictive value of RDW among CAP patients in general population of internal wards.

**Methods:** The cohort included patients of 18 years old or older who were diagnosed with CAP (defined as pneumonia identified 48 hours or

less from hospitalization) between January 1, 2005 and December 31, 2010. Patients were retrospectively analyzed for risk factors for primary endpoint of 90-day mortality. Secondary endpoint was defined as complicated hospitalization (defined as at least one of the following: In-hospital mortality, length of stay of at least 21 days or ICU admission). Binary logistic regression analysis was used for the calculation of the odds ratios (OR) with 95% confidence intervals (CI) and p values in univariate and multivariate analysis to identify association between patient characteristic, 90-day mortality and complicated hospitalization.

**Results:** The cohort included 3815 patients. In univariate analysis, patients with co-morbid conditions tended to have a complicated course of CAP. In multivariate regression analysis, variables associated with an increased risk of 90-day mortality included age>80 years, high Charlson comorbidity index (>7), blood stream infection (BSI), blood urea nitrogen (BUN) >30 mg/dL, abnormal white blood cells, systolic blood pressure <90 mmHg and elevated RDW >15% (OR 2.1 [1.8–2.5]). Variables associated with complicated hospitalization included high Charlson comorbidity index, abnormal WBC, BUN> 30 mg/dL, hemoglobin <10 g/dL, BSI on admission and elevated RDW (OR 1.5 [1.2–1.8]). Mortality rate and complicated hospitalization were significantly higher among patients with increased RDW regardless of the white blood cell count or hemoglobin levels.

**Conclusion:** Elevated RDW levels on admission are associated with significant higher rates of mortality and severe morbidity in adult patients with CAP. RDW as a prognostic marker was unrelated with hemoglobin levels.

**P729** **Obesity and metabolic syndrome as risk factors for community-acquired pneumonia**

*M.B. Vilanova\*, M. Falguera, M. Pena, V. Sánchez, I. Chica, J. Montserrat-Capdevila, C. Esquinas, J.R. Marsal (Lleida, Mollerussa, ES)*

**Objectives:** Underweight, obesity or metabolic syndrome (MS) may be associated with an increased risk of community-acquired pneumonia (CAP), but available data on this relationship are sparse and inconsistent. The aim of our study was to evaluate the potential association between some anthropometric and metabolic data, such as body mass index (BMI), waist circumference (WC) and MS, and development of CAP.

**Methods:** We conducted a population-based case-control study. All patients aged ≥18 years diagnosed as CAP in the Emergency Department of Arnau de Vilanova Hospital in Lleida (Spain) between January 2009 and March 2010 were prospectively collected. Cases were matched by age and sex with control subjects randomly selected from a Primary Care Area in Lleida. Variables recorded were weight, height, WC, metabolic syndrome, smoking status, alcohol intake, influenza and pneumococcal vaccines, presence of underlying diseases such as diabetes mellitus, hypertension, dislipemia, chronic obstructive pulmonary disease (COPD), heart failure, liver and renal diseases, stroke and cancer, and current treatment with statins, proton pump inhibitors and angiotensin-converting enzyme inhibitors (ACE inhibitors). Subjects were stratified by BMI and divided into five categories according to the World Health Organisation classification. MS was defined by the National Cholesterol Education Program Adult Treatment Panel III 2001 (NCEP-ATP III). Univariate and multivariate analyses were performed with adjustment for confounding factors.

**Results:** A total of 164 cases and 164 controls (102 men and 62 women in each group, mean age 68 years) were enrolled in the study. In the univariate analysis, CAP was significantly associated with MS, smoking habit, absence of pneumococcal vaccination, COPD and ACE inhibitors use. In the multivariate analysis, COPD (Odds ratio [OR] 6.40; 95% confidence interval [CI] 2.95–13.90) and MS (OR 2.00; 95% CI 1.11–3.61) were significantly associated with an increased risk of CAP; conversely, pneumococcal vaccine (OR 2.00; 95% CI 0.29–0.80) and ACE inhibitors treatment (OR 0.51; 95% CI 0.27–0.94) were identified as protective factors. Neither subgroups of patients according to the BMI nor WC showed association with development of CAP.

**Conclusions:** Our study suggests that there is not a relation between BMI subgroups or WC and development of CAP. However, MS, in addition to other well-recognized predictive factors, could be a significant risk factor for CAP.

**P730 Integrated care pathway community-acquired pneumonia for hospitalised patients: how many patients could be included**

R.J. Pisco\*, C. Arnold, M. Ritter, S. Bassetti (Olten, CH)

**Objectives:** Considering the continuing increase in expenses in the health care system, more and more pressure to standardize procedures in care of patients with variable health problems is set up by local or national authorities. It is supposed that standardisation will reduce costs and improve quality of care. As these procedures were successfully implemented in surgical clinics, care pathways are also stipulated in internal medicine.

**Methods:** With regard to the conditions of the care pathway we calculated the percentage of patients with community acquired pneumonia that could be treated according to the schema. A principle precondition of the pathway is the absence of multiple comorbidities, defined as active diagnosis. Comorbidities were counted separately if they involved different organ systems. Hypertension alone or other comorbidities without impact in the management or duration of the hospitalization were not counted as comorbidities. The data were obtained retrospectively based on medical records of patients hospitalized with CAP from May 2007 till May 2009. We calculated how many patients would have been excluded due to comorbidities, admission to intensive care or immunosuppression.

**Results:** Three hundred and twenty-four patients with documented community acquired pneumonia and duration of hospitalization of at least 48 hours were analyzed. Eighty-seven patients had two, 70 three and 53 patients more than three comorbidities. Of the remaining 116 patients, 18 were admitted to the intensive care unit. Five of the remaining 96 patients admitted to a general ward were immunosuppressed. One due to a advanced HIV-infection, one due to chemotherapy for NSCLC and three due to immunosuppression for rheumatological diseases. Three more patients with a PSI class V were although estimated as not eligible for an integrated care pathway. 88/324 patients (27.2% 95% CI 22.3–32%) would have been estimated as eligible to be treated according to the integrated care pathway in our retrospective analysis.

**Conclusion:** The fraction of patients with CAP eligible to be treated according to a predefined integrated care pathway is limited. As most patients could not be treated according to this pathway, we are afraid that the introduction would rather cause confusion than help. Neither cost reduction nor improvement in care can be expected.

**P731 Evaluation of an antibiotic prescribing protocol for treatment of community-acquired pneumonia in a tertiary hospital**

E. García-Almodóvar\*, A. Ramírez-Mena, I. González-Sayago, C. Marinescu, M. Riera (Palma Mallorca, ES)

**Objectives:** Descriptive study of community-acquired pneumonia (CAP) admitted in Hospital Son Espases since January 1 to March 31, 2011, aiming to verify antibiotic prescription according to Committee on Infectious Diseases Guidelines.

**Methods:** Prospective observational study includes all patients admitted with CAP during the study period, pneumonia is defined by the presence of new lung infiltrates on chest radiography with one or more of the following symptoms: fever or hypothermia, cough with or without expectoration, dyspnea, and pleuritic pain. Patients with final diagnosis other than pneumonia are excluded.

Data are collected in a standardized form where the variables related to patient are: comorbidities, previous vaccinations, associated symptoms, signs on physical examination, antibiotic and antiviral treatment,

analytical and microbiological data, complications and related data to monitoring clinical protocol.

**Results:** This study included 102 patients with a CAP diagnosis, 56% men, age average 61 year old. The 37.3% were smokers, and comorbidity is present at 75%, from which 28.4% COPD. Five patients died, 3 with ARDS. Considering the prescription of several antibiotics at the same time, the most prescribed empirical antibiotic treatment were amoxicillin/clavulanate acid (55%), azithromycin (43%) followed by levofloxacin (31.6%).

Empirical treatment is prescribed according to protocol in 75.5% of cases. The 66.7% received antibiotic treatment within 4 hours after hospital admission. In 21.6% switch to oral administration the same day the patient reached clinical stability. Antibiotic treatment was adjusted according to the results of culture and sensitivity in 42.2% of cases. The date of completion of antibiotic treatment consisted in 60.8% of discharge summaries.

**Conclusion:** Specific standard therapeutic care protocols supported by scientific evidence and criteria of efficiency are a useful tool to improve the efficiency and effectiveness of antibiotics in hospitals. The adequacy of CAP protocol was 75.5%, with early antibiotic prescription and antibiogram adjustment. The point to be improved is the appropriate switch to oral administration.

**P732 Intravenous azithromycin – single dose 1.5 g vs. 500 mg once daily for 3 days in patients with community-acquired pneumonia: a prospective and randomised study**

H. Lagler\*, R. Gattringer, V. Derler, D. Wlazny, W. Graninger, H. Burgmann (Vienna, Linz, AT)

**Introduction:** Community-acquired pneumonia (CAP) is one of the most common infectious diseases and an important cause of mortality and morbidity worldwide. The objective of the clinical study was to evaluate efficacy and tolerance of intravenously (i.v.) administered azithromycin (AZM) single dose (1.5 g) vs. 500 mg once daily for 3 days in patients with CAP. Single dose application of i.v. AZM could be an alternative for Outpatient Parenteral Antimicrobial Therapy (OPAT) of CAP.

**Methods:** Adults (18–90 years; written informed consent; achieving inclusion criteria) suffering from CAP were enrolled in this study. Severity assessment by CRB-65 score was performed. Effectiveness of single i.v. dose of 1.5 g AZM (diluted in 1000 mL Lactated Ringer's Solution, duration of infusion 4 hours) compared to a standard dose schedule of 500 mg i.v. once daily for 3 days was evaluated. The primary endpoint was clinical cure, defined as: disappearance of fever within 72 hours; disappearance of other clinical and laboratory signs of inflammation; no necessary administration of an additional antimicrobial therapy. The study was an open, comparative, prospective and randomized trial.

**Results:** A total of 72 patients with CAP were randomized. Table 1 summarizes demographic characteristics of the study population and study results. The study drug was well tolerated in all patients. The most causative pathogens were *S. pneumonia* (22.2%), followed by *M. pneumonia* (6.9%), *L. pneumophila* (6.9%), *C. burnetii* (1.4%) and

	All	A	B
No. of patients, n (%)	72 (100)	39 (54.2)	33 (45.8)
Sex m/f, n	47/25	30/9	17/16
Age, years, mean (SD)	44.6 (+/-18.7)	45.3 (+/-19.4)	43.8 (+/-18)
CRB-65: 0, n (%)	24 (33.3)	11 (28.2)	13 (39.4)
CRB-65: 1, n (%)	37 (51.4)	21 (53.8)	16 (48.5)
CRB-65: 2, n (%)	11 (15.3)	7 (17.9)	3 (9.1)
Prior oral antibiotic, n (%)	13 (18.1)	7 (17.9)	6 (18.2)
Clinical cure, n (%)	63 (87.5)	34 (87.2)	29 (87.9)

CMV (1.4%). In 59.7% of the cases no causative pathogen could be diagnosed. No differences in cure rates were seen between the two groups. For 13% of the patients an additional antimicrobial therapy was necessary to get cured.

**Conclusion:** The results of this study indicate that single administration of 1.5 g AZM i.v. seems not to be inferior to standard dosage of 500 mg i.v. once daily for treatment of CAP. Treating patients with a single dose of AZM in an OPAT setting ensures high and adequate drug levels independent from patients compliance. Oral macrolides often show bad bioavailability, mainly oral AZM (about 30%). Single dose administration of AZM could provide a cheap and safety possibility for OPAT in patients suffering from an allergy to betalactam antibiotics. Data are limited by the low number of patients included. Further prospective studies including more patients need to be done.

EudraCT No. 2005-000105-65.

This research was supported by a grant from Pfizer Research.

**P733** **Empiric use of fluoroquinolone in patients with pulmonary tuberculosis presenting as severe community-acquired pneumonia may improve survival**

Y. Tseng\*, Y. Chuang, C. Shu, C. Hung, J. Wang (Taipei, TW)

**Introduction:** Empiric treatment with a fluoroquinolone (FQ) is recommended for community-acquired pneumonia, but may delay the treatment for tuberculosis and induce resistance. This study aims to evaluate the impact of empiric fluoroquinolone use in patients with tuberculosis presenting as severe community-acquired pneumonia in an endemic area of tuberculosis.

**Method:** All patients who presented as severe community-acquired pneumonia requiring intensive care from 2005 to 2010 and were finally laboratory confirmed to have pulmonary tuberculosis were included. Patients were separated into two groups according to the empiric antibiotics (FQ vs. non-FQ groups).

**Results:** A total of 79 tuberculosis patients were identified. Among them, 44 (55.7%) received empiric FQs. The clinical characteristics were similar between FQ and non-FQ groups except there were more patients with chronic pulmonary diseases among non-FQ group and more patients presented with fever among FQ group. Ninety-five percent (n = 42) and 97% (n = 34) had underlying systemic diseases (p > 0.9). The most initial presenting symptoms included respiratory symptoms (93% and 94%) and fever (63.6% and 34.3%) among FQ and non-FQ groups separately. Sputum samples were smear-positive for acid-fast bacilli in 10% (n = 8) overall. Among FQs used and non-FQs used group separately, the mean of APACHE scores and SOFA scores were 21.3 ± 6.6 vs. 22.1 ± 7.7 (p = 0.6), and 7.9 ± 3.6 vs. 7.3 ± 3.8 (p = 0.5), the mean duration of ICU stay and hospital stay were 30.57 ± 21.07 days vs. 17.57 ± 17.63 days (p = 0.05), and 75.70 ± 67.72 days vs. 39.66 ± 26.61 days (p = 0.004). Cox regression analysis and Kaplan–Meier analysis showed FQs use was the only associated factors for benefit of survival.

**Conclusion:** Due to its excellent bactericidal activity against *Mycobacterium tuberculosis*, empiric use of fluoroquinolone for patients with severe community-acquired pneumonia may improve survival.

**P734** **Aetiologies of prolonged cough in Thai adults: the roles of *Bordetella pertussis* and atypical pathogens**

N. Siritayakorn\*, P. Leethong, S. Sripakdee, A. Kerdsin, S. Dejsirilert, T. Tantawichien (Nakhon Ratchasima, Bangkok, Nonthaburi, TH)

Although pertussis traditionally has been considered a disease of childhood, it was well-documented in adults nearly a century ago and is currently recognized as an important respiratory tract infection in adolescents, adults and elderly. The epidemiology of pertussis in the Asian region seems poised for a similar change. *B. pertussis* infections are well known to cause prolonged cough, often this diagnosis is

overlooked because of atypical presentation of the disease, low diagnostic suspicion and limited use of confirmatory tests. In countries with routine vaccination against pertussis with high coverage, pertussis is not usually taken into consideration for the etiology of prolonged cough in adults. Studies in a variety of populations have documented that pertussis is quite common, ranging from 12% to 26% of adolescents and adults with prolonged cough. The anticipation and early recognition of this change in the epidemiology is important because the affected adolescents and adults act as reservoirs of the disease to the vulnerable population of infants, for whom the disease can be life threatening. We conducted a prospective study to determine the incidence of pertussis and atypical pathogens in Thai adults with prolonged cough.

**Methods:** Seventy-six patients with cough lasting for more than 2 weeks (range, 14–180 days) were recruited, from October 2010 through February 2011. Patients had a mean age of 55 years (range, 15–85 years) with a sex ratio F/M of 1.7. At enrollment, nasopharyngeal swabs were taken for detection of nucleic acid of *Bordetella pertussis*, *Mycoplasma pneumoniae* and *Chlamydia pneumoniae* by PCR and paired serum samples were collected and tested for IgG antibody to pertussis toxin by use of ELISA.

**Results:** Fourteen patients (18.4%) with mean age of 59 years (range, 28–85 years) and mean duration of cough were 34 days (range, 14–120 days) had evidence of acute infection of pertussis; among them, PCR was positive in one patient and 13 cases were diagnosed serologically. The possible *M. pneumoniae* and *C. pneumoniae* infections among patients with prolonged cough diagnosed by PCR were 1.3% and 25% respectively. Both PCR for *C. pneumoniae* and serology for pertussis were positive in two patients.

**Conclusion:** *B. pertussis* is being increasingly recognized as a cause of prolonged, distressing cough without whooping symptoms in adults in countries where childhood pertussis vaccination is universal.

**Fungal infections: from sensitive diagnosis to rapid species identification**

**P735** **Comparison of MycAssay™ *Aspergillus* real-time PCR kit and “in-house” real-time PCR assay on culture confirmed respiratory samples**

R. Kofol\*, T. Matos (Ljubljana, SI)

**Objective:** The MycAssay™ *Aspergillus* real-time PCR kit (Myconostica, Mancheste, UK) is a commercially available real-time PCR diagnostic assay that enables detection of *Aspergillus* spp. in respiratory samples. We compared a commercially available real-time PCR diagnostic assay and »in house« real-time PCR on culture confirmed respiratory samples.

**Methods:** We included 35 respiratory samples, sent for routine microbiology diagnostic procedures. Material was divided in two, one part was cultured using standard cultivation methods, the other was used for DNA extraction. DNA was extracted and purified using MagNA Pure Compact instrument (Roche Diagnostics, Mannheim, Germany) and MagNA Pure Compact Nucleic Acid isolation kit I (Roche Diagnostics, Mannheim, Germany), following the manufacturer's instructions. Isolated DNA was amplified with MycAssay™ *Aspergillus*, according to manufacturer's instructions and with »in-house« PCR targeting 18S rRNA genes as described by Sanguinetti et al., 2003. Both amplifications were performed using SmartCycler (Cepheid, Sunnyvale, CA) system.

**Results:** All culture positive respiratory samples were identified as *Aspergillus* spp. 43% (15/35) of samples were positive with MycAssay™ *Aspergillus* real-time PCR kit and 23% (8/35) with in house real-time PCR. All in-house positive samples, were also positive with MycAssay.

**Conclusion:** Sensitivity of both PCR assays in comparison to culture is quite poor. Explanation can be found in (i) inappropriate DNA extraction method for respiratory samples or (ii) presence of inhibitors in DNA isolates or (iii) non-optimal PCR reaction mixture and

conditions of both PCR assays. PCR assay for the detection of *Aspergillus* DNA could be an important additional diagnostic approach. It's faster, but need a suitable extraction method.

#### **P736** Molecular identification of *Candida* spp. from positive blood cultures

R. Kofol\*, V. Marcic, T. Matos (Ljubljana, SI)

**Objective:** For the detection of *Candida* blood stream infection blood culture remains the gold standard. Selection of the appropriate therapy is largely dependent on the accurate species identification. Standard microbiological methods of species identification are time-consuming. Here we present the TaqMan real-time PCR assay which enables detection and identification of six most frequently isolated *Candida* species from blood cultures: *C. albicans*, *C. glabrata*, *C. krusei*, *C. parapsilosis*, *C. tropicalis* and *C. kefyr*.

**Methods:** In the study were included 136 blood cultures (six negative, 130 positive) processed with BacT/Alert 3D automated blood culture system (bioMérieux, Marcy l'Etoile, France). Positive blood cultures were subcultured using Sabouraud agar and CHROMagar *Candida* (Mast Diagnostics, Merseyside, UK). One millilitre of suspension from positive blood culture was transferred into a new tube and centrifuged. DNA from supernatant was extracted automatically on MagNA Pure Compact Instrument (Roche Diagnostics, Mannheim, Germany). Species-specific TaqMan probes and primers were designed from the variable internal transcribed spacer region ITS2 as described previously by Guiver et al. (2001). Real-time PCR was performed in a 25 µL reaction mixture volume using the SmartCycler instrument (Cepheid, Sunnyvale, CA).

**Results:** Comparing classical identification and real-time PCR detection and identification concordant results were found in 123/136 (90%) samples (117 positive, six negative). Using real-time PCR we determined *Candida* spp. in another eight samples, which we couldn't determine with standard cultivation methods. In five samples we isolated fungi other than *Candida* which were PCR negative. Results were expected, and additionally confirmed PCR specificity.

**Conclusion:** TaqMan probe based real-time PCR is fast, because it allows species identification in few hours after positive blood cultures detection, is sensitive and specific.

#### **P737** Rapid identification of *Candida glabrata* cryptic species using real-time PCR combined with denaturing high-performance liquid chromatography

O. Telleria, G. Ezpeleta\*, S. Hernaez, R. Cisterna (Bilbao, ES)

**Introduction:** During last years, the increment in incidence, and associated high morbi-mortality, has converted invasive fungal infections in one of the most important public health associated problems. Besides, non-albicans *Candida* species have emerged as etiological agents of invasive candidiasis. Since the description of two new cryptic species (*C. bracarensis* and *C. nivariensis*) phylogenetically related to *C. glabrata* with different phenotype and antifungal susceptibility profile, it seems to be necessary to develop a rapid and accurate identification technique in order to distinguish between these three microorganisms.

**Objective:** We studied the performance of real-time PCR combined with Denaturing High Liquid Chromatography (DHPLC) as an alternative, fast and novel method to perform such identification accurately.

**Methodology and results:** Fungal DNA from pure cultures of *C. glabrata* (04.229), *C. bracarensis* (NCYC-3133) and *C. nivariensis* (04.228) reference strains was extracted using a MagNAPure Compact system. A small amplicon of the ITS2 region was amplified using the ITS86-F and ITS4-R primers previously described by Grutzner et al. employing a real-time PCR scheme with SYBR Green I in a LightCycler 2.0. The PCR products obtained were purified using

Ultra Clean™ PCR Clean –Up DNA purification kit according to manufacturer's instructions.

The identification technique of the three species was performed by DHPLC using WAVE-MD System. In order to achieve a clear separation of the three species, 5 µL of a mixture of the reference strains PCR products were injected in the chromatographic system under different partially denaturing conditions predicted by the system software. The identification of the species was carried out analyzing each sample separately at optimal conditions, as shown in the figure. Once optimized, this technique was applied to check the identification of 96 strains that were previously phenotypically identified as *C. glabrata* and all the system confirmed this identification in all the samples analyzed.

**Conclusions:** Real-time PCR combined with DHPLC was an accurate, fast and reliable method to confirm *C. glabrata*, *C. bracarensis* and *C. nivariensis* identification simultaneously in culture samples.

#### **P738** Invasive aspergillosis: evaluation of several diagnosis tests

M.T. Fraile Fariñas\*, M. Chanzá Aviñó, J.L. Ramos Martí, I. Celma Armiñana, M.D. Ocete Mochón, N. Gomez Muñoz, C. Gimeno Cardona (Valencia, ES)

**Objectives:** Invasive aspergillosis (API) is a disease of high mortality and difficult to diagnose. The aim of our study is to compare the results obtained by detection of ag. Galactomannan (AG) fungal culture and molecular techniques to detect DNA (PCR), in order to establish a protocol for diagnosing and monitoring the evolution of API infection in risk patients or clinical suspicion patients.

**Materials and Methods:** In the period of 8 months, were prospectively studied 472 samples of 271 adult patients from: Infectious, Pneumology, Oncology Services and Critical Care Unit, The processed samples were: 388 respiratory (104 sputum, 263 BAS, BAL 21.) and 84 serum samples. Respiratory specimens were processed for fungal culture and detection of AG.

In cases of disagreement between them, or both negative results, was performed to detect fungal DNA in respiratory specimens; PCR and AG in serum (66).

AG test was determined by the Platelia *Aspergillus* test (Bio-Rad Ref 62 794) according to manufacturer's recommendations.

A serum samples and/or BAL negative tests can not exclude the diagnosis of API.

Molecular diagnosis is based on the detection of *Aspergillus* genomic DNA by Real-time PCR. Kits were used for the qualitative detection of genomic DNA of *Aspergillus* in respiratory specimens of lower respiratory tract and serum, using a computer SmartCyclerR (Ref Myconostica MYCO-080-045).

**Results:** Considering culture as the gold standard, AG test in respiratory samples, showed a positive predictive value (PPV) of 23%, negative predictive value (NPV) of 100%, sensitivity (S) 100% and a specificity (E) of 52%.

Comparing the results of PCR with culture, we obtained a PPV of 69%, a NPV of 89%, S of 64% and E of 82%.

In serum, the AG and PCR tests showed a 60% of discrepancy.

**Conclusions:** AG detection is a highly sensitive and useful as an adjunct to culture for diagnosis and/or possible warning API. The specificity could be improved by increasing the rate of positivity in respiratory specimens AG.

In case of disparity of results or negative determination in patients with symptoms suggestive of API, the combination of several tests in both respiratory and serum sample simultaneously would increase the specificity of the diagnostic. In order to assess the diagnostic utility of the PCR, we believe that it's needed further studies to get it. Then, it could be improving the samples tests also using the quantitative technique.

**P739 Comparison of microscopic diagnosis and a real-time PCR test for the diagnosis of *Pneumocystis jirovecii* pneumonia**

I. de Toro-Peinado, M.P. Bermúdez-Ruiz, A.M. Fernández-Sánchez\*, C. Mediavilla-Gradolph, B. Palop-Borrás (Málaga, ES)

**Objectives:** *Pneumocystis jirovecii* pneumonia (PCP) is a common opportunistic infection, with high mortality when an adequate treatment is not performed, so empirical therapy is necessary but not extent of toxicity. Microscopic diagnosis has limitations, real-time PCR may assist in diagnosis but this technology is not still validated. We compared these two techniques in respiratory samples from patients with clinical suspicion of PCP.

**Methods:** We analyzed a total of 41 respiratory samples, 23 bronchoalveolar lavage (BAL) and 18 induced sputa (IE), received in our microbiology laboratory from April to October 2011. These samples belonged to 39 patients with strong clinical suspicion of PCP, six children (<14 years) and 33 adults. All the children's samples were BAL. Samples were investigated with microscopically examination using a direct immunofluorescence assay (IF) to detect *P. jirovecii* cysts (MONOFLUO *Pneumocystis jirovecii* IFA Test Kit, Biorad®). DNA was extracted from samples and was tested with the MycAssay *Pneumocystis* kit (Myconostica®) on a SmartCycler real-time PCR platform (Cepheid®), according to the manufacturer's instructions; this is a qualitative real-time PCR test utilizing molecular beacons, whose target sequence is the *Pneumocystis* mitochondrial ribosomal large subunit. Human DNA is not detected and the kit contains an internal amplification control sequence to confirm amplification.

**Results:** Comparing both techniques, we obtained 24 IF-/PCR-samples, 9 IF+/PCR+ samples and 8 IF-/PCR+ samples, none IF+/PCR-, what meant a concordance of 80%.

Analyzing by type of sample, concordance was 100% for BAL, whereas all the discrepant cases happened with IE. Two patients with two samples showed IF-/PCR+ IE and IF+/PCR+ BAL, so they were correctly diagnosed of PCP.

We realized that PCR recovered many cases of IF- IE, what can be explained by a low-level of microorganisms present in sputum. The problem is to differentiate between infection and colonization; a positive PCR result must be supported by clinical signs and symptoms and by results in other complementary tests, such as radiography. A negative test is helpful for excluding the diagnosis of PCP.

**Conclusion:** Multidisciplinary approach is required for early PCP diagnosis. Real-time PCR seems to be very helpful in diagnosis in a compatible clinical context.

**P740 Rapid identification of yeast species by MALDI-TOF MS compared to the Prove-it™ PCR assay**

J.D. Haigh\*, M. Petrou, M. Wilks (London, UK)

**Objectives:** The aim of this study was to determine the usefulness of MALDI-TOF MS to identify yeasts of clinical importance compared to a newly developed molecular method (Aittakorpi et al, ECCMID 2011 P2098).

**Methods:** One hundred and twenty eight yeasts from clinical specimens which had been previously identified by a combination of

conventional and molecular methods, were cultured for 18–24 hour on Sabouraud Dextrose Agar at 37°C. These samples were processed using the Bruker Biotyper alcohol extraction method. Using the Bruker Real Time Classification (RTC) software (Biotyper database 3995), samples were analysed automatically and an ID produced.

**Results:** One hundred and twenty eight isolates were analysed of which 88% (113/128) were identified. Nine isolates were not reliably identified. The PCR method gave the expected ID to species for 82% (105/128) of the comparative isolates.

**Conclusion:** MALDI-TOF is a rapid identification technique with a turnaround time of 24–36 hour, and could identify a greater diversity of yeasts compared to the Prove-it™ method. MALDI-TOF correctly identified a greater percentage of the yeasts, although this was not statistically significant. Assuming the user has access to a MALDI-TOF MS, the running costs are far lower and the process much simpler.

**P741 Molecular identification of *Malassezia* species isolated from dermatological patients in Saint Petersburg, Russia**

N.V. Vasilyeva\*, E.V. Pitsik, Y.V. Mikhaylova, T.V. Bogdanova, S.M. Ignatieva, I.V. Piotrovskaya, L.P. Kotrekhoval, T.S. Bogomolova (Saint Petersburg, RU)

**Objectives:** The aim of this study was an identification of *Malassezia* species isolated from patients with various skin diseases in Saint Petersburg, Russia.

**Methods:** *Malassezia* strains were isolated from skin lesions or pustule content of patients on Leeming-Notman agar (de Hoog et al., 2000) at 32°N during 4–14 days or more. rDNA extraction from *Malassezia* cultures was performed by PrepMan Ultra kit (Applied Biosystems, USA). PCR was performed with primers NL1 and NL4 (Kurtzman et al., 1998). Amplicons were purified and sequenced on both strands using BigDye Terminator V 3.1 Kit according to manufacturer protocol. Products were analyzed on Genetic Analyzer 3500 (Applied Biosystems, USA). Comparative sequences analysis and GenBank searches were made by MEGA 5 software (Tamura et al., 2011) and nucleotide-nucleotide BLAST (Basic Local Alignment Search Tool, <http://blast.ncbi.nlm.nih.gov/>).

**Results:** Eighty seven patients with following diseases were examined: 25 – pityriasis versicolor (29%), 23 – seborrheic dermatitis (27%), 20 – atopic dermatitis (23%), 11 – *Malassezia folliculitis* (13%) and 7 (8%) – other (pemphigus vulgaris, otitis, neurodermatitis, psoriasis, dyskeratosis). For molecular identification D1/D2 sequences were obtained. Based on intraspecific sequences comparison the limit of identity for species identification by BLAST analysis was chosen as 98%.

*M. sympodialis* were 37 (43%) isolates, *M. globosa* – 32 (37%), *M. restricta* – 9 (10%) and *M. obtusa* – 4 (5%). Four isolates (5%) showed identity <98% and were considered as *Malassezia* sp. *M. sympodialis* was the most frequent species in patients with pityriasis versicolor (52.0% cases) and *Malassezia folliculitis* (72.7%). *M. sympodialis* and *M. globosa* were associated with seborrheic dermatitis and atopic dermatitis nearly at the same rate (34.8% and 43.5% of seborrheic dermatitis cases, 35.0% and 40.0% of atopic dermatitis cases, respectively).

**Conclusion:** Unambiguous identification of 95% of *Malassezia* isolates was performed using D1/D2 region sequences of 26S rDNA. The most frequent species isolated from patients with *Malassezia*-associated skin diseases were *M. sympodialis* and *M. globosa*.

**P742 Genetic diversity of *C. parapsilosis* complex**

V. Marcic\*, T. Cerar, R. Kofol, T. Matos (Ljubljana, SI)

**Objectives:** *Candida parapsilosis* is an opportunistic pathogen which is a cause fungemia, vaginitis, endocarditis, endophthalmitis, septic arthritis and peritonitis. The aim of our study was to examine the

genetic diversity of isolates of *Candida parapsilosis* complex, obtained from clinical samples and to evaluated matrix-assisted laser desorption/ionisation time-of-flight (MALDI-TOF) mass spectrometry for the rapid identification of *Candida parapsilosis*, *C. orthopsilosis* and *C. metapsilosis*.

**Methods:** We analysed 122 *C. parapsilosis* complex strains previously identified using standard cultivation methods (CHROMagar *Candida* (Mast Diagnostics, UK) and biochemical tests [ID 32 C and API *Candida* (bioMérieux, France)]. Reference strains of *C. parapsilosis* ATCC 22019, *C. metapsilosis* ATCC 96144 and *C. orthopsilosis* ATCC 96139 were also included. The genetic diversity of *C. parapsilosis* was assessed using BanI digestion at SADH fragment as previously published by Tavanti et al, 2005. MALDI-TOF (Bruker Daltonik GmbH, Germany) was done according to manufacture's instruction.

**Results:** Using BanI digestion of SADH fragment we were able to differentiate 122 *C. parapsilosis* complex strains into 109 *C. parapsilosis* (89.35%), 10 *C. metapsilosis* (8.2%) and 3 *C. orthopsilosis* (2.45%). MALDI-TOF results were in complete concordance.

**Conclusion:** *C. parapsilosis* complex strain can be divided in *C. parapsilosis*, *C. metapsilosis* and *C. ortopsilosis* using any at the described methods.

#### P743 *C. haemulonii* complex: a human multi-resistant pathogenic yeast with a high genetic biodiversity

E. Cendejas-Bueno\*, B. Theelen, A. Gómez-López, M. Cuenca-Estrella, T. Boekhout (Majadahonda, ES; Utrecht, NL)

**Background:** *C. haemulonii* is one of the rarest yeast species that can be isolated from human clinical sources. Fungal infections due to this yeast have been described in the literature, varying from superficial to deep infections. Cases of catheter related fungemia, blood stream infection, osteitis and outbreaks in intensive care units have been reported recently.

The susceptibility profile of this *C. haemulonii* shows that is resistant to Amphotericin B (AMB) and Fluconazole (FLC) with high Minimal Inhibitory Concentrations (MIC) for both compounds, which can hinder the management of patients with deep infections caused by this yeast. This antifungal profile has often been associated with clinical failure.

**Materials and methods:** Thirty strains of the *C. haemulonii* complex belonging to the Mycology Department of the National Centre for Microbiology (CNM, Majadahonda, Spain) and the CBS Fungal Biodiversity Centre (CBS-KNAW, Utrecht, The Netherlands) collections were analyzed. The amplification and sequencing of the ITS domain (ribosomal DNA), D1/D2 region and DNA Polimerase II gen (RPB2) were done.

**Results:** From the 30 isolates of the *C. haemulonii* complex used in the present study, 19 were assigned to the most commonly encountered group (*C. haemulonii* group I), seven isolates were assigned to *C. haemulonii* group II, and the other four Isolates were assigned to a new cluster. Based on the ITS sequences analysis, three main clusters were distinguished. The first one included 23 strains, four out of these 23 formed a subcluster of "atypical" strains which were positive distantly from the other 19 *C. haemulonii* group I isolates. The third cluster included strains that belong to the *C. haemulonii* group II. On the other hand, the analysis of the RPB2 gene showed the same results as the ones showed in the ITS analysis. Whereas the analysis of the D1-D2 26S rRNA gene fragment sequences only showed two different clusters. The group formed by the four "atypical isolates" was included in the same cluster as those of *C. haemulonii*.

**Conclusions:** (i) the molecular data of the RPB2, D1/D2 and ITS regions demonstrate that the *C. haemulonii* complex has a high genetic diversity. These data suggest that *C. haemulonii* complex is composed by three different clusters. (ii) Due to the resistant antifungal profile, more studies would be needed in order to establish a relationship between the susceptibility profile and each one of these three clusters.

#### P744 Genotyping of *Candida albicans* by CDC3 microsatellite length polymorphism and high-resolution melting analysis: comparison between Tunisian and Parisian clinical isolates

J. Ben Abdeljelil\*, F. Saghrouni, A. Fathallah, S. Gheith, I. Khammari, M. Ben Said, S. Bretagne (Sousse, TN; Créteil, FR)

**Objectives:** Invasive candidiasis has emerged as a major problem in neonatal intensive care units (NICUs) over the last decades. The aim of our study was to assess whether there is a specific ecology to a Tunisian NICU and to evaluate the performance of the CDC3 microsatellite MLP and HRM analysis recently described as a typing system of *Candida albicans*.

**Methods:** We genotyped 82 isolates obtained from 40 neonates collected in the NICU of Farhat Hached hospital in Sousse city (Tunisia), by using CDC3 microsatellite MLP and the HRM analysis. We compared the results with those previously reported on 95 isolates collected in some remote Parisian hospitals to identify any specific ecology.

**Results:** Twelve genotypes were identified in the Tunisian isolates and 16 genotypes in the Parisian isolates. Eleven genotypes were common to both collections of isolates. Only one genotype from the Tunisian collection was not detected among the Parisian isolates. However five genotypes detected in Parisian collection were not shown among Tunisian isolates. In addition of the 16 genotypes observed, three were significantly more frequent in the Tunisian NICU. These results argue for a specific *C. albicans* population to the investigated NICU and represents an indirect evidence of nosocomial transmission of *C. albicans* in the unit. However, we cannot rule out the fact that the difference in the patients' population may partly explain the difference in the genotypes' distribution between the compared collections in addition to the difference in the ethnic origin and the age of the patients as the Tunisian isolates were obtained from neonates whereas the Parisian isolates were obtained from adults.

**Conclusion:** The differences in genotypes distribution among Tunisian and Parisian isolates argue for a specific *C. albicans* population to the Tunisian NICU. Combined microsatellite length polymorphism (MLP) and high-resolution melting (HRM) analysis are a highly reproducible and transportable genotyping method very suitable for comparison of the *C. albicans* ecology in different hospital facilities.

#### P745 Clonal diversity of *Candida albicans* isolates causing candidaemia over a 4-year period: patients located in different departments can be infected by identical genotypes

P. Escribano, S. Recio, T. Peláez, C. Sánchez-Carrillo, M. Rodríguez-Créixems, P. Muñoz, E. Bouza, J.V. Guinea Ortega \* (Madrid, ES)

**Objectives:** Most episodes of fungaemia are caused by *Candida albicans*. Genotyping of *C. albicans* strains isolated from blood may clarify the genotypic diversity of this species, although the technique is rarely performed. We studied the clonal diversity of *C. albicans* isolates using a highly reproducible and discriminatory microsatellite marker panel.

**Methods:** We studied 186 *C. albicans* strains isolated from the blood cultures of 174 patients with candidaemia (January 2007 to December 2010). Each isolate represented one episode of candidaemia. Multiple episodes were defined as isolation of *C. albicans* in further blood cultures taken  $\geq 7$  days after the last isolation in blood culture. The isolates were identified after amplification and sequencing of the ITS1-5.8S-ITS2 region and further genotyped using a panel of six microsatellite markers (Botterel JCM 2001, Sampaio JCM 2003, Sampaio JCM 2005). Patients had one episode (n = 160), two episodes (n = 9), or 3 (n = 1) episodes. Patients with mixed genotypes in the same culture were excluded (n = 4). Identical genotypes showed the same alleles for all six markers. A similarity dendrogram was

constructed using the remaining 181 strains from the 170 patients included.

**Results:** An inpatient analysis revealed that the genotypes causing both episodes were identical in most patients with two episodes (7/9). In contrast, two different genotypes were found in the patient with three episodes, one causing the first and second episodes and the other causing the third episode (isolated 6 months later). An interpatient analysis revealed that 124 of the 143 different genotypes found were involved only in one episode (n = 121 patients); the remaining genotypes grouped in 19 clusters (n = 49 patients) including two to five patients each. In 13 of the 19 clusters, the patients were infected by the same genotype but had been admitted to different departments. In contrast, each of the remaining six clusters grouped isolates from patients infected by the same genotype in the same department; interestingly, four of the clusters had a different genotype and involved patients admitted to the same unit (neonatology).

**Conclusion:** We showed that patients admitted to hospital could develop candidaemia caused by an identical genotype of *C. albicans*. In up to 70% of cases, patients were not located in the same department at diagnosis. In contrast, in patients with multiple episodes of *C. albicans* candidaemia, the genotype causing the first episode was found in the subsequent episodes.

**P746** Catheter-related fungaemia caused by *Candida albicans*: are genotypes from the catheter tip and blood the same?

P. Escribano, J. Guinea\*, T. Peláez, P. Martín-Rabadán, S. Recio, M. Rodríguez-Crèixems, P. Muñoz, E. Bouza (Madrid, ES)

**Objectives:** *Candida albicans* is a major cause of catheter-related fungaemia (CRF). The definition of CRF requires the isolation and identification of the same fungal species from both the catheter tip and blood cultures. However, strains are rarely genotyped to prove the presence of identical genotypes in both types of sample. The aim of this study was to investigate the presence of identical *C. albicans* genotypes in blood and tip samples from patients with CRF.

**Methods:** We retrospectively studied 22 patients admitted to hospital (January 2008 to December 2010) with *C. albicans* isolated simultaneously from blood and catheter tip cultures (48 isolates: 22 from blood cultures and 26 from catheter tip cultures [an additional tip culture with isolation of *C. albicans* was studied in four patients]). In 17 cases, the tip was received in the microbiology laboratory a mean of 2 days (range, 0–5 days) after receipt of the blood sample. Isolates were genotyped using a panel of six microsatellite markers (Sampaio JCM 2003, Sampaio JCM 2005, Botterel JCM 2001). Matches between catheter and blood genotypes were defined when they both showed identical alleles for all six markers.

**Results:** We found matches between genotypes in both samples in 20 of the 22 (91%) patients. Most patients (19/20) had only one genotype, but one patient had two different genotypes found simultaneously in both the tip culture and the blood culture. Only 2 of 20 patients had different genotypes both samples. In one, the catheter tip genotype differed in two markers from the blood genotype (the catheter was received in the laboratory 5 days after the blood culture); in the other patient, the catheter tip genotype differed from the blood genotype in five markers. In the case of the four patients in whom a second catheter tip was analyzed, we again found matches between the catheter tip and blood genotypes.

**Conclusions:** The use of a microsatellite panel with high discriminatory power enabled us to show – albeit in a low proportion of cases of CRF – that the *C. albicans* genotypes colonizing catheter tips are different from those causing candidaemia. Future prospective studies including several colonies from both tip cultures and blood cultures are warranted. Jesús Guinea (CP09/00055) and Pilar Escribano (CD09/00230) are supported by a contract from FIS.

**P747** Fungal environmental control: usefulness of a pan-fungi NASBA in a protected haematology unit

M.-P. Brenier-Pinchart\*, H. Abaibou, G. Szymanski, M. Beghri, T. Berendsen, F. Lasnet, A. Thiebaut-Bertrand, C. Mabilat, H. Pelloux (Grenoble, Marcy l'Etoile, FR)

**Objectives:** The fungal surveillance of environmental contamination is necessary in protected haematology wards housing patients at high-risk of invasive filamentous fungal infections. This monitoring is usually performed with mycological culture-based method. Several PCR have been described to evaluate the fungal load but mainly in highly contaminated environment.

We describe a quantitative NASBA targeting fungal rRNA (molds and yeasts) and an original application of this method on environment samples to monitor the fungal load in protected haematology unit.

**Methods:** This quantitative pan-fungi NASBA (Zhao et al, 2009) was used in combination with an internal control (Weusten et al, 2002) and was fully developed on NucliSENS EasyQ (bioMérieux). The sample preparation and extraction were performed with a miniaturized prototype specifically designed for processing environmental samples derived from the NucliSENS easyMAG (bioMérieux).

Two different locations in a protected haematology ward were sampled: the corridor and the patient's rooms with HEPA filters and LAF. Surface samples were performed by contiguous sampling using contact plates (bioMérieux) and swabs (Copan).

**Results:** During this 12 weeks prospective study, 132 surfaces were studied (table). The percentage of agreement between culture and NASBA were 78% and 92% for samples performed in corridors and in rooms, respectively. Among discrepancies between these two methods, the positivity of NASBA associated with a negative culture (9.8%) was more frequent than negative NASBA with a positive culture (2.3%). In the five positive samples performed in corridor, the load was 2.8 CFU ± 2.5/25 cm<sup>2</sup> and 3.9 ± 2.7 Geq/25 cm<sup>2</sup> for culture and NASBA, respectively.

	0	3,8
	0	4,6

CFU = Colony Forming Unit, Geq: genome equivalent.

**Conclusion:** Pan-fungi NASBA used in this study allows to evaluate rapidly the global fungal load (3 hours instead of 1 week) and could be applied to the surface fungal environmental surveillance in protected unit, since the percentage of agreement between culture and NASBA is high. In protected area the fungal load is very low. Two surfaces although contiguous could be not strictly contaminated by the same number of spores explaining the discrepancies observed between culture and NASBA in part. Furthermore all molecular methods detect also non cultivable fungi but NASBA has the advantage to detect only viable organisms. Further, the evaluation of NASBA in air samples is necessary as well as the evolution of NucliSens technology towards an integrated system.

**P748 FGD PET features of pulmonary histoplasmosis**

H. Polenakovic\*, M. Ambalavanan, P. Gibbs, K. Wong, R. Markert (Dayton, US)

**Objective:** Pulmonary histoplasmosis (H) is an endemic mycosis that often radiographically resembles lung cancer (LCa) and complicates the evaluation of pulmonary nodules (PN). This study aims to describe the fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET) features of H and pathologic correlation.

**Methods:** The pathology records of our hospital were retrospectively reviewed over a 10-year study period in order to identify patients who had histopathologically diagnosed H and who underwent FDG-PET imaging. We then reviewed their demographic, clinical, laboratory and FDG-PET features.

**Results:** Fourteen patients (pts) (eight men; mean age 50; range 24–69 years) were included. Twelve pts (85%) had underlying lung disease. Most frequent clinical manifestations were cough in 5 (35.7%), and dyspnea in 2 (14.3%) pts. Histopathologically, fibro-caseating nodule (inactive lesion) was the most frequent finding (9 pts; 64.3%), followed by active granulomatous inflammation (5; 35.7%) and acute pulmonary inflammation (1; 7.1%). Three pts were found to have simultaneous H and LCa. The diameter of PN and lymph nodes (LN) ranged from 0.6 to 4.4 cm (mean 1.7) and 0–3 cm (mean 1.47), respectively. Positive FDG uptake was identified in 11 pts (78.6%), and negative uptake in three pts (21.4%). The mean standardized uptake values (SUV) of 14 PN and 13 LN were  $7.37 \pm 10.8$  (0–39), and  $2.93 \pm 1.8$  (0–5.2), respectively. When H-LCa cases were excluded, the diameter of PN and lymph nodes (LN) ranged from 0.6 to 2.0 cm (mean 1.24) and 0–3 cm (mean 1.5), respectively. The mean SUV of 11 PN and 10 LN were  $3.4 \pm 4.15$  (0–15), and  $2.87 \pm 2.03$  (0–5.2), respectively. Pathologically active H lesions had marginally significantly higher FDG radioactivity than inactive lesion ( $p = 0.056$ ). The mean SUV of the active PN lesions was  $5.56 \pm 5.31$  vs.  $1.2 \pm 1.71$  in inactive PN lesions. No statistical significance was found on the Spearman correlation between the density of the yeast in the lesions and SUV measures.

**Conclusion:** This retrospective study provides FDG-PET – pathologic data on H, in patients residing in H-endemic area, who underwent FDG-PET for evaluation of chest imaging abnormalities concerning for neoplasm. To our knowledge this is the largest case series of FDG-PET findings in pts with H.

**P749 Species distribution and anti-fungal susceptibility of *Candida* spp. at the Heart of England Foundation Trust, United Kingdom**

A. Hussain\* (Birmingham, UK)

**Introduction:** Invasive candidiasis has an attributable mortality of 40%. Fluconazole is extensively used for the prevention and treatment of *Candida* infections, despite its frequently reduced or absent activity against some non-albicans species. The IDSA guidelines advise using echinocandins in patients with severe illness, as well as those with prior azole exposure. Susceptibility testing guides patient management and epidemiological surveillance. This is increasingly necessary in the light of proposed new antifungal breakpoints.

**Methods:** *Candida* species were collected prospectively, identified using the AUXACOLOR™<sub>2</sub> Kit (Bio-Rad, USA) and susceptibility tested using the YeastOne® Sensititre (TREK Diagnostics, USA) Kit. Susceptibilities were interpreted using national reference laboratory breakpoints.

**Results:** Hundred and one isolates were tested in the study, of which 61% were from non sterile sites and 39% were from blood cultures. Species distribution for blood cultures showed 44% were *C. albicans* and 45% from the non-sterile sites. No fluconazole resistance in *C. albicans* from blood cultures was identified, although the rate of intermediate resistance was 12% with the new breakpoints. The non-albicans strains from blood cultures had high levels of fluconazole resistance increasing from 55% to 82% when interpreted with the new

breakpoints. Clinical data of these patients is summarised in Figure 1. Isolates of *C. albicans* from non-sterile sites, 45% ( $n = 28$ ) were from high vaginal swabs, the rest were from sputa and superficial swabs. One percent of all specimens were noted to be fluconazole resistant, with intermediate susceptibilities increasing from 25% to 32% when interpreted with the new breakpoints. In the non-albicans strains from non-sterile sites fluconazole resistance levels increasing from 15% to 41% for using the new breakpoints.

Age (yrs)	51.5±24.2
Sex (male n,%)	26, 67%
Isolate from Critical Care (n,%)	7, 18%
Fluconazole used appropriately as a first agent (n,%)	32, 82%
30 day mortality	57%
Duration of Treatment (days)	11.1±8.1

**Discussion:** There is a variation in the local epidemiology of *Candida* species from sterile and non-sterile sites. Less than 50% of organisms recovered from blood cultures were found to be *C. albicans*, and, this coupled with >50% resistance rates to fluconazole in the non-albicans suggests that patients with a probable or proven candidaemia should be managed with an echinocandin empirically and then de-escalated to fluconazole if proven susceptible. Monitoring of resistance patterns in non-sterile samples is necessary to assess the effect of systemic antifungals available without a prescription.

**P750 Early prediction of dose–response and PK/PD relationships of antifungals by quantitative measurement of tissue burden using real-time quantitative PCR in an animal model of invasive aspergillosis**

S. Seyedmousavi\*, W. Melchers, J. Bakkens, P. Verweij, J. Mouton (Nijmegen, NL)

**Objectives:** Experimental models of invasive aspergillosis (IA) have been used to explore pharmacokinetic and pharmacodynamic (PK/PD) properties of antifungal agents. Survival is still considered the most reliable effect measure to determine exposure-response. We here study the feasibility of quantitative PCR (qPCR) to measure fungal load in target tissues for early assessment of antifungals efficacy in an experimental model of IA.

**Methods:** We studied in vivo pharmacokinetics and antifungal efficacy of voriconazole (VCZ) vs. anidulafungin (AFG) in an immunocompetent model of *Aspergillus fumigatus* (AF) infection (VCZ-susceptible and VCZ-resistant isolates). Groups of 17 mice were randomized for doses regimens of 2.5, 5, 10 and 20 mg/kg/body weight. Therapy was started 24 hour after fungal inoculation for seven consecutive days, once daily intraperitoneally. The therapeutic efficacy was investigated using animal survival at 7 and 14 days postinfection, compared to the decrease in tissues fungal burden at 48 and 72 hour postchallenge, utilizing real-time qPCR targeting the 28S region of AF. Kidneys were collected from three treated and three control mice at each timepoint and also from all surviving mice at the end of the experiment.

**Results:** The mean number of genome copies detected in untreated animals was  $3 \times 10^4$  in kidneys ( $n = 3$ , range =  $1 \times 10^3$ – $2 \times 10^5$ ) at days 2 and 3 post infection. There was a mean 2–3 log<sub>10</sub> ( $n = 3$ , range =  $1 \times 10^2$ – $2 \times 10^4$ ) reduction of AF genome copies in infected animals treated with highest dosage of VCZ (100% survival at days 7 and 14). A stronger correlation between 7 days survival and qPCR was observed at day 3 post infection ( $r^2 = 0.90$ ,  $p = 0.01$ ) compared to day 2 ( $r^2 = 0.84$ ,  $p = 0.02$ ). Survival due to AFG therapy maximized at 72% and qPCR showed a significantly lower reduction (1–2 log<sub>10</sub>,  $p < 0.05$ ). The relationship between reduction in tissue burden at day 3 postinfection and 7 days survival were similar for VCZ-susceptible and VCZ-resistant isolates with highest dosage of VCZ ( $r^2 = 0.90$  vs.  $R^2 = 0.95$ ,  $p < 0.05$ ).

**Conclusion:** Our results indicate that real-time qPCR assay is a reliable and promising technique to detect *Aspergillus fumigatus* DNA. This assay could be used to measure the fungal burden in organs and thus monitor the efficacy of antifungals in animal model of IA at day 3 post challenge. Targeting molecular markers by real-time quantitative PCR can reduce the number of animal needed for dose–response and PK/PD studies of antifungals in experimental model of IA.

**P751** Detection of *Pneumocystis jirovecii* in adult patients with acute and chronic respiratory tract infections

K.K.W. To\*, I.F.N. Hung, T. Xu, R.T.Y. Wong, K.H. Chan, K.Y. Yuen (Hong Kong, HK)

**Objectives:** *Pneumocystis jirovecii* is usually considered an opportunistic pathogen. However, recent studies show that *P. jirovecii* can also be detected in the nonimmunocompromised populations. This fungus can stimulate pulmonary inflammation, and has been implicated in the pathogenesis of chronic obstructive pulmonary disease. In this study, we aim to study the prevalence of *P. jirovecii* in patients with acute and chronic respiratory tract infections.

**Methods:** This study included adult patients aged 18 years or above. Group 1 consisted of patients with nasopharyngeal specimens sent to our laboratory for respiratory virus detection by direct immunofluorescence or viral culture between November 2010 and April 2011. Group 2 consisted of patients with laboratory-confirmed *Mycobacterium tuberculosis* infection by polymerase chain reaction (PCR) between January 2010 and June 2011. The decision for specimen collection was made by the clinician, and therefore group 1 and group 2 were representative of patients with acute and chronic respiratory tract infections, respectively. Nested PCR targeting the mitochondrial large subunit ribosomal RNA of *P. jirovecii* was performed in archived nasopharyngeal specimens for group 1, and in bronchial or sputum specimens for group 2. This study was approved by the Institutional Review Board of the University of Hong Kong/Hospital Authority Hong Kong West Cluster.

**Results:** A total of 181 patients were selected. Group 1 consisted of 131 patients, in which 37 had laboratory-confirmed 2009 pandemic H1N1 virus infection, and 94 were negative for any respiratory viral pathogens by direct immunofluorescence or viral culture. Group 2 consisted of 50 patients. *P. jirovecii* was detected in the nasopharyngeal specimens from five patients (3.8%) in group 1; and in the lower respiratory tract specimens from 8 (16%) patients in group 2 (Table 1). Nine of 13 (69.2%) of *P. jirovecii* positive patients did not have high risk immunosuppressive conditions (HIV, transplant, malignancy, connective tissue disease, immunosuppressants) nor chronic obstructive pulmonary disease.

Patient no.	Group	Sex / Age (years)	Underlying disease	Outcome at 30 days
1	1	F/27	Good past health	Survival
2	1	F/81	Hypertension, gastrointestinal stromal tumour, proteinuria	Survival
3	1	M/74	Right side pleural effusion during childhood of unknown cause	Survival
4	1	F/84	Carcinoma of the breast with curative mastectomy, cerebrovascular accident with left hemiparesis, osteoporosis, gastric ulcer	Survival
5	1	M/59	Hypertension, left basal ganglion infarct, neurogenic bladder	Survival
6	2	M/79	Partial gastrectomy for peptic ulcer	Survival
7	2	M/81	Atrial fibrillation, cerebrovascular accident, spondylolisthesis	Survival
8	2	M/48	Lung cancer	Death
9	2	M/79	Chronic obstructive pulmonary disease, diabetes mellitus, benign prostatic hyperplasia, lung cancer	Death
10	2	F/78	Alzheimer's disease	Survival
11	2	F/84	Hypertension, bilateral cataract, paranoid schizophrenia, genital prolapse	Death
12	2	F/19	Anorexia nervosa	Survival
13	2	M/77	Myocardial infarction, lung cancer	Survival

**Conclusions:** *P. jirovecii* can be detected in patients with both acute and chronic respiratory tract infection, even in

nonimmunocompromised patients or those without chronic pulmonary diseases. The clinical significance of *P. jirovecii* in these patients should be further investigated.

## Invasive bacterial infections: diagnosis and clinical presentation

**P752** Analysis of 554 cases of bacterial meningitis within nationwide survey in Slovakia, 1990–2010

J. Sokolova\*, V. Krčmery on behalf of Slovak Meningitis Study Group

**Objective:** Purpose of this study was to assess whether differences in aetiology and risk factors of meningitis acquired in hospital (HAM) or in community (CAM) have impact on outcome of infected patients.

**Methods:** Among 554 cases of bacterial meningitis within last 20 years from 10 major Slovak hospitals (Bratislava, Trnava, Kosice, Ruzomberok, Nitra, Banská Bystrica, Nove Zamky, Presov, Zilina, Lucenec), 261 (47.2%) were HAM and 293 (52.8%) were CAM. Aetiology, risk factors and outcome were compared in both groups. Differences were assessed by Chi-square test and Fisher's exact test computerized with the open source statistical package "R" and  $p$  value  $< 0.05$  was considered statistical significant.

**Results:** Patients with HAM had more frequently coagulase negative staphylococci (18.5% vs. 0%), Enterobacteriaceae (17.6% vs. 5.5%;  $p = 0.001$ ), *Acinetobacter baumannii* (10.7 vs. 3.1;  $p = 0.002$ ) and *Staphylococcus aureus* (9.2% vs. 4.4%;  $p = 0.03$ ) isolated from cerebrospinal fluid (CSF) and *Streptococcus pneumoniae* (6.5% vs. 35%;  $p < 0.001$ ), *Neisseria meningitidis* (3.8% vs. 33%;  $p < 0.001$ ) and *Haemophilus influenzae* (1.2% vs. 4.8%;  $p = 0.001$ ) were more commonly isolated from cerebrospinal fluid in CAM. Concerning risk factors, neurosurgery (82% vs. 1.7%;  $p < 0.001$ ), prior sepsis (24.1% vs. 14%;  $p = 0.002$ ), neonates (12.6% vs. 3.4%;  $p = 0.001$ ) and cancer (14.6% vs. 3.7%;  $p = 0.001$ ) were more common in HAM and alcohol abuse (1.9% vs. 14%;  $p < 0.001$ ) as well as otitis/sinusitis (3.5% vs. 20.1%;  $p < 0.001$ ) in CAM. Initial treatment success (88.2% vs. 87.4%,  $p = 0.79$ ) and cure after treatment modification (13.14% vs. 14.3%,  $p = 0.75$ ) was similarly frequently observed in both groups of meningitis. Overall mortality (11.8% vs. 12.6%,  $p = 0.88$ ) in both groups was similar too. However when analysis risk factors for mortality in the groups of HAM and CAM was done separately, different risk factors could be identified for mortality. In CAM alcohol abuse ( $p = 0.01$ ), diabetes mellitus ( $p = 0.02$ ), staphylococci ( $p = 0.02$ ) and *Pseudomonas aeruginosa* in aetiology ( $p = 0.01$ ) were at risk factor for death. In HAM any risk factor or specific aetiology was significant associated with death.

**Conclusion:** Despite of numerous differences in aetiology and risk factors between CAM and HAM within 20 years of Slovak nationwide survey, no differences in outcome, neither in mortality nor in neurological post-meningitis sequelae were observed.

**P753** Increase in 2011 in Denmark of invasive meningococcal disease due to a higher number of serogroup C

L. Lambertsen, P. Valentiner-Branth, P.H. Andersen, S. Hoffmann\* (Copenhagen, DK)

**Objectives:** The aim was to present data on invasive meningococcal disease (IMD) with focus on observed changes in 2011.

**Methods:** Data were obtained from the clinical and laboratory notification systems, which both are mandatory. All isolates submitted by the Departments of Clinical Microbiology to the reference laboratory were characterized by serogroup, porA and feta type. Data presented for 2011 are based on 62 isolates and 9 PCR verified cases from 10/12 of the year (January through November) and the estimated incidences for 2011 were calculated from the number of these isolates and the population size for 2011.

**Results:** The incidence per 100 000 of laboratory confirmed IMD cases decreased from 1.61 (yearly average  $n = 86$ ) during the time period 2001–2005 to 1.18 (average  $n = 65$ ) in 2006–2010. However, in 2011 the estimated incidence increased to 1.53 per 100 000 (estimated  $n = 85$ ). The incidence decline from 2001–2005 to 2006–2010 was due to a decrease in the incidence of serogroup B IMD from 1.14 to 0.69 per 100 000 whereas the incidence of serogroup C IMD only changed from 0.36 to 0.41 per 100 000. In contrast, the estimated increase in the incidence of IMD in 2011 was due to an elevated number of sporadic cases of serogroup C. In 2011 the incidence of serogroup C IMD was 0.94 per 100 000 (estimated  $n = 52$ ) whereas it was 0.47 per 100 000 (estimated  $n = 26$ ) for serogroup B IMD. Among serogroup C isolates the prevalent finetype (porA: FetA) was 5,2: F3-3 representing 70% (21 of 30 typed serogroup C isolates) in 2011. This type was also prevalent in the previous 3 years.

**Conclusions:** In 2011 the estimated incidence of IMD in Denmark increased and for the first time became more prevalent than serogroup B IMD. This increase was due to an increase in serogroup C, porA: FetA type 5,2: F3-3.

#### **P754** *Mycoplasma hominis* meningitis – a case report and review of the current literature

H. Schuster\*, M. Tavodova, J. Busutil, M. Tebruegge, S. Faust, S. Patel, K. Forrest, K. Lang, A. Pallett, C. Harris, J. Soothill (Southampton, Newmarket, London, UK)

We present a case of a term neonate with *Mycoplasma hominis* meningitis following Group B Streptococcal sepsis. 16S rDNA PCR and sequencing played a critical role in confirming the diagnosis and directed appropriate antibiotic therapy. We determined minimal inhibitory concentrations for single and combinational antibiotics and reviewed the limited existing literature on *M. hominis* central nervous system (CNS) infection.

A 23-day-old term neonate was transferred to our tertiary healthcare facility with meningitis of unknown origin and subdural collections. Immediately after birth the infant had developed signs of respiratory distress necessitating admission to the neonatal unit. Blood cultures grew Group B streptococci. Initially intravenous (i.v.) cefotaxime was started. Following a sterile CSF culture and negative CSF group B streptococcal antigen assay, treatment was switched to i.v. amoxicillin. C-reactive protein declined over the next 2 weeks but rose again with intermittent pyrexias. A repeat CSF sample on day 23 of life was suggestive of bacterial meningitis (WCC: 1760/mm<sup>3</sup>; protein: 4.34 g/L; glucose <0.1 mM). A CT brain showed multiple bilateral extra-axial collections and evidence of non-communicating hydrocephalus. Due to clinical symptoms suggestive of raised intracranial pressure he was transferred to our hospital for extra ventricular drain placement.

At the time of transfer the CSF showed colonial growth on blood agar plates but the organism did not take up Gram or Ziehl–Neelsen stain. The sample was referred for 16S rDNA PCR and was positive for *M. hominis*. Following identification of the causative organism the antibiotic treatment was modified to intravenous ciprofloxacin, which was changed to intravenous moxifloxacin after 4 days. Within 2 days the infant became afebrile, and the inflammatory markers declined.

The published literature suggests that *M. hominis* CNS infection is an uncommon entity that mainly affects neonates. This case highlights that isolation of an organism from the CSF of a neonate that cannot be stained by routine methods should prompt colleagues to consider *M. hominis* and request molecular diagnostic tests that allow correct identification and appropriate choice of antibiotic therapy.

#### **P755** Meningitis caused by *Campylobacter jejuni*

A. Kansouzidou\*, N. Tseniklidou, M. Rigkos, A. Karabournidis, K. Karantani, E. Michailidou, I. Kavaliotis (Thessaloniki, GR)

**Objective:** *Campylobacter jejuni* infection is one of the most common bacterial causes of acute gastroenteritis worldwide. Extraintestinal

infections are rare and most reports of meningitis due to *C. jejuni* species describe only a small number of cases. A case of meningitis caused by *C. jejuni* in a newborn is described in this report.

**Case report:** A newborn infant (15-days-old) presented to the hospital with a 5-hour history of fever (38.8°C) and no other symptoms. Initial investigation showed that total WBC count 10750/mm<sup>3</sup>, hemoglobin 13.5 g/dL and the other biochemical examinations were within normal limits. The cerebrospinal fluid (CSF) analysis revealed leukocyte count 1150/mm<sup>3</sup> (polymorphonuclear 85%, lymphocytes 15%), protein 95 mg/dL and glucose 31 mg/dL. CSF microscopy was negative for microorganisms, but conventional CSF culture yielded a curved Gram(–) organism. Also, blood and faecal specimens were cultured and they were negative. The organism, that was isolated from CSF culture, was identified as *C. jejuni* and was resistant to cephalothin and sensitive to ampicillin, erythromycin, cephalexin and ceftriaxone. The patient was treated with a combination of cephalexin 150 mg/kg and ampicillin 200 mg/kg daily intravenously. After the 12 day, the treatment with cephalexin was continued for other 9 days. In order to determine the source of infection faecal specimens from six family members were cultured and *C. jejuni* was isolated from the faecal specimen of the father and that supports the domestic transmission. Also, the brother of the neonate suffered from acute gastroenteritis some days ago. The patient's condition gradually improved and he remained afebrile and was discharged.

**Conclusion:** To our knowledge this is the first case of *C. jejuni* meningitis that was reported in Greece. This case shows that *C. jejuni* can cause meningitis in neonates and that it should be considered in the differential diagnosis of meningitis, since the clinical symptoms are not specific in the meningitis caused by *C. jejuni*, in neonates.

#### **P756** Case series of brain abscesses and empyemas: 11-year experience of a Portuguese infectious diseases department

D. Seixas\*, P. Crespo, N. Marques, L. Malcata, J.E. Serra, J. Oliveira, J.G. Saraiva da Cunha (Coimbra, PT)

**Introduction:** Abscesses and empyemas in the Central Nervous System (CNS) are rare but potentially fatal. Early diagnosis is associated with better prognosis, favored by new imaging techniques, antibiotic regimens and neurosurgical approaches.

**Objectives and methods:** A retrospective study was performed aiming the characterization of clinical presentation, treatment and outcome of patients hospitalized at the Department of Infectious Diseases between January 2000 and December 2010, who were diagnosed with ‘brain empyemas and/or abscesses’.

**Results:** The authors identified sixty-eight patients, 76.4% male, with a mean age of 47 years [13, 80]. It was not possible to determine the prior duration of symptoms in 23.5% patients, while within 25% of total were symptomatic 4 days before admission in Emergency Room (ER), and 32.4% more than 2 weeks prior to it.

Upon admitted in the ER, 44.1% patients had made previous antibiotic therapy. 63.2% presented with headache, 57.3% with altered mental status, 51.5% with fever and 47% with neurological deficits. All patients underwent image studies: 33.8% had frontal lobe lesions, 19.1% temporal lesions and multifocal lesions in 5.9%. Fifty-four patients (79.4%) underwent at least for one neurosurgical drainage.

As predisposing conditions: a contiguous focus was identified in 54.4% (paranasal sinus infection 18 cases, otogenic infection 14 cases and dental infection five cases), while 19.1% of the patients underwent prior neurosurgery.

From the specimens collected ( $n = 62$ ), Gram negative bacilli rods were isolated in 6.5%, Streptococcus rods in 9.7%, Staphylococcus rods in 14.5% and anaerobes in similar percentage. No species were identified in 17.7% while culture was polymicrobial in 30.6% of the total.

The antibiogram was initiated empirically to all patients and kept for a period of 6 weeks in 25% and 20.6% in 8 weeks.

On average, patients remained hospitalized during a 53 days period. It was possible to detect sequelae in 14.7% of patients, while a mortality rate of 10.3% was registered.

**Conclusion:** Despite technical advances, poor specificity of signs and symptoms require a high degree of suspicion so that the diagnosis won't be delayed. Establishing an empirical antibiotic considering the predisposing factors and early surgical intervention where both crucial to the low morbidity and mortality registered.

**P757 Intracranial abscess: epidemiology and local antimicrobial guideline development**

*J.S. Cargill\*, K. Sethi (Leeds, UK)*

**Objectives:** Brain abscesses and subdural empyemas are associated with mortality rates of up to 24%. The aetiology has changed over time, with decreasing otogenic abscesses and an increase in those associated with immunosuppression. Therapeutic outcomes vary greatly in brain abscesses, according to different pathogens. We reviewed the laboratory processing of specimens from intracranial abscess, and report here the bacterial aetiology and the design of an empirical antimicrobial regime based on this local data.

**Methods:** Thirty-two patients (42 procedures; 18 excisions, 26 burr-hole drainage) procedures were identified by the neurosurgical department. All but one procedure had samples sent for microbiology. The laboratory records for the samples received were reviewed to obtain microscopy and culture results. The patients' clinical notes were not obtained and so correlation with potential sources of infection is not possible.

**Results:** A total of 42 pus samples, nine tissues and 10 swabs were identified. Forty-one pus samples (97.6%), nine tissues (100%) and five swabs (50.0%) received Gram stains, (90.2% of all samples). Gram stains were performed on at least one specimen sent from forty procedures (95.2%); the two procedures from which no Gram-stains were available each had one sample only sent to the laboratory. In the case of the swab specimens, some were not clearly labelled as operative samples and were processed as superficial swabs.

The most frequently identified bacterial pathogens are *Streptococcus* species and *Staphylococcus aureus*, with no bacterial cause identified in one third of cases. There were small numbers of other Gram-positive organisms, including *Nocardia*, and of Enterobacteriaceae. Mixed infections were not unusual.

**Conclusions:** Gram staining of intracranial tissue and pus samples should be routine; staining of pus swabs is not indicated when other specimens are available. Only one episode was identified where additional organisms were isolated from a swab compared to pus or tissue samples. Molecular identification may be useful in unusual cases and where conventional techniques fail to identify an organism; 16S ribosomal RNA gene sequencing was used in several local cases, either to identify an isolate, or to identify bacteria where no isolates were recovered but organisms were seen on Gram stain.

This local data was used to develop an empirical antimicrobial regime.

**P758 Co-infection with *Borrelia burgdorferi* and tick-borne encephalitis virus in humans, ticks and tick cells – analysis of clinical cases, literature and experimental possibilities**

*A. Moniuszko\*, P. Czupryna, L. Bell-Sakyi, J. Fazakerley, J. Zajkowska, S. Pancewicz (Bialystok, PL; Edinburgh, UK)*

**Objectives:** *Borrelia burgdorferi* sl (Bb) and tick-borne encephalitis virus (TBEV) are both transmitted in central and eastern Europe by the same tick, *Ixodes ricinus*. An individual tick can be infected simultaneously with both pathogens, and therefore a patient could be infected simultaneously with Bb and TBEV. This should be taken into account in the diagnosis of patients who suffer from meningoencephalitis and who live in or have visited tick-endemic regions, because the treatments of these two infectious diseases differ, and co-infection may intensify the clinical course of both diseases. We aimed to determine the incidence of simultaneous infection in patients, influence on clinical picture, and to explore the use of tick cells

coinfected in vitro with Bb and an arbovirus to test whether the pathogens act synergistically or antagonistically in the vector.

**Methods:** We examined our clinical records concerning influence of co-infection with Bb and TBEV on patients hospitalized in our department. Additionally we analyzed the literature concerning prevalence of multiple pathogen species in *I. ricinus* ticks in Poland. Moreover, we used a model system to study co-infection with Bb and the arbovirus Semliki Forest virus (SFV) in *Ixodes* spp. cell lines.

**Results:** Between 1993 and 2008 in eastern Poland we observed that, out of 687 patients with TBE, 116 (16%) were coinfecting with Bb. Among them 13 (2%) were diagnosed with neuroborreliosis. The clinical picture and results of cerebrospinal fluid examination differed between TBE patients with and without coinfection. Coinfection of *I. ricinus* ticks with different pathogens is quite common. In Poland, the prevalence of *I. ricinus* ticks co-infected with at least two pathogens varies from 0.1% to 8.3%. In preliminary experiments we found that the presence of Bb spirochaetes in tick cell lines tended to enhance short-term replication in vitro of SFV RNA, while the presence of the virus had no effect on spirochaete DNA replication.

**Conclusion:** We propose that not only clinical observation, but also experimental research may be useful to discover more about coinfection with Bb and TBE virus in humans and ticks. Very little is known about the influence of multiple infections on either the tick life cycle or the coinfecting pathogens reactions. Tick cell lines offer the possibility to study in vitro the effect of coinfection with multiple pathogens on ticks at the cellular and molecular level.

**P759 Osteoarticular infections in children: an Italian cohort**

*C. Bertaina\*, S. Aguzzi, M. Pinon, M. Cuzzo, F. Mignone, S. Virano, S. Garazzino, C. Gabiano, P.-A. Tovo (Turin, IT)*

**Objectives:** Prompt diagnosis and proper treatment of osteoarticular infections (OAIs) are essential to prevent short- and long-term complications in children, including growth impairment. We performed a retrospective analysis of children with OAIs to define their epidemiology, aetiology, clinical manifestations, treatment and outcome.

**Methods:** Clinical records of children discharged with a diagnosis of OAI from Regina Margherita Children's Hospital (Turin, Italy) between January 2006 and January 2010 were retrospectively analyzed. T-student test was used for statistical significance assessment.

**Results:** Fifty-six children (mean age 6.4 years; 36 male, 20 female) were evaluated. 71% was diagnosed with osteomyelitis (OM), 22% with septic arthritis (SA) and 7% with spondylodiscitis (SD). Mean age at presentation was significantly lower in children with SA vs those with OM (3.3 years vs 7.7;  $p < 0.05$ ). The most frequent trigger event of OAI was a recent traumatic event in OMs (33%) and a concomitant focus of infection in SAs (42%). The most common symptoms at presentation were pain (96.4%) reduced motility (87.5%) and fever (64.2%). OMs and SAs involved lower limbs in 75% of cases. All SDs involved lumbar column. Nuclear Magnetic Resonance was the most reliable diagnostic technique for OMs (100% sensibility), joint ultrasound for SAs (90% sensibility). In 42% of OMs and 67% of SAs the causative pathogen was not detected. Methicillin-sensible *Staphylococcus aureus* was the most frequently isolated pathogen (22.5%). *Mycobacterium tuberculosis* was detected in one case of SD. Most of the patients was treated with an association of antibiotics, initially administered intravenously and then switched to an oral formulation. Mean duration of antimicrobial treatment was 1.8 months (range 0.5–6.7 months); in particular 2.2 months in OMs, 1.2 months in SAs and 2.7 months in SDs. Mean follow-up after treatment completion was 16 months. Recovery was achieved in 83.4% of patients. Infection became chronic in two children. No growth defect was recorded.

**Conclusions:** In our study we found a high rate of therapeutic success in children with OAIs. This finding suggests that a proper and

prolonged course of antimicrobials (at least 14 days) is essential to prevent recurrences and complications. OAI aetiology may be difficult to identify, but *S. aureus* is often the causative pathogen: therefore, empiric treatment with *S. aureus* coverage should always be considered.

**P760 Spondylodiscitis: case review, 1988–2011**

A. Lebre\*, J. Velez, E. Rabadão, J. Oliveira, J. Saraiva da Cunha, A. Meliço Silvestre (Coimbra, Aveiro, PT)

The authors conducted an analysis of Spondylodiscitis (SD) cases at their institution from January 1988 to September 2011. The aim was to evaluate epidemiological, etiological, clinical, imaging and therapeutic aspects of this pathology. The inclusion criteria were SD evidenced by imaging study. Clinical records of 140 patients were reviewed. Sixty three (63%) were male; average age was 57 years [17–83]; mean cases/year ratio was 5.8; mean hospital stay was 46 days [1–190]. The most frequent symptoms at admission were pain (96%), fever (46%) and neurological symptoms (26%). Average duration of symptoms was 4.5 months [3 days–48 months]. MRI was the imaging technique more often performed. It was done in 116 of the patients, showing abnormalities compatible with SD in 115. The lumbar segment was predominantly involved (55%). In 61% of cases a certainty diagnosis was achieved (*Brucella* spp 47 cases; *Staphylococcus aureus* 19 cases; other bacteria 11 cases; *Mycobacterium tuberculosis* seven cases; *Candida albicans* one case). Certainty diagnosis criteria were: *Brucella* spp. (Wright  $\geq 160$  or blood culture yielding *Brucella* spp.); bacteria (blood culture or abscess needle puncture/vertebral biopsy specimen yielding the agent); *M. tuberculosis* (abscess needle puncture/vertebral biopsy specimen yielding the agent); *C. albicans* (abscess needle puncture specimen yielding the agent). Etiology was presumed in 26%, and considered undetermined in 13% of the patients. The most prevalent etiological agent -certainty or empirical diagnosis- was *Brucella* spp. (39%)

mostly with a serological diagnosis, followed by *M. tuberculosis* (24%) with diagnosis made mainly by abscess needle puncture, *S. aureus* and other bacteria (23%) with diagnosis made mainly by positive blood cultures and *C. albicans* (1%) diagnosed by abscess needle puncture. The etiological agent changed over the years (Grap.1) as well as treatments. The outcome was favourable in 82% of the patients, 5% died and 10% were lost to follow-up. In 3% there was no clinical improvement. SD is a typically complex and time-consuming pathology to diagnose. Although it is associated with low mortality, a prompt diagnosis and adequate therapy are important determinants that might improve the long term prognosis. In Portugal, like in other Mediterranean countries, *Brucella* spp. and *M. tuberculosis* were frequently implicated. In the last years a sharp decline in *Brucella* etiology was observed probably due to better control of the animal endemy.

**P761 Diagnostic clues for Brucella spondylodiscitis**

N. Aktug Demir, S. Kolgelier, S. Ozcimen, L.S. Demir, A.C. Inkaya\* (Adiyaman, Konya, Adana, TR)

**Aim:** Brucellosis, which was once described as the great imitator, is an endemic zoonosis in Turkey and causes complications affecting multiple systems. *Brucella spondylodiscitis* may cause diagnostic obstacles for the physician. Symptoms are subtle and nonspecific at the beginning. This study aims to determine predictive factors for brucellar spondylodiscitis.

**Methodology:** This case-control study included 227 consecutive brucellosis patients who applied to Adiyaman State Hospital and Adiyaman 82nd Year State Hospital Infectious Diseases Clinics between January 2010 and July 2011. Demographic figures and clinical findings of patients were recorded in follow up sheets. Spondylodiscitis was diagnosed radiologically by Contrast Enhanced Magnetic resonance imaging. Data were entered to SPSS 16.0 package program and statistical analyses were made using T test, Mann-Whitney U test and chi-square test. p values < 0.05 were accepted to be statistically significant. Logistic regression analyses was done in order to find diagnostic risk factors.

**Results:** Among 227 brucellosis patients included in this study, 88 (38.7%) were males, 139 were females, and mean age was 43.1 ± 15.2. Ninety one patients were housewives, 81 were breeding stock and 40 were public servants. Route of transmission could be determined in 98.7% of patients. The most frequent three symptoms were arthralgia, malaise, and anorexia. Hepatomegaly was detected in 56, splenomegaly in 32 and lymphadenopathy in three patients. Spondylodiscitis, sacroileitis and neurobrucellosis were diagnosed in 54 (23.7%), 21 (9.2%) and 1 (0.45%) patients, respectively. Laboratory tests revealed anaemia, thrombocytopenia and leucopenia in 27.3%, 14.1% and 10.6% of the patients, respectively. C reactive protein (CRP) was elevated in 167 and erythrocyte sedimentation rate (ESR) was increased in 136 patients. Blood cultures yielded *Brucella* spp. more frequently in patients with spondylodiscitis (p = 0.021). ALT, AST, ESR, and CRP were found to be higher (p = 0.005, p = 0.001, p = 0.047, p = 0.033, respectively) and leukocyte number was significantly lower (p = 0.029) in patients with spondylodiscitis. Mean STA titre was also higher in patients with spondylodiscitis (p = 0.005). Results of logistic regression analyses was shown on table 1.

	B	p	Odds Ratio
Sweating	1.3	0.008	3.69
AST level (> 40 iu/ml)	1.4	0.003	4.41
Leucopenia (<2000/mm <sup>3</sup> )	1.4	0.009	4.12

In conclusion, treating physicians should consider spondylodiscitis when treating leucopenic brucellosis patients with high ALT, AST, ESR and CRP values.

**P762 Clinical presentation, complications, and treatment outcome of spondylodiscitis caused by brucellosis**

A. Ulu-Kilic\*, M. Sayar, E. Tutuncu, F. Sezen, I. Sencan (Kayseri, Ankara, TR)

**Objective:** Spondylodiscitis is a frequent and important complication of brucellosis. Attention is drawn to this disease given the need for prolonged duration of treatment in order to avoid possible sequelae.

**Methods:** Twenty patients with brucellar spondylodiscitis were retrospectively evaluated in terms of their clinical, laboratory, and radiologic features and their response to antibiotic regimens.

**Results:** Of the 96 patients with brucellosis, 20 (20.8%) were diagnosed with spondylodiscitis. Patients who had brucellar spondylodiscitis aged 15–81 years (average 54 + 14.6 years). The demographic and clinical characteristics of these patients were compared with those of all patients with brucellosis who did not have spondylodiscitis (Table 1). Patients with spondylodiscitis were more likely to be older ( $p = 0.001$ ), have erythrocyte sedimentation rates (ESRs) higher ( $p = 0.01$ ) and were more likely to have anemia ( $p = 0.017$ ) than those patients with brucellosis who did not have spondylodiscitis. Back pain (95%) and debility (65%) were most common symptoms in patients with spondylodiscitis ( $p < 0.05$ ). *Brucella melitensis* biovar III was isolated from blood cultures of six (30%) patients. A computed tomography-guided needle aspiration of the paravertebral collection of two patients yielded purulent material that also grew *B. melitensis* biovar III. Magnetic resonance imaging (MRI) showed that the lumbar segment (19/20) was the most frequently involved region. Sacral (8/20), thoracic (3/20) and cervical (1/20) involvement of vertebral column were seen less common. Spondylodiscitis was accompanied by paravertebral or epidural abscess in seven, psuedo abscess in five and radiculitis in six of cases. Antibiotic regimens including two or three antibiotics with combination of doxycycline, rifampin and streptomycin were used. In this series, the mean duration of antimicrobial therapy was 22.6 weeks (range, 12–56 weeks) varied according to clinical response and the presence of epidural or paravertebral masses and radiculitis. Surgical intervention was required for four patients. At the end of treatment all patients had a complete response.

**Conclusions:** Brucellar spondylodiscitis should be considered particularly in elderly patients with back pain and debility in endemic areas. The patients can be treated effectively with appropriate antibiotic combinations at least 12 weeks. Prolonged treatment is suggested for patients with spondylodiscitis accompanied by abscess or radiculitis.

#### **P763** The prevalence of brucellosis in adults in northeastern region of Turkey

G. Arvas, Y. Akkoyunlu, M. Berktaş, B. Kaya, T. Aslan\* (Iğdir, Istanbul, Van, TR)

**Objectives:** Brucellae are primarily animal pathogens, infecting humans after contact with infected animals or their body products. Brucellosis exists in animals worldwide. Human brucellosis presents when the bacteria enter the body via abrasions in the skin, via the alimentary tract or most commonly, via the respiratory tract. The disease is prevalent in the Mediterranean basin, the Indian subcontinent, the Arabian peninsula, and in parts of Central Asia, Africa, Central and South America. However it continues to be one of the major health problems in developing countries, as well as in Turkey. The treatment of the disease leads to loss of time, labour, and results economical burden. The purpose of this study is to determine the prevalence of brucellosis which is previewed to be very common in the northeastern region of Turkey and make an emphasis on the problem.

**Material and method:** In this study, seroprevalence of brucellosis has been examined in sera of a total of 2913 adult patients (18 years of age and older). Of those, 889 were men and 2024 were women who applied to Iğdir State Hospital between February and December in year 2010. The existence of brucellosis antibody has been investigated in sera samples taken from patients using the method of Standard Tube Agglutination Test (STA, Wright's Agglutination Test). The attained results have been evaluated statistically using chi-square trend analysis method.

**Results:** At the end of the survey, significantly high level (1/40 dilution) of specific antibodies have been detected in 380 (18.8%) women and 145 (16.3%) men with a total of 525 (18%) patient sera ( $p = 0.111$ ). Positive test results have been found in 2 (0.4%) with 1/40 dilution, in 3 (0.6%) with 1/80 dilution, in 216 (41.1%) with 1/160 dilution, in 303 (57.7%) with 1/320 dilution and in 1 (0.2%) with 1/640 dilution ( $p = 0.258$ ). There was no significant difference between the positivity distribution in men and women.

**Discussion and conclusion:** According to the test results, brucellosis prevalence in the northeastern region of Turkey is one of the major public health problems. Existing region of country has borders with three different countries. Therefore, we should fight against the disease with measures like controlling animal transportations, improving public awareness upon processing and consuming milk and milk products, paying attention to co-operation between sectors.

#### **P764** Serological follow-up after laboratory exposures to *Brucella* in the UK and Ireland

S. Murray\*, R. Cooke, N. Beeching, P. Lal (Liverpool, UK)

**Objectives:** Brucellosis is a zoonosis transmitted to humans through contact with infected animals or ingestion of infected unpasteurised cheese. However brucellosis has also been reported in staff after laboratory exposure incidents. Following such an incident, current UK guidance suggests serological testing on all staff encountering a "high risk" exposure, at 0, 6 and 24 weeks. These individuals should also receive post exposure antibiotic prophylaxis. Though current guidance lacks an evidence base, the incubation period of brucellosis is known to range from a few days to 6 months. Serological testing in the UK is currently provided at the Brucella Reference Unit (BRU) in Liverpool. The aim of this study was to review the results of serological samples sent to the BRU for testing following laboratory exposures and assess the appropriateness of current guidance.

**Methods:** A retrospective review of all the serological samples sent for testing following laboratory exposure incidents over a 38 month period. Results were stored under ILog numbers (each representing a single exposure incident). Samples from 01/11/2007 until the most recent closed ILog (21/01/2011) were reviewed from the microbiology computer database. Standard interpretation criteria were used to assess serological results.

**Results:** Seven ILog numbers were identified representing exposures in Dublin, Derby, Leicester, Birmingham and 3 London laboratories. The total number of serum samples reviewed was 296. The number of laboratory staff included under each ILog ranged from 0 to 106, and the number of specimens received under each ILog varied from 0 to 212. All the specimens were found to be negative, showing no evidence of brucellosis. The majority of sera were collected at 0 and 6 weeks post exposure.

**Conclusions:** Over the period studied, no exposed laboratory staff showed serological evidence of brucellosis. In addition, figures suggest that there was poor compliance with the recommended number of follow up tests. Based on these findings, current guidance needs to be revised and should recommend that baseline blood is taken for storage, and only follow up serum taken if symptoms consistent with brucellosis occur. This would bring the laboratory exposure guidance in line with existing UK guidance on exposure following a deliberate release of brucella. This approach should also reduce staff anxieties and laboratory costs.

#### **P765** Antimicrobial susceptibility of *Brucella* spp. isolates from blood samples

S. Aljohani\* (Riyadh, SA)

**Aim:** Brucellosis is a worldwide zoonotic disease that remains an important public health problem in rural Saudi Arabia. The aim of the present study was to assess the antimicrobial susceptibility of isolates from blood samples.

**Materials and methods:** The study included 401 *Brucella* isolates grew in culture at microbiology laboratory between 2003 to 2008 at King AbdulAziz Medical City, a 1000 beds tertiary care center. The minimal inhibitory concentration (MIC) values of tetracycline, rifampin, streptomycin, ciprofloxacin, and tigecycline were determined using the E test method.

Testing was under BSC at our level III laboratory.

**Results:** Isolates showing different susceptibility patterns against different antibiotics, tetracycline and rifampin remain the most potent agents against *Brucella* isolates, but their susceptibility patterns start to show some resistance in the last few years. (Table 1) MIC90 values of tetracycline, streptomycin, rifampin, ciprofloxacin, and tigecycline were 0.25, 0.50, 1.0, 0.25, and 1.0 mg/L, respectively.

National Guard Health (Spain)  
King Abdul Aziz Medical City  
Section Of Microbiology

Brucella Antibigram Year 2003 to 2008 - All Departments (Department & outpatient)

Total Number Of Isolates Relative To The Percentage Of Sensitive Strains

YEAR	TOTAL # OF ISOLATES	% SUSCEPTIBLE ISOLATES					
		Ciprofloxacin	Rifampin	Streptomycin	Tetracycline	Trimeth/Sulfa	* Tigecycline
2003	44	100	100	--	100	59	--
2004	79	98	100	100	100	64	--
2005	66	100	100	100	100	59	--
2006	79	97	100	100	100	79	--
2007	74	98	98	93	100	95	--
2008	59	88	81	84	86	74	57

**Conclusions:** In recent years there has been tremendous interest in the identification of *Brucella* strains and their antimicrobial susceptibility. According to antimicrobial susceptibility test results, we have few of the isolates were resistant to the currently recommended antibiotics. This data need to studied further in collaboration with other centers as our number of isolates worth further studies.

#### P766 A strange case of co-infection from *Leishmania infantum* and *Brucella melitensis*

I. Dimitriadis\*, A. Pappas, A. Panoutsopoulos, A. Tarantili, M. Pavlaki, G. Andrianopoulos (Argos, GR)

**Objectives:** Visceral leishmaniasis is the most severe form of leishmaniasis, constituting the second largest parasitic killer in the world. On the other hand, although great efforts have been made in order to extinct brucellosis from the cattle population, it still stands as a problem in public health. We are going here to present a case of illness from visceral leishmaniasis and brucellosis.

**Methods:** A 37 year old male of Romanian descent, immigrant, working in livestock occupations, presented in our emergency department, febrile (38.9oC) and reporting pain in his left side abdomen along with fatigue and anorexia for the last week. During the clinical examination, the patient was hemodynamically stable and liver and spleen were palpable (15 cm under abdominal ribs). The laboratory findings were indicative of pancytopenia (white blood cells 2240/mm<sup>3</sup>, hematocrit 20.6%, platelets 71 000/mm<sup>3</sup>) but showed no significant change in blood biochemistry except for a slight increase in alkaline phosphatase, gamma-glutamyltransferase and reverse albumin/globulin ratio. An ultrasound check of the abdomen confirmed the clinical findings. Blood and urine cultures were taken along with a full serologic and virus check.

**Results:** Serologic and virus control was negative for HIV, hepatitis A, B, C, cytomegalovirus, toxoplasmosis. The clinical and laboratory findings raised the suspicion of leishmaniasis. The patient started receiving treatment with liposomal amphotericin B (Ambisome®) along with supportive treatment. After 24 hours he became afebrile and his clinical condition started improving. On the same time rK39 *Leishmania infantum* dipstick test proved positive and so was the indirect fluorescent antibody test (1:1600). *Brucella melitensis* was cultivated in blood culture and treatment with ciprofloxacin, rifampicin and doxycycline was commenced. After one week the patient the patient was dismissed from the hospital in a much improved condition, and continued receiving treatment for brucellosis for a total duration of

six weeks and amphotericin B for leishmaniasis on day 14 and day 21 after his admission.

**Conclusion:** The recent movement of population and living in poor sanitary conditions should always raise the possibility of a zoonosis infection. Therefore diseases considered extinct from Europe should always been taken into account in differential diagnosis.

#### P767 Invasive pneumococcal disease in adults older than 59 years in the autonomous region of Madrid Spain, 2008–2010

M.A. Gutiérrez Rodríguez, M.E. Rosales Statkus\*, E. Córdoba Deorador, J.A. Taveira Jiménez, A. Arce Arnáez, J.C. Sanz Moreno, D. Barranco Ordóñez, M. Ordoñas Gavín (Madrid, ES)

**Objectives:** The pneumococcal capsular polysaccharide vaccine (PCPV) is recommended in the Region of Madrid in specific risk groups and in adults over 59 years. Furthermore, pneumococcal conjugate vaccine (PCV) is included into the routine childhood schedule, changing heptavalent (PCV7) to 13-valent (PCV13) in 2010. The objectives of this study are to describe the incidence and the epidemiological characteristics of invasive pneumococcal disease (IPD) in adults older than 59 in the Region of Madrid in the period 2008–2010.

**Methods:** IPD is a notifiable disease in the Region of Madrid. The case definition of the disease includes the identification of pneumococcus in a normally sterile site. Pneumococcal strains were serotyped by latex agglutination assay and Quellung reaction. Clinical and epidemiological data are collected through a structured questionnaire for every case. Incidence and mortality annual rates per 100 000 inhabitants were calculated. We compared the rates in 2010 to 2008, and also the vaccinated and non-vaccinated patients by risk ratio (RR).

**Results:** IPD incidence rate was 19.99/100 000 in 2008 and 15.45/100 000 in 2010 (RR = 0.77 p = 0.007) and mortality was 3.48/100 000 in 2008 and 2.04/100 000 in 2010 (RR = 0.59 p = 0.029). Of the 662 cases registered in this period 33.8% were older than 79, and 55.9% were males. Pneumonia (64.3%), bacteraemia (14.6%) and septicaemia (9.3%) were the most frequent diagnoses. The case-fatality rate for this period was 15.2%. Underlying risk factor for pneumococcal was observed in 56.2% of the patients, being the most frequent chronic respiratory disease (16.1%). Among all patients 38.3% were vaccinated with PCPV, this proportion being 41.4 among those with risk factor. Serotype was identified in 91.6% of the cases. The six most frequent serotypes were 3, 19A, 7F, 1, 14 and 8 that account approximately 50% of cases, with those included in PCV7 causing 12.6%, those included in PCV13 55.4% and those included in PCPV 76.6% of cases. Vaccinated patients had lower risk of PCPV serotypes disease (RR = 0.63 p = 0.020).

**Conclusions:** The incidence and mortality decreased in this period. The low proportion of patients with risk factor that were vaccinated makes necessary to improve de vaccine coverage in this group. The lower risk of disease by PCPV serotypes in vaccinated patients is compatible with the vaccine efficacy described.

#### P768 Invasive pneumococcal disease in the autonomous region of Madrid, Spain: from 2008 to 2010

M.E. Rosales Statkus\*, M.A. Gutiérrez Rodríguez, M. Martínez Blanco, M.D. Lasheras Carbajo, F. Martín Martínez, A. Arce Arnáez, B. Ramos Blázquez, M. Ordoñas Gavín (Madrid, ES)

**Objectives:** Invasive pneumococcal disease (IPD) was declared a notifiable disease in the Autonomous Region of Madrid in 2007, after the inclusion of the pneumococcal conjugate vaccine (PCV) into the child immunization schedule, first as the heptavalent vaccine (PCV7) in 2006, replaced by the 13-valent vaccine (PCV13) in 2010. Pneumococcal polysaccharide vaccine (PCPV) has been recommended in Spain since 2001 for persons 2 years and older with certain underlying medical conditions. In the Region of Madrid this

vaccine is also recommended in adults older than 59 since 2005. The objectives of this study are to describe the incidence and the characteristics of IPD cases in the period 2008–2010.

**Methods:** We selected the cases from 2008 to 2010 registered in the notifiable disease system. Case definition includes the identification of the pneumococcus in a normally sterile site. Data cases are collected through a structured questionnaire. Pneumococcal strains were serotyped by latex agglutination assay and Quellung reaction. We estimated annual incidence rates per 100 000 inhabitants according to age, sex and serotypes included in the pneumococcal vaccines. We compared incidence in 2010 to 2008 by risk ratio (RR).

Age group (years)	2008 N=764		2009 N=491		2010 N=827		RR 2010/2008
	%	Rate	%	Rate	%	Rate	
< 5	21.1	47.42	19.4	36.02	21.0	26.81	0.57*
5-14	6.4	6.44	7.4	8.51	4.3	3.24	0.30*
15-39	13.1	4.11	15.5	4.39	10.5	2.04	0.50*
40-59	27.9	12.46	25.8	10.16	22.1	5.74	0.46*
60-74	16.4	16.31	15.1	14.13	17.8	10.34	0.63*
> 74	15.2	26.39	16.9	26.60	24.4	24.12	0.91

<b>Sex</b>							
Male	57.9	14.54	59.3	13.25	58.7	8.77	0.60*
Female	42.1	9.97	40.7	8.54	41.3	5.79	0.59*
<b>Serotypes identified</b>	94.4		92.8		93.4		
Included in PCPV	72.1	8.79	77.7	8.41	74.1	5.36	0.61*
Included in PCV13	55.6	6.79	53.9	6.42	57.0	4.12	0.61*
Included in PCV7	10.3	1.26	9.1	0.99	6.6	0.40	0.30*
<b>Case-fatality rate</b>	10.3		8.7		8.4		
<b>Underlying medical conditions</b>	32.2		39.4		49.3		
<b>Vaccinated patients</b>	29.7		33.7		43.5		
PCPV	11.1		15.3		23.6		
PCV	18.5		18.5		19.9		
<b>Clinical presentation</b>							
Pneumonia/pneumonia	59.9		64.8		64.7		
Bacteremia	16.6		12.4		13.1		
Sepsis	6.4		6.9		7.7		
Meningitis	9.2		8.0		7.9		
Other	3.8		4.5		5.6		
Unknown	4.1		3.3		1.1		

\*p<0.05

**Results:** (results are shown in table submitted).

**Conclusion:** Incidence rates are higher in extreme age groups and in males. Incidence in all age group and case-fatality rates decreased along the study period. Incidence for serotypes included in vaccines also decreased. This is compatible with the efficacy of pneumococcal vaccines. Proportion of patients older than 59, cases with underlying medical conditions and vaccinated with PCVP increased, which is compatible with the limited effect of PCVP.

#### **P769** Kinetics of old and novel biomarkers in severe bacterial infections

O. Beran\*, P. Chalupa, N. Kasprikova, M. Holub (Prague, CZ)

**Objectives:** Accurate diagnosis and management of severe bacterial infections are still important issues. Therefore, we analyzed the kinetics of novel and routinely used biomarkers in severe bacterial infections and compared the usefulness of these parameters in monitoring of the empirical antibiotic therapy efficacy.

**Methods:** This prospective observational study, which included 54 patients hospitalized with community-acquired bacterial infection was conducted in an infectious disease department of a teaching hospital. As controls, 27 patients with viral infections and 19 healthy persons were enrolled. Paired samples of whole peripheral blood and serum were obtained upon the admission to the study – day 1 (D1), at D4 and D8. Next parameters were evaluated: neutrophil and lymphocyte counts, neutrophil to lymphocyte count ratio (NLCR), C-reactive protein (CRP), procalcitonin, cortisol, interleukin (IL)-1beta, IL-6, IL-8, IL-10, IL-12 and TNF-alpha. Statistical analysis was performed using SPSS software™ software.

**Results:** The highest sensitivity and specificity for the diagnosis of bacterial infection demonstrated increased values of PCT, NLCR, cortisol and IL-6. Appropriate empirical antibiotic therapy was

associated with a more rapid normalization of IL-6, IL-8, lymphocyte count and NLCR compared to neutrophil count, C-reactive protein, procalcitonin and cortisol at D8. At D8, significant differences between patients with bacterial infections and controls were still observed for CRP (p < 0.001), PCT (p = 0.001), neutrophil count (p = 0.007) and cortisol (p = 0.007).

**Conclusion:** Our results demonstrate that successful antibiotic therapy is associated with the earlier normalization of lymphocyte count, NLCR, IL-6 and IL-8 compared to other parameters during severe bacterial infections. Further studies are needed to assess if the use of these biomarkers with the faster kinetics can improve to rationalize antibiotic therapy.

Acknowledgment: The study was supported by the grant IGA NT/11390-5.

#### **P770** Bacterial agents in the aetiology of today's diabetic foot infections: shift to more Gram-negative pathogens

V. Turhan\*, M. Mutluoglu, A. Acar, M. Hatipoglu, Y. Önem, G. Uzun, H. Ay, O. Öncül, L. Görenek (Istanbul, TR)

**Background:** Identification of organisms and effective, early and appropriate treatment is important to avoid complications of diabetic foot infections. This study was undertaken to determine the organisms associated with diabetic foot infection (DFI) and their antibiotic sensitivity pattern.

**Methods:** A total of 107 patients having diabetes mellitus with Wagner's grade 1–5 foot ulcers attending our tertiary hospital between the period of May, 2005 and July, 2010 included in the retrospective designed study. Specimens were processed for aerobic culture. The bacteriological isolation and antimicrobial sensitivity tests of the isolates (Quantitative culture) were done by standard microbiological methods according to the CLSI criteria. Gram negative bacilli were tested for inducible betalactamase positivity (IBL) and extended spectrum beta lactamase (ESBL) production. *S. aureus* and coagulase negative staphylococci were screened for methicillin resistance.

**Results:** Of the 107 patients, 74 (69%) were male and 33 (31%) female, mean age was (62 ± 13). The mean HbA1c level was 9 ± 2.5. Culture taken from 298 samples; 165 (55%) wound, 108 (36%) tissue and 25 (9%) bone yielded 311 bacteria. There was no growth in the 31 (10%) samples. A total of 311 bacteria were isolated from 267 samples and an average of 1.16 isolates per culture was reported. Of the positive culture, (223/267) 83.5% had monomicrobial, (44/267) 16.4% had multiple organisms. Gram negative bacteria (n = 192; 62%) were isolated more often than gram-positive ones (n = 119; 38%) in our retrospective study. Most frequently isolated microorganisms were *Pseudomonas* spp. (30.5%), *Staphylococcus aureus* (17%), *Enterococcus* spp. (11.3%), *E. coli* (7.1%) and *Enterobacter* spp (7.1%). IBL and ESBL positivity detected in 25% (48/192) of the gram negative bacteria. Methicillin resistance was detected in 45% (24/53) of *S. aureus* isolates.

**Conclusions:** This study has shown that infection with multidrug resistant gram negative bacilli is the most common cause of DFI in our tertiary care hospital and this is a new phenomenon which is widely occurring in the nowadays world. Amikacin, piperacillin-tazobactam, cephaperazon-sulbactam and imipenem were active against gram-negative bacilli, while vancomycin was found to be active (100%) against gram-positive bacteria including enterococci. Fusidic acid was found to be active against MRSA. The choice of empirical antimicrobial therapy can be done according to this data.

#### **P771** Leptospirosis associated with Hashimoto thyroiditis: a case report

F.S. Erdinc, M.C. Sonmez, M. Demirelli, S. Kurkcuoglu, G. Tuncer Ertem\*, B. Oral, N. Tulek (Ankara, TR)

**Objective:** Leptospirosis is a worldwide zoonosis. Mild anicteric form is observed in 90% of the patients with leptospirosis, however Weil's disease occurs in 5–10% of the patients. The disease has been rarely

shown to be related with autoimmune disorders. In this report a patient with leptospirosis who developed acute renal failure, thrombocytopenia and Hashimoto thyroiditis was presented.

**Case:** A 38-year old previously healthy male patient with fever, fatigue, nausea, vomiting, abdominal pain and diarrhoea with 10 days of history, referred to our clinic due to rapid deterioration and increase in serum creatinine. The patient's history revealed that he had interested in hunting. He had been to a lake for hunting 20 days before symptoms have started. Intravenous metronidazole treatment was administered for 2 days in another hospital. On physical examination the patient was conscious, cooperate, and temperature was 38.7°C, blood pressure was 90/50 mmHg, and pulse was 90/minute. Liver was palpated 2 cm below the ribs. Laboratory findings were as; platelets:118.000/mm<sup>3</sup>, CRP:465 mg/L, procalcitonin:26.5 ng/mL, creatinine:5.3 mg/dL, AST:99 U/L, ALT:59 U/L and microscopic hematuria. After blood cultures were taken empiric intravenous meropenem 2 × 1 g was started with unknown aetiology of sepsis. All culture samples were negative. Brucella standard tube agglutination and Gruber–Widal tests were negative. Abdominal ultrasonography revealed mild hepatomegaly and grade 1–2 increase in both renal parenchymas. Hepatitis serology were negative. Serum sample was positive for *Leptospira Bratislava Jez Bratislava* antibody at 1/100 titer by MAT. Since Anti-Tg (236.2 U/mL) and Anti-TPO (317.8 U/mL) antibodies were high, a thyroid ultrasonography was performed and Hashimoto thyroiditis was diagnosed. Serum creatinine levels increased in the 2nd day of admission and hemodialysis was performed. Fever decreased on the third day of treatment, serum creatinine began to decline on the 4th day of admission and normalized on 7th day as thrombocyte count and liver function tests. Serum sample was positive for *Leptospira Bratislava Jez Bratislava* antibody at 1/800 titer in the second week of hospitalization. The patient was discharged healthy on 9th day of admission.

**Conclusion:** Leptospirosis diagnosis was confirmed in the second week of admission as patient history was consistent with the disease. Although seem rarely, autoimmune disorders may be point at issue in leptospirosis.

#### P772 Haemolytic uraemic syndrome associated with *Streptococcus dysgalactiae* ssp. *equisimilis*

F. Galan-Sanchez\*, I. Guerrero-Lozano, A. Hernandez, A. Garcia-Tapia, M. Rodriguez-Iglesias (Cadiz, ES)

**Objectives:** The haemolytic uraemic syndrome (HUS) includes haemolytic anaemia, thrombocytopenia, and acute renal failure. HUS can be distinguished in typical HUS and atypical HUS (aHUS). Enterohaemorrhagic *Escherichia coli* and *Shigella dysenteriae* are the cause of typical HUS. Atypical HUS defines non-Shiga-toxin HUS and designated a primary disease due to a disorder in complement alternative pathway regulation. Although extremely rare, infections due to *Streptococcus pyogenes* (GAS) have been associated with HUS. *Streptococcus dysgalactiae* subsp. *equisimilis* (SDSE) causes invasive streptococcal infections. Similarly to GAS, SDSE possesses virulence factors. We report the first case of bloody diarrhoea and HUS due to SDSE.

**Methods:** A 3-year-old girl was transferred to University Hospital Puerta del Mar with a history of bloody diarrhoea. On admission, BUN and serum creatinine were 167 and 3.1 mg/dL, respectively, haemoglobin was 11.3 g/dL and platelet count was 100 000/μL. She was transferred to the intensive care unit. Blood smear showed polychromasia with the presence of schistocytes. By the fourth hospital day, C3 levels were low (79 mg/dL). Her renal function continued to deteriorated and peritoneal dialysis was started. Blood and stools samples were sent on admission and 1 day after for culture and detection of Shiga toxin by PCR (GenoType EHEC, Hain LifeScience).

**Results:** tools cultures showed pure growth of SDSE. Identification was made in accordance to phenotypical, serological and biochemical characteristics. No *Salmonella*, *Shigella*, *Campylobacter*, *Vibrio*, *Aeromonas* or *Yersinia* were isolated. The presence of Shiga toxins genes, intimin gene *eae*, and virulence factor *ipah* gene, to detect enterohaemorrhagic, enteroinvasive and enteropathogen *E. coli* and *Shigella* were negative.

**Conclusion:** The prevalence of invasive and noninvasive SDSE infections has increased gradually year by year. The association of β-hemolytic streptococcus with HUS is not well known. The release of inflammatory mediators in the presence of SDSE infection may play a role in the pathogenesis of HUS. Hypocomplementemia typically is found in aHUS and low C3 levels predict a poor outcome. Although aHUS has been demonstrated to be a disorder of the regulation of the complement alternative pathway, an interesting point is the high frequency of an infectious triggering event, which suggests that complement anomalies are risk factors rather than the only cause of the disease.

#### P773 A cost-effectiveness analysis of identifying *Fusobacterium necrophorum* in throat swabs followed by antibiotic treatment to reduce the incidence of Lemierre's syndrome and peritonsillar abscesses

S. Bank\*, K. Christensen, L. Hagelskjær Kristensen, J. Prag (Viborg, Aarhus, DK)

**Objectives:** The main objective was to estimate the cost per quality adjusted life year (QALY) saved by identifying *Fusobacterium necrophorum* in throat swabs followed by proper antibiotic treatment, to reduce the incidence of Lemierre's syndrome and peritonsillar abscesses (PTA) originating from a pharyngitis. The second objective was to estimate the population size required to indicate that antibiotic treatment has an effect.

**Methods:** Data from publications and our laboratory were collected. Monte Carlo simulation and 1-way sensitivity analysis were used to analyse cost-effectiveness.

**Results:** The cost-effectiveness analysis shows that examining throat swabs from 15 to 24 years old for *F. necrophorum* followed by antibiotic treatment probably will be less costly than most other life saving interventions, with a median cost of 8 795US \$ per QALY

saved. To indicate a reduced incidence of Lemierre's syndrome and peritonsillar abscess in Denmark, the intervention probably has to be followed for up to 5 years.

**Conclusion:** Identifying *F. necrophorum* in throat swabs from 15 to 24 years old followed by proper antibiotic treatment only requires a reduction of 20–25% in the incidence of Lemierre's syndrome and PTA to be cost-effective.

This study warrants further examination of the effect of antibiotic treatment on the outcome of *F. necrophorum* acute and recurrent pharyngitis as well as the effect on Lemierre's syndrome and PTA.

## Epidemiology, risk factors and clinical presentation of fungal infections

### P774 Clinical score of candidaemia in non-ICU, non-neutropenic patients

D. Vinuesa, V. Portillo, M. Ruiz-Ruigómez, C. Dueñas, A. Peña, C. Tomás-Jiménez, M. Mantecón, L. Muñoz, R. Cabo, M. Cuesta, J. Hernández-Quero, J. Parra-Ruiz\* (Granada, Burgos, Murcia, ES)

**Background:** *Candida* spp. is the leading cause of invasive fungal infections in hospitalized patients and the fourth most common isolates recovered from patients with bloodstream infection. Few data exist on risk factors for candidemia in non-ICU patients, so we performed a population based case-control study of patients with candidemia to evaluate main predictors for candidemia in non-ICU patients.

**Methods:** This retrospective, multicenter study included all non-neutropenic, non-surgical and non-ICU adult patients with candidemia between January 2006 and January 2011. Cases and controls were identified using laboratory records. Patient with positive, non-candidal blood culture obtained at the same day were selected as controls. Patients were matched according to hospital ward, age and clinical characteristics. A multiple regression analysis was performed to identify risk factors.

**Results:** We identified 60 patients with candidemia. Median age was 67 years (25–90). Most patients were male (35; 58%). *Candida albicans* was the most frequent specie (29 cases; 48%) followed by *C. parapsilosis* (13 cases; 22%). Time to positivity was significantly shorter in patients with bacteraemia than in those with candidemia (10.2 ± 14 days vs 17.6 ± 14.1 days; p = 0.043). Mortality rate was significantly higher for patients with candidemia than that for patients with bacteraemia [22/60, (37%) vs. 12/60 (18%); p = 0.04. OR 2.57 (95%CI 1.11–5.96)].

Univariate analysis identified prior use of antibiotics (p < 0.001; OR 9.34 95%CI 3.6–23.8), total parenteral nutrition (p = 0.014; OR 3.37 95%CI, 1.29–8.77), central venous catheter (p = 0.033; OR 2.4 95%CI 1.09–5.29) and subcutaneous implantable devices, (p = 0.025; OR 4.58 95%CI 1.22–17.2). In multivariate analysis factors independently associated with candidemia included were prior use of antibiotics [p < 0.001; Exp (B): 9.26; (95%CI 3.52–24.39)], central venous catheter [p = 0.032; Exp (B): 2.36; (95%CI 1.22–16.83)] and presence of subcutaneous implantable devices [p = 0.045; Exp (B): 4.52; (95%CI 1.12–19.6)]. Predicted probability of having various combinations of the aforementioned factors ranged from 12% to 45%.

**Conclusion:** Crude mortality was 37% highlighting the need for prompt identification and initiation of therapy in these patients. We identify a set of easily determinable independent predictors of the occurrence of candidemia in non-ICU patients. Our results provide a rationale for initiating early antifungal treatment in high-risk non-ICU patients.

### P775 Invasive aspergillosis in onco-haematology: environmental study in central Tunisia

S. Gheith, F. Saghrouni, J. Ben Abdeljelil, I. Khammari, W. Bannour, Y. Ben Youssef, S. Ben Salma, A. Khelif, M. Ben Said, M. Njah, A. Fathallah\* (Sousse, TN)

**Objectives:** Invasive aspergillosis (IA) is a major infectious complication in patients with prolonged neutropenia. Difficulties in diagnosis and treatment underline the importance of preventive approach. The aim of our study was to assess the spectrum of filamentous fungi isolated in respiratory samples of patients suffering from haematological malignancies and the environmental mycological contamination in their rooms of hospitalization in Onco-Haematology Department of Farhat Hached University hospital at Sousse City, Tunisia.

**Methods:** A 2-year prospective study (December 2009 to September 2011) was carried out. We collected weekly environmental samples (air,

surfaces) in 11 rooms (with two to four beds each) and, three times a week, sputum from 70 patients suffering from haematological malignancies and admitted in the same rooms over the study period. Suspected IA cases are classified as proven, probable or possible according to the EORTC criteria.

**Results:** We collected 1398 surfaces samples, of which, 1229 (87.9%) had a positive cultures with filamentous fungi. Of 439 air samples collected, 339 (90.9%) were positive. The most frequently isolated genus in all environmental samples was *Aspergillus* sp (21%), followed by *Alternaria* sp (16.4%), *Penicillium* sp (14.1%), *Cladosporium* sp (9.3%) and *Rhizopus* sp (7.8%). *Aspergillus* sp was isolated in 60.1% of air samples and in 52.6% of surfaces samples. *Aspergillus niger* was the most frequent species (52.4%), followed by *A. flavus* (27%), *A. nidulans* (5.4%) and *A. fumigatus* (2.9%).

Of the 70 investigated patients, 19 were diagnosed with probable IA and 19 with possible IA. The overall estimated incidence of probable IA was 13%.

Of 660 sputum collected from these 70 patients, *Aspergillus* sp species were isolated in 49 samples (7.4%): *A. niger* in 22 sputum (44.8%), *A. flavus* in 21 sputum (42.8%), *A. nidulans* in three sputum, and *A. fumigatus* in two sputum.

**Conclusion:** Our findings showed that the mycological contamination of the Onco-Haematological Department of our hospital is high. This highlights the pertinence of the HEPA filters' use in reducing the aspergillosis risk. In both, hospital environment and sputum samples, *A. niger* and *A. flavus* are the most common species. *A. fumigatus* seems rare in our region.

### P776 Epidemiology and clinical manifestations of candidaemia in non-neutropenic patients

C. Amador\*, J.T. Algado, M.J. Carratalá, C. Martínez, G. Verdú, N. Galipienso, J. Ena, F. Pasquau (Villajoyosa, ES)

**Objective:** To describe the predisponent factors, clinical features and outcome of non neutropenic patients with *Candida* bloodstream infections diagnosed in a community teaching hospital.

**Methods:** Retrospective analysis of the records of patients diagnosed of candidemia according to the database of Microbiology department from January 2003 to October 2011.

**Results:** Fifty-three episodes of candidemia corresponding to 52 patients were included on the period of study. Seventy percent were men, the mean age was 67 years (12–85) and 77.4% had underlying diseases. The most frequent conditions were solid neoplasms (51%) chronic renal failure (24.5%) and diabetes mellitus (19%). Previous to fungemia, 43 patients (81%) had undergone surgery, mainly gastrointestinal and urological (92%) and 96.2% of the cases had received broad spectrum antibiotics. Forty-five subjects (85%) had central line catheters, 75.5% had indwelling urinary catheters and 70% received total parenteral nutrition. Sixty-eight percent of the patients presented clinical manifestations of sepsis and septic shock. Of the total cases of candidemia, 39.6% were catheter related infections, 20.8% were from intra-abdominal infections and 32.1% were due to a primary source.

*C. albicans* was the most common isolate (43%), followed by *C. tropicalis* (18.9%), *C. parapsilosis* (17%), *C. glabrata* (15.1%) and other species (5.7%). Twelve of non albicans isolates (22%) showed decreased susceptibility to fluconazole (MIC ≥ 4 µg/mL). Thirty-five patients received fluconazole therapy (66%) and only 20.8% of the cases begun antifungal treatment on day 0 from the culture date of the first blood sample positive for yeast. Nineteen patients died within the first week after candidemia (36%) and six cases (11%) were included as late mortality (8–30 days). Mortality was considered to be related to candidemia in 37.7% of the cases. Non-albicans *Candida* species isolation was statistically significant related to early mortality [p < 0.000, (RR : 13.73 (IC 95% : 2.71–69.39)].

**Conclusions:** It is crucial to suspect candidemia in abdominal surgical patients with persistent fever and/or criteria of sepsis and prior antibiotic therapy.

2 The leading cause of fungemia in our institution were non- albicans *Candida* species.

3 There is a high mortality rate associated to non-albicans *Candida* species and that may be related to a decreased sensitivity to empirical fluconazol therapy.

**P777** **Epidemiology of *Candida* bloodstream infections and antifungal susceptibility profiles: 10-year experience with 381 candidaemia episodes in a tertiary care university centre**

S. Alp\*, S. Arikan-Akdaglı, D. Gulmez, S. Ascioğlu, O. Uzun, M. Akova (Ankara, TR)

**Objectives:** 1 To review the epidemiology of candidemia and its frequency among bloodstream infections over the last 10 years in a 1000-bed university hospital.

2 To evaluate the antifungal susceptibility among candidemia isolates.

**Methods:** We retrospectively evaluated our database from January 2001 to December 2010. Patients with at least one positive blood culture yielding *Candida* species were included in the study. In case of multiple candidemia episodes, only the first episode was included. Available antifungal susceptibility test (AST) results were interpreted according to currently approved CLSI breakpoints.

**Results:** During the study period, there were 18.426 positive blood cultures of which 858 grew *Candida* spp. For the current analysis 381 candidemia episodes were included. *Candida* ranked the fifth (ranged 4–7 during individual years) frequent cause of bloodstream infection. The distribution of species in 381 candidemia episodes and ranking of *Candida* isolates among all positive blood cultures are shown on the Table. *C. albicans* was always the dominant one [p-value for trend test between years 2001–2010 for *C. albicans* and non-albicans *Candida* species (NAC) was non-significant (p > 0.05)]. There were 213 *Candida* strains with available AST results (123 *C. albicans*, 37 *C. parapsilosis*, 27 *C. tropicalis*, 12 *C. glabrata*, 5 *C. krusei*, 3 *C. kefyr*, 3 *C. guilliermondii* and one of each *C. dubliniensis*, *C. lusitanae*, *C. rugosa*). Not all drugs were tested for each isolate. The number of resistant-(susceptible-dose-dependent [SDD])/total strains to fluconazole were as follows: *C. albicans* 1-(2)/122, *C. glabrata* 1-(11)/12, *C. parapsilosis* 0-(2)/22, and *C. tropicalis* 0-(1)/18. The respective values for voriconazole were: *C. albicans* 1-(4)/93, *C. glabrata* 1-(6)/8, *C. krusei* 1-(1)/3, *C. parapsilosis* 0-(2)/18 and *C. tropicalis* 4-(6)/21. Except for one intermediate *C. krusei*, all *Candida* isolates were susceptible to voriconazole. No resistance was detected against caspofungin, the number of intermediate/total strains were: *C. glabrata* (2)/4, *C. parapsilosis* (1)/29, and *C. krusei* (1)/3.

Species	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	Total
	n (%)	n (%)	n (%)	n (%)	n (%)	n (%)	n (%)	n (%)	n (%)	n (%)	n (%)
<i>C. albicans</i>	13 (50.0)	21 (61.8)	14 (66.7)	23 (65.7)	34 (58.6)	35 (62.5)	31 (65.9)	16 (42.1)	16 (61.6)	19 (54.3)	222 (58.3)
<i>C. parapsilosis</i>	3 (11.5)	8 (23.5)	2 (9.5)	3 (8.6)	6 (10.3)	6 (10.7)	9 (19.1)	5 (13.2)	4 (12.9)	8 (22.9)	38 (10.2)
<i>C. tropicalis</i>	3 (11.5)	2 (5.9)	5 (23.8)	4 (11.4)	4 (6.9)	11 (19.6)	4 (8.5)	6 (15.8)	4 (12.9)	1 (2.9)	31 (8.1)
<i>C. glabrata</i>	3 (11.5)	1 (2.9)	-	3 (8.6)	2 (3.4)	3 (5.4)	1 (2.1)	1 (2.6)	4 (12.9)	4 (11.4)	26 (6.8)
<i>C. krusei</i>	-	-	-	-	1 (1.7)	-	1 (2.1)	3 (7.6)	-	1 (2.9)	5 (1.3)
<i>C. kefyr</i>	1 (3.8)	-	-	-	-	-	-	-	2 (6.5)	1 (2.9)	4 (1.1)
Other NAC*	3 (11.5)	2 (5.9)	-	2 (5.7)	4 (6.9)	1 (1.8)	-	-	1 (3.2)	1 (2.9)	14 (3.7)
<b>Total</b>	<b>26</b>	<b>34</b>	<b>21</b>	<b>35</b>	<b>58</b>	<b>56</b>	<b>47</b>	<b>38</b>	<b>31</b>	<b>35</b>	<b>381</b>
Ranking among all positive blood cultures	6	4	7	7	4	4	5	6	4	6	5

\*Other non-albicans *Candida* species (NAC) included in this study were: 4 *C. guilliermondii*, 4 *C. lusitanae*, 2 *C. nonspouanonegensis*, 2 *C. rugosa*, 1 *C. dubliniensis*, 1 *C. colubrosa*.

**Conclusions:** *Candida* spp. play a prominent role among the common bloodstream isolates in our center. Among all *Candida* species, *C. albicans* has been the most common cause of candidemia and this trend

has not changed during the study period. Resistance to tested antifungal drugs is not common among our candidemia isolates except for itraconazole. Decreased susceptibility to fluconazole in *C. glabrata* is remarkable.

**P778** **Candidaemia in hospital, Como, Italy, from 1997 to July 2011 and sensitivity to antifungal drugs**

E. Sala\*, R. Mauri, S. Armitano, T. Tamborini, L. Villa, G. Tagliabue, V. Caneva, D. Santoro, G. Giana (Como, IT)

**Objectives:** Candidemia 1997–July 2011 and evaluation of antifungal drugs referring to EUCAST and CLSI breakpoints are reported.

**Methods:** Blood culture was performed by automated system, and those samples positive for yeast were subcultured on Sabouraud agar and Chromagar *Candida* (BD); *Candida* identification: Auxacolor (Remel) and Yeast card VITEK2 (bioMerieux); antifungal susceptibility: Sensititre Yeastone.

**Results:** Since 1997 to July 2011, 155 candidemia were detected: *C. albicans* 82 (53%), *C. glabrata* 26 (17%), *C. parapsilosis* 29 (19%), *C. tropicalis* 10 (6%), other species eight cases (5%). Eighty-two cases occurred since 1997 to 2007, with 7.4 cases/year; since 2008 there was an increase with 73 candidemia until July 2011 and 20.3 cases/year. Candidemia cases April 2010–July 2011: 39 cases, 16 males (41%) and 23 females (59%). *C. albicans* is the species most frequently found with 20 isolates (51%); *C. glabrata* 10 isolates (26%); minor surveys of candidemia from other *Candida* species (*C. famata*, *C. krusei*, *C. lusitanae*, *C. parapsilosis* and *C. tropicalis*). Sensititre provides MIC for different antifungal drugs. *C. albicans*: 17 isolates susceptible to fluconazole and voriconazole based on CLSI, 16 based on EUCAST; referring to posaconazole, 17 susceptible with CLSI breakpoint, 13 based on EUCAST; there are no differences for anidulafungin and amphotericin-B with all the isolates susceptible. All *C. glabrata* isolates result susceptible to anidulafungin and amphotericin-B. Two out of three isolates of *C. parapsilosis* and two isolates of *C. tropicalis* are resistant to posaconazole with EUCAST and susceptible with CLSI. There were no differences for *Candida* spp. with anidulafungin and amphotericin B.

**Conclusions:** Over the past 14 years, there has been a significant increase in *Candida* spp. bloodstream infections; non-albicans *Candida* species reach almost half of the *Candida* isolates; *C. albicans* EUCAST breakpoints show an increase of isolates resistant to fluconazole, posaconazole and voriconazole; the use of antifungal susceptibility test is now mandatory.

**P779** **Candidaemia in Polish hospitals – a multicentre survey**

U. Nawrot\*, M. Wrobel, H. Przondo-Mordarska, M. Fleischer, A. Samet, E. Swoboda-Kopec, B. Sulik-Tyszka, E. Gospodarek, E. Tryniszewska, T. Ozorowski, K. Golec (Wroclaw, Gdansk, Warsaw, Bydgoszcz, Bialystok, Poznan, Rzeszow, PL)

**Objectives:** The aim of the study was to examine the epidemiology of candidemia in selected Polish hospitals in years 2006–2007.

**Methods:** Nineteen microbiological laboratories distributed in sixteen Polish cities reviewed retrospectively the documentations from years 2006–2007 and collected the information about each episode of isolation of *Candida* from blood. The patient's data were obtained in cooperation with the staff of particular hospitals. Blood cultures were performed using Bact/ALERT (BioMerieux) or Bactec (Becton Dickinson) systems. Statistical analysis of the data was performed using the STATISTICA software system, version 8.0. (StatSoft, Inc., 2008).

**Results:** A total of 308 episodes in 300 patients (145 women and 155 man) were identified in 94 hospital's units of 20 hospitals. Eight patient showed two candidemia episodes, divided by 2–12 months long period of recovery with blood negative cultures. A total number of examined blood samples was 2783, of them fungi were cultured from 774 (27.8%). Most blood samples were described as being "venous"

(2402), 334 as ‘‘catheter-taken’’ and in 59 samples the method of sampling was unknown. The higher number of the infections were noted in Intensive Care Units – ICU (30.19%), and surgical (28.8%), followed by hematological (16.5%), ‘‘others’’ (61; 19.8%) and neonatological (14; 4.5%) units. *C. albicans* represented main fungal blood pathogen, responsible for almost half of reported episodes (49.84%), however its prevalence was significantly lower in hematology (20.78%) ( $p < 0.0015$ ), and higher in ICU and neonatology (60.61%, and 73.33%, respectively). The frequency of *C. krusei* and *C. tropicalis*, was significantly higher (23.53 and 16.98%) in hematology, than in the rest units ( $p < 0.02$ ), whereas distribution of *C. glabrata* (13.79%) and *C. parapsilosis* (12.85%) do not differ statistically between compared departments. Similarly, analysis of distribution of fungal species in relation to patient underline disease indicated highest frequency of *C. albicans* isolation in patients with traumas (83.33%) and the lowest in patients with blood neoplasms (21.95%), who showed the highest percentage of *C. krusei* and *C. tropicalis*.

**Conclusion:** Obtained data indicated that the species distribution of *Candida* blood isolates in polish hospitals reflects the worldwide trends of increase in the number of infection due to *Candida* non-albicans, especially these with resistance to azoles.

#### **P780** Risk factors for *Candida* infections in a neurology intensive care unit: a case-control study

C. Bulut\*, Y. Kurtoglu Gul, C. Ataman Hatipoglu, S. Yagci, A.P. Demiröz (Ankara, TR)

**Objectives:** *Candida* species has an emerging importance in intensive care units (ICU) in recent years. The aim of this study was to describe the epidemiologic and microbiologic characteristics as well as the risk factors for *Candida* infections in the neurology ICU (N-ICU).

**Methods:** All adult patients who were hospitalized over 48 hours in the N-ICU between 1st January 2010 and 30th October 2011 were included into the study. Patients group was composed of all patients with proven *Candida* infection. Control group comprised of other ICU patients who didn't have any *Candida* infection at all. For the statistical evaluation, the first *Candida* attack of infection was selected for each patient. Identification and antifungal susceptibility of *Candida* species was performed by VITEK II system (Biomerieux, France). CDC criteria's were used for the definition of hospital infection (HI).

**Results:** During the study period a total of 693 patients were hospitalized into the N-ICU. The patient day was 6170 days. Two hundred and ninety one HI were detected in 137 patients. HI rate was 42.0 per 100 patients and HI density was 47.2 per 1000 patient days. The control group comprised of 243 patients. Fifty-seven *Candida* strains were isolated in 44 patients. Among isolates, 11 *C. albicans*, 8 *C. tropicalis*, 31 *C. parapsilosis*, 5 *C. glabrata*, and 2 *C. krusei*. Twenty two of all *Candida* infections were catheter related bloodstream infections while remaining were urinary tract infections. When patient and control groups were compared, older age; having any of the following: nasogastric tube, central venous catheter, arterial catheter, enteral feeding and parenteral feeding were found as risk factors for

	Patient Group n=44 (%)	Control Group n=243 (%)	p	OR (%95 CI)
Age (mean)	73.0±12.1	64.2±18.1	<b>0.002</b>	
Gender (M/F)	17/27	126/117	0.107	0.7 (0.50-1.12)
Underlying diseases				
Malignity	4 (9.1)	7 (2.9)	0.070	3.9 (0.96-10.33)
Diabetes mellitus	10 (22.7)	34 (14.0)	0.170	1.6 (0.87-3.04)
Chronic heart diseases	10 (22.7)	30 (12.3)	0.067	1.8 (0.97-3.49)
Chronic Lung Diseases	2 (4.5)	15 (6.2)	0.674	0.7 (0.17-3.10)
Invasive procedure				
Urinary catheter	40 (90.9)	198 (81.5)	0.126	1.2 (0.99-1.25)
Nasogastric tube	29 (65.9)	52 (21.4)	<b>0.000</b>	3.1 (2.23-4.25)
Central venous catheter	30 (68.2)	30 (12.3)	<b>0.000</b>	5.5 (3.73-8.17)
Arterial catheter	12 (27.3)	17 (7.0)	<b>0.000</b>	3.9 (2.00-7.58)
Ventilatory	12 (27.3)	42 (17.3)	0.177	1.6 (0.90-2.75)
Tracheotomy	2 (4.5)	5 (2.1)	0.292	2.2 (0.44-11.03)
Enteral feeding	7 (15.9)	7 (2.9)	<b>0.001</b>	5.5 (2.03-14.91)
Parenteral feeding	36 (81.8)	94 (38.7)	<b>0.000</b>	2.1 (1.71-2.61)
Peripheral venous catheter	34 (77.3)	163 (67.1)	0.244	1.5 (0.96-1.38)
Hospital stay (days-mean)	44.8	7.4	<b>0.000</b>	37.4 (25.8-49.1)
Mortality	37 (84.1)	72 (29.6)	<b>0.000</b>	2.8 (2.2-3.5)

*Candida* infection ( $p < 0.05$ ) (Table 1). When these factors were evaluated on multivariate analysis, only having central venous catheter and parenteral feeding were detected as independent risk factors for *Candida* infections. Overall mortality in patient and control groups were 84.1% and 29.6% respectively. Mean length of the hospitalization was also longer in the patient group. These differences were found to be statistically significant ( $p < 0.000$ ).

**Conclusion:** *Candida* infections caused by non-albicans species occurred more frequently in our N-ICU. Medical device usage increases the risk for *Candida* infections. *Candida* infections has to be kept in mind particularly for those patients with central venous catheter and parenteral feeding. *Candida* infections were also associated with higher mortality.

#### **P781** Epidemiological trends of nosocomial candidaemia over a 7-year period at a Nantes University Hospital, France

L. Tadeu, J.-P. Talarmin, P. Le Pape, M. Leterrier, P. Moreau, D. Villers, M. Miegville, F. Morio\* (Nantes, FR)

**Objectives:** To determine the main epidemiological characteristics of candidemia in our hospital over a 7-year period.

**Methods:** All episodes of candidemia occurring between February 2004 to December 2010 were analysed retrospectively. Demographic and clinical data (age, sex, medical unit, risk factors) as well as antifungal therapy were recorded. Species identification was performed using phenotypical methods. Isolates belonging to the *C. parapsilosis* and *C. glabrata* species complex and rare *Candida* species were confirmed by ITSrDNA sequencing. In vitro susceptibility to fluconazole, voriconazole, amphotericin B and caspofungin were determined by E-test®.

**Results:** One hundred and eighty-seven episodes of candidemia ( $n = 193$  *Candida* spp. isolates) occurring in 184 patients were analysed (sex ratio = 1.5, mean age = 53.4 years). Global incidence of candidemia was 0.37 per 1000 admissions. Incidence rate increased from 0.27‰ to 0.45‰ between 2005 to 2009. Higher incidences were noted in Hematology (6.65‰) and intensive care units (ICU, 2‰). Central venous catheter and antibiotherapy were the most frequent risk factors (67% and 75% respectively). *Candida albicans* was the predominant species (51.8%) followed by *C. parapsilosis* (14.5%), *C. glabrata* (9.8%), *C. tropicalis* (9.8%), *C. kefyr* (3.6%) and *C. krusei* (3.1%). No trend toward an increased prevalence of non-albicans species was noted over the time. Species distribution among episodes clearly differed between units, *C. tropicalis* being the most prevalent in Hematology (27%) whereas *C. albicans* was the dominant species in the ICU (73%). Prevalence of non-albicans was higher in Hematology compared to any other medical units (33 of 37 episodes, 89.2%). Fluconazole followed by caspofungin were the main antifungals given at the time of diagnosis (43% and 28% of the episodes). Notably, over the study, a clear trend over an increased use of caspofungin was observed. Overall in vitro susceptibility to the four antifungal drugs was noted. Twelve-weeks mortality rate was 29%, being lower for *C. parapsilosis* (18%) than for *C. tropicalis* (47%). Despite the limited number of patients, a trend to a better survival was noted in patients with catheter removal.

**Conclusion:** This study highlights that *C. albicans* is the main species responsible for candidemia at our hospital as well as the significant prevalence of *C. kefyr* ranking at the fifth common *Candida* species. Important differences in species distribution was noted between medical units.

#### **P782** A retrospective study of candidaemia in a Greek hospital, 2007–2011

N. Skarmoutsou\*, V. Mitraj, D. Adamou, S. Konstantopoulou, G. Kasdaglis, P. Katsika, M. Martsoukou, M.E. Fakiri (Athens, GR)

**Objectives:** The aim of this study was to investigate the prevalence of *Candida* spp. in blood stream infections (BSI) during the last 5 years in

a tertiary Greek hospital, to determine the species distribution among *Candida* isolates and their susceptibility to antifungals and finally to evaluate the risk factors associated with candidaemia.

**Methods:** A total of 18,802 blood cultures were incubated in BacT/Alert system (bioMerieux). Isolation of *Candida* and species identification carried out according to conventional methods. Susceptibility testing to Amphotericin B (AB), Fluconazole (FZ), Itraconazole (IZ), Voriconazole (VZ), Posaconazole (PZ), Caspofungin (CS) and 5-Flucytosine (FC) performed with Sensititre Yeast One Test Panel (Trek Diagnostics). MIC's were evaluated according to CLSI criteria. Clinical and demographic data obtained from patients' files.

**Results:** *Candida* sp were recovered from 220 blood cultures (1.17%). *C. albicans* remained the most prevalent species, accounting for 50.4% of all isolates, followed by *C. parapsilosis* (25.9%), *C. glabrata* (10.8%) and *C. tropicalis* (10.8%), while only 2.1% of the strains were identified among other species. Patients had a mean age of 73 years (range from 41 to 89) and BSI was established after an average hospitalization of 25 days. Most of them were hospitalized in Medical Wards (44.3%), 29% in ICU and 26.7% in Surgical Wards, 91.3% had previously received antibiotics and 43.7% had central IV catheters; however only in 19.8% of BSI, central IV catheters were determined as the source of candidaemia, followed by urinary tract infections in 8.4%, while in most cases no source could be identified. Antifungal MIC's ranged for AB: 0.06–1, FZ:  $\leq 0.125$ –32, IZ:  $\leq 0.008$ –4, VZ:  $\leq 0.008$ –1, PZ: 0.03–2, CS: 0.03–1 and FC:  $\leq 0.03$ –2  $\mu\text{g/mL}$ .

**Conclusions:** Candidaemia's prevalence was low (1.17%) with *C. albicans* being considered as the causative agent in half of the infections. Previous administration of antibiotics and presence of IV catheters were the most frequent risk factors. All *Candida* isolates were susceptible to AB, FC, VZ and CS, 26.7% of *C. glabrata* exhibited resistance to IZ, while reduced susceptibility to FZ encountered at 73.3% of *C. glabrata* and 5.5% of *C. parapsilosis* and to IZ at 53.3% of both *C. glabrata* and *C. tropicalis*, 36.1% of *C. parapsilosis* and 5.7% of *C. albicans*.

**P783** **Is the incidence of candidaemia caused by *Candida glabrata* increasing in Brazil? Five-year surveillance of *Candida* bloodstream infection in a university reference hospital in southeastern Brazil**

M.L. Moretti, P. Trabasso, L. Lyra, R. Fagnani, M.R. Resende, L.F. Bachur, L.G.O. Cardoso\*, A.Z. Schreiber (Campinas, BR)

**Objective:** To determine the epidemiology of *Candida* bloodstream infection in a 5-year surveillance.

**Methods:** From 2006 to 2010, a retrospective study was conducted in a university referral tertiary care hospital to study the frequency and distribution of *Candida* species in different medical specialties. The use of mechanical ventilation, central venous catheter and urinary catheter were recorded per 1000 patient-days and the use of antifungal was calculated using defined daily dose (DDD).

**Results:** A total of 313 episodes were identified and the overall incidence was 0.57 (0.43–0.71) episodes per 1000 patients-day. *C. albicans* caused 44% of the overall episodes, followed by *C. tropicalis* (21.7%), *C. parapsilosis* (14.4%), *C. glabrata* (11.2%) and *C. krusei* (3.5%). The incidence of *C. glabrata* significantly increased from 2006 to 2010 (range: 4.3–23.5%) ( $p = 0.024$ ) and *C. parapsilosis* decreased ( $p = 0.046$ ). *C. glabrata* was associated with malignancies ( $p = 0.004$ ) and *C. krusei* with hematologic malignancies ( $p < 0.0001$ ). The use of antifungal was higher in the hematology/bone marrow transplant units and represented 40% of all fluconazole prescription in the hospital. There was no correlation with the use of fluconazole and the increasing ratio of *C. glabrata* ( $r = 0.60$ ). The use of invasive devices was significantly higher in the ICUs than the medical and surgical emergencies units ( $p < 0.001$ ). In contrast, the emergencies had higher incidence of candidemia (2–2.1 episodes/1000 patients-day) than the ICUs (1.6 episodes/1000 patients-day).

**Conclusion:** *C. glabrata* showed a significant raise differently from the current national literature where *C. parapsilosis* remained the most

important non-albicans species in Brazilian hospitals. Our findings suggested that the increasing incidence of *C. glabrata* was not associated with use of fluconazole and other risk factors might play an important role.

**P784** **Risk factors and outcome of mixed *Candida*/bacterial bloodstream infections: a case-control study**

S.H. Kim\*, Y.K. Yoon, M.J. Kim, D.W. Park, W.S. Choi, J.W. Sohn (Seoul, KR)

**Objectives:** Invasive *Candida* infections are increasingly problematic in critically ill patients as a result of the high crude mortality. Mixed *Candida*/bacterial bloodstream infections (BSIs) have been reported to have an incidence among cases of candidaemia ranging between 7% and 27%. However, the clinical impact of mixed *Candida*/bacterial BSIs is unknown.

**Methods:** We reviewed medical records of all consecutive patients developing candidemia at a tertiary care center from July 2006 to June 2011. Mixed *Candida*/bacterial BSIs were defined as isolation of bacterial species growing concomitantly within the same blood culture bottles or within the 48 hour of each other. We performed a case-control study comparing mixed *Candida*/bacterial BSIs with monomicrobial candidaemia.

**Results:** During the 5-year study period, 37 (29.3%) of 126 patients with *Candida* BSIs met the definition for mixed *Candida*/bacterial BSIs. Non-albicans *Candida* species (74 of 126 isolates, 58.7%) were more frequently identified. The most common bacteria were coagulase-negative staphylococci (10 of 44 isolated, 22.7%). In multivariate analysis, previous bacteraemia originated from gastrointestinal tract within 30 days prior to positive blood cultures for *Candida* (OR 6.249, 95% CI 1.892–20.639,  $p = 0.003$ ) and corticosteroid administration (OR 3.584, 95% CI 1.364–9.415,  $p = 0.010$ ) were significantly associated with mixed *Candida*/bacterial BSIs. Persistent candidaemia  $\geq 3$  days in duration occurred more frequent in patients with mixed *Candida*/bacterial BSIs (36.7% vs. 15.8%, OR 3.088, 95% CI 1.104–8.638,  $p = 0.035$ ). The 12-week mortality was not different between mixed *Candida*/bacterial BSIs and monomicrobial candidaemia (70.3% vs. 56.2%). Independent predictors for 12-week mortality were persistent positive blood culture for *Candida* (HR 7.721, 95% CI 4.154–14.350,  $p < 0.001$ ), SOFA score  $\geq 5$  (HR 5.509, 95% CI 3.033–10.004,  $p < 0.001$ ), no administration of antifungal agents (HR 4.172, 95% CI 2.291–7.596,  $p < 0.001$ ), total bilirubin  $\geq 2$  mg/dL (HR 2.422, 95% CI 1.442–4.068,  $p = 0.001$ ), corticosteroid administration (HR 2.166, 95% CI 1.235–3.800,  $p = 0.007$ ), and Charlson's comorbidity index  $\geq 4$  (HR 2.088, 95% CI 1.251–3.487,  $p = 0.005$ ).

**Conclusion:** Mixed *Candida*/bacterial BSIs were associated with recent bacteraemia originated from gastrointestinal tract and corticosteroid administration. However, mixed *Candida*/bacterial BSIs did not show a higher mortality rates compared with monomicrobial candidaemia.

**P785** **Changing roles of non-albican *Candida* species in candidaemia in Western China hospital from 2007 to 2010**

C. He\*, M. Kang, Y. Xie, Z. Chen, Y. Xiao, L. Guo, L. Wang (Chengdu, CN)

**Objectives:** To investigate the pathogenic and clinical characteristics of candidaemia in a teaching hospital in Western China from 2007 to 2010.

**Methods:** A retrospective analysis of the microbiological results for candidaemia from 1 January 2007 to 31 December 2010 was conducted. Clinical data of candidaemia in intensive care unit (ICU) were reviewed and statistics analyses were performed to compare the characteristics of the cases due to albicans and non-albicans *Candida* species.

**Results:** A total of 198 episodes of candidaemia were defined during the study period. Overall, the species distribution of *Candida* spp.

has changed. The non-*albicans Candida* species were predominant, and increased rapidly from 52.6% (10/19) in 2007 to 81.0% (17/21) in 2010 among all isolates recovered in ICU ward. In non-ICU wards, non-*albicans Candida* species accounted for 72.7% (24/33) of all isolates in 2010. Of non-*albicans Candida* spp. isolated, *C. parapsilosis* was the leading species, followed by *C. tropicalis* and *C. glabrata*, but *C. krusei* remained rare. All the *C. albicans* isolated in 2007, 2009 and 2010, were susceptible to amphotericin B and 5-Fluorouracil, while a few isolated in 2008 were non-susceptible to them. During the last 4 years, azole susceptibility has changed but didn't make a statistical significance for the *C. albicans* isolates ( $p > 0.05$ ). In terms of the non-*albicans Candida* species, non-susceptibility of azole in 2007 and itraconazole in 2008 were observed ( $p < 0.05$ ). No statistically significant differences with regard to age, sex, admission service (medical or surgical), underlying condition, usage of antibiotics, immunosuppressive therapy, total parenteral nutrition, major operation during ICU stay, catheterization, and mechanical ventilation for the 48 ICU patients studied were found ( $p > 0.05$ ).

**Conclusion:** Change in the species distribution of *Candida* spp. causing candidaemia in West China Hospital from 2007 to 2010 has been observed. The non-*albicans Candida* species played more important roles, especially for the patients admitted to ICU, while the factors associated with candidaemia caused by non-*albicans Candida* species vs. *C. albicans* remained to be found.

#### P786 Secular trends in fungaemia in a large teaching hospital over a 26-year period

M. Rodríguez-Creixéms\*, P. Muñoz, T. Pelaez, J. Guinea, L. Alcalá, C. Sanchez, E. Bouza (Madrid, ES)

**Objectives:** Data on bloodstream infections caused by yeasts (YBSI) are usually restricted to short periods, specific clinical backgrounds, and specific pathogens or they are simply outdated. The high mortality of YBSI and the impact of efficacious empirical therapy make microbiological surveillance of invasive fungal infections essential. We evaluated the workload, incidence and etiology of YBSI in a general hospital over a 26-year period (1985–2010).

**Method:** We prospectively analyzed the laboratory workload and trends in incidence per 1000 admissions of different YBSI in a general 1750-bed hospital. All yeasts isolated in blood from the same patient within 1 week were considered a single episode.

**Results:** We recorded 1205 episodes of significant YBSI in 1050 patients (1129 *Candida* spp. and 78 other yeasts; 3.44% of all BSI). The species involved were 534 *Candida albicans*, 364 *Candida parapsilosis*, 101 *Candida glabrata*, 83 *Candida tropicalis*, 18 *Candida krusei*, 16 *Candida guilliermondii*, 8 *Candida dubliniensis*, 6 *Candida lusitanae*, 2 *Candida kefyr*, and 15 *Candida* spp. The other yeasts were 40 episodes of *Cryptococcus neoformans*, 14 *Saccharomyces cerevisiae*, 10 *Trichosporon* spp., 6 *Blastoschizomyces capitatus*, 6 *Rhodotorula* spp. and 2 *Hansenula anomala*. The departments in which the yeasts were isolated were adult medical (37.9%), adult intensive care unit (22.7%), adult surgical (15.5%), and pediatrics (23.9%).

Incidence increased from 0.20 episodes/1000 admissions in 1985 to 1.51 episodes/1000 admissions in 2010, ie, an annual increase of 0.07 episodes/1000 admissions (95%CI, 0.05–0.09;  $p < 0.0001$ ). The global incidence/1000 admissions and the annual increase in different yeast species are summarized in Table 1.

Microorganism	N. of episodes	Annual average (per 1,000 admissions)	Annual increase (CI95%)	p
Yeasts	1,205	46.35 (0.88)	0.069 (0.05-0.09)	<0.0001
<i>Candida</i>	1,129	43.42 (0.82)	0.071 (0.05-0.09)	<0.0001
<i>C. albicans</i>	534	20.54 (0.39)	0.038 (0.02-0.05)	<0.0001
<i>C. parapsilosis</i>	364	14.00 (0.27)	0.019 (0.01-0.03)	0.002
<i>C. glabrata</i>	101	3.88 (0.07)	0.009 (0.00-0.01)	0.001
<i>C. tropicalis</i>	83	3.19 (0.06)	0.004 (0.00-0.01)	0.043
<i>C. krusei</i>	18	0.69 (0.01)	-	0.402
Other yeasts	78	3.00 (0.06)	-	0.647

**Conclusions:** The long-term, unbiased perspective of a large teaching hospital shows a significant increase in the incidence of fungaemia, mainly that caused by *C. albicans*, *C. parapsilosis*, *C. glabrata* and *C. tropicalis*.

#### P787 Candidaemia in critically ill patients, 2005–2010

R. Patel\*, B. Saberwal, S. Quan, A. Gonzalez-Ruiz (London, UK)

**Objectives:** To provide a picture of local epidemiology and to assess whether appropriate antifungal therapy is administered in a timely fashion. To evaluate risk factors, outcome and the associated costs.

**Methods:** Retrospective analysis of all candidaemias between January 2005 and December 2010 at a 460 bed district general hospital.

**Results:** There were a total of 60 candidaemias between 2005–2010 resulting in a prevalence of 0.24 per 1000 patient admissions. The most predominant species were *C. albicans* which accounted for 43 cases (73%). From a total of 60 candidaemias, 55 cases were investigated further. It was found that 56% of cases were diagnosed in intensive care (ITU) resulting in ITU prevalence of 9.4 per 1000 admissions compared to a non ITU prevalence of 0.10 per 1000 admissions. This equates to approximately a 100-fold difference between ITU and non ITU cases, consistent with previous reports. The most common risk factor was a central venous pressure line (67%). Forty out of 45 (88.9%) patients received appropriate antifungal treatment within 24 hours of positive blood culture.

From a total of 54 candidaemias, crude mortality rate was 36.6% (15/41) and 46.2% (6/13) for *C. albicans* and non-*albicans Candida* respectively. The difference between the crude mortality is 9.6% and is not significant ( $p = 0.75$ , Fisher's exact test). Hospitalization plus antifungal costs were £48 698/pt and £67 809/pt for the *C. albicans* and non-*albicans Candida* groups respectively. The average length of stay per patient was 58 bed days however, the *C. albicans* group accounted for 18.6 bed days/pt in ITU and 34.5 bed days/pt in non ITU wards, compared to the non-*albicans Candida* group who accounted for 23.8 bed days/pt in ITU and 50.7 bed days/pt in non ITU wards.

**Conclusions:** 88.9% of patients received timely antifungal treatment. There is a high mortality rate in patients with candidaemias. The care of *C. albicans* infections was on average £19 111/pt cheaper. Trust outcome would be to devise and implement a candidaemia score card to improve outcomes and costs.

#### P788 Clinical characteristics of ocular candidiasis: when should fundoscopy be performed to rule out ocular candidiasis?

M. Nagao\*, T. Saito, G. Hotta, S. Doi, M. Yamamoto, Y. Matsumura, A. Matsushima, Y. Ito, S. Takakura, S. Ichiyama (Kyoto, JP)

**Objectives:** Ocular candidiasis is a major complication of *Candida* bloodstream infection (BSI), but little information is known about the clinical characteristics. This study was conducted to investigate the incidence, risk factors and the outcome of ocular candidiasis and the optimal timing of fundoscopy.

**Methods:** We analyzed 216 cases with positive blood cultures of *Candida* species from January 2005 to June 2011 in two teaching hospitals to determine the incidence and the clinical characteristics of ocular candidiasis. Infectious diseases physicians in these hospitals performed proactive intervention in all of the *Candida* BSI cases and recommended fundoscopic examinations by ophthalmologists.

**Results:** One-hundred sixty three of 216 *Candida* BSI cases had ophthalmology consultations during the course of the antifungal therapy. Fifty-three (32.5%) cases had findings consistent with the diagnosis of ocular candidiasis, consisting of 44 cases with possible/probable chorioretinitis and nine cases with vitritis. The groups with and without ocular involvement did not differ in age, sex, steroid use or diabetes mellitus, but more cases had digestive organ abnormalities or malignancies. Of these 53 cases, 42 (79.2%) were diagnosed within 7 days after a positive blood culture. The average time from a positive fungal culture to the diagnosis was 5.5 days. Twelve ocular candidiasis

cases died during antifungal therapy and 40 of 41 cases completed antifungal therapy without any worsening of visual acuity. Four cases were negative for ocular manifestation on the first examination, but were subsequently diagnosed as ocular candidiasis on a second examination more than 10 days after a positive fungal culture. Among the patients with ocular candidiasis, more cases were due to *Candida albicans* ( $p = 0.004$ , OR; 2.99 95%CI 1.42 – 6.33) and had higher beta D-glucan values ( $p = 0.002$ , OR; 4.17 95%CI 1.05–5.52). Thirty-day mortality rate was relatively higher in the ocular candidiasis cases, although the difference was not statistically significant. (26.4% vs 18.8%  $p = 0.303$ ).

**Conclusions:** When determining the optimal antifungal drug of choice and duration of therapy, fundoscopic examination should preferably be performed soon after a positive blood culture especially in those who had BSIs by *C. albicans* and had higher beta D-glucan values, and follow-up fundoscopic examination should also be considered in such high risk patients.

**P789** **Mannose-binding lectin gene polymorphisms. Impacts on the colonisation by *Candida* spp. and on the anti-*Candida* immune response**

S. Damiens\*, J. Poissy, A.-S. Druchbert, P.-M. Danze, I. Fajardy, N. François, T. Jouault, D. Poulain, B. Sendid (Lille, FR)

**Objectives:** Invasive candidiasis (IC) is a persistent public health problem linked to difficulties of diagnosis. Several recent observations suggest an “immunogenetic disparity” against IC. Among anti-*Candida* host defenses, the mannose-binding lectin (MBL) has a major role in clearance of yeasts by opsonisation and activation of complement pathway. The aim of this study is to assess serum MBL levels in IC vs. controls and to analyse relationship between serum MBL, mannanemia and anti-mannan antibodies during the time course of IC.

**Methods:** Between January 2005 and December 2007, 112 sera was retrospectively collected in different wards of CHRU of Lille coming from 49 IC patients (22 females and 27 males) proved by positive blood culture. Two control groups were also included in this study: 70 presumed healthy subjects (HS) and 82 hospitalized patients (HP) without evidence of infection.

Polymorphism of MBL-2 gene was analyzed through PCR-SSP, circulating levels of MBL were determined by ELISA.

**Results:** Association between MBL-2 gene mutations and MBL serum levels in sera of controls patients was confirmed during this study. On the other hand, serum MBL concentrations were significantly higher in IC than HP (2700 vs. 1200 ng/mL;  $p < 0.0001$ ) and HS (2700 vs. 1850 ng/mL;  $p = 0.0035$ ). In HP, significantly lower level of MBL seems to be associated with colonization ( $p = 0.0291$ ). During the time course of IC, significant variations of MBL levels was observed before ( $p = 0.013$ ) and during candidemic episodes ( $p = 0.006$ ). This dynamic evolution of MBL is correlated with anti-mannan antibody and both decrease in case of detectable mannanemia.

**Conclusion:** This study is the first evidence of variation in serum MBL levels during the time course of IC. MBL levels were paralleled to anti-mannan antibodies and vary according to circulating *Candida* mannan. More exploration of these serological/mycological and genetic analyses could help in understanding the role of MBL among IC risk factors.

**P790** **DHPS gene mutations in *Pneumocystis jirovecii* and clinical outcome in non-HIV patients with *Pneumocystis* pneumonia in China**

Y. Long, C. Zhang, L. Su, C. Que\* (Beijing, CN)

**Backgrounds:** *Pneumocystis* pneumonia in non-HIV immunocompromised patients usually present with severe disease with high mortality. It is unknown whether treatment failure was

associated with *pneumocystis* resistance. The purpose of our study is to investigate dihydropteroate synthase (DHPS) gene mutations in our non-HIV patients with *Pneumocystis* pneumonia (PCP) and their clinical context.

**Methods:** DHPS gene from HIV-negative patients with PCP presented between January 2008 and April 2011 were amplified by polymerase chain reaction (PCR) and sequenced. Clinical data from medical records were reviewed.

**Results:** (i) DNA was extracted successfully from 20 of 22 patients' respiratory samples. The most common point mutation at codons 55 and 57 were not detected. (ii) Two other nonsynonymous point mutations, Asp90Asn and Glu98Lys were identified in *P. jirovecii* from two patients. (iii) The percentage of circulating lymphocytes was significantly lower in non-survivors than in survivors (4.2%[IQR2.4–5.85] vs. 10.1%[IQR5.65–23.4]  $p = 0.019$ ). Neutrophil proportion in BALF was significantly higher in non-survivors than in survivors (49.78 + 27.67% vs. 21.33 + 15.03%  $p = 0.047$ ). Apart from the co-trimoxazole as the first line therapy, nine (50%) patients received Caspofungin during treatment (one monotherapy and eight in combination), but only two patients (22.22%) survived.

**Conclusions:** No common DHPS gene mutations of *Pneumocystis jirovecii* were found in our HIV-negative PCP patients. However, other mutations did exist, in which the significance needs to be identified. The reduction of lymphocyte in peripheral blood and elevation of neutrophil counts in BALF seem to be associated with poor outcome. The beneficial effect of adjunctive caspofungin to non-HIV PCP patients requires further investigation.

**P791** **Imported Tinea capitis in adopted children in Spain: a 6-year retrospective study**

A. Enriquez\*, P. Trevisi, B. Lopez, C. Toro (Madrid, ES)

**Background:** With human migration, some species uncommon in developed countries are being diagnosed currently. To analyze the epidemiology and clinical features of these infections, a 6-year retrospective study of imported dermatophytoses in adopted children from underdevelopment regions diagnosed in the Pediatric department of our centre was performed.

**Methods:** A retrospective analysis of samples from adopted immigrant children with scalp lesions with clinical suspicion of mycosis from January 2005 to October 2011 was performed. Specimens (hair or skin) were pressed on plates of agar medium with added chloramphenicol with/without cycloheximide, which were sealed and incubated at 30°C for 21 days. Readings were conducted once a week. In case of growth, the identification was made by macroscopic and microscopic morphology.

**Results:** A total of 71 samples were studied. The mean age of the study population was 4.5 years old (range: 6 months to 11 years). Forty-five (63.3%) samples yielded dermatophytes. The etiologic agent isolated more frequently was *Trichophyton violaceum* ( $n = 29$ , 64.4%) followed by *T. rubrum* ( $n = 6$ , 13.3%), *T. mentagrophytes* ( $n = 4$ , 8.8%), *T. soudanense* ( $n = 4$ , 8.8%), *Microsporum audouinii* ( $n = 2$ , 4.4%) and *T. schoenleinii* ( $n = 1$ , 2.2%). Two different dermatophytes in a single lesion were two patients: *T. rubrum* with *M. audouinii*, and *T. violaceum* with *T. mentagrophytes*. Regarding the origin of the adopted children, most of them came from Ethiopia ( $n = 30$ ) and *T. violaceum* was the most frequent dermatophyte isolated ( $n = 26$ , 76.6%).

**Conclusion:** Tinea capitis is a public health issue because of their transmissibility from human to human that involved mainly children of school age. In developed countries, incidence of dermatophytoses has showed a change in their clinical and epidemiological pattern with an increase of anthropophilic dermatophytes. Although the reasons are not clear, immigration of other geographical areas has a remarkable role. The accuracy detection and diagnosis of these exotic species is essential for its therapeutic implications, prevention measures and an update on their epidemiology.

**P792 Fungal malignant external otitis**

B. Hammami\*, A. Ben amor, D. Lahieni, I. Maaloul, F. Makni, A. Ayadi, M. Ben jema (Sfax, TN)

**Objective:** To investigate the clinical characteristics and outcome of fungal malignant external otitis (MOE).

**Methods:** We report in this retrospective study, seven cases admitted to our infectious diseases department over a 5-year period (2007–2011), for a MOE. The diagnosis was based on a combination of clinical finding, biological and radiological investigations.

**Results:** We identified one man and six women, all diabetics. The mean age was 63 years (50–73 years). The main symptoms were severe otalgia (seven cases), otorrhoea (seven cases), oedema of the external ear canal (six cases) and headache (three cases). Three patients developed facial paralysis during disease progression. The pathogens identified on culture or PCR of ear samples were *Aspergillus* (two cases), *Candida albicans* (two cases), *Candida parapsilosis* (one case), *Candida tropicalis* (one case) and *Candida krusei* (one case). All patients have bone erosion on computed tomography. After treatment by amphotericin or fluconazole or voriconazole, the evolution was favorable in five cases, one patient has persistent infection, and one patient died.

**Conclusion:** Fungal malignant external otitis should be suspected in cases where there is no response to antipseudomonal antibiotic therapy. Samples and deep biopsies from the external ear canal are needed to confirm the diagnosis.

**P793 Pulmonary aspergillosis in a burn patient**

A. Silva\*, G. Mota, F. Xambre, L. Krebs (Lisbon, PT)

**Introduction:** In acute phase of burn injury, thermal damage to the human skin barrier and local and systemic immune dysfunction predisposes patients to potentially serious fungal infections. The nature of burns injuries often result in complex intensive care and exposure to multiple risk factors for fungal infection. *Aspergillus* spp. is a fungus acquired by inhalation of airborne spores and may cause various clinical conditions. Pulmonary disease caused by *Aspergillus*, mainly *A. fumigatus*, can result in Invasive Pulmonary Aspergillosis (IPA), especially in immunocompromised patients, and has become the most important airborne pathogen in developed countries.

**Case report:** A 56 years old man was admitted with electrical burns to 23.5% total body surface area involving his neck, back and bilateral upper extremities. There was no evidence of inhalation injury and the patient had no other pathological condition. Resuscitation was started immediately, using the Parkland formula and the patient was ventilated and treated with piperacillin/tazobactam. Patient was taken several times to the operating room for amputation of upper extremity, escharectomy and skin grafting. Ten days after admission in burn unit, the patient developed high fever, expectoration and leukocytosis. A fiberoptic bronchoscopy with bronchoalveolar lavage was performed and 11 days later revealed *aspergillus fumigatus*. A therapy with amphotericin B was initiated and continued for 29 days, and he has discharged free from symptoms and signs. On 37<sup>o</sup> day did another fiberoptic bronchoscopy. On 50<sup>o</sup> day bronchoalveolar lavage culture and galactomannan detection were negative. After 39 day the patient was extubated and clinically he had no signs of infection.

**Conclusion:** Infections remain a primary cause of morbidity and mortality in burned patients, with fungal infections being among the main pathogens.

Advancements in burn care therapy have extended survival of seriously burned patients, exposing them to increased risk of infectious complications, notably fungal infections. Invasive Aspergillosis must be considered as an emerging and devastating infectious disease in intensive care unit (ICU) patients, even in the absence of an apparent predisposing immunodeficiency. Total body surface area (TBSA) burn and length of stay (survival after burn) were identified as

contributing factors for the incidence of fungal infection and mortality due to fungus.

**P794 Acremonium endophthalmitis after cataract extraction: a report of two rare cases**

A. Calderaro\*, F. Motta, C. Gorrini, S. Larini, G. Piscopo, C. Chezzi (Parma, IT)

**Objectives:** Infective endophthalmitis is one of the most significant complications of cataract surgery. Typically it is caused by the perioperative introduction of microbial organisms (mainly gram-positive bacteria) into the eye from the patient's normal conjunctival and skin flora. On the contrary, fungal aetiology is considered an extremely rare occurrence.

We report two cases of *Acremonium endophthalmitis* after cataract surgery on the same day in the same operating room of the hospital's ophthalmology clinic.

Both patients, a 75-years-old man and a 64-years-old woman, developed endophthalmitis 2 and 3 weeks after cataract extraction, respectively, with decrease in visual acuity, loss of media clarity, ocular hyperemia followed by palpebral edema, conjunctival hyperemia and hypopyon.

**Methods:** The samples culture was performed using conventional methods for bacteria and fungi. Fungal DNA for molecular analysis was extracted from colonies grown on Sabouraud dextrose agar at 30°C using "HPPT Preparation Kit" (Roche Diagnostics) following the yeast and moulds extraction manufacturer's protocols. A restriction fragment length polymorphism (RFLP)-PCR of the nuclear 5.8S and internal transcribed spacer (ITS2) regions of the ribosomal DNA, amplified with the universal ITS3 and ITS4 fungal primers, was performed by the endonucleases *Hinf*I, *Msp*I, *Sau*3 AI and *Taq*I.

**Results:** Moulds with similar macroscopic and microscopic features, consistent with *Acremonium* genus, were isolated from all the samples (vitreous washing, aqueous fluid and intraocular lens from the first patient and aqueous fluid from the second). Bacterial cultures were negative. Amplification products, ranging from 360 to 380 bp, were obtained from all the cultures indicating the presence of *Acremonium* spp. DNA. RFLP of the amplicons showed the same restriction pattern for all the samples culture from both the patients.

**Conclusion:** Since filamentous fungi with similar morphologies and the same 5.8S and ITS2 rDNA restriction pattern (though it was not possible to identify the *Acremonium* species involved, it is likely that it was the same in the two cases) were isolated from all the analyzed samples and the two patients underwent surgery on the same day in the same operating room, it is possible to speculate that inadequate sterilization procedures of the instruments or contaminated irrigation fluids and disposables could have been involved in the transmission of the infection.

**P795 Penicilliosis, cryptococcosis, and histoplasmosis: a comparative study between epidemiology, clinical features, microbiology, treatment, and outcome**

P. Uppathannarakorn\*, A. Jindamporn, C. Suankratay (Bangkok, TH)

**Objectives:** Penicilliosis, cryptococcosis, and histoplasmosis are among the most common yeast infections in Thailand. It is very much difficult to distinguish disseminated infection caused by these three fungi based on clinical manifestations alone. The aim of this study was to compare epidemiology, clinical features, microbiology, treatment, and outcome between these three fungal infections.

**Methods:** Medical records of all patients with diagnosis of *Penicillium marneffe*, *Cryptococcus neoformans*, *Histoplasma capsulatum* attended at King Chulalongkorn Memorial Hospital, Bangkok, Thailand from January 2001 to December 2010 were analyzed.

**Results:** Of 122 patients, there were 28, 50, and 42 *P. marneffe*, *C. neoformans*, and *H. capsulatum* infections, respectively. HIV infection

was the most common preexisting condition, accounting for 82.1%, 46%, and 82.1% of penicilliosis, cryptococcosis, and histoplasmosis, respectively. Of 28 patients with penicilliosis, all had disseminated infections. Of 50 patients with cryptococcosis, there were 35 (70%) localized (33 and 2 patients with meningitis and lung infection) and 15 disseminated infections. Of 42 patients with histoplasmosis, there were 5 (11.9%) localized (four and one patients with adrenal glands infection and myelitis) and 37 disseminated infections. Interestingly, the characteristic umbilicated skin lesions were noted in 22 (78.5%), 2 (4%), and 17 (40.5%) patients with penicilliosis, cryptococcosis, and histoplasmosis, respectively. The most common diagnostic method was based on microscopic examination of clinical specimens in 25 (89.3%), 49 (98%), and 41 (97.6%) patients with penicilliosis, cryptococcosis, and histoplasmosis. A definite diagnosis was made based on positive cultures in 17 (58%), 12 (24%), and 6 (14%) patients with penicilliosis, cryptococcosis, and histoplasmosis, respectively. The mortality was 7 (24%), 9 (18%), and 10 (23%) in penicilliosis, cryptococcosis, and histoplasmosis, respectively.

Variable	Penicilliosis (N=25)	Cryptococcosis (N=50)	Histoplasmosis (N=42)
<b>I. Epidemiology</b>			
-HIV infection	23 (82.1)	23 (46)	32 (82.1)
<b>II. Clinics</b>			
-Localized infection	0	35 (70) <sup>1</sup>	5 (11.9) <sup>2</sup>
-Umbilicated skin	22 (78.5)	2 (4)	17 (40.5)
<b>III. Microbiology</b>			
-Positive culture	17 (58)	12 (24)	6 (14)
-Positive microscopic examination	25 (89.3)	49 (98)	41 (97.6)
<b>IV. Outcome</b>			
-Mortality	7 (24)	9 (18)	10 (23)

1. Localized infection in cryptococcosis :33 meningitis and 2 lung infection

2. Localized infection in histoplasmosis : 4 adrenal glands infection and 1 myelitis

All data are shown as number and percentage in parenthesis.

**Conclusion:** Most patients with penicilliosis and histoplasmosis present with disseminated infection. In contrast, subacute and chronic meningitis is the most common presentation in most patients with cryptococcosis. In addition, the characteristic umbilicated skin lesions are frequently noted in patients with penicilliosis and histoplasmosis, compared to those with cryptococcosis.

#### **P796** Cryptococcosis risk factors for HIV-infected patients in Latvia

P. Aldins\*, I. Eksteina, G. Sture (Riga, LV)

Latvia HIV incidence is 12.9/100000, it is higher than EU average. The first HIV cases in Latvia was detected in the end of 80ties, but after 10 years HIV epidemic in drug users population was started. The result is increasing number of patients with different opportunistic diseases, very common are invasive fungal diseases, including cryptococcosis.

**Objectives:** Identify risk factors for cryptococcosis in HIV-infected patients in Latvia.

**Methods:** Investigated all patients with confirmed extrapulmonary Cryptococcosis diagnosis from 2001 to 2008 in AIDS department in Infectology Center of Latvia.

**Results:** In total, 97 patients included; 70% males, 79% IVDU. Diagnose of cryptococcosis based on antigen detection in 69%, on morphological findings in 4%.

All patients had evidence of HIV infection. CD4 < 350 mm<sup>3</sup> 67%, on HAART 42%. More than in common population were found serious illnesses: HCV 85%, TB 26%, Syphilis 14%, Manganese Parkinsonian syndrome and other.

Initially treatment started for 91 patient, with Fluconazole (77%), Amphotericin B (7%), Itraconazole (6%), Voriconazole (4%). Prophylactic treatment was continued for 81%.

Twenty-two of the discussed patients died, 15 of them had not received prophylactic treatment.

Disease cured 79% with CD4 > 350 mm<sup>3</sup>, 60% with CD4 < 350 mm<sup>3</sup>. Relapse showed in 13%, mainly in patients with CD4 < 350 mm<sup>3</sup> (62%).

**Conclusions:** Increased risk of cryptococcosis in Latvia has HIV infected patients with other serious disease, with CD4 < 350 mm<sup>3</sup>, not receiving HAART. Mortality risk increased if the patient does not continue to receive prophylactic antifungal treatment.

#### **P797** Genital white piedra caused by *Trichosporon japonicum*

J. Lozano\*, E. Simarro, C. Faura, M.D. Crespo (Albacete, ES)

**Introduction:** *Trichosporon* species have been reported as emerging pathogens in humans. *T. japonicum*, named by Sugita et al. (1998), was isolated from air but few cases isolated from clinical specimens have been reported. We believe this is the first reported genital white piedra case caused by *T. japonicum*.

**Clinical case:** A female patient, aged 83, with hypertension, osteoarthritis and osteoporosis, came to the dermatology consultation with 1-month pruriginous vulva lesions. Physical examination revealed two whitish-brownish overlapping plaques in the labia majora, with slight oedema and erythema. No alopecic plaques were seen in pubic hair. On friction, plaques came away with difficulty; she had no other body skin lesions.

**Methods:** A sample of lesion flakes was taken by scalpel scraping and sent to the microbiology laboratory for direct fluorescence microscopy with calcofluor and the corresponding culture in Sabouraud dextrose agar (SDA) with chloramphenicol, and SDA with chloramphenicol and cycloheximide. Culture plates were incubated at 30°C for up to 21 days. Colonies were examined in a lactophenol cotton blue wet mount for microscopic characteristics.

**Results:** Direct microscopy showed no compatible fungal cells. By day 10 (30°C), colonies were observed on SDA and were yeast-like in consistency, butyrous, cream, smooth with a mucoid texture, becoming irregular to warty in older cultures. Observation microscopy with lactophenol-blue showed budding yeast cells, hyphae and arthroconidia. Urease activity and growth at different temperatures (25, 37 and 42°C) were seen. The Vitek II yeast identification system (bioMérieux) misidentified the isolate as *T. asahii*. Molecular identification of the isolate was performed in the Microbiology National Centre of Spain. The patient was treated empirically with 2% topical Itraconazol every 12 hours after shaving pubic hair. After isolating *T. japonicum*, the patient had 2-monthly check-ups. After a 6-month follow-up, only slight clinical improvement was noted so oral Itraconazol treatment began (100 mg/12 hour; 4–8 weeks). Microbiological controls were negative after oral treatment.

**Conclusions:** *T. japonicum* emerges as a pathogen agent in humans. Difficulties in the identification imply the delay of an earlier usage of appropriate antifungal therapy. Moreover, the Vitek II yeast identification system is not reliable enough to correctly identify clinically relevant *Trichosporon* species and molecular analysis is required.

#### **P798** Evaluation of invasive fusariosis in haematological patients: a 10-year retrospective study

H.M. Morales\*, J. Nobrega, F. Dullely, M. Giudice, M.A. Shikanai-Yasuda, S.F. Costa (Sao Paulo, BR)

**Objectives:** The epidemiology of Invasive Fungal Infection in the hematological population has changed over the last two decades. *Fusarium* spp. represents the third most common cause of IFI among those patients. We aimed to evaluate the cases of Invasive Fusariosis (IF) in hematological patients from a Brazilian center.

**Methods:** IF patients were collected between 2001 and 2011. IF was diagnosed by EORTC/MSG criteria. The patient's charts were analyzed retrospectively for demographic, clinical and therapeutical

characteristics. The clinical outcome was obtained at 12 weeks and a Kaplan-Meier Survival Analysis with Logrank Significance Test performed using GraphPad Prism 5.0.

**Results:** Twelve patients with IF were identified. There were eight male and four female subjects. The mean age was 32 (16–52) years. The most common underlying diseases were Aplastic Anemia (4) and Acute Leukemia (4). Six patients were previously submitted to bone marrow transplant, five of them allogeneic. Five patients were classified as nosocomial fusariosis. The majority of cases (11) were neutropenic in the time of diagnosis and fever was the most common sign (11). Five patients had concomitant bacteremia. The median SOFA score in the time of diagnosis was 4 (3–11) and 27 days was the median time of neutropenia before the diagnosis. The diagnosis was made mainly by blood culture (5) and by cutaneous culture (4). Nine patients had disseminated fusariosis. No inflammatory response (2) and purpuric perivascular dermatitis (2) were the major findings in the cutaneous biopsy. Pulmonary fusariosis had radiographic manifestations of an angiotropic mold; nodules (6) and consolidation (6) were the most common findings on CT. Monotherapy was used in three patients. Eight received combined therapy, all of them consisting of amphotericin B plus voriconazole. The survival rate at 12 weeks was 33% and the median time of survival was 8 days. The use of high dose corticosteroids ( $p = 0.04$ ) and the neutrophil recovery ( $p = 0.002$ ) were statistically related with mortality at 12 weeks (figure 1).

**Conclusion:** Invasive Fusarial is a rare yet lethal disease with no defined therapy. The impact of combined therapy on the outcome of IF is still controversial. We couldn't demonstrate the potential benefit of this strategy; on the other hand, our data reinforced the importance of high dose corticosteroids and the neutrophil recovery on survival of our patients.

#### **P799** Efficacy of micafungin on *Geosmithia argillacea* infection in a cystic fibrosis patient

L. Favennec\*, L. Couderc, O. Matray, S. Giraud, R. Zouhair, S. Bertout, G. Gargala, C. Marguet, J. Bouchara (Rouen, Angers, Montpellier, FR)

Cystic fibrosis are at risk of colonization by a number of fungi, including *Geosmithia argillacea*. We report here a case of clinical and

microbiological efficacy of micafungin in a cystic fibrosis patient chronically colonized with *Geosmithia argillacea*.

O.D., a female F508Del-CFTR homozygous patient was diagnosed at birth with cystic fibrosis in January 1996. She was found chronically colonised with *Aspergillus fumigatus* from 2001 to 2006. She was treated alternatively with oral voriconazole and itraconazole from 2004 to 2008, and with posaconazole since february 2008. *Geosmithia argillacea* was first diagnosed in May 2007, and chronic colonisation was persistent from this date to August 2010 with 23/28 fungus positive sputum samples, in spite of posaconazole therapy. For an isolate obtained in October 2008, minimal inhibitory/effective concentrations (MIC/MEC, mg/mL) determined using the Eucast method were 2.0, 2.0, 16.0, 2.0, 0.25 and 0.015 for amphotericin B, itraconazole, voriconazole, posaconazole, caspofungin and micafungin, respectively. The FEV1 predicted value was 73% at the time of first fungus isolation and was decreased to 47% in October 2009. She then was given caspofungin for 21 days ((70 mg/day, later reduced to 50 mg) which resulted in clinical improvement (FEV1 = 64% in January 2010) without eradication of *G. argillacea*. O.D. was then treated from September, 23 to November 3, 2010 with micafungin (100 mg bid for 21 days and 100 mg/day for the following 21 days) which resulted in clinical and microbiological improvement. FEV1 predicted ranged 67–68% in October and December 2010, and February and May 2011, and from the end of treatment to December 2010, 5/6 sputum samples were found negative for *G. argillacea*. The positive sample contained fungus of the same genotype as previous isolates.

The present case is to our knowledge the first description of *G. argillacea* eradication in a chronically colonized cystic fibrosis patient. Since no change in bacterial colonization was observed before, during, and after *G. argillacea* colonization, the present case is consistent with a pathogenic role of the fungus in cystic fibrosis patients. In vitro antifungal susceptibility assays suggested that echinocandins are most effective agents against this fungus with a lowest MEC for micafungin (seven isolates studied, MEC range: 0.015–0.03), although eradication could only be obtained with high dose micafungin for a long time (6 weeks).

#### **P800** Central nervous system aspergillosis in Saint Petersburg, Russia

N.V. Vasilyeva\*, Y.V. Borzova, E.A. Desyatik, S.N. Khostelidi, R.M. Chernopjatova, T.S. Bogomolova, S.M. Ignatyeva, R.A. Araviyskiy, I.S. Zjuzgin, A.S. Kolbin, M.O. Popova, A.G. Volkova, N.V. Vavilov, S.N. Bondarenko, N.N. Klimko (Saint Petersburg, RU)

**Objectives:** To define demographic parameters, underlying diseases, aetiology, clinical features and survival rate in patients with central nervous system (CNS) aspergillosis in Saint Petersburg, Russia.

**Methods:** Retrospective analysis. The diagnosis was established on the basis of EORTC/MSG 2008 criteria. Cases of proven or probable invasive aspergillosis (IA) were included.

**Results:** In 1998–2010 year. Two hundred and ninety-five cases of IA were registered in 19 hospitals in Saint Petersburg. CNS aspergillosis was revealed in 11 (3.7%) patients, three men and eight women, 4–67 years old (median – 30.5), seven adults and four children.

Primary host conditions were hematological disorders (55%) (including acute leukemia – 36%), non-hematological malignancy (9%), viral meningitis (9%), infectious hepatitis (9%).

Major risk factors were prolonged neutropenia (72%), lymphocytopenia (72%), cytostatic chemotherapy (64%), corticosteroid therapy (45%), stem-cell transplantation (9%), bacteremia (18%).

Extra-CNS sites of infection were revealed in 82% of patients and included: lungs (55%), myocardium (9%), more than two organs (18%). The most common symptoms were: fever, headache, mental status alterations, drowsiness, dysarthria, hemiparesis ans seizures.

Galactomannan test in serum and cerebrospinal fluid was positive in 72% of patients, positive histology – in 36%, *Aspergillus fumigatus* was isolated from cerebral abscess in 9% of patients.

Antifungal therapy was conducted in 64% of patients: amphotericin B – 45%, voriconazole – 36%, itraconazole – 36%, caspofungin – 18%, amphotericin B lipid complex – 9%. Surgical treatment was used in 9% of cases. Four patients (36%) died before initiation of treatment.

Twelve-week overall survival rate in patients who received treatment was 86%, 12 months – 57%. Overall survival rate in patients with CNS aspergillosis did not differ significantly from the survival rate in patients with invasive pulmonary aspergillosis.

**Conclusion:** CNS aspergillosis developed in 3.7% of patients with invasive aspergillosis. Main underlying diseases were hematological malignancies (55%). Extra-CNS sites of infection were revealed in 82% of patients. Twelve-week overall survival rate was 86%.

#### **P801** Considerable increase in frequency of *Saccharomyces* species in vaginitis

L. Bereczki\*, J. Deák (Szeged, HU)

**Objects:** In contrast with the tendencies seen for the distribution of fungal agents of invasive infections, where non-*C. albicans* *Candida* species and non-*Candida* species are becoming increasingly more frequent new opportunistic agents of infection, our statistical analysis did not reveal such a tendency for genital samples; recent literature sources confirm this [1].

**Methods:** Between 2003 and 2010, we processed 15 000–20 000 genital samples annually (vaginal, urethral, glans, etc.), mainly from women. The results were analysed statistically to examine the tendencies in frequency of fungal pathogenic agents.

**Results:** Fluconazole-resistant emerging invasive fungi such as *C. glabrata* and *C. krusei* decreased in frequency in genital samples, as did *C. inconspicua*. Fluconazole-sensitive non-*C. albicans* *Candida* species likewise decreased in frequency (*C. parapsilosis* and *C. kefyr*), or exhibited a constant low frequency (*C. tropicalis* and *C. guilliermondii*), but none of them became more frequent in the examined period. The incidence of the main pathogenic agent, *C. albicans*, rose slowly (85–90%). Most of the non-*Candida* fungi (*Rhodotorula*, *Kloeckera*, *Pichia*, *Cryptococcus*, *Geotrichum*, etc.) displayed only a low frequency. On the other hand, independently of the age groups, the rise in frequency of *Saccharomyces* species (mainly *S. cerevisiae*) in frequency was spectacular: in the examined 8-year interval, i.e. from 1.14% to 3.37%, a 2.95-fold increase in frequency.

**Conclusions:** The pathogenic processes in cases involving *Saccharomyces* sp. frequently lead to chronic vaginitis as *Saccharomyces* sp. often have intrinsic resistance to fluconazole and other antifungal agents (other azoles). Such circumstances are possibly responsible not only for the chronic pathogenic processes [2], but also for the considerable rise in frequency. 1. Hetticarachchi, N., Ashbee, HR., Wilson, JD. Prevalence and management of non-albicans vaginal candidiasis. Sex Transm Infect 2010; 86: 250. 2. Sobel, JD., Vazquez, J., Lynch, M., et. al. Vaginitis due to *Saccharomyces cerevisiae*: epidemiology, clinical aspects, and therapy. Clin Infect Dis 1993; 16 (1): 93–99.

#### **P802** Could a shorter incubation period be possible for dermatophytes?

A. Rezusta\*, M. Vidal García, C. Colmenarejo, M.L. García Zurita, C. Gonzalo, R. Lisbona, G. Martín Saco, M.J. Revillo (Zaragoza, ES)

**Objective:** Dermatophytes are a group of fungi able to infect nails, skin or hair of a living host, causing dermatophytosis. Diagnosis is carried out by conventional culture in most hospitals. Most authors recommend to incubate the cultures for a minimum of 4 weeks if dermatophytes are suspected. In this study we try to analyze the necessity to incubate the samples over four weeks and the effectiveness of a shorter incubation time, evaluating if dermatophytes could grow in two weeks, in order to decrease the incubation time.

**Methods:** A total of 3573 samples were examined in a period of 27 months. The samples were cultured in Sabouraud dextrose agar, Potato Dextrose agar (PDA) and Dermatophyte Test Media (DTM) and were incubated at 30°C for four weeks. Culture plates were examined twice a week (on Monday and Thursday) and the day on which the fungal growth was first noted, was recorded.

**Results:** From the total of 3573 samples examined, 606 (16.94%) were positive for dermatophytes' growth and 2967 (83.04%) were negative. For 571 (94.22%) samples dermatophytes appeared earlier than two weeks of incubation. In 9 (1.46%) cases the time of detection was between 15 and 17 days. In 10 (1.65%) isolates growth took place after 18 days of incubation. Finally, the day of dermatophytes' growth couldn't be determined in 16 samples (2.64%).

Due to the limitation of examining plates twice a week, occasionally it was unable to perform the examination just at the fourteenth day so the examination time were in some cases between 15 and 17 days.

The negative predictive value (NPV) was calculated taking as false negative the number of samples in which dermatophytes' growth was after 18 days of incubation and considering true negative the number of samples in which the dermatophytes' growth was negative after a 4 weeks incubation. The NPV was 99.66%.

**Conclusion:** In the light of this study, to summarise we can conclude that after 15 days of incubation period the possibilities of dermatophyte grow are minimum. Thus, plates could be incubated only for this time with the aim of decreasing the laboratory workload and therefore costs.

#### **P803** *Candida* peritonitis after abdominal transplantation

M. Bartoletti, C. Cervera, I. Hoyo, L. Linares, G. Sanclemente, J. Puig de la Bellacasa, F. Marco, F. Cofan, M.J. Ricart, M. Navasa, A. Moreno\* (Barcelona, ES)

**Objectives:** To evaluate the characteristics, incidence rate and outcome of *Candida* peritonitis in abdominal transplantation.

**Methods:** All liver and pancreas transplant recipients from July 2003 to December 2009 were included. Pre-, peri- and post-transplant variables were prospectively collected. *Candida* peritonitis was diagnosed on the basis of macroscopic findings and positive culture of peritoneal fluid collected during operation or by needle aspirate in the early post-transplant period (first 30 days).

**Results:** During the study period we included 717 patients, 530 (74%) orthotopic liver, 130 (18%) simultaneous kidney-pancreas, 31 (4%) double liver-kidney, 24 (3%) isolated pancreas and 2 (1%) double liver-heart transplantation. We diagnosed five cases of *Candida* peritonitis: 3 in pancreas recipients (all *C. albicans*) and 2 in liver recipients (*C. tropicalis* and *C. krusei*). The incidence rate of *Candida* peritonitis during the first 30 days after transplantation was 6.5 cases/10 000 transplants days in pancreas recipients and 1.2 cases/10 000 transplant days in liver recipients ( $p = 0.035$ ). Fungal infection occurred in 38 patients in the cohort (19 aspergillosis, 15 candidiasis, 2 cryptococcal and 2 other fungi) of which 19 occurred in the first 30 days (*Candida* peritonitis represented 26% of cases). All five patients received oral nistatin previous to the development of *Candida* peritonitis. Four patients developed complications that required abdominal surgical reoperation. No cases with fungemia were diagnosed. Four cases had concurrent bacterial coinfection, three with peritonitis. Treatment included echinocandins plus fluconazole in three patients, fluconazole in monotherapy in one (*C. tropicalis*) and echinocandin plus amphotericin B in one (*C. krusei*). No cases of related mortality were registered and all patients were alive at 1 year follow-up.

**Conclusions:** *Candida* peritonitis risk was 5.4-folds more frequent in pancreas than in liver recipients. With appropriate treatment no fatal cases were observed. Although the number of patients is low, we must consider appropriate antifungal prophylaxis in patients with abdominal complications in the post-transplant period.

**P804 Invasive aspergillosis among heart transplant recipients: a 24-year perspective**

P. Muñoz\*, I. Cerón, M. Valerio, J. Palomo, A. Villa, A. Eworo, J. Guinea, I.A. González, E. Bouza (Madrid, ES)

**Background:** Invasive aspergillosis (IA) has very high mortality in heart transplant (HT) patients (pts). However, no recent series provide an updated, non-biased perspective of the problem.

**Methods:** Prospective follow-up of all HT pts from Aug 1988 to Aug 2011 (24-year study) with IA. Antifungal prophylaxis was started in Oct 1994.

**Results:** IA was diagnosed in 31/479 consecutive HT pts (6.5%): 25 proven (80.6%) and 6 probable. The incidence of IA decreased: 74% of the cases occurred in the first 12 years (1988–1999). Early IA (first 3 months after HT) accounted for 23 cases (median 34 days after Tx [19–58]) and eight cases (26%) were late (median 125.5 days after HT [100–237]). The main risk factors were other cases of IA in the program (58.1%), CMV disease (54.8%), re-operation (38.7%) and post-Tx hemodialysis (19.4%). IA emerged despite antifungal prophylaxis in eight cases with low levels (7 itra, 1 caspo). The most common symptoms were fever (45%), dyspnoea (35%) and cough (32%). Six pts were asymptomatic (19%). The predominant radiographic patterns were nodular (58%), cavitation (42%), pleural fluid (39%) and alveolar infiltrate (23%). IA affected the lungs (90.3%), central nervous system (CNS) (16%), mediastinum (9.7%), myocardium (6.5%) and skin, prostate and paranasal sinuses (3.2% each). Dissemination occurred in 26%. The efficacy of the diagnostic methods was as follows: culture 27/30 (90%) and PCR 4/5 (80%). Monotherapy was used in 77% (amphotericin B, 7; lipid amphotericin B, 12; voriconazole, 2), combined therapy in 7 pts (2 as rescue therapy) and surgery in 7 (22.6%). In four cases of early IA, diagnosis was postmortem. Related mortality was 32% (43.5% [10/23] in 1988–1999 cases and 0/8 in 2000–2011). Mortality was lower in early cases (16% vs 58%,  $p = 0.074$ ). Risk factors for mortality in the univariate analysis were long pre-Tx stay, pre-Tx mechanical ventilation (MV), emergency surgery, OKT3 induction, concomitant CMV disease, CNS involvement (mortality 100%), alveolar infiltrate, need of MV (mortality 50%) and thrombocytopenia. Multivariate analysis showed that CNS involvement and CMV during IA were independent risk factors for mortality.

**Conclusion:** The incidence of IA in HT has decreased, partially due to implementation of antifungal prophylaxis. Most cases occur in the first 3 months post-HT with a high frequency of disseminated disease and atypical sites of infection (heart, mediastinum, prostate). Mortality has decreased significantly in recent years.

**P805 Isolation of *Aspergillus* species from the respiratory tract of lung transplant recipients is associated with increased mortality**

T. Felton\*, S. Roberts, S. Brennan, A. Philips, S. Whiteside, H. Doran, C. Leonard, M. Al-Aloul, B. Isalska, N. Yonan, W. Hope (Manchester, UK)

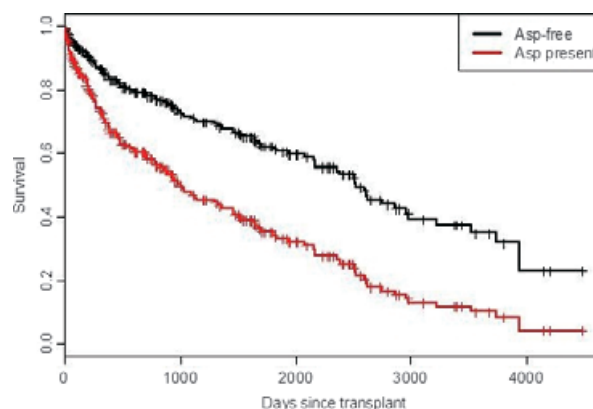

**Objectives:** *Aspergillus* spp. are the leading cause of invasive fungal infection in lung transplant patients. Invasive pulmonary aspergillosis (IPA) is responsible for an unacceptably high mortality despite optimal medical therapy. We investigated the relationship between the isolation of *Aspergillus* spp. from the respiratory tract of lung transplant recipients and their risk of mortality.

**Methods:** A retrospective, observational cohort study of all patients who received lung allografts between January 1999 and May 2011, at a single UK centre was performed. All patients received antifungal prophylaxis with fluconazole alone or in combination with nebulised amphotericin B deoxycholate. Patients were included in the *Aspergillus* group if they had at least one positive culture of *Aspergillus* spp. from the respiratory tract. The time from transplantation (Tx) to death was analysed using a Cox regression model. Covariates included gender, age, single vs. double lung Tx, ischaemic time, presence of airway

complication, antifungal prophylaxis regimen, episode of acute rejection, a diagnosis of cystic fibrosis vs. all other underlying diagnoses, donor and/or recipient cytomegalovirus (CMV) serostatus and whether *Aspergillus* was acquired before or after Tx.

**Results:** Two hundred-thirteen patients were included. The median follow-up time was 5 years during which 102 patients (47.9%) died. *Aspergillus* was isolated in 74 patients. In 15 patients (20.3%) *Aspergillus* was identified prior to Tx. Twenty patients (34%) had their first *Aspergillus* isolate in the first 60 days post Tx. Forty one patients (55.4%) in the *Aspergillus* group and 61 patients (43.9%) in the control group died during follow-up. Other than *Aspergillus*, CMV serostatus was the only covariate that had an impact upon mortality. A hazard ratio of 2.2 (95% CI 1.5–3.3;  $p < 0.001$ ) for death following a positive *Aspergillus* sample was observed from the regression model (See figure). Adjustment of the model for CMV status did not affect the hazard ratio. Isolation of *Aspergillus* prior to Tx was not associated with increased mortality.

**Conclusion:** Isolation of *Aspergillus* spp. from patients following lung

Tx is associated with a significant increase in mortality. Novel preventative strategies are required to minimise *Aspergillus* spp. colonisation in lung transplant recipients.

**P806 Mucormycosis in patients with haematological and oncological diseases in Saint Petersburg, Russia**

N. Klimko\*, S. Khostelidi, T. Bogomolova, R. Araviyskiy, V. Zinzerling, Y. Borzova, S. Ignatyeva, I. Zjuzgin, M. Popova, A. Volkova, S. Bondarenko, V. Vavilov, A. Kolbin, E. Boychenko, N. Medvedeva, E. Podoltseva, A. Klimovich, M. Belogurova, N. Vasilyeva (St. Petersburg, RU)

**Background and Objectives:** Mucormycosis is an increasingly common infection in immunocompromised patients. The aim of the study – to evaluate clinical characteristics and results of treatment of haematological and oncological patients with mucormycosis in St. Petersburg, Russia.

**Methods:** The prospective study during the period 2005–2011. The diagnosis of mucormycosis was made according to EORTC/MSG criteria (2008).

**Results:** We observed 16 patients with underlying haematological and oncological diseases who developed proven (56%) or probable (44%) mucormycosis. The mean age of patients was 25 years (range 10–54), male and female ratio 1.2:1. Underlying diseases included: acute myeloid leukemia (44%), acute lymphoblastic leukemia (25%), neuroblastoma (6%), Hodgkin's lymphoma (6%), aplastic anemia (6%), myelodysplastic syndrome (6%), and myeloid sarcoma (6%).

In 50% of patients mucormycosis were diagnosed after or with invasive aspergillosis.

Main clinical forms of mucormycosis were: pulmonary (82%), subcutaneous (6%), osteomyelitis (6%), and gastrointestinal (6%). Two and more organs were involved in 44% of patients.

Diagnosis was established by histology and/or microscopy in all patients. In 56% of cases the diagnosis was confirmed by culture. Aetiologic agents included: *Lichtheimia corymbifera* (2), *Rhizopus microsporus* var. *oligosporus* (1), *Rhizopus* spp. (3), *Rhizomucor pusillus* (1), and *Rhizomucor* spp. (2).

Antifungal therapy was performed in 13 patients (three cases were diagnosed post-mortally). Posaconazole was used in 77% of patients, amphotericin B deoxycholate – 69%, caspofungin – 54%, amphotericin B lipid complex – 46%, and liposomal amphotericin B – 8%. Combination therapy was performed in 69% of patients (amphotericin B deoxycholate + caspofungin, posaconazole + amphotericin B deoxycholate). Twelve weeks overall survival was 38%.

**Conclusions:** 1 Main underlying diseases were acute myeloid leukemia and acute lymphoblastic leukemia;

2 Mucormycosis were diagnosed after or with invasive pulmonary aspergillosis in 50% of patients;

3 Pneumonia was most common clinical manifestation (82%); two and more organs were involved in 44% of patients;

4 Twelve weeks overall survival of haematological and oncological patients with mucormycosis was 38%.

#### P807 **Kodomaea ohmeri as an emerging pathogen in Southwestern China: three case reports and literature review**

Y. Xiao\*, Y. Xie, Y. Tang, Z. Zong, M. Kang, C. He, Y. Deng, Y. Zhang, H. Fan (Chengdu, CN)

**Objectives:** *Kodomaea ohmeri* (*K. ohmeri*) is emerging as a new opportunistic fungal pathogen along with the increasing number of immunocompromised patients worldwide. It has recently been identified as an important etiology of fungemia, endocarditis, cellulitis, funguria and peritonitis in immunocompromised patients. However, risk factors, laboratory diagnoses, and treatments for *K. ohmeri* infection have been limited, and the optimal therapy for *K. ohmeri* infection has not been identified.

**Methods:** We report three new cases of infection caused by *Kodomaea ohmeri*. In the past 20 years 30 cases have been described in the English medical literatures. We review all cases described thus far to investigate the nature and treatment of *K. ohmeri* infections, and compare the new cases with those described in the literature.

**Results:** Case 1 presents a 61-year-old woman with *K. ohmeri* peritonitis. This is the second reported case of *K. ohmeri* peritonitis associated with CAPD and the first case of infection caused by *K. ohmeri* in China. Case 2 and Case 3 report two man suffered from *K. ohmeri* fungemia, which were the first reported two cases of *K. ohmeri* fungemia in Chinese mainland. We investigated 30 cases of *K. ohmeri* infection which have been reported in the English medical literatures (including the present three cases). Among these cases, 26 patients presented with fungemia, 2 with peritonitis, one with funguria and one with a wound infection. 73.3% (22 cases) of *K. ohmeri* cases were related to placement of central or peripheral venous catheters. Good outcomes (10/14 cases; 71.4%) were found following removal of indwelling catheters and implants. Amphotericin B and echinocandins, such as caspofungin and micafungin, also showed excellent minimum inhibitory concentrations against *K. ohmeri*. In addition, 40.0% (12/30) of the patients died as a result of overwhelming infection despite antifungal therapy.

**Conclusion:** *K. ohmeri* can cause systemic infections in a broad range of patients categories, particularly in immunocompromised patients with (without) catheter/prosthetic implants insertion. The increasing numbers of infection cases indicates that *K. ohmeri* would be added to the list of potential yeast pathogens. With high mortality of *K. ohmeri* fungemia, early identification and appropriate antifungal therapy in combination with removal of any implanted devices are of great significance to survival outcomes.

Priate antifungal therapy in combination with removal of any implanted devices are of great significance to survival outcomes.

#### P808 **Fungiscope – a Global Rare Fungal Infection Registry**

M. Vehreschild\*, A. Hamprecht, G. Fischer, S. de Hoog, J. Vehreschild, O.A. Cornely (Cologne, Stuttgart, DE; Utrecht, NL)

**Background:** We are coordinating a global registry for cases of rare invasive fungal diseases (IFD). Our objective is to broaden the knowledge on epidemiology, to determine the clinical pattern of disease, to describe and improve diagnostic procedures and therapeutic regimens, as well as to facilitate exchange of clinical isolates among the contributors.

**Methods:** Fungiscope™ – A Global Rare Fungal Infection Registry uses a web-based electronic case form accessible via [www.fungiscope.net](http://www.fungiscope.net). For inclusion in the registry we require positive cultures or histopathological, antigen or molecular genetic evidence of IFD and the associated clinical symptoms and signs of invasive infection. The data entered onto the registry include demographics, underlying conditions, neutrophil count, concomitant immunosuppressive medications, clinical signs and symptoms of IFD, site of infection, diagnostic tests performed, pathogen identification, antifungal treatment, surgical procedures performed, response to treatment, overall survival and attributable mortality. For an overview on the project's structure see figure 1.

**Results:** Overall, 244 cases have been completed. Zygomycetes (n = 95; 39%), yeasts (n = 40; 16%), *Fusarium* spp. (n = 37; 15%), and Dematiaceae (n = 31; 13%) were the most frequently registered pathogens.

Chemotherapy or allogeneic stem cell transplantation for a haematological malignancy was the most predominant risk factor (n = 118; 48%), as well as diabetes mellitus (n = 64; 26%), stay at an ICU (n = 42; 17%) and chronic renal disease (n = 34; 14%).

Sites of infection included the lung in 94 patients (39%), followed by blood stream infections (n = 45; 18%), the sino-nasal region (n = 35, 14%) and deep soft tissues (n = 33; 14%).

For 123 (50%) patients, a favourable outcome, defined as a complete or partial response to treatment of IFD was documented. Overall mortality and mortality attributable to IFD was 42% (n = 102) and 28% (n = 69), respectively.

**Conclusion:** The clinical relevance of rare IFD is increasing steadily. In a short period of time, a wide variety of cases from Europe, Asia and South America could be documented. Further investigators are cordially invited to contribute to Fungiscope.

**P809 Host factors for invasive fungal infection among patients with haematological malignancies: a case control study**

M. Hoenigl\*, T. Valentin, A. Strohmaier, V. Strenger, H. Salzer, C. Koidl, A. Valentin, K. Seeber, I. Zollner-Schwet, A. Woelfler, W. Buzina, R. Krause (Graz, AT)

**Objectives:** Host factors defined by revised EORTC/MSG criteria describe predisposing conditions of the individual for development of invasive fungal infection (IFI). Fulfilment of these factors is required for establishing diagnosis of possible or probable IFI which account for the majority of IFI in recent epidemiologic studies among patients with hematological malignancies. Host factors have, therefore, a major impact on IFI epidemiology when current criteria for defining IFI applied. This study evaluates host factors among patients with hematological malignancies.

**Methods:** This is a single center study. Fifty-eight patients with haematological malignancies who developed probable (n = 38) or proven (n = 20) IFI within a 5-year-period were retrospectively evaluated regarding host and risk factors for IFI such as neutropenia, use of corticosteroids or t-cell suppressants, stem cell transplantation (SCT), underlying diseases and demographic factors. *Aspergillus* spp. was the leading causative pathogen (n = 36), followed by *Candida* spp. (n = 12). Results obtained were compared to results of patients with hematological malignancies who did not develop IFI (120 patients who received systemic antifungal therapy and 197 patients who did not, all data collected in 2010). Patients with possible IFI were excluded from the study.

**Results:** Prolonged neutropenia, recent allogeneic SCT, steroid therapy and t-cell suppressive therapy were significantly associated with development of IFI and/or invasive mould infection (IMI) in our patient collective. In the case of prolonged corticosteroid use a cut-off of 14 days was highly significantly, while the currently proposed cut-off (21 days) was significantly associated with development of IFI. Results are depicted in Table 1.

	Group 1 Patients with Probable/Proven IFI	Group 2 Patients with Systemic Antifungal Therapy but without IFI	Group 3 Patients without Systemic Antifungal Therapy and without IFI	P Value if Significant
n	58	120	197	
Sex				
Male/female	40/18	72/47	100/97	
Age in Years (Median)	50.70	54.24	62.54	
Room of Care Hepa-filtered Room/Standard Room	14/44	19/101	9/188	
Underlying Disease				
AML	24	48	13*	P<0.001
MDS	4	12	3*	P<0.01
MM	2	4	3*	P<0.01
T-CLL	4	9	33*	P<0.01
T-ALL	10	8	3*	P<0.01
Others	7	11	18	
Polychemotherapy				
High Dose	30*	66	87	p<0.01
Low Dose	8	17	49	
None	11	37	61	
Bronchoscopy Rate	30/58 (52%)*	10/120 (8%)	54/197 (3%)	P<0.001
GWB	10	18	0	
1 or more Host Factors Present	19/58 (33%)*	15/120 (12.5%)	11/97 (11.5%)	p<0.01

No	17	62	175	
< 10 Days	6	39	15	
> 10 Days	35*	29	7	p<0.001
Median (Days) in Case of Neutropenia	17	10.5	6	
T-Cell-Suppressants within 90 Days	41	69	36*	P<0.001
Use of Corticosteroids (Mean Minimum Dose of 0.3 mg/kg/day of Prednisone Equivalent)				
No	32	80	121	
< 14 Days	0	31	12	
> 14 Days < 21 Days	5*	3	1	P<0.001
> 21 Days	13*	6	3	P<0.001
HSCt				
Allogeneic Current	11	12	0*	P<0.001
Allogeneic Prior	9	22	17	
Autologous Current	2	5	0	
Autologous Prior	3	2	2	

**Conclusion:** We conclude that host factors according to revised EORTC/MSG criteria were significantly associated with development of IFI/IMI in our collective of patients. In case of previous allogeneic

SCT not related to current onset of IFI we found, however, no association with IFI. Concerning prolonged corticosteroid treatment a cut-off of 14 days may seem favourable when compared to the currently proposed cut-off. Further and bigger studies are necessary to evaluate these issues.

**P810 Registry for systemic mycosis in Germany (ReSyMe) – role of EORTC/MSG diagnostic criteria in clinical practice**

M. Ruhnke\*, A. Mikojalewska, A. Groll, O.A. Cornely, C. Lass-Flörl on behalf of the ReSyMe working group

**Introduction:** The Registry of Systemic Mycoses (ReSyMe) was developed as a multi-center prospective study by the German-speaking Mycological Society (DMyG) and the Paul-Ehrlich-Society (PEG) to study the current use of antifungal therapy in Germany with regard to the EORTC/MSG diagnostic criteria (version from 2002).

**Material and methods:** In this prospective, non-comparative study, 543 patients treated with systemic antifungal therapy were documented within a 1 year period (5/2008–4/2009) via an online-documentation system. Primary questions of the registry addressed: (i) analyzing the current epidemiology for invasive fungal infections in Germany. (ii) analyzing the proposed definitions for invasive fungal diseases (possible, probable, and proven disease) on the bedside in everyday practice (EORTC/MSG). (iii) analyzing antifungal therapy in the ICU, as compared to non-ICU patients.

**Results:** Fifteen clinical units from 10 hospitals participated in the study. In total, 543 patients (3–101 patients per clinical unit) were documented, with a median age of 60 years (1–95 years). 61.5% were male (51.8–70%), 38.5% were female (48.2–30.4%). Two hundred and forty-two patients were treated at the ICU (44%) and 56% (n = 301) were non-ICU patients. Among the ICU patients, 67.8% underwent a surgical procedure (SD), 16.2% suffered from an internal disease (MD), 12.8% from haematological cancer (HC), and 3.3% had a solid tumor. According to the main underlying disease, all patients were divided into four groups: the largest group represented patients with a haematological malignancy (55.9%), followed by patients with surgical procedure (30.7%), internal disease (8.4%), and solid tumors (5%).

Patients with MD (mean 70 years) and SD (mean 64 years) were older as compared to the other two groups. Ninety-eight percent (SD) and 85% (MD) of patients were treated in an ICU as compared to 10% with HC. According to the EORTC criteria for the definition of an invasive fungal disease (IFD), antifungal therapy could be applied in ICU patients (SD) in 21% for proven IFD, 15% probable, and 36% possible IFD. In 21% treatment was given as empirical therapy in ICU patients as compared to 35% in non-ICU patients. The lungs (61%) were the most common site of IFD, 18% had a disseminated infection. The majority of patients received first-line treatment with azoles (33% fluconazole, 29% voriconazole). Echinocandins were given in 10% of patients. EORTC-MSG criteria could be applied in 72% of ICU patients, but in only 65% of non-ICU patients.

**P811 Pre-hospital risk factors for invasive fungal disease in patients with acute myeloid leukaemia at diagnosis: preliminary results from the SEIFEM 2010 Study**

M. Caira\*, A. Candoni, A. Busca, C. Caramatti, G. Specchia, N. Vianelli, R. Fanci, G. Rossi, M. Offidani, A. Manna, A. Vacca, M.R. De Paolis, L. Verga, M. Picardi, M.E. Mitra, C. Castagnola, S. Storti, R. Invernizzi, P. Salutati, B. Martino, A. Bonini, A. Spadea, M.G. Garzia, A. Chierichini, L. Fianchi, L. Fianchi, A. Venditti, L. Melillo, V. Pavone, G. Nadali, D. Caselli, E. Castagnola, M. Giacchino, S. Cesaro, M. Luppi, F. Aversa, A. Nosari, M. Tumbarello, L. Pagano on behalf of the SEIFEM group

**Objectives:** To investigate the potential relationship between pre-hospital exposures to fungal sources and the development of invasive

fungal diseases (IFDs) in adult acute myeloid leukemia patients (AMLs).

**Methods:** From January 2010 to March 2011, in 31 Italian participating centers, all consecutive patients (pts) with newly diagnosed AMLs were registered. Information about personal habits and possible environmental exposures were investigated. In particular we collected data about: comorbidities, job, hygienic habits, work and living environment, voluptuary habits (i.e. smoking, alcohol, illicit substances abuse), hobbies, pets. We also included data on other well-known risk factors, such as age, neutropenia, mucosal damages, etc. In order to make our study population very homogeneous, we focuses on pts treated with conventional chemotherapy only. All cases of proven/probable IFDs occurred until the 30th day from the end of first induction were recorded.

**Results:** Five hundred and ninety-three pts were enrolled in the study; of them, 447 were included in the present analysis and 43 developed a proven/probable IFDs (30 molds and 13 yeasts) (incidence 9.6%). Median age was 61 (range 18–81). Main variables included in the risk analysis have been reported in the table. In particular, at preliminary analysis a significant association with IFDs development was found for performance status ( $p < 0.001$ ), chronic obstructive pulmonary diseases ( $p 0.04$ ), urinary catheter ( $p < 0.001$ ), neutropenia ( $<500$  neutrophils/ $\mu\text{L}$ ,  $>7$  days) ( $p 0.03$ ).

A not significant trend was noted for incidence by gender (males 12% vs females 7%), for diabetes (yes 18%, no 9%), construction sites in the last 3 months to  $<500$  m from home (yes 12%, no 8%), home restructuring in the last 6 months (yes 14%, no 9%). We did not find any association for weight, occupational exposure, geographical origin. For mold infections only, those patients living in a flat resulted to be at higher risk when compared to those living in house with garden ( $p 0.03$ ). Other variables showing a correlation with the onset of invasive yeast diseases were chronic kidney failure ( $p 0.006$ ) and liver diseases ( $p < 0.001$ ).

VARIABLES	# <sup>a</sup> pts	# <sup>b</sup> cases	p-value

Construction site near home			
- No	310	24 (8%)	0.18
- Yes	137	17 (12%)	

**Legend:**

CVC: central venous catheter; COPD: chronic obstructive pulmonary disease

<sup>a</sup>: it comprehend oral mucositis, esophagitis, vomiting, diarrhea. Zero means none of them.

<sup>b</sup>: Neutrophils  $<500/\mu\text{L}$ , duration  $> 7$  days.

<sup>c</sup>: In the last 6 months.

<sup>d</sup>: in the last 3 months, within 500 meters.

**Conclusions:** Several hospital-independent fungal sources emerged at univariate analysis to potentially influence IFDs onset. Investigation of

these factors at time of admission may be helpful in defining patients' risk category and in better targeting prophylactic strategies.

**P812** Prospective registry of invasive fungal diseases in acute myeloid leukaemia: preliminary results on 142 cases

M. Caira\*, A. Candoni, A. Busca, M. Delia, C. Caramatti, C. Cattaneo, L. Melillo, M.E. Mitra, L. Paris, L. Potenza, G. Leone, A. Nosari, F. Aversa, L. Pagano on behalf of the SEIFEM group

**Objectives:** To evaluate epidemiological characteristics, treatments and outcome of invasive fungal diseases (IFDs) in acute myeloid leukemia patients (AMLs).

**Methods:** From January 2010 to March 2011, 31 Italian participating centers registered all consecutive cases of IFDs in adult AMLs at first induction (until 30th day from the end of chemotherapy). The parameters we analyzed were: age, sex, severity and duration of neutropenia, antifungal prophylaxis, certainty of IFD diagnosis, empirical/pre-emptive therapy, target therapy, etiologic agent, outcome. Response rate to antifungal therapy and mortality rate were thus analyzed.

**Results:** over a 15 month period, 142 IFDs were collected in 593 newly diagnosed AMLs (incidence 23.6%). Median age was 60 (range 18–81), with a male/female ratio of 1.6/1. The most part of IFDs (128, 90%) occurred in pts who had received conventional chemotherapy (128/498, incidence 25.7%). As expected, IFDs incidence was lower in those receiving either supportive or low dose therapy (14/95, 14.7%). Probable and proven IFDs were 37 and 14, respectively; remaining cases were classified as possible IFDs (91, 64%). A deep neutropenia (PMN count  $<500/\mu\text{L}$ ) lasting for at least 7 days occurred in 129 of them (91%). Antifungal approaches are reported in the table. Most of pts had received systemic antifungal prophylaxis (120/142, 85%), more frequently with posaconazole. Liposomal AmB and caspofungin were the most frequently employed drugs, as empirical/pre-emptive therapies. Of 51 proven/probable IFDs, the majority were mold infections (36, 69%), with a mold/yeast ratio of 2.4/1. Among molds, aspergillosis (IA) were predominant (27, 75%). Four cases of rare fungal agents were identified (one *Fusarium*, one Blastoschizomices, one Geotrichum and one Trichosporon). At 30th day, 104 pts had achieved a favourable response; the overall response rate was 73%. IFD-attributable mortality rate (AMR) was 11.3%, ranging from 5.5% for possible to 21.6% for proven/probable cases.

	ALL CASES (142)	Possible IFDs (91)	Proven/probable IFDs		
		N° cases (91)	N° cases (51)	Molds (36)	Yeasts (15)
Systemic antifungal prophylaxis	120 (85%)	72	42 (82%)	30	
> Administered	22 (15%)	13	9 (18%)	6	12
> Not administered					3
Prophylactic systemic drug					
> Itraconazole	34 (28%)	22	12 (29%)	9	3
> Fluconazole	28 (23%)	14	14 (33%)	9	5
> Posaconazole	55 (46%)	40	15 (36%)	12	3
> Other	3	2	1 (2%)	0	1
Empirical/pre-emptive					
> Performed	124	85	39 (76%)	31	8
> Not performed	18	6	12 (24%)	5	7
Empirical/pre-emptive drug <sup>1</sup>					
> Caspofungin	25 (24%)	17	8 (23%)	6	2
> L-AmB	51 (48%)	37	16 (46%)	11	5
> Voriconazole	17 (16%)	8	6 (23%)	7	1
> Abirater	8 (7.5%)	7	1 (3%)	1	0
> Other	5 (4%)	3	2 (5%)	1	0
Drug in 1 <sup>st</sup> line target therapy <sup>2</sup>					
> L-AmB			11 (27%)	8	3
> Caspofungin			4 (14%)	0	5
> Voriconazole			20 (48%)	17	5
> Combined			3 (7%)	0	3
> Other			2 (5%)	1	1
Favourable responses (RR)	104 (73%)	72 (79%)	32 (63%)	25 (69%)	7 (47%)
IFD attributable deaths (AMR)	16 (11.3%)	5 (5.5%)	11 (21.6%)	5 (13.9%)	6 (40%)

**Conclusions:** IFDs continue to be a challenging complication in high risk patients. Our results confirm the recently reported trend in reduction of IFD-AMR. On the contrary, cases with unidentified origin continue to be the most frequent. This datum makes it necessary

to improve our diagnostic work-up to better target treatment and preventive strategies, and to reduce the risk of overtreatment.

## Lab news: from diagnosis, in vitro activity, pathomechanisms to antifungal resistance

### P813 Investigation of efflux pumps and ERG11 gene expression levels in fluconazole resistant *Candida albicans* isolates

S. Gulat, O. Irmak, M. Doluca Yucesoy\* (Izmir, TR)

**Objectives:** Widespread and repeated use of fluconazole in the prophylaxis and therapy resulted in resistance among *Candida albicans* strains. In this study, investigation of the expression of efflux pump encoding genes, CDR1, CDR2, and MDR1 and lanosterol demethylase encoding gene, ERG11 by reverse transcription- and real-time polymerase chain reaction (PCR) was aimed in fluconazole susceptible (S)/resistant (R) *C. albicans* isolates in order to determine the role of these mechanisms in fluconazole resistance.

**Methods:** Five fluconazole R, six S and three trailing effect showing S *C. albicans* strains, isolated from clinical specimens in three hospitals in Turkey were included. MIC values of fluconazole were determined by microdilution method performed according to CLSI M27-A3 standards and E-test on yeast extract peptone dextrose agar with and without cyclosporin A.

The expression of CDR1, CDR2, MDR1 and ERG11 transcripts were determined by semi-quantitative reverse transcription (RT)-PCR and quantitative real-time PCR methods. The expression of these genes was normalized with their housekeeping gene (ACT1) levels and compared with the drug susceptible *C. albicans* ATCC 14053 strain. Gene expression data were analyzed by Kruskal–Wallis and Mann–Whitney *U* tests via using SPSS version 15.0 software.

**Results:** For the detection of efflux pump gene expressions, both methods were generally consistent with each other. Mean CDR1, CDR2, MDR1 and ERG11 gene expression levels were higher in the fluconazole R isolates than the trailing effect showing S and S ones. Among five fluconazole R isolates, two and one isolate overexpressed CDR1 and CDR2 (Figure 1), and MDR1, respectively but none of them overexpressed ERG11. Statistically significant differences were observed for CDR1 and CDR2 expression levels between fluconazole R, trailing and S isolates when tested with RT-PCR ( $p < 0.05$ ), whereas this was not true when tested with real-time PCR ( $p > 0.05$ ). On the other side, no statistically significant difference was detected for MDR1 and ERG11 expressions among the isolate groups ( $p > 0.05$ ).

**Conclusion:** It can be concluded that overexpression of efflux pump genes, but not of ERG11, can be important mechanisms of resistance in our fluconazole R *C. albicans* isolates.

### P814 Combination of voriconazole and anidulafungin for the treatment of triazole-resistant *Aspergillus fumigatus* in an in vitro model of invasive pulmonary aspergillosis

A.R. Jeans\*, S.J. Howard, Z. Al-Nakeeb, J. Goodwin, L. Gregson, P.A. Warn, W.W. Hop (Manchester, UK)

**Objectives:** Voriconazole (VCZ) is the preferred treatment for invasive pulmonary aspergillosis but isolates of *Aspergillus fumigatus* with elevated VCZ MICs are increasingly seen and carry a greater risk of treatment failure. We investigated whether the combination of VCZ with anidulafungin (AFG) may be beneficial for the treatment of *A. fumigatus* strains with elevated VCZ MICs.

**Methods:** We used an in vitro model of the human alveolus to define the exposure response relationships for wild-type strains and those with defined molecular mechanisms of triazole resistance. A wild-type isolate (VCZ MIC 0.5 mg/L) and two strains with amino acid substitutions in the VCZ target protein Cyp51A (L98H; MIC 4 mg/L, G138C; MIC 16 mg/L) were studied. All strains had AFG minimum effective concentrations (MECs) of 0.0078 mg/L. Twenty-five different combinations of VCZ and AFG were investigated for each strain. Exposure response relationships were estimated using galactomannan (GM) as a biomarker. Drugs were administered to the endothelial compartment 6 hours post inoculation. Concentrations of VCZ and AFG were measured using HPLC. The interaction of VCZ and AFG was described using the Greco model.

**Results:** Fungal growth was progressively inhibited with higher drug exposures of VCZ. Strains with elevated VCZ MICs required proportionally greater VCZ exposures to achieve a comparable antifungal effect, but GM levels could be suppressed for all strains. GM levels were reduced by AFG monotherapy but not fully suppressed, and no additional reduction was achieved by further increases in concentration above the MEC. An additive effect between VCZ and AFG was demonstrated.

**Conclusion:** The combination of VCZ and AFG may be beneficial in the treatment of invasive pulmonary aspergillosis for isolates of *A. fumigatus* with reduced susceptibility to VCZ.

### P815 Evaluation of antifungal activity of ZnO/Ag nanoparticles on *Candida albicans* biofilm

F. Haghighi\*, S. Roudbar Mohammadi, E. Farahbakhsh, M. Eskandari (Tehran, IR)

**Objectives:** Biofilms represent the most common type of microbial growth in nature and are critical to development of many infections in human. Recently it has been reported that 65% of all human infections involve biofilms. Nowadays *Candida albicans* has more effective role among nosocomial pathogens due to proper potential for biofilm formation. Using a novel method in field of inhibitory formation of *C. albicans* biofilm and elimination of fungal mass over surfaces is valuable for controlling infections. In this study antifungal effect of ZnO/Ag nanoparticles were evaluated on standard strain of *C. albicans*.

**Methods:** ZnO nanoparticles and Ag were synthesized through the sol-gel method by Zinc Acetate Dehydrate [ $Zn(CH_3COOH)_2 \cdot 2H_2O$ ] and  $AgNO_3$  as precursor respectively. The morphology properties of the products were analyzed by using Scanning Electron Microscopy (SEM). Biofilm of standard strain of *C. albicans* (ATCC 10231) was developed on flat-bottomed 96-well microtiter plates and antifungal effects of ZnO/Ag nanoparticles were evaluated by using standard accurate method, CCK8 (Cell Counting Kit 8) as colorimetric assay for measuring metabolic activity of sessile cells within the biofilm as it relates to cellular viability. Data were analyzed using t-test statistical method and SPSS software.

**Results:** Different Concentrations of synthesized ZnO/Ag (0.01–0.5 µg/mL) were assessed on *C. albicans* biofilm. Evaluation of the Morphology properties of the nanoparticles with SEM showed that nanoparticles were spherical and regular. Optical density of survival cells in coated samples was less than control samples (not treated) and at the concentration of 0.317 µg/mL was determined  $0.091 \pm 0.04$  in comparison of control groups  $0.253 \pm 0.07$ . Data of treated samples showed significant difference with control samples ( $p < 0.05$ ).

**Conclusion:** According to findings of this study ZnO/Ag nanoparticles were synthesized by means of wet chemical were showed significant antifungal property. So in field of elimination of the nosocomial infection, ZnO/Ag nanoparticles could be proper candidates as self cleaning or disinfectant agents and also could be used as coating of surfaces, utensils, furniture and lots of other materials. They could even be used with other antimicrobial agents with greater efficiency than ever.

**P816** **In vitro activity of isavuconazole against 1488 *Aspergillus* isolates – a pooled analysis of nine studies**

J. Smart\*, M. Jones, N. Azie (Deerfield, US; Basel, CH)

**Background:** Invasive aspergillosis remains an important cause of morbidity and mortality. Isavuconazole (ISA) is a novel, intravenous and orally available, broad-spectrum, water-soluble triazole currently in Phase III clinical trials for treatment of patients with invasive *Aspergillus*, *Candida*, and rare mould infections, including patients with renal impairment. The active moiety of ISA is BAL4815, which has been shown to have in vitro antifungal activity against clinically relevant species of yeasts and moulds including *Aspergillus* as well as Zygomycetes.

**Methods and Results:** We examined the in vitro activity of ISA against 1488 isolates of *Aspergillus* (Table 1). These data represent a compilation of minimal inhibitory concentration (MIC) data from 7 published reports and 2 unpublished laboratory studies undertaken by various academic investigators in EU and US laboratories during the period 2004–2010. All MIC data in the pooled analysis were derived using CLSI (M38-A) or EUCAST standard methodologies, although there were differences in methodologies between the test centers related to incubation period, determination of MIC endpoint, and number of replicates.

**Results:** Overall, ISA was active against all clinically relevant species of *Aspergillus* tested. The MIC results were evaluated at either 24 hours or 48 hours. The ISA and voriconazole (VRC) MIC ranges, MIC50s, and MIC90s are listed in Table 1 for each of the *Aspergillus* species tested. For the majority of the *Aspergillus* species, the 24 and 48 hour

MIC results were within a two-fold dilution for both ISA and VRC. At 24 and 48 hours, the overall MIC90 for all *Aspergillus* species was 1.0 mg/L for both ISA and VRC.

**Conclusions:** This pooled analysis of multiple studies demonstrates the potent in vitro activity of ISA against diverse range of *Aspergillus* species, including species refractive to other therapies such as *A. terreus*. These MICs are within clinically relevant concentrations achievable with clinical dosing. ISA is a promising agent for the treatment of invasive aspergillosis.

**P817** **Antifungal susceptibility of clinical *Cryptococcus neoformans/C. gattii* complex isolates in Korea**

E.J. Kang\* (Suwon, KR)

**Objectives:** Cryptococcosis is an opportunistic infection caused by two species of the genus *Cryptococcus neoformans* and *Cryptococcus gattii*. We previously reported the molecular epidemiological analysis of 78 clinical strains of the *C. neoformans/C. gattii* species complex, but antifungal susceptibility test was not taken. The Purpose of this study is to demonstrate the pattern of antifungal susceptibility of *Cryptococcus neoformans/C. gattii* Complex of South Korea.

**Methods: Strains** The 78 strains were isolated from the clinical specimens recovered from cryptococcosis patients who had been hospitalized between 1999 and 2008 in seven medical centers in South Korea.

**Antifungal susceptibility 1** Microdilution test

Microdilution test was carried out according to the Clinical Laboratory Standard Institute M27-A3 document. Amphotericin-B, voriconazole and fluconazole were tested against all isolates twice. *C. parapsilosis* ATCC 22019 was included as quality control.

**2** VITEK-2 system

VITEK-2 system was performed according to the manufacturer’s instructions.

**Statistics:** Statistical analysis was performed using the program SPSS version 18.0 software, and p-value < 0.05 was used to define significance. We compared the MIC of fluconazole in microdilution test according to the time period divided by 1999–2000 and 2001–2008. The Mann–Whitney test was used for comparison of MIC according to the time period.

**Results:** Among 78 strains, 75 strains (96%) were *C. neoformans* serotype A and three strains (4%) were *C. gattii*, serotype B. The antifungal susceptibility test results shows in Table 1. There is no resistant strain to amphotericin-B and voriconazole. Two strains are susceptible dose dependent for fluconazole in broth microdilution test. One strain in 73 strains appears to be resistant for flucytosine in VITEK-2 system. Eleven strains were recovered in 1999 to 2000 and 67 strains were in 2001 to 2008. Geometric means were 5.84 and 4.54 respectively. The difference of MIC between the two time periods was not statistically significant. ( $p = 0.698$ )

(a) Antifungal susceptibility test result by microdilution test<sup>†</sup>  
 (b) Antifungal susceptibility test result by VITEK-2<sup>‡</sup>

**Conclusion:** We measured antifungal susceptibility against 78 *Cryptococcus* isolates. Amphotericin-B and voriconazole showed good potency against all *Cryptococcus* strains. Reduced fluconazole susceptibility was seen in two strains in microdilution test. One strain

was resistant against flucytosine in VITEK-2 system. In vitro susceptibility of fluconazole was not significantly different according to the time period.

**P818** Inhibitory effect of aspirin and diclofenac treatment on some non-albicans *Candida* species

E. Rusu, C.D. Cristescu, A. Boiangiu\*, I. Avram, D. Pelinescu, T. Vassu (Bucharest, RO)

The most common organisms implicated in fungal infections are species of *Candida*, which are under normal circumstances in commensally relation with human host. While *Candida parapsilosis* is common in neonatal and pediatric age group, *C. glabrata* and *C. krusei* infections are becoming more frequent in the elderly population.

**Objectives:** The main goal of our study was to evaluate aspirin and diclofenac sodium antifungal activity and in vitro susceptibility of some non-albicans *Candida* strains to these non-steroidal anti-inflammatory drugs.

**Methods:** Eight yeast strains were isolated from pharyngeal and vaginal secretions. Strains were identified by conventional and biochemical test as: one strain *C. glabrata*, three strains *C. parapsilosis* and four strains *C. krusei*. Tests of viability cells in the presence of 2 mg/mL aspirin and diclofenac sodium were done by the microdilution method.

**Results:** Our results showed an antifungal activity of both non-steroidal anti-inflammatory drugs against tested strains. Viability reduction in presence of aspirin was 48% for *C. glabrata*, between 30–68% for *C. parapsilosis* strains and between 20–65% for *C. krusei* strains. For diclofenac sodium the results were similar, viability strains decreased with 50% for *C. glabrata* strain, 35–75% for *C. parapsilosis* strains and 23–60% for *C. krusei* strains. The greatest inhibitory effect that we observed was on *C. parapsilosis* strains in the presence of aspirin and *C. krusei* strains in the presence of diclofenac. Antifungal effect was strain depending.

**Conclusions:** According to our results, aspirin and diclofenac sodium have inhibitory activity against some non-albicans strains: *C. parapsilosis*, *C. krusei* and *C. glabrata*. These data underline the potential utility of these drugs in the management of fungal infections. The anti-inflammatory and analgesic properties of sodium diclofenac and aspirin might represent an additional advantage for their use in the management of infection with *Candida* species.

**Keywords:** viability, anti-inflammatory, antifungal effect

**Acknowledgements:** This work has been supported by the national research project CNCIS Human Resources TE66/2010.

**P819** Susceptibility profile of deep-seated yeasts isolates from a university hospital in the northern region of Portugal

I. Faria-Ramos\*, J. Santos-Antunes, S. Costa-de-Oliveira, A.G. Rodrigues, C. Pina-Vaz (Porto, PT)

**Objectives:** An observational study was conducted at the biggest hospital in Portugal, aiming to evaluate the susceptibility profile of yeasts isolated from invasive fungal infections and relevant epidemiological data.

**Methods:** Between September 2010 and 2011, all yeasts isolated from invasive fungal infections admitted at the university hospital S. João, in Porto, were collected. All strains were identified using Vitek2 system and the antifungal susceptibility profile was determined according to CLSI M27-A3 protocol regarding eight antifungals. Clinical and demographic data were registered. Mortality attributed to fungal infections was calculated. Chi-square test and multivariable logistic regression were used to analyze data.

**Results:** The incidence of invasive infections was 3.2 per 1000 admissions. One hundred and forty six isolates were collected, from blood (61.5%), peritoneal liquid (29.5%), cerebrospinal fluid (6.4%) and pleural effusion (2.6%) cultures. Fifty-two percent corresponded to *Candida albicans*, followed by *C. glabrata* (15.2%), *C. parapsilosis*

(10.9%), *C. lusitaniae* and *Cryptococcus neoformans* (5.4% each), *C. krusei* (3.3%), *C. tropicalis* and *C. dubliniensis* (2.2% each) and *C. famata*, *C. kefyr* and *Trichosporon mucoides* (1.1% each). Regarding antifungal susceptibility profile, 16.3% of all strains were resistant to fluconazole; 4.7% were resistant to voriconazole and posaconazole and 2.3% to 5-flucytosine and caspofungin; no resistance was found to anidulafungin, micafungin or amphotericin B. Most isolates were collected from the Surgery department (38%) and Intensive Care Units (19.6%). Most patients were aged between 41 and 60 years (39%) and 67% were male. Most fungal infections were associated with surgical procedures (OR = 1.95, 95%CI [1.39–2.74]), gastrointestinal disease (OR = 5.33 [3.82–7.42]), neoplasia (OR = 5.22 [3.73–7.30]), and diabetes (OR = 1.56, [1.04–2.34]). Mortality rate attributed to fungal infections was 46%: 60% had gastrointestinal disease and 40% were oncological patients.

**Conclusion:** Epidemiological studies concerning fungal infections are scarce in Portugal, but extremely valuable. *C. albicans* was the most common isolate. Susceptibility profiles showed low antifungal resistance except to fluconazole; all isolates were susceptible to anidulafungin, micafungin and amphotericin B. Surgery and gastrointestinal disease were frequently associated with fungal infections being the outcome often fatal.

This work is supported by Pfizer Inc.

**P821** Activity of amphotericin B, caspofungin and anidulafungin on planktonic and biofilm *Candida* spp. by microcalorimetry

E. Maiolo\*, U. Furustrand Tafin, D. Sanglard, A. Trampuz (Lausanne, CH)

**Objectives:** *Candida* biofilms are difficult to treat due to reduced susceptibility in biofilm. We compared the activity of amphotericin B (AMPB) and two echinocandins, caspofungin (CAS) and anidulafungin (AFG), against planktonic and biofilm *Candida* spp. using microcalorimetry, a real-time and highly sensitive assay for measurement of growth-related heat production.

**Methods:** *C. albicans* (ATCC 90028), *C. krusei* (ATCC 6258) and *C. glabrata* (DSY 562) were tested. Minimal inhibitory concentration (MIC) was determined by microbroth dilution according to the EUCAST guidelines (EDef 7.1) and confirmed by E-test. Microcalorimetry was performed using an isothermal calorimeter (TAM III, TA Instruments) at 37°C in sealed glass ampoules containing 3 mL RPMI. Planktonic *Candida* species ( $5 \times 10^5$  CFU) were added to RPMI containing serial dilution of AMPB, CAS or AFG (0.125–512 µg/mL). *Candida* biofilm was formed on porous glass beads (diameter 4 mm, pore size 60 µm) and incubated for 24 hour at 37°C in RPMI. Beads were washed and incubated for 24 hour in RPMI containing serial dilution of AMPB, CAS or AFG (0.5–1024 µg/mL). Beads were then washed and placed in 3 mL of RPMI into the calorimeter to quantify recovering yeasts. The minimal heat inhibitory concentration (MHIC) was defined as the lowest antifungal concentration reducing the heat-flow peak by ≥50%.

**Results:** The MICs for tested *Candida* spp. ranged from 0.5–2 µg/mL for AMPB, 0.125–0.5 µg/mL for CAS and 0.03–0.015 µg/mL for AFG. Table shows MHICs (in µg/mL) for planktonic and biofilm *Candida*. Compared to planktonic counterparts, the activity of AMPB was significantly reduced against *Candida* biofilms (MHIC ≥32 µg/mL). CAS showed antibiofilm activity against *C. albicans* and *C.*

Species	AMPB (µg/ml)		CAS (µg/ml)		AFG (µg/ml)	
	Planktonic	Biofilm	Planktonic	Biofilm	Planktonic	Biofilm
<i>C. albicans</i>	0.5	64	0.125	4	0.03	0.5
<i>C. glabrata</i>	2	32	0.125	2	0.015	1
<i>C. krusei</i>	1	32	0.5	32	0.03	1

*glabrata* (MHIC = 2–4 µg/mL), but not against *C. krusei* (MHIC = 32 µg/mL). AFG showed good activity against all *Candida* biofilms (MHIC ≤1 µg/mL). At high concentrations (>8 µg/mL), CAS and AFG induced paradoxical growth of planktonic *C. albicans* and CAS induced the same effect on *C. glabrata*.

**Conclusions:** Microcalorimetry allows real-time evaluation of antifungal activity on planktonic and biofilm *Candida* spp. AFG showed better activity against *Candida* biofilms than AMPB, whereas CAS showed variable results. In future, microcalorimetry might be used to study novel antifungals (alone or in combination) to determine the optimal treatment strategies.

**P822** **Loss-of-heterozygosity of FCY2 leading to the development of flucytosine resistance in *Candida tropicalis***

Y. Chen, H. Lo, C. Wu, H. Ko, T. Chang, Y. Yang\* (Hsinchu, Miaoli, TW)

**Objective:** We have found that certain clinical isolates of *Candida tropicalis* were able to produce drug-resistant progeny upon exposures to flucytosine (5FC) on agar media. Hence, we were interested in unveiling the molecular mechanism of the resistance.

**Methods:** We have collected the 5FC-resistant progeny within the inhibitory ellipses on the agar media and subjected them to sequence analyses on the genes known to be involved in 5FC metabolism. After identification of the potential mutations responsible, we then conducted site-directed mutagenesis on the genomic copy of the genes of a susceptible strain to assess the effect.

**Results:** Thirty susceptible clinical isolates could produce resistant progeny after exposure to the drug. Twenty-two of them had heterozygous G/T at the 145th position on FCY2, encoding purine-cytosine permease, whereas their progeny recovered from the inhibitory ellipses had homozygous T/T, resulting in null alleles for both copies of the gene and produced only truncated proteins, effecting the 5FC resistance. Furthermore, we found that two major fluconazole-resistant clinical clones, diploid sequence type 98 (DST98) and DST140, had homozygous G/G at the 145th position and neither was able to produce 5FC resistant progeny within the inhibitory ellipses.

**Conclusion:** *Candida tropicalis* strains containing heterozygous alleles may develop 5FC resistance readily whereas those with homozygous G/G wild-type alleles can be treated with 5FC. Therefore, a combination of 5FC and another antifungal drug is applicable for treating infections of *C. tropicalis*.

**P823** **Antifungal susceptibility from the Spanish fungaemia surveillance multicentre study (FUNGEMYCA): are there any differences among ICU and non-ICU patients?**

R. Zaragoza\*, J. Pemán, E. Cantón, J. Camarena, J. Ayats, L. Torroba, D. Navarro, G. Royo, J. Echavarría, J. Martínez, R. Guna, I. Martínez on behalf of the Spanish FUNGEMYCA group

**Objectives:** The introduction of new antifungal agents together with the emergence of new fungal species with unknown susceptibility requires surveillance for the detection of isolates with decreased susceptibility to antifungal agents, especially in critical care setting, in order to optimize the antifungal treatment. The aim of this study was to determine whether there are any differences in the antifungal susceptibility among ICU and non ICU adult patients in the age of new agents.

**Methods:** Isolates from a recent bloodstream nosocomial fungemia Spanish surveillance study were tested by the SensititreYeastOne (Y09) method in each participating centre (Forty-three institutions participated in the study) for susceptibility to eight antifungal agents. All isolates identified and results of the Y09 test were sent to the central laboratory. Clinical and microbiological variables were recorded. An univariate analysis as performed using SPSS 15.00 package. A p value < 0.05 was considered significant.

**Results:** A total of 1174 isolates (543 *C. albicans*, 306 *C. parapsilosis*, 150 *C. glabrata*, 101 *C. tropicalis*, 25 *C. krusei* and 49 other species) were studied, 367 from ICU patients. The overall rate of non susceptible isolates (applying M27-S3 clinical breakpoints) to fluconazole (MIC >8 mg/L), itraconazole (>0.12 mg/L), voriconazole (>1 mg/L), and posaconazole (>1 mg/L) were: 8.8%, 33%, 2.4%, and 3.6%, respectively; anidulafungin, caspofungin, and micafungin (>2 mg/L), 2.4%, 2.2% and 2.9%, respectively, and that to amphotericin B (>1 mg/L) was 0.1%. There were no statistical differences among ICU and non ICU patients in resistance rates for the three echinocandins (anidulafungin 1.6% vs. 2.7%; caspofungin 1.6% vs 2.4%; micafungin 2.4% vs 3.1%), for Amphotericin B (0.02% vs 0%) and for itraconazole (29.5% vs. 34.4%) However the resistance rates for fluconazole (4.6% vs 10.7%; p = 0.001), voriconazole (0.5% vs.3.3%; p = 0.005) and posaconazole (1.3% vs. 4.7% p = 0.005) were statistically lower in ICU patients.

**Conclusions:** The rate of azole resistance is lower in ICU patients than other hospitalization patients in the age of new antifungal agents whereas the rate of echinocandins resistance remains lower than azole agents in all episodes included. However Amphotericin B is still the agent with the lowest global rate of resistance.

**P824** ***Scopulariopsis* spp: epidemiology and in vitro antifungal susceptibility in a general hospital**

T. Peláez\*, B. Gama, L. Alcalá, E. Bunsow, M. Valerio, A. Fernández-Cruz, J. Guinea, E. Bouza (Madrid, ES)

**Background:** The genus *Scopulariopsis* contains hyaline and dematiaceous species, some of which are considered infectious agents in humans, mainly immunocompromised patients. Limited data are available on the susceptibility of *Scopulariopsis* species. We evaluated the epidemiology and antifungal susceptibility of clinical *Scopulariopsis* spp. isolates in our hospital.

**Methods:** A total 30 isolates of *Scopulariopsis* (collection of Hospital General Universitario Gregorio Marañón) were found between 1993 and 2010. The minimum inhibitory concentrations (MICs) were determined using the CLSI M38-A2 microdilution method with amphotericin B (AMB), itraconazole (IZ), voriconazole (VZ), posaconazole (POS), caspofungin (CAS), micafungin (MF), and anidulafungin (AND).

**Results:** We obtained 30 *Scopulariopsis brevicaulis* isolates (30 patients) from the following sites: nails (21), respiratory tract (3), sterile fluids (3), and other sites (3). The MICs and MECs ranges of *Scopulariopsis* spp. were as follows: AMB, 2–16; IZ, 4–32; VOR, 8–32; POS, 2–32; CAS, 32–64; MF, 16; and AND, 16. The geometric mean/MIC90 and MEC in µg/mL for *Scopulariopsis* spp. were as follows: AMB, 4.9/16; IZ, 23.1/32; VOR, 15.3/32; POS, 18.8/32; CAS, 36.1/64; MF, 16/16; and AND, 16/16.

**Conclusions:** During the study period, the number of *Scopulariopsis brevicaulis* isolates in our institution increased. The MICs of all antifungal agents tested against *Scopulariopsis* isolates were very high. Azoles and candins have no or very limited in vitro activity. Only amphotericin showed variable activity against *Scopulariopsis* isolates.

**P825** **Investigation for azole resistance mediating *Aspergillus fumigatus* cyp51A gene mutations using improved PCR assays and consecutive DNA sequence analysis in clinical samples of immunocompromised patients**

B. Spiess\*, W. Seifarth, M. Reinwald, N. Merker, S. Will, W.K. Hofmann, D. Buchheidt (Mannheim, DE)

**Objectives:** The incidence of azole resistance in *Aspergillus fumigatus*, the major fungal pathogen causing invasive aspergillosis (IA) in immunocompromised patients, is rising. As the diagnosis of IA is rarely based on positive culture yield in this group of patients, detection of azole resistance directly from clinical samples is urgently needed.

**Methods:** We established three sensitive and specific polymerase chain reaction (PCR) assays followed by DNA sequence analysis to detect the most frequent mutations in the *A. fumigatus* *cyp51A* gene conferring azole resistance (TR (tandem repeat) alteration in the promoter region, L98H and M220 alterations) directly from clinical bronchoalveolar lavage (BAL) and tissue samples. Furthermore the sensitivity of the original L98H PCR assay was optimised.

Up to now we screened 40 samples from 38 immunocompromised patients that had been tested positive for *Aspergillus* DNA previously in our diagnostic nested *Aspergillus* PCR assay.

**Results:** The detection threshold for the optimised L98H PCR assay was 200 fg of *A. fumigatus* DNA.

Using primarily this most sensitive assay, 23 of 40 samples yielded a positive signal, 17 samples were found to be PCR-negative.

The positive-tested samples were further submitted to the TR and M220 PCR assays. For the TR assay 16 samples resulted in positive and seven samples in negative signals, whereas 17 positive signals and six negative signals were found for M220 PCR assay.

DNA sequence analysis revealed a single L98H mutation in a lung tissue specimen of a steroid treated COPD patient and a L98H alteration in combination with the TR in a brain tissue sample of a patient with acute lymphoblastic leukemia and IA.

**Conclusions:** In order to detect azole resistance mediating mutations of the *A. fumigatus* *cyp51A* gene directly from clinical samples, we optimised our PCR assays. Positive PCR signals suggest the feasibility of the approach, however; DNA sequence analysis is mandatory to detect the gene mutations.

We consider our assay of high epidemiological and clinical relevance to detect azole resistance and to optimise antifungal therapy in patients with IA.

Supported by a grant of the Deutsche Krebshilfe/Dr. Mildred Scheel Stiftung für Krebsforschung (Project number 109 411).

We acknowledge the support of Susan J. Howard, Manchester, and Anne Dietz, Mannheim.

**P826 Unique step-wise development of a homozygous FKS mutation (S80P) in *Candida tropicalis* in vivo**

R.H. Jensen\*, H.K. Johansen, M.C. Arendrup (Copenhagen, DK)

**Objectives:** An increasing number of reports demonstrate acquired echinocandin resistance associated with both hetero- and homozygous mutations in the *fks* target gene. Here we analyse three sequential *C. tropicalis* isolates received from a leukemic patient over a 4-month period in which echinocandin resistance developed despite treatment with alternating drug classes.

**Methods:** Susceptibility testing was done according to EUCAST (azoles and anidulafungin) and by Etest (amphotericin B and caspofungin). The *fks1* gene was sequenced for resistant isolates and compared to a reference sequence for the ATCC 750 *C. tropicalis* strain. Genotyping was done by multilocus sequence typing (MLST) applying the pubMLST database covering 205 different sequence types from 260 isolates [http://pubmlst.org/perl/mlstdbnet/mlstdbnet.pl?file=ct\\_profiles.xml](http://pubmlst.org/perl/mlstdbnet/mlstdbnet.pl?file=ct_profiles.xml). Two unrelated isolates of *C. tropicalis* were included for comparison.

**Results:** The patient was initially blood culture (BC) positive 19.12.10. Five BCs drawn from 27.01.11–01.03.11 were all negative. *C. tropicalis* was again detected 05.03.11–16.03.11 in five subsequent BCs. Systemic antifungal treatment was as follows (daily dose): 19.12.10–24.01.11: caspofungin (70/50 mg), 24.01.11–11.02.11 fluconazole (800 mg), 11.02.11–09.03.11 caspofungin (70.50 mg), 09.03.11–31.03.11 ambisome (3 mg/kg), 31.03.11–04.05.11 posaconazole (800 mg). A Hickman catheter was kept in place but attempted sterilised with acid and fluconazole lock. Date and origin of study isolates are shown in the Table.

Susceptibility testing showed isolate #1 was susceptible whereas isolate #2 and #3 were echinocandin resistant (Table). Isolate #2 had a heterozygous S80S/P mutation in the *fks* gene (corresponding to S645P in *C. albicans*), whereas this alteration was demonstrated at both alleles

in isolate #3 (S80P). The MLST data suggested isolate #2 and #3 were clonally related since DNA sequences in six housekeeping genes were 100% identical and shared a unique pubMLST sequence type.

Isolate	Species	Date	Resistance mechanism	Allele profiles according to the pubMLST database							EUCAST (EU 7.1) (µg/ml)						Etest (µg/ml)

**Conclusion:** To our knowledge, this is the first report of a stepwise development in vivo of a heterozygous to homozygous S80P mutation in *C. tropicalis* after caspofungin treatment and despite 1 month of suppressive fluconazole therapy. Even the heterozygous mutant isolate was classified as echinocandin resistant illustrating the importance of the codon S80 of *C. tropicalis*. This study may contribute to our understanding of resistance development in vivo as a consequence of antifungal treatment.

**P827 In vivo activity of anidulafungin, caspofungin and micafungin against *C. glabrata* with and without FKS mutations**

M.C. Arendrup\*, D.S. Perlin, R.H. Jensen, S.J. Howard, J. Goodwin, W. Hope (Copenhagen, DK; Newark, US; Manchester, UK)

**Objectives:** We have recently observed that for some *C. glabrata* isolates with *fks* hot spot mutations, the MIC elevation for micafungin may be less pronounced than for the other echinocandins. In this study we investigated whether the efficacy of micafungin may be differentially dependent on certain *fks* mutations in the hot spot regions of *C. glabrata*.

**Methods:** Three clinical *C. glabrata* isolates with or without (S#3) *fks* hotspot mutations [R#83 (*fks2p-S663F*) and the RR#24 (*fks1p-S629P*)] were used. In vitro susceptibility (EUCAST and CLSI ± bovine serum albumin supplemented medium and disk testing) and in vitro growth rate in RPMI-2G broth were determined. In vivo efficacy in a haematogenous immunocompetent mouse model using three doses of each of the echinocandins was investigated. Drug concentrations were determined in plasma and kidney tissue and PK/PD relationships evaluated.

**Results:** In vitro testing confirmed differential susceptibility S#3: susceptible, R#83 moderately resistant and RR#24 most resistant. Compared to the S#3 isolate, the R#83 isolate showed slightly reduced maximal growth and the RR#24 isolate prolonged lag phase and reduced maximal growth. None of the echinocandins were efficacious in mice challenged with the RR#24 isolate even at doses associated with AUCs approximately three to eight times greater than in humans (Table). Micafungin was equally efficacious against the S#3 and the R#83 isolate with a ≥1 log reduction at doses associated with an AUC of ≥187. In contrast, for mice challenged with the R#83 isolate a ≥1 log reduction was achieved for caspofungin at the medium and high doses (AUC 393 and 787, respectively) but not the low dose (AUC 197). Anidulafungin failed to induce a ≥1 log reduction for any of the isolates at any of the doses (AUC range 139–557).

Agent	First experiment			Second experiment			Mean

Low dose (0.2 mg/kg)										

\* Six animals per group.  
†† Three animals per group.

**Conclusion:** Differences in echinocandin MIC values associated with individual fks mutations appear to be associated with differential antifungal activity in an immunocompetent animal model. The mutant with the most clearly elevated MIC above the standard range for wild type isolates was not treatable with any of the echinocandins, whereas the isolate for which the micafungin MIC was only marginally elevated, and which may be difficult to discriminate from wild type isolates in routine testing, responded equally well to micafungin as the wild type. This study has implications for clinical practice and echinocandin breakpoint determination.

**P828** Emergence in vivo of *Aspergillus terreus* with reduced azole susceptibility and a CYP51A M220I alteration in a cystic fibrosis patient

M.C. Arendrup\*, R.H. Jensen, K. Grif, H.K. Johansen, M. Skov, T. Pressler, K.L. Mortensen, C. Lass-Flörl (Copenhagen, DK; Innsbruck, AT)

**Objectives:** Aspergilli are frequently found in the airways of CF patients. *A. fumigatus* is the predominant species and 4.5% of these have recently been shown to be azole resistant in a Danish cohort. Azole resistance in *A. terreus* is rarely reported but of clinical significance due to this species being intrinsically resistant to amphotericin B. We here report the emergence of *A. terreus* isolates with reduced azole susceptibility and investigate the underlying mechanism and origin.

**Methods:** Twenty sequential *A. terreus* isolates from a single CF patient (MB) obtained over a 7.5 year period and six unrelated *A. terreus* isolates were included. Susceptibility testing was performed (EUCAST EDef 9.1 methodology). Breakpoints have not yet been established but *A. terreus* isolates with itraconazole (ITR) MIC ≤0.5 mg/L were regarded as susceptible based on MIC ranges for wild type isolates. The CYP51A gene and promoter was sequenced (primers designed based on the reference strain NIH2624 ATEG05917). The isolates genotyped using RAPD-PCR and five different primers for maximal discriminatory power: A-ter2 (5-GCTGGTGG-3), NS7 (5-GAGGCAATAACAGGCTGTGATGC-3), (R108 (5-GTATTGCC CT-3), CII (5-GCGCACGG-3) and P4 (5-GATAGATAGATAGAT-3).

**Results:** Susceptibility testing of the isolates from MB identified five isolates as ITR S (MICs 0.25–0.5 mg/L): 2/2 from 2003 to 4, 2/7 from 2007 and 1/9 isolates from 2009. ITR MICs for the remaining 15 isolates were 1–4 mg/L. In contrast the ITR MICs of the six control isolates were 0.06–0.125 mg/L. Voriconazole (VOR) MICs were 1–4 mg/L for the MB isolates but 0.25–0.5 mg/L for the control isolates. The posaconazole (PSC) MICs were 0.06–0.5 mg/L for the MB isolates and <0.03–0.06 mg/L for control isolates. Genotyping showed 18/20 MB isolates to be identical. The remaining 2 MB isolates differed for one (A.terr-2) or two primers (Aterr-2 and NS7), respectively. Cyp51A sequencing identified a M217I alteration (corresponding to M220I in *A. fumigatus*) in the 15 isolates with elevated ITR MICs.

One control isolate with wild type susceptibility had an A221V alteration.

**Conclusion:** To our knowledge this is the first report on acquired azole resistance in *A. terreus* involving an M217I alteration. This alteration was found in all ITR resistant isolates and genotyping suggested this alteration was of endogenous origin. VOR and PSC MICs were elevated also in isolates without CYP51A mutations suggesting several mechanisms may act in concert in these isolates.

**P829** A unique amino acid substitution in the ERG11 gene mediated azole cross-resistance in *Candida tropicalis* bloodstream isolates

E. Borghi\*, R. Iatta, R. Sciota, D. Cirasola, M.T. Montagna, G. Morace (Milan, Bari, IT)

**Objectives:** Compared with *C. albicans* there are relatively few studies examining the virulence factors of *C. tropicalis*, and its mechanisms of drug-resistance.

*C. tropicalis* accounts for a significant proportion of *Candida* bloodstream infection, and traditionally is considered as second to *C. albicans* in terms of virulence and clinical importance. Here we investigated the molecular mechanism responsible for cross-resistance to fluconazole and voriconazole in *C. tropicalis* clinical strains isolated from bloodstream infections.

**Materials and methods:** During a 10-year retrospective surveillance of candidemia we collected ten *C. tropicalis* isolates, showing resistance to fluconazole and voriconazole. For comparative purpose an equal number of azole-susceptible strains were studied. Isogenicity of the isolates was investigated by RAPD (primers OPE03, GC70 and UBC703) and Maldi-TOF analysis.

Antifungal susceptibility testing was performed by Sensititre procedure and broth microdilution method. Quantification of the expression of the CtMDR1, CtCDR1 and CtERG11 genes was performed by real-time PCR, using SYBR Green chemistry. To stimulate the expression of efflux pumps genes, all the isolates were cultured in presence and absence of various fluconazole concentrations. The primers have been designed with the primer express 3.0 software (Applied Biosystems). For ERG11 sequencing, five pairs of oligonucleotide primers (Bouchara et al., 2005) were used.

**Results:** The resistant isolates, coming from four different hospitals, clustered in three groups. No significant differences were found in the expression levels of the resistant isolates compared to the susceptible ones, even if cultured in the presence of sub-MIC concentration of fluconazole.

Comparison of the CtERG11 gene sequences of the ten *C. tropicalis* resistant isolates with the available corresponding sequence in the GenBank database (accession number M23673) revealed the point mutation Y132F in the coding region. This mutation is located in the region between the B' and C helices that have been postulated to be involved in inhibitor- or substrate-induced structural changes.

**Conclusions:** In contrast to what observed in *C. albicans*, where azole resistance is usually the result of a combination of different mechanisms, in *C. tropicalis* we found a unique single point mutation sufficient to induce a decreased affinity of fluconazole and its derivative voriconazole.

**P830** Posaconazole concentrates within the endoplasmic reticulum of host and fungal cells

P. Campoli\*, O. Attias, A.S. Kristof, D.S. Perlin, D.C. Sheppard (Montreal, CA; New Jersey, US)

**Objectives:** Infections due to *Aspergillus fumigatus* remain a critical concern in high risk hematology patients. Posaconazole (PCZ) prophylaxis has proven highly effective in preventing these infections, despite relatively low serum concentrations. We have previously shown that PCZ concentrates within host cell membranes to a high enough concentration to both inhibit growth and prevent

fungal damage. However, the specific subcellular location of membrane associated PCZ within host and fungal cells is unknown. The objectives of this study are to determine where PCZ localizes in both epithelial cells and fungi in order to better understand its mechanism of action.

**Methods:** Fluorescent PCZ was synthesized by conjugation with the fluorophore BOPIDY (BOPIDY-PCZ). A549 epithelial cells were exposed to varying concentrations of BOPIDY-PCZ and examined using confocal microscopy. Cells were costained with DAPI and an endoplasmic reticulum (ER) specific anti-ERP57 antibody to facilitate visualization of cell microstructures. In parallel, these experiments were also conducted with *A. fumigatus* hyphae. Finally, to confirm the specificity of these findings, competitive inhibition assays using unlabelled PCZ and voriconazole (VCZ) were performed.

**Results:** A549 epithelial cells exposed to BOPIDY-PCZ exhibited increased total cell fluorescence, centred around the peri-nuclear area. Similar findings were observed with hyphae of *A. fumigatus*, with increased fluorescence localizing to the perinuclear area, corresponding to the location of the ER. To confirm this finding, A549 cells were immunostained for ER protein 57 (ERP57). Staining for this protein demonstrated co-localization with BOPIDY-PCZ in the perinuclear region, suggesting that posaconazole concentrates within the membrane rich endoplasmic reticulum. Co-culture of host and fungal cells with BOPIDY-PCZ and unlabelled PCZ resulted in a decreased in fluorescence of the cells, while the addition of VCZ had little effect on ER concentration of PCZ, suggesting that the concentration of PCZ within the ER membranes is specific to this azole.

**Conclusion:** These results suggest that PCZ concentrates specifically to the endoplasmic reticulum within host and fungal cells. Since the target of PCZ, CYP51A, is found within the ER, this finding suggests that the ability of PCZ to concentrate to high concentrations in the endoplasmic reticulum may contribute to its antifungal activity.

**P831** Performance of a commercial real-time PCR assay using the ABI 7300 instrument for the detection of *Aspergillus* and *Pneumocystis* DNA in bronchoalveolar lavage fluid samples from critical patients

C.F. Orsi\*, W. Gennari, C. Venturelli, G. Bertazzoni, A. La Regina, M. Machetti, M. Pecorari, F. Rumpianesi, E. Blasi (Modena, Genoa, IT)

**Objectives:** To investigate the performance of the MycAssay™ *Aspergillus* (MycAspAssay) and of the MycAssay™ *Pneumocystis* (MycPCPAssay) in detecting *Aspergillus* (Asp) or *P. jirovecii* (Pj) DNA in BAL samples from critical patients, using ABI 7300 instrument.

**Methods:** We enrolled 20 patients with or without fungal infections, according to the EORTC classification. In detail, seven patients were diagnosed with invasive aspergillosis (IA), eight patients with pulmonary infection by Pj (PCP) and five hospitalized patients with non-fungal infections (CTRL). DNA extracted by MycXtra™ (Myconostica) from BAL samples was amplified by real-time PCR by MycAspAssay and MycPCPAssay kits (Myconostica) using ABI 7300 instrument (Applied Biosystem). The real-time PCR data were compared with the results obtained with conventional diagnostic tests, namely culture, galactomannan (GM), immunofluorescence (IF), sequencing and *Aspergillus* spp. Q-PCR Alert Kit or *P. jirovecii* Alert kit (Nanogen).

**Results:** All the seven patients with IA as well as one of eight patients belonging to the PCP group were MycAspAssay positive whereas all the CTRL-group patients (n = 5) provided negative PCR results. All the MycAspAssay positive results were confirmed either by GM-assay or *Aspergillus* spp. Q-PCR Alert Kit.

Seven of the eight patients with PCP as well as four of the seven patients belonging to the IA group were MycPCPAssay positive, whereas all the CTRL-group patients provided negative PCR results. Six of the 7 MycPCPAssay positive results were in line with the IF, nested PCR and sequencing data.

**Conclusion:** Although being considered as a preliminary step towards a validation of the MycAssay™ *Aspergillus* and MycAssay™

*Pneumocystis* kits on ABI 7300, these data provide initial information on the performance of this platforms for the detection of DNA of either Asp or Pj in BAL of patients with suspected invasive mycosis. Work partially supported by GRANT MIUR-PRIN 2009.

**P832** Clinical validation of multiplex quantitative real-time PCR in critically ill patients for invasive candidiasis diagnosis: preliminary analysis

J. Fortún\*, Y. Meije, M.J. Buitrago, S. Gago, L. Bernal-Martínez, E. Gómez-Gª Pedrosa, N. Madrid, G. Fresco, V. Pintado, J. Cobo, S. Moreno, M. Cuenca-Estrella (Madrid, ES)

**Background:** Mortality associated with invasive candidiasis in critically ill patients may reach 70%. Diagnostic limitations makes empirical treatment a common practice nowadays. New techniques like real-time quantitative PCR (RT-PCR) could help in daily management of these patients.

**Objectives:** Sensitivity (S), specificity (E), positive and negative predictive value (PPV and NPV) of RT-PCR in comparison to blood culture were calculated in a prospective study in patients at high risk of invasive candidiasis that have been admitted to an intensive care unit. Blood cultures and RT-PCR samples (serum and total blood) were periodically obtained at baseline, day +2, day +7, day +14 and day +21. Techniques based on PCR multiplex with molecular beacons were used. They detect the six most common species of *Candida* (*C. albicans*, *C. parapsilosis*, *C. tropicalis*, *C. glabrata*, *C. krusei* and *C. guilliermondii*). We also studied 20 healthy controls.

**Results:** The first eight patients were excluded because of blood cultures and RT-PCR samples were obtained through a catheter central-line and all of them showed a false positive RT-PCR result, probably related to central-line contamination. In the other 38 patients, samples were obtained from venipuncture. Results are shown in table 1.

All healthy controls showed negative blood cultures a negative RT-PCR. S, E, PPV and NPV of RT-PCR were: 59%, 90%, 71% and 84%, respectively. In three of four patients with a false-positive RT-PCR *Candida* spp were obtained from abdominal collections. All false-negative RT-PCR results were obtained in patients with catheter-related candidemia. When we analysed all samples obtained, the results were as followed: 15 true-positive, 116 true-negative, 14 false-positive and 15 false-negative RT-PCR results in comparison to blood cultures. To evaluate the best sample for RT-PCR, we observed a positive rate of 86% and 67% of serum and total blood, respectively, among the total positive RT-PCR samples.

In candidemic patients the most frequent *Candida* species isolated were *C. albicans* (59%) followed by *C. parapsilosis* (35%).

	Positive RT-PCR	Negative RT-PCR	
Positive blood culture	10	7	17
Negative blood culture	4	17 (+20 healthy controls)	41
	14	44	58

**Conclusions:** The quantitative real-time PCR has been positioned as a useful method for the diagnosis of invasive candidiasis and for monitoring anti fungal therapy response in critically ill patients. A special consideration can be obtained in patients with abdominal collections and negative blood cultures.

**P833** Molecular characterisation of fungal cultures by PLEX-ID broad fungal assay

C. Massire\*, E. Clark, R. Lovari, H. Matthews, D. Toleno, R. Ranken, T. Hall, D. Metzgar, R. Sampath, L. Blyn, D. Ecker, S. Zhang, R. Hayden (Carlsbad, Baltimore, Memphis, US)

**Objectives:** We have developed and evaluated an assay for the characterization of fungal pathogens using the PLEX-ID technology, where PCR amplicons are analyzed by ESI-MS. The assay provides

broad fungal coverage across Ascomycota, Basidiomycota and Zygomycota, with an emphasis towards the individual characterization of 50 clinically important yet phylogenically diverse pathogens (e.g. *Aspergillus fumigatus*, *Candida albicans*, *Fusarium* spp., *Cochliobolus* spp., *Pneumocystis jirovecii*, *Cryptococcus neoformans*, *Mucor* spp).

**Methods:** We assembled a 16-primer pair assay that provides a balance between universal fungal detection and fine characterization of the most common fungal pathogens. For each sample, the resulting 4- to 10-loci signatures are compared to an in-house signature database built using in silico determination from publicly available fungal sequences and direct determination from over 70 reference isolates from ATCC. The assay was tested against a diverse collection of 305 culture samples from clinical isolates.

**Results:** The PLEX-ID detected fungi in 299/305 positive culture samples (98.0%), specifically retrieving culture results in 267 samples (87.5%). Fungi were also detected in 25 samples (8.2%) but were not fully characterized as the determined signatures did not have a decisive database match at the time of analysis. Seven samples with divergent culture and PLEX-ID characterization were further investigated by ITS1/ITS2 sequencing, confirming the PLEX-ID call in 4/7 instances. Fungal detection were missed in 6/305 samples (2.0%).

Correlation between PLEX-ID and culture ID results	Samples	%
Full agreement	267	87.5%
Agreement: Fungus detected, species not represented in DB	25	8.2%
Disagreement; ITS1/ITS2 sequencing confirms PLEX-ID result	4	1.3%
Disagreement; ITS1/ITS2 sequencing confirms culture ID result	3	1.0%
No detection by PLEX-ID	6	2.0%
<b>All samples from clinical isolates</b>	<b>305</b>	<b>100.0%</b>

**Conclusions:** The PLEX-ID fungal assay provides broad detection and identification of clinically relevant fungi. Testing with ~300 specimens showed 97% accuracy of identification. The instances of partially or incorrectly characterized isolates resulted primarily from gaps in the initial signature database that the present study helped to identify and eliminate. The assay can screen up to six samples per plate, allowing the analysis of up to 90 samples in 12 hour on a single instrument.

#### **P834** Molecular identification of yeasts causing fungaemia: are cryptic species frequent?

P. Escribano, S. Recio, T. Peláez, C. Sánchez-Carrillo, M. Rodríguez-Créixems, P. Muñoz, E. Bouza, J.V. Guinea Ortega\* (Madrid, ES)

**Objectives:** The study of the epidemiology of fungaemia is necessary to optimize empirical and proven treatment. However, morphological and biochemical procedures are unable to uncover the presence of closely related species (cryptic species) in complexes of *Candida parapsilosis*, *Candida guilliermondii*, and *Candida glabrata*. We used molecular techniques to provide definitive identification of species causing fungaemia in patients admitted to a tertiary hospital.

**Methods:** We studied 445 fungal isolates from the blood cultures of 401 patients with fungaemia admitted to our hospital between January 2007 and August 2011. Each isolate represented one fungaemia episode. Multiple episodes were defined as isolation of the same fungal species in further blood cultures taken  $\geq 7$  days after the last isolation in blood culture. Isolates were identified after amplification and sequencing of the ITS1-5.8S-ITS2 region. A phylogenetic tree based on the sequenced ITS1-5.8S-ITS2 region was constructed to detect the presence of cryptic species within the *C. parapsilosis*, *C. guilliermondii*, and *C. glabrata* complexes.

**Results:** Only 9 (2%) fungaemia episodes were caused by a mixture of two different yeast species. The distribution of species involved in the fungaemia episodes was as follows: *Candida albicans* (n = 217, 48.7%), *C. parapsilosis* (n = 129, 29%), *C. glabrata* (n = 45, 10.1%), *Candida tropicalis* (n = 28, 6.3%), *C. guilliermondii* (n = 6, 1.3%), *Candida krusei* (n = 6, 1.3%), *Candida dubliniensis* (n = 4, 0.9%), *Candida kefyr* (n = 2, 0.5%), *Candida lusitanae* (n = 2, 0.5%),

*Candida pelliculosa* (n = 1, 0.25%), other non-*Candida* yeasts (n = 14, 3.1%). Only three isolates from the *C. parapsilosis* complex were cryptic species. One adult patient who underwent cardiac surgery developed candidemia by *Candida metapsilosis*. Two adult patients with digestive cancer developed candidemia by *Candida orthopsilosis*. Only one of the isolates identified as *C. guilliermondii* was confirmed as *Pichia caribbica* (the isolated was from a patient with digestive cancer). No cryptic species were found in the isolates identified as *C. glabrata*. **Conclusion:** In our hospital, most episodes of fungaemia were caused by *C. albicans*, followed by *C. parapsilosis*. The presence of cryptic species within the *C. parapsilosis*, *C. guilliermondii*, and *C. glabrata* complexes was infrequent and represented only 2% of their isolates. Jesús Guinea (CP09/00055) and Pilar Escribano (CD09/00230) are supported by a contract from FIS.

#### **P835** PCR for the detection of invasive aspergillosis in bronchoalveolar lavage – systematic review and meta-analysis

D. Yahav\*, T. Avni, I. Levi, L. Leibovici, M. Paul (Petah-Tikva, IL)

**Objectives:** To assess the sensitivity and specificity of PCR in bronchoalveolar lavage (BAL) for the diagnosis of invasive aspergillosis (IA), and to examine the standards of PCR performance and their effects on the diagnostic accuracy of PCR.

**Methods:** Systematic review. We included prospective, retrospective or case-control studies using PCR on BAL or bronchial secretions for the diagnosis of IA. We included only patients at risk for IA as defined by the EORTC host criteria (both cases and controls). Any PCR test was acceptable, including standard PCR, real-time, nested, multiplex or other PCR, using any primer gene and targeting all or specific *aspergillus* spp. We used only PCR tests taken within 14 days of infection onset. In the primary analysis we considered only proven and probable IA, defined by EORTC criteria. In a secondary analysis we also considered possible IA as disease. Risk of bias assessment was conducted using the QUADAS-2 tool. Coupled sensitivity and specificities were summarized using the bivariate model, from which hierarchical summary receiver operating curves (HSROC) were drawn. Covariates effects were investigated through meta-regression of diagnostic odds-ratios (DORs)

**Results:** Eighteen studies (1499 patients) were included. Ten used real-time PCR. Most studies used the 18S rRNA gene for primers. For the primary analysis (probable or proven IA), the summary sensitivity and specificity values were 90.5% (95% CI 79.2–95.9%) and 96.1% (95% CI 93–97.9%), respectively (figure). The DOR was 235.1 (95% CI 83.3–663.6). An analysis restricted to eight studies with an appropriate reference standard yielded summary sensitivity, specificity and DOR values of 80.7% (95% CI 63.6–90.9%), 92.9% (95% CI 90–94.9%) and 54.5 (95% CI 22.5–131.8), respectively. The pooled sensitivity and specificity for possible, probable or proven IA was 86.8% (95% CI 68.4–95.3%) and 94.9% (91.5–96.4%), respectively. Prior antifungal treatment decreased sensitivity. PCR methods did not affect results.

**Conclusions:** PCR from BAL in patients at risk for IA has >90% specificity. Considering the high mortality rate of IA, positive BAL PCR mandates appropriate antifungal therapy. Negative PCR cannot rule out IA, especially amongst previously treated patients.

**P836** Comparative sequence analysis of *Fusarium* spp. isolated from fungal keratitis specimens

X. Lu\*, M. Zhu, X. Shang, Z. Wang, X. Sun, M. Wang, Y. Sun, Y. Huang (Beijing, CN)

**Objectives:** To find out the exact pathogen of the fungal keratitis caused by *Fusarium* spp. that was one of the most common pathogen of fungal keratitis in China.

**Method:** One hundred and eighty-seven *Fusarium* strains were isolated from the corneal scraps from 2007 to 2010 in Beijing Tongren hospital, Capital medical University. All the isolates were identified on the basis of colony and microscopic features. All the

Table Results of identification of the 187 fusarium isolates

Fusarium	Morphology	ITS	EF-1 $\alpha$	MtSSU
<i>F. solani</i>	105	103	103	103
<i>F. moniliforme</i>	81	81	80	80
<i>F. delphinoides</i>	0	3	3	3
<i>F. thapsinum</i>	0	0	1	1
<i>F. oxysporum</i>	1	0	0	0
Total	187	187	187	187

Figure 1-1 *F. delphinoides* (PDA)

Figure 1-2 *F. delphinoides* (SDA)

Figure 2-1 *Gibberella thapsina* (PDA)

Figure 2-2 *Gibberella thapsina* (SDA)

Figure 1-3 *Fusarium delphinoides* (10% potassium hydroxide (KOH) stain,  $\times 400$ )

Figure 2-3 *Gibberella thapsina* (lactophenol cotton blue stain,  $\times 400$ )

isolates were also identified by comparative sequence analysis using the internal transcribed spacer (ITS), the translation elongation factor 1 alpha (EF-1alpha), and mitochondrial small subunit rDNA (MtSSU) regions.

**Results:** By EF-1alpha and MtSSU regions sequence-based identification, 55.1% (103/187) isolates were *Fusarium solani* and 42.8% (80/187) were *Fusarium moniliforme* (table). The *Fusarium oxysporum* identified by morphological method was *F. solani* confirmed by the three regions sequence analysis. Three isolates were identified as *Fusarium delphinoides* that were the member of the *Fusarium dimerum* species group by comparative sequence analysis using the three regions, but they were *F. solani* by morphological features (figure 1-1, 1-2 and 1-3). One isolate was *Gibberella thapsina* (*Fusarium thapsinum*) by EF-1alpha and MtSSU regions sequence-based identification, but it was identified as *F. moniliforme* species complex using the ITS sequence analysis and its morphological feature was similar to *F. moniliforme* (figure 2-1, 2-2 and 2-3).

**Conclusion:** *F. solani* was the major pathogen of the fungal keratitis caused by *Fusarium* spp., followed by *F. moniliforme*. Other species of *Fusarium* spp. was rarely. The comparative sequence analysis using EF-1alpha and MS regions was better than morphological method and the sequence-based analysis using the ITS region.

**P837** Inter-laboratory comparison of treatment response in a murine model of invasive candidiasis using two *Candida albicans* isolates

N.P. Wiederhold\*, P.A. Warn, L.K. Najvar, J. Livermore, R. Bocanegra, W.R. Kirkpatrick, T.F. Patterson (San Antonio, US; Manchester, UK)

**Objective:** Murine models of invasive candidiasis are frequently used in the preclinical evaluation of investigational antifungals as these models are typically robust and inexpensive. However, there have been few inter-laboratory studies of outcome variability with the same model. Our objective was to conduct an inter-laboratory comparison of treatment response between two laboratories (UTHSCSA and University of Manchester) using a murine model of invasive candidiasis with two different *C. albicans* clinical isolates.

**Methods:** Immunocompetent 30 g outbred ICR or CD1 mice were inoculated intravenously with *C. albicans* SC5314 or ATCC 90028 (target starting inoculum  $1.5 \times 10^5$  and  $1.5 \times 10^6$  cells/mouse, respectively). Antifungal therapy began 1 day later and continued for 5 days. Treatment groups consisted of control, fluconazole (FLC) 10 mg/kg PO QD, and caspofungin (CFG) 1 mg/kg IP QD. Treatment continued until day 5 and mice were followed off therapy until day 21 to assess survival. Kidneys and brains were collected on day 8 in the fungal burden arm. Fungal burden was assessed by colony-forming units (CFU), and survival was assessed by Kaplan–Meier analysis. Each laboratory evaluated both isolates and conducted the experiments independently.

**Results:** Antifungal response, as measured by reductions in kidney fungal burden and improvements in survival, was very similar between the two laboratories (Table). CFG significantly improved survival and

Isolate	SC5314 (target starting inoculum $1.5 \times 10^5$ cells/mouse)							
	Kidney Tissue Log <sub>10</sub> CFU/g (mean SD)		Brain Tissue Log <sub>10</sub> CFU/g (mean SD)		Median Survival		Percent Survival

Control	4.71 (0.59)	5.46 (0.62)	1.52 (0.10)	1.50 (0.14)	9.5 days	7.5 days (p = 0.033)	20%	0%
FLC	2.13 (0.60)	2.73 (0.65)	1.48 (0.04)	1.48 (0.13)	>21 days	20 days	65%	30%
CFG	2.13 (0.60)	2.01 (1.21)	1.52 (0.08)	1.42 (0.04)	>21 days	>21 days	95%	100%
Isolate	ATCC 90028 (target starting inoculum $1.5 \times 10^6$ cells/mouse)							
	Kidney Tissue Log <sub>10</sub> CFU/g (mean SD)		Brain Tissue Log <sub>10</sub> CFU/g (mean SD)		Median Survival		Percent Survival	
Outcome	Manchester	UTHSCSA	Manchester	UTHSCSA	Manchester	UTHSCSA	Manchester	UTHSCSA
Control	5.01 (0.41)	5.85 (0.50)	2.00 (0.53)	3.66 (0.32) (p < 0.05)	4 days	10 days (p < 0.001)	5%	20%
FLC	3.28 (0.85)	3.59 (0.57)	1.97 (0.79)	2.95 (0.62) (p < 0.05)	14 days	16 days	10%	30%
CFG	1.58 (0.47)	2.69 (0.64)	1.69 (0.31)	2.71 (0.67) (p < 0.05)	15 days	>21 days	30%	60%

p-value UTHSCSA vs. Manchester data

reduced fungal burden in mice infected with SC5314, while modest reductions in fungal burden and survival improvements were observed with FLC. Similarly, both laboratories also reported significant improvements in survival and reductions in fungal burden for each antifungal in mice challenged with ATCC 90028. Interestingly, there were significant differences in median survival and fungal burden in the brains of untreated mice infected with ATCC 90028. These may have been due to differences between laboratories in the number of viable *C. albicans* cells used to challenge the mice or the subjective criteria used to judge moribund animals.

**Conclusions:** Antifungal treatment response was highly reproducible between these two laboratories. Both CFG and FLC were effective at improving survival and reducing fungal burden against two *C. albicans* clinical isolates. These results demonstrate that our murine model of invasive candidiasis provides a useful and reproducible tool for evaluating therapeutic agents.

**P838** Species distribution, biofilm production, and antifungal susceptibility of *Candida* bloodstream isolates at a university hospital

J. Pongracz\*, K. Kristóf (Budapest, HU)

**Objectives:** The aim of our study was to determine the incidence of candidaemia at our hospital with data on species distribution, biofilm production and in vitro antifungal susceptibility (planctonic and sessile) of the isolates.

**Methods:** All *Candida* bloodstream isolates were obtained at Semmelweis University in 2010–2011. The isolates were identified by their carbohydrate assimilation profile (API 20 C AUX) and morphology on malt agar. Biofilms were formed in 96-well polystyrene microtiter plates, in RPMI 1640 medium substituted with glutamate and MOPS, incubated at 37°C on a rocker. Following 72 hours of incubation, biofilms were washed three times with sterile saline, and biofilm mass was quantified by measuring the fluorometric emission of calcofluor-white stain added to the biofilms. Planctonic MIC (pMIC) values for fluconazole and anidulafungin were determined using the Eucast standard broth dilution method. For determination of sessile MIC (sMIC) values for fluconazole and anidulafungin, 72 hour biofilms were washed, and reincubated for 48 hours in serial dilutions of the antifungal agents. SMIC50 (defined as the antifungal concentration that results in 50% growth inhibition compared to the control well with no antifungal agent) was determined by Alamar blue assay.

**Results:** *Candida* species were isolated from the bloodstream in 40 cases over a 2-year time period (3% of all bloodstream isolates). *Candida albicans* was the predominant species (52.5%), followed by *C. parapsilosis* (17.5%), *C. glabrata* (12.5%), *C. tropicalis* (10%), *C. krusei* (2.5%), *C. lusitanae* (1%) and *C. kefyr* (1%). High biofilm producers were found among the *C. albicans* (33%), *C. tropicalis* (75%), and *C. parapsilosis* (33%) isolates. Fluconazole sMIC values were significantly elevated compared to pMIC for every high biofilm producer isolate, while anidulafungin remained active against the biofilms.

**Conclusion:** Thirty percent of all *Candida* bloodstream isolates were high biofilm producers. While all the high biofilm producers were susceptible to fluconazole in vitro by the EUCAST standard susceptibility testing method, fluconazole had no effect on mature biofilms. Anidulafungin was active against planctonic cells and biofilms as well.

**P839** A 3-year study of in vitro activity of new antifungal agents against *Candida* isolates causing candidaemias

A. Stylianakis\*, V. Papaioannou, S. Tsiplakou, P. Thomaidis, K. Tsopelas, D. Argyris, S. Mantzari, K. Mouta (Athens, GR)

**Objectives:** to evaluate the in vitro antifungal activity of caspofungin (CSF), anidulafungin (ANG), micafungin (MCF) and posaconazole

(PSC) against *Candida* clinical isolates not undergone selective pressure by the examined agents previously.

**Methods:** We examined n = 104 *Candida* isolates which caused candidaemias to equal numbered patients of our hospital during October 2008 till September 2011. These patients were hospitalized in the medical ward (n = 16), in the surgical ward (n = 48) and in the ICUs (n = 40) of our hospital. The fungal isolations were the first recovered ones from patients' blood samples. The examined agents were not administered to the included patients previously, so the examined isolates were considered as selection pressure free ones. The identification was performed by using germ tube test and the automated system VITEK II (Biomérieux). The determination of MIC levels of the CSF, ANG, MCF and PSC was performed using the E-test strips (Biomérieux, ABI-Biodisk) according to the manufacturer's instructions. The interpretation of results for echinocandines was done according to CLSI guidelines and for posaconazole referred to *C. albicans* and *C. parapsilosis* according to EUCAST guidelines.

**Results:** The identification of the isolates was *C. albicans* (n = 40), *C. parapsilosis* (n = 48), *C. glabrata* (n = 8), *C. dubliniensis* (n = 4) and *C. lusitanae* (n = 4). The number of susceptible isolates against the antifungal agents was shown in the following Table.

<i>Candida</i> spp (n)	CSF	ANG	MCF	PSC
	Susc. (n)	Susc. (n)	Susc. (n)	Susc. (n)
<i>C. albicans</i> (40)	40	40	40	28
<i>C. parapsilosis</i> (48)	40	24	48	48
<i>C. glabrata</i> (8)	8	8	8	-
<i>C. dubliniensis</i> (4)	4	4	2	-
<i>C. lusitanae</i> (4)	4	4	4	-

**Conclusions:** The new antifungal agents were in vitro active against the examined *Candida* clinical isolates and they may be good alternate solutions for treating invasive candidiasis. However the decreased susceptibility to posaconazole of *C. albicans* and, as expected, to caspofungin and anidulafungin of *C. parapsilosis* clinical isolates underlines the necessity to perform antifungal susceptibility testing of clinically relevant yeasts.

**P840** Ndt80p :a transcriptional regulator involved in stress response in human fungal pathogen *Candida albicans*

Y. Yang\*, S. Wu, C. Hsiung, C. Chen, C. Hsiao, H. Lo (Hsinchu, Miaoli, Taipei, TW)

**Objective:** The increased use of antifungal agents has led to an increase in incidences of drug resistance. We have found that Ndt80p, a transcription factor, was involved in drug resistance in *Candida albicans*, the most common human fungal pathogens for systemic infection. This study was to understand how Ndt80p regulated its target genes and its roles in the physiology of *C. albicans*.

**Methods:** We have applied genetic and functional studies to characterize the cellular functions of Ndt80p as well as site-directed mutagenesis to identify the potential binding site of Ndt80p on one of its target genes YHB1. We have also performed electrophoretic mobility shift assays (EMSA) to assess the direct interactions between the Ndt80p and the binding site.

**Results:** We found that Ndt80p directly regulated its target genes, such as YHB1, via the mid-sporulation element (MSE). Furthermore, the ndt80R432A allele, with a reduced capability to bind MSE, failed to complement the defects caused by null mutations of NDT80. In fact, the R432 residue in the Ndt80p DNA-binding domain was involved in all tested functions, including drug resistance, nitric oxide inactivation, germ tube formation, hyphal growth, and virulence.

**Conclusion:** Ndt80p is an important transcription modulator to various stress-response genes in *Candida albicans*. It directly regulated its

target genes via MSE. In addition, the importance of the R432 residue suggests a novel approach to design new antifungal drugs through screening compounds blocking the interaction between Ndt80p and its targets.

**P841** *Cryptococcus gattii* induces a distinct pro-inflammatory cytokine pattern compared to other cryptococcal species

T. Schoffelen\*, J. Meis, L.A.B. Joosten, M.G. Netea, T. Boekhout, T. Sprong (Nijmegen, Utrecht, NL)

**Objectives:** *Cryptococcus gattii* is an emerging pathogen. It can cause serious infections in immunocompetent patients, whereas infection caused by other cryptococcal spp. is only seen in immunocompromised patients. We investigated whether this distinction in virulence also relates to differences in cytokine production by host immune cells. Furthermore, we investigated which pattern recognition receptors (PRR) are involved in eliciting a cytokine response to *C. gattii*.

**Methods:** Human blood mononuclear cells were incubated in-vitro with *Cryptococcus gattii*, *C. neoformans* var. *neoformans* and *C. neoformans* var. *grubii* strains and with hybrid strains. A total of 40 cryptococcal isolates were used, comprising clinical and environmental isolates as well as laboratory strains. Cytokines were measured in culture supernatant using ELISA. Subsequently, cells were pre-incubated with receptor antibodies and inhibitory ligands to investigate the involvement of specific PRRs.

**Results:** We found that proinflammatory cytokines, including IL-1beta, IL-6 and IL-17, were induced more strongly by *C. gattii* isolates compared to the other cryptococcal species. Moreover, the hybrid strains containing *C. gattii* as a partner of the mating pair also induced higher levels of proinflammatory cytokines than the hybrid strains which were the result of mating between both *C. neoformans* varieties. In addition, stimulation with clinical *C. gattii* isolates resulted in significantly higher proinflammatory cytokine levels compared to stimulation with *C. gattii* environmental isolates.

*C. gattii* induced IL-1beta and TNF-alfa were substantially inhibited by blocking TLR4, while no effect was seen by blocking TLR2. Furthermore, blocking of TLR9 inhibited IL-17, but not IL-22 production, indicating that there was an IL-17 independent IL-22 response. In addition, inhibition of TLR9 tended to result in more IL-1beta and TNF-alfa production by *C. gattii*.

**Conclusion:** *C. gattii* elicited a more powerful proinflammatory cytokine response than other cryptococcal species. Moreover, clinical isolates induced higher levels of proinflammatory cytokines than environmental isolates. Furthermore, *C. gattii* induced a Th22 response independent of IL-17 production. Both TLR4 and TLR9, but not TLR2, seemed to be involved in *C. gattii* induced cytokine production.

**P842** Investigating clinical cryptococcosis in the context of phagocyte-Cryptococcus interactions

W. Sabiiti\*, T. Bicanic, R.C. May (Birmingham, London, UK)

**Background and objective:** Cryptococcal meningoencephalitis (CM) is a leading cause of death in HIV/AIDS patients in Sub-Saharan Africa. Intracellular parasitism of *Cryptococcus neoformans* in macrophages is an important factor in disease dissemination. Our previous work has demonstrated that *Cryptococcus gattii* isolates with high intracellular proliferation rates (IPR) within macrophages were more virulent and caused fatal disease in a murine model of cryptococcosis. In this study, we explore the association of rate of phagocytosis and IPR in clinical *C. neoformans* isolates with clinical parameters and outcome in patients with HIV-associated CM.

**Methods:** Forty-seven *Cryptococcus neoformans* isolates from patients enrolled in clinical trials were analysed in vitro for (i) Rate of phagocytosis (number of cryptococci engulfed by macrophages within 2 hour); (ii) IPR inside murine J774 macrophages at time points, zero (2 hour), one (18 hour), two (24 hour) and three (48 hour); and

(iii) Melanisation rate on L-2,3-dihydroxyphenylalanine agar. Intracellular proliferation rate was determined as a ratio of number of intracellular cryptococci at time point one to number of cryptococci at time point zero. Association with baseline CSF quantitative cryptococcal cultures, cryptococcal antigen titre, white blood count, glucose, opening pressure; rate of clearance of cryptococci and 2-week mortality was explored using linear and logistic regression.

**Results:** IPR was negatively correlated with the rate of phagocytosis at time point zero ( $r^2 = 0.2$ ,  $p \leq 0.01$ ). Rate of melanisation positively correlated with uptake ( $r^2 = 0.1$ ,  $p = 0.03$ ). Clinical parameter analysis showed positive correlation between CSF quantitative cryptococcal culture and rate of phagocytosis ( $r^2 = 0.1$ ,  $p = 0.03$ , see graph) while cryptococcal antigen titre was negatively correlated with IPR ( $r^2 = 0.13$ ,  $p = 0.01$ ).

**Conclusion:** Macrophages from HIV/AIDS patients are reported to have dysfunctional phagocytosis machinery, implying that highly phagocytosed cryptococcal strains are more likely to systemically disseminate to the central nervous system. The association of melanisation and high phagocytosis rate suggests that *Cryptococcus* require melanin for protection and survival inside the hostile intracellular environment. We hypothesize that high cryptococcal uptake by macrophages results in macrophage-cryptococcal overload, lysis and subsequent release of cryptococci, which accounts for high CSF fungal burden and cryptococcal antigen titre.

**P843** Thrombocyte activation in invasive fungal infections

C. Speth\*, M. Hagleitner, H. Ott, C. Lass-Flörl, R. Würzner, G. Rambach (Innsbruck, AT)

**Objectives:** Invasive fungal infections are associated with thrombocytopenia or thrombosis, but the mechanism by which fungi affect the thrombocytes is as yet unknown. The influence of *Aspergillus* and Mucormycetes on platelets is of particular relevance since the platelets represent a relevant part of the innate immunity and to participate in the antifungal immune defense. Therefore we studied whether *Aspergillus* and Mucormycetes secrete factors that modify activity and functionality of thrombocytes.

**Methods:** Fungi were grown for 2 days; the supernatant was harvested and given to human thrombocytes. Activation of the platelets was quantified by aggregometry and by FACS analysis quantifying specific markers.

**Results:** Even minimal volumes of the *Aspergillus* culture supernatant were able to potently stimulate the platelets, inducing high expression of the activation markers on the surface, annexin binding to the platelet

membrane and significant thrombocyte aggregation, even after few minutes of incubation. *Aspergillus*-derived compounds also harbored the capacity to stimulate internalization of labeled beads by the thrombocytes. In contrast, supernatants of different Mucormycetes harbored no or only minimal platelet-activating activity.

Two active components in the *Aspergillus* culture supernatant could be identified. First, the role of a fungal serine protease was confirmed by usage of serine protease inhibitors, which partly eliminated the thrombocyte-stimulating capacity of the *A. fumigatus* supernatant. Second, the mycotoxin gliotoxin seems to play a role, since an *A. fumigatus* mutant unable to synthesize this mycotoxin does not stimulate the thrombocytes to an large extent. Furthermore, the effect of the fungal supernatant could be mimicked by purified gliotoxin. Preliminary experiments with glutathione, a reducing compound that inactivates gliotoxin, suggest the possibility to counteract the action of the mycotoxin and thus to reduce the danger of excessive platelet activation during invasive aspergillosis.

**Conclusions:** Secreted fungal factors such as proteases and mycotoxins might participate in thrombocyte activation during invasive aspergillosis. Putative consequences could be a platelet-driven antimicrobial response and platelet-mediated stimulation of the innate immune network, but also, on the other hand, negative effects such as thrombosis and thrombocytopenia. Mucormycetes seem to use different mechanisms to influence thrombocytes.

## Treatment strategies and economic aspects in invasive fungal infections

### P844 Efficacy of liposomal amphotericin B alone or in combination with caspofungin vs. caspofungin alone or caspofungin followed by liposomal amphotericin B for treatment of murine *Candida parapsilosis* infection

J.A. Olson\*, D.J. Hahka, N. Nguyen, J.P. Adler-Moore (Pomona, US)

**Objectives:** Given the increased incidence of *Candida glabrata* and *Candida parapsilosis* infections, the limited efficacy of echinocandins against *C. parapsilosis* and the reported synergy of caspofungin (Cs) and liposomal amphotericin B (LAB) for treating murine *C. glabrata* infection, we tested this latter combination in a murine *C. parapsilosis* systemic infection to try to improve treatment outcome.

**Methods:** A broth microdilution assay was used to determine the *C. parapsilosis* (ATCC 22019) MIC of LAB (AmBisome®) and Cs (Cancidas®). Swiss Webster mice were challenged i.v. with  $3.5 \times 10^7$  *C. parapsilosis*, and daily treatment initiated 24 hour later with one of the following regimens: 5 or 7.5 mg/kg LAB, 1 mg/kg Cs, 5 or 7.5 mg/kg LAB + 1 mg/kg Cs, 1 mg/kg Cs (d1–3) followed by 5 or 7.5 mg/kg LAB (d4–6), or 5% dextrose (D5W). Day 4, tissues were collected from seven mice/gp, homogenized and used to determine Log<sub>10</sub> cfu/g (Lcfu) by plating on Sabouraud's agar, and to assess drug concentration in spleen, kidneys and heart using a *Candida albicans* agar bioassay. Another seven mice/gp received 6 days of treatment and were monitored for morbidity for 21 days.

**Results:** *C. parapsilosis* MIC for LAB was 0.5 µg/mL and for Cs, 3 µg/mL. Survival with either dose of LAB alone (100%) or combined with Cs (87% for 5 mg/kg LAB+Cs and 100% for 7.5 mg/kg LAB+Cs) was significantly better ( $p < 0.05$ ) than with Cs alone or Cs prior to LAB (14%). D5W mice all died. Fungal burden (Lcfu) for 7.5 mg/kg LAB, with or without Cs, was 5.1–5.3 (spleen), 5.0–5.4 (kidneys), 4.5–4.7 (liver), 5.6–6.4 (heart), 4.4–4.7 (brain). These values were significantly lower ( $p < 0.05$ ) than those for Cs or D5W (spleen 6.6 and 7.1; kidneys 6.3 and 6.9; liver 5.1 and 5.9; heart 7.3 and 7.8; brain 5.2 and 5.3). Mean tissue concentrations were similar for 5 or 7.5 mg/kg LAB (spleen, 1576–1665 µg/g; kidneys, 17–21 µg/g; heart, 3.2–4.5 µg/g) with Cs levels <2.5 µg/g in these tissues.

**Conclusion:** No synergy was observed with the combination of LAB and Cs for the treatment of *C. parapsilosis* infection since LAB alone was as effective as LAB plus Cs in prolonging survival and decreasing

tissue fungal burden. Animals initially treated with Cs for 3 days could not be rescued by switching treatment to LAB.

### P845 In vivo efficacy of voriconazole therapy in an invertebrate model of *Aspergillus fumigatus* infection

A. Forastiero\*, L. Bernal-Martinez, E. Mellado, E. Cendejas-Bueno, M. Cuenca-Estrella, A. Gomez-Lopez (Majadahonda, ES)

**Objective:** To investigate whether the greater wax moth *Galleria mellonella* is an alternative model to assess the in vivo efficacy of voriconazole (VOR) against different strains of *Aspergillus fumigatus*.

**Methods:** A total of 180 larvae of *G. mellonella* in the sixth instar larvae were inoculated with  $10^5$  cfu/larva of different *A. fumigatus* strains, including parental strain (wild type for the gene encoding the azoles target cyp51A, MICVOR 0.5 mg/L) and five isogenics mutants with altered cyp51A which confer changes in antifungal drugs susceptibility (MICVOR ranging between 0.25 and 4 mg/L, EUCAST methodology). Within 120 minutes after infection, different doses of VOR were administered. The doses used were calculated taking into account the therapeutic dose in humans and the MIC values of strains studied. Additional control groups of 50 larvae were also included (untouched, pierced, inoculated with PBS; toxicity control of antifungal and DMSO/water). Larvae were incubated at 37°C and the larval survival was monitored daily considering that the larvae die when they do not respond to touch. Each experiment was performed three times. Survival data were plotted using the Mantel-Cox tests (GraphPad Software Inc) and comparisons between untreated and treated groups were assessed with the Long Rank test ( $p < 0.01$ ).

**Results:** Larval survival was dependent both on the dose and the MICVOR. The  $p$  values show no significant larval survival differences between untreated and treated groups with VOR 1.25 and 2.50 mg/kg/day (subtherapeutic doses), with none of the strains included. When a dose of 10 mg/kg/day was administered, the larval survival increased for all, except for those infected with the VOR resistant strain (MICVOR 4.0 mg/L). In all cases, 80% of infected/untreated larvae died between the 3rd and 4th day, while a 100% survival was observed with therapeutic doses of VOR at the last day of the experiment (7 days). The group of larvae infected with the VOR resistant strain all died on day 4.

**Conclusions:** (i) VOR treatment significantly prolonged the survival of *G. mellonella* caterpillars infected with *A. fumigatus* strains that showed low in vitro MICs compared with the ones showing higher VOR MICs. (ii) *G. mellonella* is a relatively simple, nonmammalian model that can be used to facilitate the in vivo-in vitro correlation studies with antifungals. More studies with a larger number of strains and doses would be needed.

### P846 Activity of posaconazole in invasive fungal infections associated with a variety of moulds and yeasts

S. Haider\*, M. Laverdiere, C. Rotstein, K. Doucette, M. Power, J. Lipton, P. Phillips, A. Galarnau, J.-F. Pouliot (Hamilton, Montreal, Toronto, Alberta, Vancouver, CA)

**Objective:** Invasive fungal infections (IFIs) cause serious complications in immunosuppressed patients. Although *Candida* and *Aspergillus* species (sp) are the most common pathogens, other rare fungi can occasionally be involved. Extensive use of azoles as first line therapy may result in the emergence of less common fungal infections. Posaconazole is a second generation antifungal drug with wide yeast and mould coverage and could play a role in the treatment of these rare infections.

**Methods:** This is a multicenter single arm phase II study of Posaconazole (400 mg BID) in patients with IFIs who have failed or been intolerant to only one prior line of therapy. The primary objectives are safety and efficacy. Safety was evaluated in all patients; efficacy on those who survived more than 7 days.

**Results:** Forty patients were included in the study of which 29 (73%) had proven or probable IFIs. Conditions leading to IFI were AML (31%), stem cell transplant (26%), lung transplant (11%), renal transplant (9%), pulmonary disease (9%) and others (14%). A specific organism could be identified in 30 patients, with *Aspergillus* sp representing the majority of cases (55%). *A. fumigatus* was the most common sp but *A. niger*, *A. flavus* and *A. cervinus* were also found. *Candida* sp accounted for 18% of fungi: *C. albicans*, *C. glabrata* and *C. krusei* were detected. Less common fungi such as mucormycetes (*Rhizomucor* and *Rizopus*), *Coccidioides*, *Exophiala*, *Fusarium* and *Histoplasma* were also identified. Prior therapy included voriconazole (47%), amphotericin B (28%), fluconazole (16%) and others (9%). Patients were either refractory (70%) or intolerant (30%) to these prior therapies. Efficacy could be evaluated in 32 patients at the time of analysis. Response rate in both proven and probable infected patients based on the EORTC criteria was 53% (9% CR and 43% PR); two patients with early death were classified as non responders. The response rates were similar in all patients including those infected with rare fungi and those with possible infections. Safety was assessed in all 40 patients common toxicities reported were: nausea and vomiting (26%), diarrhea (26%), rash (15%), edema (12%) and elevated liver enzymes (9%). No drug related grade 4 toxicities were reported.

**Conclusion:** Several less common fungi were isolated supporting the emergence of rare sp. Posaconazole was equally effective in all patients and may represent a valuable alternative even after prior exposure to other azoles.

**P847 Treatment of candidaemia in patients with haematologic malignancies**

I. Kalinina\*, M. Maschan, N. Myakova, D. Litvinov, G. Klyasova, A. Maschan (Moscow, RU)

Candidemia is a severe complication in children with hematological malignancies leading to a high mortality rate up to 50%. Increasing resistance to azoles of *C. albicans* and prevalence of *C. non-albicans* are two most significant modern trends in candidemia.

**Patients:** Thirty-four patients (24 M/10 F) with median age 6 (0.36–17) years with different malignancies and bone marrow failures developed 43 episodes of candidemia (EC). Systemic antifungal prophylaxis was applied in 35 (82%) before EC, mostly with azoles used in 32 pts. Absolute neutrophil count (ANC) at onset of EC was  $<0.5 \times 10^9/L$  in 26 (60.5%). Clinical manifestations were fever (100%), pneumonia (30%), endocarditis (9.3%), multiorgan failure (7%), septic shock (SS) (4.7%), chronic disseminated candidiasis (4.7%), skin rash (4.7%) and meningitis (2.4%).

**Results:** *C. albicans* was isolated in five pts (eight strains) and *Candida non-albicans* – in 29 pts (36 strains). Twenty (45.5%) strains were resistant to fluconazole: 4/8 (50%) *C. albicans* and 16/36 (44%) *C. non-albicans*. All pts received antifungal therapy (monotherapy 19 EC, combination therapy 24 EC). Central venous catheter (CVC) was removed in 25 (58%) EC. In 21 (49%) EC G-CSF was administered.

**Outcome:** Thirty-seven EC were cured, 6 (14%) patients died. Overall 30 days survival was  $0.7 \pm 0.13$ ; 5-years' OS –  $0.45 \pm 0.09$ . Factors of unfavorable prognosis were: advanced malignancy – 5 death of 10 EC vs 1 death of 33 EC in remission or aplasia after 1-st remission induction ( $p = 0.000$ ), neutropenia at onset of EC: 6 of 26 vs 0 of 17 EC of pts with ANC more and less  $500/mm^3$  respectively ( $p = 0.04$ ), hematopoietic recovery (0 of 35 EC vs 6 of 8 EC with or without recovery, ( $p = 0.000$ ) and CVC removal (1 of 25 EC with CVC removed vs 5 of 18 with CVC remained ( $p = 0.03$ )).

**Conclusion:** Candidemia remains an unresolved issue in pediatric hematology/oncology with high attributable mortality. Most of cases occur in spite of systemic antifungal prophylaxis. Stage of underlying disease, CVC removal and ANC recovery are the main variables influencing survival.

**P848 Correlation between incidence of candidaemia and consumptions of antifungal agents in a medical centre in Taiwan**

K.-L. Kao\*, C.-C. Lai, Y.-T. Huang, P.-R. Hsueh (Taipei, Tainan, TW)

**Background:** To analyze the epidemiology of candidemia and its association with the use of antifungal agents, we review the secular trend and species distribution of candidemia and the consumption of antifungal agents.

**Methods:** Patients with candidemia were identified by central laboratory personnel. The incidences of patients with candidemia were defined as number of patients with candidemia per 1000 inpatient-days, and the incidence of healthcare-associated candidemia (HCAC) was defined as the cases of patients with HCAC per 1000 admissions. Data on annual consumption (defined daily dose [DDD] per 1000 patient-days) of amphotericin B, ambisome, fluconazole, itraconazole, and ketoconazole, from 2000 to 2010 were obtained from the pharmacy department.

**Results:** In this period, a total of 2682 episodes of candidemia were identified. There are 2468 (92%) cases belonged to HCAC and 214 (8.0%) cases were identified as community acquired candidemia. The most prevalent species were *C. albicans* ( $n = 1429, 53.3\%$ ) followed by *C. tropicalis* ( $n = 551, 20.5\%$ ), *C. glabrata* ( $n = 413, 15.4\%$ ), *C. parapsilosis* ( $n = 378, 14.1\%$ ), *C. guilliermondii* ( $n = 46, 1.7\%$ ), *C. krusei* ( $n = 39, 1.5\%$ ). Overall, the incidence of all cases of candidemia remained stable, however, the incidence of *C. parapsilosis* and *C. guilliermondii* fungemia decreased significantly with time. The total incidence of HCAI-candidemia was ranged from 2.66 to 4.27 per 1000 admissions. The consumption of caspofungin, micafungin, and, voriconazole significantly increased, but the consumption of amphotericin remained stable. In contrast, the usage of itraconazole significantly decreased with time. A significant negative correlation was found between the use of echinocandins and voriconazole, and incidence of *C. parapsilosis* fungemia, and the use of caspofungin and the incidence of *C. guilliermondii* fungemia, respectively. In contrast, there are significant positive correlation found between the use of echinocandins and the incidence of *C. tropicalis* fungemia, and the use of azole and the incidence of *C. glabrata*, the use of itraconazole and the incidence of *C. parapsilosis*, and *C. guilliermondii* fungemia.

Correlation between each antifungal agent and the incidence of candidemia caused by each candida species

Candidemia	Total		<i>C. albicans</i>		<i>Non-albicans Candida</i>		<i>C. tropicalis</i>		<i>C. glabrata</i>		<i>C. parapsilosis</i>		<i>C. guilliermondii</i>		<i>C. krusei</i>	
	r	P	r	P	r	P	r	P	r	P	r	P	r	P	r	P

r, the correlation coefficient; Statistically significant association (marked in bold type,  $P < 0.05$ )

**Conclusions:** This 11-year surveillance study in Taiwan showed the incidence of candidemia, including *C. albicans* and non-albicans *Candida* fungemia remains stable, however, the incidence of HCAI-candidemia was higher than in other regions. The impact of each antifungal agent on the incidence of candidemia caused by different *Candida* species is various.

**P849 How low can you go? Use of low- and standard-dose liposomal amphotericin B for treatment of invasive fungal infections at a USA public hospital**

Z. Kassamali\*, L. Danziger, R. Glowacki, D. Schwartz (Chicago, US)

**Objectives:** Recommended doses of liposomal amphotericin B (L-AMB) range from 3 to 6 mg/kg/day but 1 mg/kg/day may be equally effective and a lower cost alternative for many indications. Low dose L-AMB (1 mg/kg/day rounded up in 50 mg increments) has been used for most indications in our urban public hospital. We describe and

compare clinical indications and outcomes of patients receiving low-dose (LD: <2 mg/kg/day) and higher dose (HD: ≥2 mg/kg/day) L-AMB for the treatment of invasive fungal infections.

**Methods:** We reviewed consecutive adult L-AMB recipients with probable and proven infections per EORTC/MSG 2008 criteria at a single center from 2006 to 2011.

**Results:** Of 98 adult L-AMB recipients, 38 with proven or probable infections met inclusion criteria. Twenty (53%) received LD and 18 (47%) received HD L-AMB; median doses were 1.5 and 3.0 mg/kg, and median duration of therapy was 8.5 and 8.0 days respectively. Baseline characteristics including ICU admission, need for mechanical ventilation, vasopressors and/or inotropes were similar between the two groups. LD subjects more commonly had HIV/AIDS and a history of invasive fungal disease. Meningitis and pneumonia were the most common sites of infection in both groups. *Cryptococcus* was the most common fungal pathogen (40%) in the LD group whereas *Candida* sp. were more common in the HD group (44%). Other fungal pathogens included *Aspergillus*, histoplasma, blastomyces, coccidioides, and zygomycetes. Fifty percent of subjects in both groups improved clinically. Reasons for failure by frequency of occurrence in both groups were: worsening or absence of improvement, requirement for L-AMB dose escalation, persistent positive cultures, and hospital readmission for the same indication. L-AMB was discontinued to consolidate to azole therapy in 70% of the LD and 50% of the HD groups. Seventy percent and 78% of subjects in the LD and HD groups respectively survived to discharge. Rates of nephrotoxicity and hypokalemia were comparable. Median cost of therapy, based on drug acquisition cost, was \$1140 in the LD and \$2058 in the HD groups.

**Conclusion:** We found comparable rates of clinical improvement and survival to discharge using LD vs. HD L-AMB. LD L-AMB has been an effective and cost-saving treatment option for common invasive fungal infections in our institution.

#### **P850** Impact of an antifungal stewardship programme in a teaching hospital: a prospective study

V. Mondain, F. Lieutier, M. Gari-Toussaint, L. Hasseine, C. Lions, C. Pulcini\* (Nice, Marseille, FR)

**Objectives:** A multifaceted antifungal stewardship program has been in place in our teaching tertiary-care hospital since 2005, with several actions implemented successively, including systematic evaluation of all costly antifungal prescriptions (echinocandins, lipid formulations of amphotericin B, posaconazole and voriconazole). We assessed the impact of this program on antifungal prescriptions and cost (between 2003 and 2010), and on standards of care regarding the management of invasive aspergillosis and candidemia.

**Methods:** We conducted a prospective observational study over an 8-year period.

**Results:** Six hundred and thirty-six antifungal prescriptions were discussed by the antifungal management team from 2005 to 2010, mainly from the haematology department (72%). In 344/636 (54%) cases, a piece of advice was fed back in real time to the physician in charge of the patient, with an 88% compliance rate. Optimal standard of care was achieved for performance of chest CT-scan, galactomannan antigen testing and voriconazole therapeutic drug monitoring for invasive aspergillosis, with no antifungal combination therapies used since 2008. Regarding candidemia, optimal standard of care was achieved for timing of antifungal therapy, recommended 1st-line therapy, duration of therapy and removal of central venous catheters. Antifungal prescriptions and cost were stable between 2003 and 2010.

**Conclusion:** Implementation of an antifungal stewardship program was feasible, sustainable and well-accepted, and we observed an improved quality of care and no increase in antifungal use or cost.

#### **P851** Liposomal amphotericin B in ICU patients with continuous renal replacement therapy

M. Rodríguez\*, M.C. Soriano, M. Catalán, A. Llorente, N. Vidart, M. Garitacelaya, E. Maraví, E. Fernández Rey, F. Alvarado, M. López Sánchez, B. Álvarez, D. Granado, E. Quintana, F. Álvarez-Lerma and the Study Group of Liposomal Amphotericin B

**Objective:** To assess the effectiveness of liposomal amphotericin B (L-AmB) in ICU patients with continuous renal replacement therapy.

**Methods:** An observational, retrospective and multicenter study was conducted in critically ill patients with continuous renal replacement therapy, treated with L-AmB for at least 3 days. Patients with renal replacement therapy before or within 48 hour after starting L-AmB were included. The primary endpoints were both clinical and microbiological response. Demographics, underlying illness, APACHE II score, fungal infectious disease, use of antifungals, and vital status at ICU and hospital discharge were collected.

**Results:** A total of 36 patients recruited in 16 ICUs were included (range: 1–8). L-AmB was mainly selected because of broad spectrum of the drug and hemodynamic instability of the patients. The mean age of the patients was 47 years, and the majority was men (26 out of 36; 72%). The mean APACHE II score was 21.4 ± 8.8 at the start of L-AmB treatment. Related to infection the reasons for L-AmB use were proven (38.9%), probable (16.7%), possible (16.7%) fungal infection or clinical suspicious (27.8%). Roughly half of the patients had received previous treatment with antifungals (55.6%). The median duration of L-AmB treatment was 13.5 days (range: 4–42), with most patients treated for seven or more days (4 out of 36; 88.9%), and the L-AmB median daily dose was 4.8 mg/kg/day (range: 2.8–7.0). The main reasons for renal replacement therapy were uraemia (47.2%), fluid retention (41.7%) and metabolic acidosis (22.2%). The median time of ICU and hospital stay were 28 and 48 days, respectively. *Candida* spp was present in 73% (19 out of 26) of those patients in whom a fungal species was isolated and *Aspergillus* spp was in 3 out of 26 patients (11.5%). Related to clinical response 66.1% responded to treatment (complete and partial response) and microbiological response was observed in 85.7% of patients with proven infection. Twenty-two out of 36 patients survived (61.1%) and 64.3% of deaths were unrelated to fungal infection.

**Conclusions:** Clinical and microbiological responses of critically ill patients with continuous renal replacement treated with L-AmB were very similar to those already described in ICU patients without it. Although this is a small sample it seems that L-AmB is also effective in ICU patients with continuous renal replacement therapy.

#### **P852** Substudy of the multicentre, retrospective study to evaluate renal function in patients with chronic obstructive pulmonary disease admitted to intensive care units and treated with liposomal amphotericin B

M. Rodríguez\*, M.C. Soriano, M. Catalán, A. Llorente, N. Vidart, M. Garitacelaya, E. Maraví, E. Fernández Rey, F. Alvarado, M. López Sánchez, B. Álvarez, D. Granado, E. Quintana, F. Álvarez-Lerma and the Study Group of Liposomal Amphotericin B

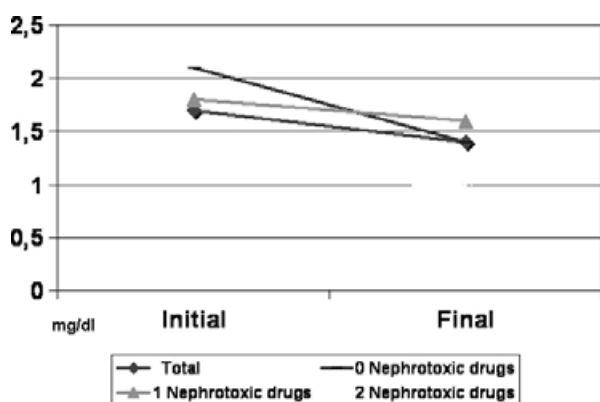

**Objective:** To assess the renal safety of L-AMB in patients with COPD admitted to ICUs in Spanish hospitals.

**Materials and methods:** This is a study of patients admitted to ICU and treated with L-AMB for any reason for at least 3 days during 2008–2009 and 2006. A “study case” was defined as any patient with COPD who had not undergone extrarenal clearance during L-AMB treatment.

**Results:** A total of 37 patients from 21 ICUs were included. On admission, the mean Apache II score was 21.4 (7.5). At the start of L-AMB therapy, 100% of patients had a central venous line and bladder catheter, 89.2% had received antibiotics in the previous 7 days, 84.2%

had an arterial line, 86.5% required mechanical ventilation, and 62.2% needed total parenteral nutrition.

L-AMB was used mainly due to its broad spectrum and the patients' hemodynamic instability and was administered as first-line therapy in 21 patients (56.8%). The mean course of L-AMB was 12.2 (5.9) days and the mean dose was 3.1 (1.0) mg/kg/day. At the start of L-AMB therapy, creatinine was  $\leq 1.5$  mg/dL in 64.9% (24/37) of patients. By the end of treatment, 91.7% of patients with baseline creatinine  $\leq 1.5$  mg/dL still had  $\leq 1.5$  mg/dL. The mean baseline creatinine was 1.71 (1.5) mg/dL, but dropped to 1.40 (1.0) mg/dL by the end of treatment ( $p = 0.089$ ) (Figure 1). In terms of percentages, creatinine had dropped or held steady in 67.57% of patients by the end of treatment. Although 66.7% (24/36) of patients were receiving concomitant nephrotoxic drugs, a two-fold increase in creatinine compared to baseline was observed in only 2 (5.41%) patients. No patients discontinued the treatment for nephrotoxicity or another reason, and there were no serious adverse events.

**Conclusions:** Patients with COPD admitted to ICU experienced no renal impairment during L-AMB therapy and there were no discontinuations due to renal toxicity despite the use of concomitant nephrotoxic drugs. Although the patient sample was small, the data suggest that L-AMB can be safely administered to critical patients with COPD.

**P853** **Costs of posaconazole compared to standard prophylaxis in patients with a high-risk of invasive fungal diseases: an economic analysis from the Cologne cohort of neutropenic patients**

S. Heimann\*, O.A. Cornely, H. Wisplinghoff, M. Vehreschild, B. Franke, J. Glossmann, J.-J. Vehreschild (Cologne, DE)

**Background:** Controversy exists about the cost effectiveness of posaconazole prophylaxis in neutropenic patients with a high risk of invasive fungal diseases. We performed an analysis comparing the direct costs of posaconazole prophylaxis against topical polyene (thrush) prophylaxis in patients with acute myelogenous leukemia (AML) and myelodysplastic syndrome (MDS).

**Methods:** Data of AML/MDS patients receiving remission-induction chemotherapy were extracted from the Cologne Cohort of Neutropenic Patients (CoCoNut) to compare hospital costs of patients before (2003–2005) and after (2006–2008) introduction of posaconazole prophylaxis. All cases were part of an earlier analysis demonstrating effectiveness of posaconazole over topical prophylaxis (Vehreschild et al., J Antimicrob Chemother. 2010 July; 65[7]:1466–71). Duration on general ward, intensive care unit, mechanical ventilation, diagnostic procedures and all anti-infective drugs were included into the cost analysis.

**Results:** Patient groups were well matched according to age, gender, underlying disease, and duration of neutropenia. The mean costs per patient in the posaconazole group ( $n = 76$ ) and the topical polyene group ( $n = 81$ ) were 23 235 (95% CI: 19 722–26 749) and 26 531 (95% CI: 21 887–31 175) per patient, respectively. Average daily

treatment costs were 495 (95% CI: 434–555) and 508 (95% CI: 433–582). Antifungal treatment costs were nominally lower in the posaconazole group (6773 [95% CI: 5187–8360] vs. 7419 [95% CI: 5062–9775]). The costs for other anti-infectives were also numerically decreased in the posaconazole group (4845 [95% CI: 4019–5671] vs. 5402 [95% CI: 4507–6297]). Average duration of ICU stays were 1.79 (95% CI: 0.68–2.90) days per patient for the posaconazole group compared to 3.83 (95% CI: 1.53–6.13) days per patient in the topical polyene group. Costs for diagnostic procedures were 611 (95% CI: 478–744) and 653 (95% CI: 552–754) per patient, respectively.

**Conclusions:** In our hospital, there was a trend towards cost-saving by posaconazole prophylaxis in patients receiving remission-induction chemotherapy. These cost savings were demonstrated in all aspects taken into consideration, including overall treatment costs as well as cost of anti-infective and antifungal medication.

**P854** **Cost analysis of candidaemia in patients on the intensive care unit**

S. Heimann\*, O.A. Cornely, H. Wisplinghoff, M. Vehreschild, B. Franke, J. Glossmann, J.-J. Vehreschild (Cologne, DE)

**Objectives:** Direct costs caused by candidemia in ICU patients are currently unknown. We performed an analysis comparing costs depending on the type of antifungal treatment.

**Methods:** Comprehensive data of patients from the University Hospital of Cologne with at least one blood culture positive for *Candida* spp. while staying on the ICU between 2005 and 2010 were documented into a database provided by the Cologne Cohort of Neutropenic Patients (CoCoNut). Analysis was split for patients treated with new (i.e. echinocandins, liposomal amphotericin B, or voriconazole) or conventional antifungals (i.e. amphotericin B deoxycholate or fluconazole).

**Results:** Out of 120 patients identified, 41 received new and 55 conventional antifungals; 24 patients were excluded (19 died within 96 hours after positive blood culture, five were rated as contamination). Both groups were well matched by age and baseline intubation status. Mean durations of medical care per patient in the new and conventional antifungal groups were as follows: ICU treatment 21.5 days (95% CI: 15.2–27.9 days) vs. 13.7 days (95% CI: 9.4–17.9 days), general ward treatment 10.12 days (95% CI: 5.3–15 days) vs. 9.2 days (95% CI: 5.3–13.2 days), mechanical ventilation 474 hour (95% CI: 323–624 hour) vs. 304 hour (95% CI: 197–410 hour), and dialysis: 31.5 hour (95% CI: 9.6–53.3 hour) vs. 39.7 hour (95% CI: 16.0–63.4 hour). Mean direct costs per patient in the new and the conventional antifungal groups were as follows: ICU treatment 27 291 (95% CI: 19 282–35 300) vs. 17 188 (95% CI: 11 783–22 593,  $p = 0.032$ ), antifungal treatment 4916 (95% CI: 3595–6238) vs. 1812 (95% CI: 866–2758,  $p < 0.001$ ), total direct costs 44 451 (95% CI: 33 157–55 745) vs. 27 844 (95% CI: 19 968–35 720,  $p = 0.014$ ).

**Conclusion:** Our cost-of-illness analysis shows the high treatment costs of patients with candidemia. Actual antifungal drug costs play a minor role compared to the substantial costs of clinical and supportive care. In our analysis, treatment with new antifungals was associated with higher costs and a longer period of hospitalisation. However, as new antifungals are often considered less toxic, less interacting, better tolerated, and/or more effective, there may have been a treatment bias towards sicker patients more likely receiving treatment with these drugs.

**P855** **Pharmacokinetics of intravenous itraconazole followed by itraconazole oral solution in patients with candidaemia**

H. Mikamo\*, Y. Yamagishi (Nagakute, JP)

**Background:** According to various clinical practice guidelines, antifungals should be administered at least for 14 days after fungal eradication in candidaemia. However, step down therapy from

intravenous to oral antifungal agent might be also recommended from the aspect of pharmacoeconomics.

**Methods:** This randomized, open-label, comparative study assessed the pharmacokinetics and safety of intravenous itraconazole (ITCZ) and oral ITCZ solution in patients with candidaemia caused by *Candida* species with MIC level of under 0.125 mg/L. All patients received ITCZ, 1-hour intravenous drip infusions at the dose of 200 mg twice daily for 2 days, following 200 mg once daily for 8 days. Then, patients were randomized to receive ITCZ oral solution, 200 mg twice daily or 200 mg once daily, for further 14 days. Twenty-one patients were enrolled and analyzed (n = 6 for oral twice daily, n = 5 for once daily). ITCZ and hydroxyitraconazole (OH-ITCZ) plasma concentrations at day 10 and 15 after the first ITCZ administration were assayed with HPLC method.

**Results:** At the final intravenous dosing (day 10), mean trough plasma concentrations of ITCZ and OH-ITCZ were 910 ng/mL and 1720 ng/mL, respectively. During oral dosing, mean trough plasma concentrations of ITCZ and OH-ITCZ were increased in the ITCZ 200 mg twice-daily group, however, almost maintained in the ITCZ 200 mg once-daily oral dose. ITCZ was generally well tolerated and had a favorable safety profile in this study.

**Conclusions:** ITCZ 200 mg given intravenously twice daily for 2 days, following once daily for 8 days, then ITCZ oral solution, once daily for 14 days, would maintain ITCZ trough concentration in the level of over 250 ng/mL, which would be lead to good clinical outcome and low recurrent rate for candidaemia.

#### P856 Pre-emptive/targeted prophylaxis with voriconazole in lung transplant patients: a retrospective cohort study

C.F. Neoh, G. Snell, B. Levvey, T. Kotsimbos, O. Morrissey, M. Slavin, K. Stewart, D. Kong\* (Melbourne, AU)

**Objective:** Invasive fungal infection is one of the major complications, contributing to high mortality and morbidity among lung transplant (LTx) patients. Data for voriconazole use in pre-emptive/targeted prophylactic setting remain scant. This study aimed to investigate the efficacy and safety of voriconazole pre-emptive/targeted prophylaxis among LTx patients once airway fungal colonisation was confirmed.

**Methods:** A retrospective, single-centre, observational cohort study was conducted. All adult LTx patients who received voriconazole pre-emptive/targeted prophylaxis for the first time between July 2003 and June 2010 were followed up for 1 year. Outcomes were determined at 6 months (primary end-point) and at 12 months after initiation of voriconazole prophylaxis. Chi-square test was used to assess the relationships between variables and outcomes (i.e. fungal infection, *Aspergillus* colonisation, death and drug-related hepatotoxicity). Cumulative survival rate at 12-month after initiation of prophylaxis were estimated using the Kaplan–Meier method.

**Results:** A total of 62 LTx patients were included. *A. fumigatus* (75.8%) was the most common colonising isolate. Median duration of voriconazole prophylaxis was 84 days. At the 6-month end-point, one (1.6%) had developed probable fungal pneumonia, 48 (77.5%) had successful eradication of colonisation, three (4.8%) had persistent colonisation, six (9.7%) had recurrent colonisation, two (3.2%) had aspergilloma and two (3.2%) were clinically unstable but no culture was performed. Sixteen (25.8%) had died by the 12-month end-point, half due to Bronchiolitis Obliterans Syndrome. Ten (16.1%) had drug-related hepatotoxicity. Patients with diabetes mellitus within 30 days before commencing voriconazole prophylaxis (OR: 8.4, 95% CI: 2.1–33.4, p = 0.003) were at higher risk for *Aspergillus* colonisation at 12-month end-point. Preliminary analyses suggest that acute rejection (OR: 4.9, 95% CI: 1.2–19.4, p = 0.026) and chronic rejection (OR: 6.5, 95% CI: 1.3–31.5, p = 0.022) within 30 days prior to voriconazole prophylaxis were significantly associated with 12-month mortality. LTx patients older than 55 years old were 5.9 times more likely to have hepatotoxicity after initiation of prophylaxis (95% CI: 1.1–30.6, p = 0.036).

**Conclusions:** Voriconazole pre-emptive/targeted prophylaxis resulted in low incidence of fungal infection and fungal infection-related mortality in adult LTx recipients, and was generally well-tolerated.

#### P857 Impact of testing posaconazole plasma concentrations on epidemiology of antifungal prophylaxis and therapy in patients with haematologic malignancies: case-control study

M. Hoenigl\*, K. Seeber, R. Raggam, T. Valentin, A. Valentin, A. Strohmaier, I. Zollner-Schwetz, A. Woelfler, A. Grisold, W. Linkesch, R. Krause (Graz, AT)

**Objective:** Therapeutic drug monitoring (TDM) has shown useful for oral antifungal agents in patients with hematologic malignancies. The effect of introduction of TDM on prescribing praxis is unknown. We evaluated the impact of posaconazole TDM on antifungal prophylaxis and therapy.

**Methods:** Applied antifungal prophylaxis and therapy were assessed in patients with underlying hematologic diseases by conducting a prospective observational single-centre study at the Division of Hematology, Medical University of Graz, Austria, for 7 months in 2010. To analyze the impact of PPC testing on antifungal prophylaxis and therapy results obtained were compared to a representative collective of patients assessed by the same investigators at the same institution over 7 months in 2007 before testing of posaconazole plasma concentrations (PPCs) has been introduced.

**Results:** In 2010, 129/729 (18%) of cases with hematologic malignancies received systemic antifungal prophylaxis and therapy. Of those, fifty-seven percent received prophylactic, 44% empiric, 30% preemptive and 6% directed antifungal therapy. Main reasons for prophylaxis were neutropenia in AML patients (40/74; 54%), followed by GVHD (18/74; 24%) and allogeneic HSCT (16/74; 22%). Eleven out of 39 (28%) cases receiving preemptive therapy had clinical/radiological and microbiological evidence of IFI, 26/39 (67%) had clinical/radiological and 2/39 (5%) only microbiological evidence of

anisulafungin	0	1/129 (1%)

**Note:**

<sup>a</sup> Significant difference between 2007 and 2010 in patient collective with antifungal therapy  
P < 0.05

<sup>b</sup> Data from 2007 previously published (11)

IFI. In 2010 posaconazole was the most commonly administered antifungal agent followed by caspofungin which had been the leading antifungal agent at the study site in 2007. Posaconazole usage increased significantly after introduction of posaconazole TDM when compared to 2007 ( $p < 0.05$ ). Concerning prescription rates of antifungal agents other than posaconazole no significant difference was found. In both study collectives (2007 and 2010) posaconazole was the primary antifungal agent used for prophylaxis, while itraconazole was used mainly in allogeneic HSCT. Demographic data, chemotherapeutic approach and antifungal modalities for cases receiving antifungal therapy in 2007 and 2010, respectively, are depicted in Table 1.

**Conclusion:** We found a significant increase of posaconazole usage after introduction of posaconazole therapeutic drug monitoring (TDM). As TDM was available for posaconazole only, the feasibility of monitoring plasma concentrations may have influenced the selection of this antifungal agent in clinical routine.

**P858** **Posaconazole plasma concentrations and invasive mould infection in patients with haematologic malignancies: a cohort study**

M. Hoenigl\*, R. Raggam, T. Valentin, H. Salzer, A. Valentin, A. Woelfler, K. Seeber, A. Strohmeier, I. Zollner-Schwetz, A. Grisold, H. Sill, R. Krause (Graz, AT)

**Objectives:** Posaconazole is a new triazole antifungal agent that has broad activity against pathogenic fungi and is increasingly used for prophylaxis and treatment of invasive mould infections (IMI). Posaconazole is available only as oral formulation with varying absorption from the gastro-intestinal tract. Reports correlating posaconazole plasma concentrations (PPCs) with breakthrough IMI, however, are rare.

**Methods:** We analyzed posaconazole plasma concentrations (PPCs) in a prospective observational single-centre study in 2010 and evaluated correlation of PPCs with breakthrough IMI in patients with hematological malignancies. We further evaluated risk factors associated with low PPCs.

**Results:** A total of 109 PPCs were measured in 34 patients receiving posaconazole prophylaxis ( $n = 31$ ) or treatment ( $n = 3$ ). Insufficient levels were detected in 24/34 (70%) of patients; in 15 of these 24 patients concentrations were found under the limit of detection ( $< 0.20 \mu\text{g/mL}$ ). Insufficient PPCs yielded either way in a modification of intake procedures, discontinuation of PPIs or switch of antifungal therapy. In 12 of these 24 cases with insufficient PPC, modification of intake – i.e. with a high fat meal – led to sufficient PPCs. As discontinuation of PPIs led to an improvement of PPC levels in only 1/24 cases, antifungal therapy had to be switched due to insufficient PPCs in another five cases. In three patients with insufficient PPCs, antifungal therapy had to be changed from posaconazole prophylaxis to echinocandin empiric treatment due to development of febrile neutropenia, these patients did not fulfil IFI criteria.

Three patients on posaconazole prophylaxis met the criteria of breakthrough infection. Prior to development of invasive fungal infection (IFI), however, PPCs were insufficient in all three patients.

Fungal species	Posaconazole MIC (mg/L)	Patient's age years/sex	Specimen of fungal detection	Days of posaconazole prophylaxis before breakthrough infection	Last posaconazole plasma level before diagnosis of IMI (days before diagnosis)	Antifungal therapy after IMI diagnosis	Outcome
<i>Aspergillus fumigatus</i>	0.032	58f	BAL	8	0.28 $\mu\text{g/ml}$ (3)	Venconazole	Died
<i>Aspergillus</i> spp.	n.a.	20m	BAL/Serum	23	<0.20 $\mu\text{g/ml}$ (4)	Venconazole	Survived
<i>Geotrichum argillaceum</i>	0.25	52m	BAL/Blood culture	>60	0.31 $\mu\text{g/ml}$ (7)	Venconazole, EpAmph B	Died

Details are depicted in table 1. Associated risk factors for insufficient PPCs varied from previous reports.

**Conclusion:** These data demonstrate that therapeutic drug monitoring (TDM) of posaconazole is mandatory in all patients with hematological malignancies as low PPCs are common and may be associated with development of IFI.

**P859** **Gentian violet can be used as topical oral anti-fungi and anti-stigma agent by people living with HIV/AIDS**

E. Agwu\*, J. Inyang, J. Ihongbe (Ishaka, UG; Ekpoma, NG)

**Background:** The challenges of poor reduction of oral fungal load are complicated by rampant report of refractile (Multidrug resistant) oropharyngeal Candidiasis, permitting the need to search for possible alternative to current treatment regimen.

**Objective:** To demonstrate a concentration of gentian-violet effective against oral yeasts but not stigmatize the patients by painting the mouth with blue/violet.

**Methods:** Department of Microbiology, Kampala International University, supplied for this investigation, the 148 (100 *Candida albicans*, 10 *Candida glabrata*, 10 *Candida norvegensis*, 6 *Candida parapsilosis*, 6 *Zygosaccharomyces* species, 5 *Candida tropicalis*, 5 *Saccharomyces cerevisiae*, 3 *Candida sake* and 3 *Saccharomyces kluyveri*) clinical oral yeast samples previously recovered from the oral lesions of HIV/AIDS patients attending clinics in South-Western Uganda. Standard methods were used to test the serially diluted 0.5% gentian violet solutions against the oral yeasts.

**Results:** It was observed that 1:32 was the least dilution of 0.5% gentian-violet which was able to give the minimum sensitive 14 mm zone diameter according to CLSI with *Candida albicans*. Again 14 mm zone diameter was obtained from 1:10 dilution of *C. glabrata* and *C. sake*; while 1:8 dilutions of *C. tropicalis*, *C. norvegensis*, and *C. sake* respectively. Topical (1:32 dilution of 0.5% GV) antifungal alternative is cheap, available and will not stain the mouth thus removing associated stigma.

**Conclusion:** Therefore, 1:32 dilution of 0.5% gentian-violet can be used as topical anti-*Candida albicans* and 1:8 dilution of GV as topical-anti-non *Candida albicans* respectively. This assures the efficacy, availability and sustainability of oral fungal lesions treatment in resource poor setting.

**P860** **Intrafungal concentration of posaconazole**

F. Farowski\*, A. Hamprecht, C. Müller, A. Steinbach, J.J. Vehreschild, M.J.G.T. Vehreschild, O.A. Cornely (Cologne, DE)

We recently showed that various antifungal drugs, i.e. anidulafungin, micafungin, and posaconazole, accumulate within cells of the peripheral blood. The ratio between the cellular and the extracellular (C/E) concentration depends on the composition, i.e. the protein concentration, of the surrounding medium. However, the composition of the surrounding medium might also influence the antifungal concentration within the fungi themselves and significantly contribute to the efficacy of these drugs. Hence, we currently develop a method to determine intrafungal antifungal concentrations. We present data on the "intrafungal concentration" of posaconazole within *Candida albicans*.

**Method:** Suspensions of *Candida albicans* were prepared in RPMI-1640 medium and incubated with different concentrations of posaconazole (33–990 ng/mL). Following an incubation period of 1 hour the drug was removed by two consecutive washings with sterile water. Afterwards, cell counts were determined using a Neubauer chamber and samples were stored at  $-80^{\circ}\text{C}$  until use. The intrafungal concentrations were determined by a chromatography tandem mass spectrometry (LC-MS/MS) method similar to the previously described method for the quantitation of different antifungals within human peripheral blood cells. An additional step to concentrate the samples was added to increase the sensitivity of the method.

**Preliminary results:** The method is feasible to detect antifungal concentrations as low as 0.5 ng/10<sup>6</sup> cells. The accuracies of all concentrations were within ± 15%. For posaconazole the intra-fungal concentration within *Candida albicans* correlated with the concentration of the medium; however a saturation of the intrafungal concentration was observed (2 ng/10<sup>6</sup> cells).

**Conclusion:** To our knowledge, we established the first method to quantitate intrafungal antifungal drug concentrations by LC-MS/MS. The limit of quantification is sufficient for the expected concentrations.

#### **P861 Invasive aspergillosis in liver transplant recipients in the antifungal targeted prophylaxis era**

I. Hoyo, C. Cervera, M. Bartoletti, G. Sanclemente, L. Linares, J. Puig de la Bellacasa, J. Colmenero, A. Escorsell, M. Navasa, A. Moreno\* (Barcelona, ES)

**Background:** Invasive aspergillosis is a devastating complication affecting liver transplantation. Risk factors have been widely described and the use of antifungal prophylaxis seems to be justified in high-risk scenarios. Our aim is to evaluate the characteristics and incidence of IA in the era of antifungal targeted prophylaxis.

**Methods:** All liver transplants recipients from July 2003 to December 2009 were included. Pre, peri and post-transplant variables were reviewed. Proven or probable invasive aspergillosis was defined according to the EORTC/MSG. Categorical variables were compared with the chi-square test or Fischer's exact test. Backward step logistic regression analysis was used for multivariate analysis.

**Results:** A total of 556 patients were evaluated. Overall, 135 patients (24%) fulfilled criteria of high-risk LT, in whom 57 (42%) antifungal prophylaxis was administered. In the study period, 16 patients developed IA (3%) with mortality related to IA in eight patients (50%). According to the presence of risk factors, 8.1% of high-risk LT developed IA vs 1.2% of patients without risk factors ( $p < 0.001$ ). Five out of 16 cases of aspergillosis occurred in patients without criteria for high-risk LT. Most patients (38/59, 64%) received amphotericin B for antifungal prophylaxis. The incidence of IA from 2003 to 2009 was: 2.1%, 1.3%, 2.3%, 5.2%, 4.4%, 1.1%, 3.6% ( $p = 0.348$ ). The species isolated from cases with IA were: *A. fumigatus* 11, *A. terreus* 4, *A. niger* 2, *A. flavus* 1 (two patients had coinfection with two species). Twelve cases of IA occurred in the first 3 months after transplantation of which 11 (fulfilling high risk criteria) could have been prevented with antifungal prophylaxis. Of these 12 patients, two received no prophylaxis, five intravenous amphotericin B, one nebulized amphotericin B, and two fluconazole. Breakthrough aspergillosis occurred in five patients under prophylaxis with amphotericin B. A multivariate analysis adjusted by age and gender show that urgent transplantation (OR 9.2, 95%CI 2.2–38.3) and post-transplant reoperation (OR 5.9, 95%CI 1.9–18.0) were the main risk factors for the development of IA.

**Conclusions:** The incidence of IA in LT has not decreased along time. High-risk definitions for LT were associated with higher risk of IA. We detected 5 out of 12 preventable IA that occurred during or after prophylaxis with amphotericin. Reevaluation of antifungal prophylaxis in LT is warranted.

#### **P862 Recategorisation of reasons for premature discontinuation of antifungal prophylaxis in the IMPROVIT study – focus on IFI-related reasons**

H. Schlamm\*, E.J. Bow, O.A. Cornely, M. Slavin, M. Roden, P. Biswas (New York, US; Manitoba, CA; Cologne, DE; Melbourne, AU; Severna Park, Colledgeville, US)

**Objectives:** In the recently published IMPROVIT study, which compared voriconazole (VOR) to itraconazole (ITR) for antifungal prophylaxis (AFP) after allogenic HSCT, 251/465 (54%) subjects prematurely discontinued within 100 days, primarily for intolerance or toxicity. There were two cases in which AFP was discontinued because of proven or probable IFI, both had received ITR. This analysis further

categorized the reasons for premature discontinuation of prophylaxis in this study, with a focus on IFI-related reasons.

**Methods:** The DRC (OAC, EJB, MS) reviewed data (blinded to study treatment) from all subjects who prematurely discontinued AFP and adjudicated the primary reason for discontinuation using the following categories: proven, probable or possible IFI (using 2002 or 2008 MSG/EORTC criteria), suspected IFI (evidence of IFI not meeting criteria for possible IFI), persistent fever and neutropenia, gastrointestinal intolerance, LFT abnormality, other drug toxicity, progression of underlying disease, other medical condition, administrative reason, or unable to assess.

**Results:** Following are the proportion of subjects who discontinued AFP for the following reasons (VOR vs ITR): Probable or possible IFI: 2 (0.9%) vs 18 (7.5%),  $p < 0.01$ ; Suspected IFI or persistent fever and neutropenia: 8 (3.6%) vs 11 (4.6%), NS; Gastro-intestinal intolerance: 4 (1.8%) vs 45 (18.7%),  $p < 0.001$ ; LFT abnormality: 45 (20.1%) vs 15 (6.2%),  $p < 0.001$ ; Other toxicity: 9 (4.0%) vs 1 (0.4%),  $p < 0.01$ ; Progression of disease: 5 (2.2%) vs 2 (0.8%), NS; Other medical condition: 20 (8.9%) vs 26 (10.8%), NS; Other reason/unable to assess: 11 (4.9%) vs 29 (12.0%),  $p < 0.01$

**Conclusion:** In this retrospective analysis of the IMPROVIT study, more allo HSCT recipients prematurely discontinued AFP with ITR because of IFI-related reasons than previously thought. Broader definitions of IFI-related reasons for discontinuation should be incorporated in future clinical trials of AFP.

#### **P863 Isavuconazole is widely distributed in rat tissue**

A. Schmitt-Hoffmann\*, W. F. Richter (Basel, CH)

**Objectives:** To assess tissue distribution of 14C/3H-BAL8557, a prodrug of BAL4815 (isavuconazole), a novel, broad-spectrum triazole active vs moulds/yeasts, in phase 3 trials for treatment of invasive fungal infections, using quantitative whole body autoradiography (QWBA) in rats. The 14C label was in the active drug moiety and the 3H label was in the pro-moiety.

**Methods:** Male rats received a single IV infusion of 3 mg/kg double-labelled BAL8557 and were sacrificed at 0.5, 8, 24, 72, and 144 hour post dose. QWBA used separate specific detection of 14C and 3H radioactivity; total radioactivity in blood and plasma was analyzed by liquid scintillation counting; urine was collected to assess renal excretion of both radioactive isotopes.

**Results:** 14C radioactivity was widely distributed, with maximum concentrations at 0.5 hour post dose in nearly all tissues. All tissues except eye lens had tissue/plasma concentration ratios above unity, with highest levels found in the adrenal cortex (6.92 mcg equiv/g) and liver (6.14 mcg equiv/g)—tissue/plasma concentration ratios of 15.2 and 13.5, respectively. High levels of 14C radioactivity (tissue/plasma ratios >5) were found in the small intestinal mucosa, brown fat, Harderian gland, pancreas, intra-orbital lacrimal gland, kidney cortex, adrenal medulla, stomach mucosa, and thyroid. Lung/brain plasma ratios at 0.5 hour postadministration were 2.28/1.86, respectively. 14C radioactivity in tissue declined by a factor of 5 at 8 hour post infusion; only adrenal medulla and liver contained quantifiable levels (>0.02 mcg equiv/g) at 144 hour. 3H radioactivity was widely distributed at 0.5 hour and tissue levels declined rapidly, with all tissues containing low/non-detectable 3H radioactivity by 8 hour, except intestinal contents and kidney. Excretion was almost complete within 144 hour, with ~80% 14C radioactivity recovered in bile/faeces and 20% in urine. Tritium levels in blood declined rapidly, with 1.88 and 0.087 mcg equiv/mL at 0.5 and 24 hour post dose, respectively. 3H activity was rapidly eliminated, with no indication of relevant retention in tissues and ~86% recovered in urine; the remainder recovered in faeces/bile within 144 hour. 3H radioactivity was rapidly eliminated from tissues and 14C radioactivity was distributed in most tissues, with no indication of tissue-specific retention of either label.

**Conclusions:** These results show that isavuconazole is widely distributed in tissue, including eye and brain.

**P864** Fibrillar – a novel antifungal delivery method: most unusual case of *Aspergillus fumigatus* empyema and bronchopleural fistulae after right-sided pneumonectomy, treated successfully by innovative salvage therapy

A. Guleri, A. Duncan, M. Hassan, T. Al-Badawi\*, M. Purohit (Blackpool, UK)

**Background:** We present a most unusual and challenging case of *Aspergillus fumigatus*[AF] empyema and bronchopleural fistulae after right sided pneumonectomy. The topography and expanse of fungal growth within the chest cavity made drug delivery and sustained exposure to antifungal agent a challenge. Literature search/consultation with experts was of limited benefit. An innovative and novel antifungal delivery method was planned as a salvage to treat the infection.

**Case Study:** A 52-year old gentleman, heavy smoker for 35 years, was hospitalised with chest symptoms and diagnosed with right upper lobe mass. He underwent an elective pneumonectomy. Histology showed well differentiated squamous cell carcinoma, T3N1M0. His postoperative period was complicated by development of a bronchopleural fistula. An Elossier flap (open stoma) was created to drain the space. This followed long term follow up review in outpatient clinic. In February 2010, review in clinic revealed the presence of thick layer of deposit with a green sheen visible through Elossier flap on the inner wall of chest cavity. Tissue samples for culture isolated pure growth of *Aspergillus fumigatus*. Systemic treatment with voriconazole did not clear the fungus.

Salvage therapy was planned, discussed with patient and consent obtained. Access to inside of chest cavity through Elossier flap, debridement of thick layer of deposit and amphotericin powder insufflation to cover pleural surface. This was packed with Fibrillar [haemostat] to allow sustained exposure to amphotericin. The patient had four such procedures and systemic posaconazole 400 mg q12h po was continued postoperatively. He made slow but good progress and increased some weight by April 2010. He was kept on long term posaconazole and follow up review in clinic. Culture of swabs were negative for fungus. Video of the procedure is available.

**Discussion:** Fibrillar, an absorbable haemostat, conforms, adheres and melts into bleeding tissue. It has antibacterial properties. Body temperature, humidity, nutrients, oxygen and access to environment provided perfect conditions for fungal growth. Systemic antifungals failed to clear the fungus because of limited vascularity of the area. The topography and extensive spread of fungus along pleural surface of chest cavity presented a challenge for choice of delivery method, choice, dose, duration, sustained exposure to a suitable antifungal agent. The patient continues to be infection free and in good health.

**P865** Effectiveness of once-weekly fluconazole on the incidence of invasive candidiasis in a reverse-isolation haematological unit

D. Vuichard, M. Weisser\*, R. Frei, D. Heim, J. Passweg, A. Widmer (Basel, CH)

**Objectives:** Fluconazole 400 mg once daily was recommended as first line prophylactic agent for patients with acute leukemia and for those receiving allogeneic HSCT. Since 2001 our institutional policy for hematological high risk patients has been 400 mg fluconazole once weekly despite the fact that doses below 400 mg/day have not shown a significant benefit in preventing invasive fungal infections. Our study aimed to evaluate the impact of this policy on incidence of invasive candidiasis (IC) and the potential of emergence of resistance to fluconazole.

**Methods:** Patients received antifungal prophylaxis with fluconazole 400 mg weekly if they underwent high-dose chemotherapy, allogeneic or autologous stem cell transplantation. Antifungal prophylaxis was routinely stopped when antifungal treatment for invasive fungal infection (IFI) was initiated. Our hematological unit (HU) is located in a separate wing, equipped with laminar air flow, has restricted access and dedicated staff.

Data from patients were prospectively recorded by standardized case report forms. IC was defined as isolation of *Candida* spp. from blood or normally sterile compartments.

**Results:** From January 2003 until December 2010 a total of 1358 patients were treated in the HU, among them, 563 underwent allogeneic or autologous transplantation. Fifty-six *Candida* spp. were isolated from all submitted specimens, among them 28 were regarded as invasive and 28 as colonization. Identification of *Candida* spp. from this unit – including also non-IC isolates – remained stable over the whole period of 8 years with an average of 1.71/1000 patientdays (PD) (all *Candida* isolates) and 0.86/1000 PD for IC, respectively ( $p < 0.05$ ). Fifty-five of 56 strains were tested for fluconazole susceptibility. There was no significant increase of non-albicans *Candida* spp. or an increase of fluconazole resistant isolates of *Candida* spp. ( $p < 0.05$ ). There was no trend for increased resistance over the study period (figure).

**Fluconazole Susceptibility of all *Candida* spp. 2003-2010**

**Conclusion:** This policy of once weekly fluconazole did not result in emergence of *Candida* resistance or a shift towards non-albicans *Candida* spp. and might therefore be considered as alternative to once daily fluconazole.

**P866** Fungi and finance – an innovative project at a district hospital in northwestern England for cost-effective management of candidaemia driving quality and efficiency

A. Guleri\*, S. Ellershaw, A. Peel, A. Ibrahim, M. Przybylo (Blackpool, UK)

**Background:** *Candida* blood stream infections[CBSI] are 4th commonest cause of BSI, and associated with high mortality and

high potential costs of treatment. The incidence of CBSI in Europe is 0.20–0.38/1000 hospital admissions and 0.31–0.44/10 000 patient days. Literature and recent clinical trials suggest *Candida* BSI due to *Candida* species other than albicans are increasing. The cost of newer antifungals [AF] can potentially erode limited drug budgets. We present an innovative project with potential for adoption at any district hospital. This included in-house *Candida* identification [CID] and fluconazole susceptibility testing [FST], cost comparison of local in-house and outsourcing of CID and susceptibility testing, local epidemiology of CBSI over 10-years and economic modelling to enhance quality and efficiency of patient care and significant cost savings.

**Methods:** Retrospective 10 year review of pathology database for 272 CBSI [2000 – till date]; cost comparison and turn-around-time [TAT] of *Candida* ID and FST [inhouse or outsourced]; cost comparison [BNF 2011] of various systemic antifungals and potential cost savings from in-house ID/FST based antifungal treatment [esp for germ tube negative *Candida*].

**Results:** Key results from 272 CBSI over 10-years included *C. albicans* [CAL] was commonest [48.5%]; followed by 23.5% *C. glabrata* [CGL], 10.3% *C. parapsilosis* [CPA]; 5.1% *C. tropicalis*; and nil *C. krusei*. Incidence of *C. albicans* has remained flat in last 10 years. Fully fluconazole sensitive *Candida* species with the exception of 39% *C. glabrata*. Cost differential between in-house CID/FST incl staff time [£18.32] and outsourcing CID/ST against full panel [£93.73] for 272 CBSI *Candida* is £20 511.52. Cost differential of systemic AF treatment per day/over 2-weeks ranges from £7.78/£108.92 for fluconazole 400 mg IV and £483.45/£6768 for liposomal amphotericin 250 mg IV. A potential of upto £932 272 cost differential in treatments of 140/272 germ tube negative CBSI [inhouse v/s outsourced]. Details to be presented.

**Conclusions:** In-house *Candida* ID and FST is user friendly and easy to setup. MIC using E-test for fluconazole can be available within 24 hour. This has potential for early switch from expensive 2nd or 3rd line antifungals to fluconazole. Knowledge of local epidemiology for different clinical areas offers confidence in fluconazole use as 1st line even for germ tube negative *Candida*. Details of economic modelling and epidemiological profiling to be presented.

#### P867 Mixed treatment comparison of randomised clinical trials of primary antifungal prophylaxis in allogeneic haematopoietic stem cell transplant recipients – focus on invasive aspergillosis

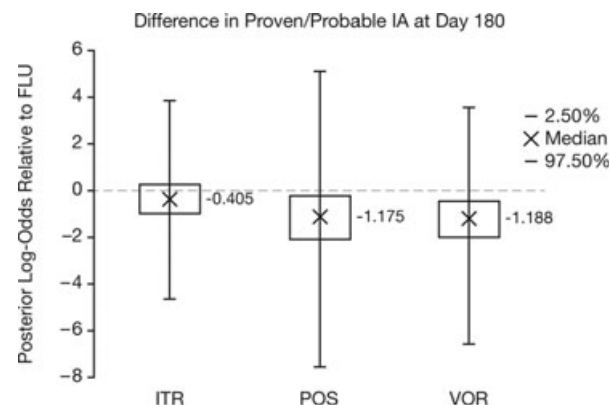

E.J. Bow\*, D.J. Vanness, C. Cordonnier, O.A. Cornely, D.I. Marks, A. Pagliuca, M. Slavin, C. Solano, A. Shaul, S. Sorensen, L. Cragin, R. Chambers, M. Kantecki, D. Weinstein, H. Schlamm (Winnipeg, CA; Madison, US; Creteil, FR; Cologne, DE; Bristol, London, UK; Melbourne, AU; Valencia, ES; Manitowoc, Bethesda, Collegeville, US; Paris, FR; New York, US)

**Objectives:** Invasive aspergillosis (IA) is the most frequent invasive fungal infection (IFI) in allogeneic haematopoietic stem cell transplant (alloHCT) recipients post-engraftment and is associated with high mortality. The oral azoles fluconazole (FLU), itraconazole (ITR), posaconazole (POS), and voriconazole (VOR) can potentially prevent IFI in this setting. The optimum choice for primary prophylaxis of IA in alloHCT is unknown, since these agents have not been directly

compared in a single randomised clinical trial (RCT). Indirect mixed treatment comparison (MTC) is currently the best available approach to evaluate this question.

**Methods:** Based on expert consensus, we conducted a systematic literature review of published RCTs of FLU, ITR, POS, and VOR as primary IFI prophylaxis, in which >50% of patients underwent alloHCT. The respective cumulative proportions of patients with proven/probable IA at 180 days were extracted from each RCT. These data were incorporated into a Bayesian hierarchical random-effects MTC that used an unconstrained baseline (Lu & Ades. Stat Med 2004; 23: 3105–24) to account for potential heterogeneity in study designs and patient populations, as per expert consensus. Using posterior credible intervals estimated from the MTC, we evaluated the following: (i) log-odds of developing proven/probable IA at day 180 for ITR, POS, and VOR relative to FLU and (ii) the probability that each agent was superior to FLU for this endpoint.

**Results:** Six RCTs were identified, of which 1 was excluded from the MTC due to lack of data on IA. The five remaining RCTs (three open-label and two double-blind RCTs) randomized 2147 patients in total. FLU (n = 813) was a comparator in four trials, ITR (n = 485) in 3, VOR (n = 548) in 2, and POS (n = 301) in one trial. Estimates for median log-odds (see figure) suggest that VOR and POS most reduced the probability of proven/probable IA at day 180 relative to FLU (–1.188 and –1.175, respectively), followed by ITR (–0.405). VOR had a higher probability of being superior to FLU (ie, 84.5%) than did POS (79.7%) and ITR (68.9%).

Log-odds below the dotted line indicate reduced probability of proven/probable IA at day 180 relative to FLU.

Boxes indicate interquartile range from 25% (top) to 75% (bottom).

**Conclusion:** The probability of being superior to FLU in preventing IA was high (>75%) for VOR and POS. Mould-active prophylaxis with VOR and POS appeared to result in a greater reduction of IA than ITR. The findings may have clinical relevance, suggesting that in those alloHCT recipients for whom post-transplant IA prophylaxis with an oral azole is deemed valuable, VOR and POS are the most effective options.

#### P868 Evaluation on “real life” prescriptions of antifungal prophylaxis in high-risk patients: preliminary results from a prospective survey

M. Caira\*, A. Busca, L. Melillo, A. Candoni, C. Caramatti, G. Specchia, R. Fanci, G. Rossi, C. Cattaneo, A. Vacca, C. Quintavalle, M. Picardi, M.E. Mitra, M. Delia, B. Landini, C. Gasbarrino, R. Invernizzi, P. Salutari, B. Martino, M.G. Garzia, A. Chierichini, A. Venditti, N. Vianelli, G. Nadali, M. Luppi, G. Leone, A. Nosari, F. Aversa, L. Pagano on behalf of the SEIFEM group

**Objectives:** To describe the current use of antifungal (AF) prophylaxis in consecutive, unselected adult patient with acute myeloid leukemia patients (AMLs) at first induction of remission and to analyze the

efficacy of prophylaxis with posaconazole (POS) when compared to old azoles in a “real life” setting.

**Methods:** From January 2010 to March 2011, all newly diagnosed AMLs have been consecutively registered and prospectively monitored in 31 Italian participating centers. Only adult cases that received conventional chemotherapy were included in the present study. Principal demographic and clinical data, as well as antifungal treatments were collected. In particular we analyzed data about systemic AF prophylaxis: the drug of choice, the duration of treatment, and its efficacy were thus evaluated. To determine prophylaxis efficacy, incidence of proven/probable IFDs was assessed at 30th day from the end of chemotherapy.

**Results:** Four hundred and ninety-eight AML were evaluated in the present analysis. The most part of them (448, 90%) received systemic antifungal prophylaxis. POS was the most frequently employed drug (224/448, 50%), followed by fluconazole (128, 29%) and itraconazole (86, 19%). When comparing the POS group (224 pts) to those receiving itraconazole or fluconazole (214 pts) (FLU/ITRA) no significant differences emerged in terms of the main risk factors for IFDs (table). In particular the two groups resulted to be comparable in terms of age, sex, frequency and duration of deep neutropenia, days of prophylaxis. On the contrary, there were significant differences in breakthrough IFDs (6.2% in POS vs 11.7% in FLU/ITRA, p-value 0.04). Except for one case of fusariosis, all mold infections were invasive aspergillosis. Yeast infections also were more frequent in the FLU/ITRA group. Caspofungin and amphotericin B compounds were the most frequently employed drugs, as empirical/pre-emptive treatments. There were no significant differences in the response rate, nor in the IFDs attributable mortality rate.

	FLU/ITRA	POS
	214	224
Mean age (years)	57.7	53.3
Sex		
- male	112 (52%)	101 (45%)
- female	102 (48%)	123 (55%)
Deep neutropenia	210 (98%)	213 (95%)
Central venous catheter	119 (56%)	143 (64%)
Mean duration of deep neutropenia (days)	19.5	21.5
Median AF prophylaxis duration (days)	20	20
Empirical/pre-emptive therapies	59 (28%)	71 (32%)
Most used drugs as empirical/pre-emptive therapy	- L-AmB 18 (30%) - Caspo 17 (29%) - Vorico 8 (14%) - CL-AmB 8 (14%) - Others 8 (14%)	- L-AmB 39 (55%) - Caspo 12 (17%) - Vorico 6 (8%) - CL-AmB 2 (3%) - Others 12 (17%)
Proven/probable IFDs	25 (11.7%)	14 (6.2%)
• moulds	- 17 (7.9%)	- 11 (4.9%)
• yeasts	- 8 (3.7%)	- 3 (1.3%)
Molds/yeasts ratio	2.1/1	3.7/1
Favourable responses (RR)	14/25 (56%)	11/14 (79%)
N° deaths (AMR)	7/25 (28%)	2/14 (14%)
• moulds	4	1
• yeasts	3	1

Legend: AF: antifungal; IFD: invasive fungal disease; L-AmB: liposomal Amphotericin B; CL-AmB: lipid complex Amphotericin B; RR: response rate; AMR: attributable mortality rate; pos: posaconazole; flu: fluconazole itra: itraconazole

**Conclusion:** During the last few years the use of POS prophylaxis in high risk pts has significantly increased. Although not randomized, our study demonstrates in a “real life” setting the increased use and the higher efficacy of POS prophylaxis, when compared to FLU/ITRA. Only 14 patients developed a breakthrough IFDs. Surprisingly, POS superiority emerged for both molds and yeasts infections. Previous AF prophylaxis doesn't seem to impact IFDs outcome.

### P869 Antifungal prophylaxis for patients with haematological malignancies in “real life”: a prospective cohort study of compliance, toxicity and outcome

E. Giannatou\*, J. Cleverley, C. Symeonidou, A. Prentice, C.C Kibbler (London, UK)

**Objectives:** This prospective cohort study assesses the compliance with the institution's antifungal prophylaxis (AP) strategy for patients with haematological malignancies and reasons for deviation.

HSCTs patients	89
Full course of itra	50
Itra discontinued, given alternative	22
1. Intolerance to itra	9 ambi=4, posa=4, vori=1
2. Toxicity to itra	6 (ambi)
3. Interaction of itra with other drugs	2 Ambi=1(itra+Efavirenz), caspo=1(itra+cyclosporine+renal artery stenosis)
4. continuing prior antifungal treatment	1(ambi)
5. change from 1 <sup>st</sup> line to 2 <sup>ry</sup> prophylaxis due to clinical suspicion of IFD	4 Vori=3, posa=1
Secondary prophylaxis from the beginning of the course	9 Vori=8, posa=1
Received >2 antifungal drugs as prophylaxis	8
1. toxicity to ambi	2(caspo)
2. intolerance to ambi	4(caspo)
3. change from protocol 2 <sup>ry</sup> to another 2 <sup>ry</sup> prophylaxis	2
Overall RFNE treated with antifungal drugs	28
RFNE treated with 1 drug	20
RFNE treated with > 1 drug	8

AMLs post chemotherapy courses	92 (40 patients)
Full course of itra	68
Itra discontinued, given alternative	18
1. Due to mylotard	13 Ambi=12, caspo=1
2. Due to arsenic	1(ambi)
3. Interaction of itra with other drugs	1 Ambi (itra +everolimus)
4. Intolerance to itra	0
5. Toxicity to itra	3(ambi)
Secondary prophylaxis	6 Vori=5, posa=1
Overall RFNE treated with antifungal drugs	24
RFNE treated with 1 drug	19
RFNE treated with > 1 drug	5

ALLs post chemotherapy courses	51(26 patients)
Full course of itra	23
Itra discontinued, given alternative	27
1. Change of risk for IFD	11 Fluconazole due to maintenance chemotherapy
2. Intolerance to itra	1(ambi)
3. Toxicity to itra	2(ambi)
4. To prevent vincristine toxicity	13 Ambi=11, posa=1, fluco=1
Secondary prophylaxis	1
Overall RFNE treated with antifungal drugs	9
RFNE treated with 1 drug	7
RFNE treated with > 1 drug	2

**Methods:** One hundred and fifty-five consecutive patients admitted for allogeneic haematopoietic stem cell transplantation (HSCT) or chemotherapy for acute myeloblastic (AML) or acute lymphoblastic leukemia (ALL) from 01/08/2008 to 31/07/2010 were reviewed. First line AP on our unit is itraconazole oral solution except during concomitant use with vincristine to avoid potentially fatal interactions. The alternative is IV AmBisome and secondary (2ry) prophylaxis is voriconazole. One hundred and fifty-five HRCTs from 73 patients who developed refractory febrile neutropenic episodes (RFNE) were independently reviewed by two different radiologists. Invasive fungal disease (IFD) was classified according to EORTC/MSG criteria.

**Results:** (i) Eighty-nine HSCTs were studied. Fifty remained on itra for the full course of AP, 22 received itra, stopped and were given an alternative drug for the remainder of AP, 9 were on 2ry AP throughout the course and 8 received >2 drugs as AP. The reasons why alternative AP was given to 22 patients were: intolerance 9, toxicity 6, drug interaction 2, continuing prior antifungal treatment 1, change to 2ry AP due to clinical suspicion of IFD 4. The reasons why eight patients received >2 drugs as AP were: toxicity to AmBi (alternative AP) 2, intolerance to AmBi (alternative AP) 4, change from the protocol 2ry to another 2ry AP 2. (Table 1). (ii) Forty AMLs who had 92 post-chemotherapy courses (CC) were studied. In 68 CC itra was given, 18 CC alternative AP and 6 2ry AP. The reasons for alternative AP were: treatment with mylotarg 13, drug interaction 1, treatment with arsenic 1, toxicity to itra 3 (Table 1). (iii) Twenty-six ALLs had 51 CC. In 23 CC itra was given, 27 alternative AP and 1 2ry AP. The reasons for alternative AP were: change of risk for IFD 11, intolerance 1, toxicity 2, treatment with vincristine 13 (Table 1). (iv) The overall incidence of IFD was 5.8%, probable IFD 1.2% and possible IFD 4.5% patients.

**Conclusion:** AMLs and ALLs tolerate itra well and their course of AP is compliant with our institution's strategy. The prolonged AP duration combined with the interactions between drugs given after transplantation are the major reasons for the low percentage of HSCTs who stayed on itra. However, the overall percentage of IFD is low, which justifies our practice to deviate when necessary from the AP strategy.

#### **P870** Incidence of breakthrough fungal infection during primary antifungal prophylaxis in acute myeloid leukaemia patients in a cancer centre

M.Z.R. Gomes\*, R.E. Lewis, P.M.C.M. Farias, C. Wu, D.P. Kontoyiannis (Houston, US)

**Objectives:** To investigate the patterns of primary antifungal prophylaxis (PAP) use and the incidence of breakthrough fungal infection (BFI) in patients with acute myeloid leukemia (AML) in a cancer center.

**Methods:** We analyzed 75 unselected patients with newly diagnosed AML admitted to MD Anderson Cancer Center who received PAP through August 2009 to March 2011.

PAP drug	# of Patients (%)	Patient-days of PAP	BFI all criteria* / definite or probable EORTC criteria	Incidence of BFI all criteria* / definite or probable EORTC criteria*	Isolated Agents of BFI	1A*
Voriconazole (PO)	41 (55)	5,142	9/6	1.8/1.2	-	0
Posaconazole	28 (37)	3,040	7/4*	2.3/1.3	Mold sterile hyphae; <i>Fusarium</i> sp.; <i>Aspergillus glaucus</i> ;	1
Fluconazole (PO/IV)	23 (31)	2,039	6/4	2.9/2.0	<i>C. glabrata</i> ;	3
Caspofungin	33 (44)	725	4/3*	5.5/4.1	<i>Fusarium</i> sp.; <i>Mucor</i> sp.	1
Anidulafungin	9 (12)	350	2/2	5.7/5.7	<i>Aspergillus fumigatus</i> ;	1
Micafungin	9 (12)	194	3/3	13.8/13.8	<i>Candida glabrata</i> ; <i>Candida krusei</i> and <i>Candida parapsilosis</i> ; <i>Coccidioides</i> sp. (positive IGM serology).	0
Voriconazole (IV)	9 (12)	131	0/0	0/0	-	-
Total AML patients	75 (100)	11,571	30/21	2.6/1.8	-	-

\*definite, probable, possible or suspected BI, <sup>1</sup>/1000 patient-days of PAP, <sup>2</sup>Invasive aspergillosis (IA) detected by *Aspergillus galactomannan* antigen tests, <sup>3</sup>1 case during caspofungin and posaconazole double covered prophylaxis on the 66<sup>th</sup> day of HSCT

**Results:** Patients had a median of two different antifungal drugs as primary prophylaxis; range 1 (24 patients) to five drugs (one patient) for a mean of 154 days (median 103 days, range 3–680 days) during hospitalizations or as outpatients (Table 1).

**Conclusions:** The preliminary findings in this real world study of PAP in a contemporary cohort of AML patients indicate that molds accounted for 85.7% (18/21) of BFIs on PAP. Despite frequent use (82%) of agents having *Aspergillus* activity, no statistical significant variation in the incidence of BFI was observed so far among drugs (p = 0.71).

#### **P871** Breakthrough mycosis in HSCT recipients receiving micafungin prophylaxis

A. Cheng\*, H.Y. Sun, B.S.K. Ko, H.F. Tien, Y.C. Chen, S.C. Chang (Taipei, TW)

**Objectives:** To assess incidence and risk factors of breakthrough mycosis under micafungin prophylaxis for hematopoietic stem cell transplantation (HSCT).

**Methods:** A total of 50 HSCT recipients receiving micafungin as prophylaxis in 2010–2011 were analyzed. Patients were followed for 100 days post-transplantation for the development of mycosis defined by EORTC.

**Results:** Of the 50 patients, 38% received HSCT for lymphoma, 18% for AML, 14% for ALL, and 14% for MDS; 40% received allogeneic and 36% autologous HSCT. Breakthrough mycosis developed in 4 (8%) patients, including probable aspergillosis in 3 and definite trichosporosis in 1, after a median of 6 days post-transplant and after micafungin use for a median of 16 days. Of the three patients with probable aspergillosis, persistent elevation of *aspergillus* antigen levels and newly developed pulmonary nodules were the most common presentations. The case with trichosporosis developed fever and disseminated papular rash, and *Trichosporon* species was isolated from the blood. All these four patients were successfully treated with voriconazole. Compared with 46 patients without breakthrough mycosis, positive cases were more like to be older (mean, 53 vs. 43 years old, p < 0.05) and had graft-versus-host-disease (50% vs. 28.3%, p > 0.05). All patients had surveillance nasal and throat fungal cultures post-transplant, and 10 patients had positive results, including *C. albicans* in seven patients, *C. glabrata* in 1, unidentified *Candida* species in 1, *Trichosporon* species in 1, and Mycelium sterile in 1.

**Conclusion:** The incidence of breakthrough mycosis during micafungin prophylaxis for HSCT was 8%. Although micafungin had anti-*Aspergillus* attribute, aspergillosis was the most common breakthrough mycosis.

## Molecular virology

#### **P872** Apoptosis induced by highly pathogenic avian influenza A virus H5N1 NS1 protein and the intrinsic pathway activation

Q. Bian\*, Y. Chi, Y. Li, Z. Shi, H. Wang (Nanjing, CN)

Recent outbreaks of H5N1 influenza virus infections had important health and economic consequences and raised concerns that a new influenza pandemic would occur in the near future. Non-structural protein 1 (NS1) is an important virulence factor of the highly pathogenic H5N1 avian influenza virus and is found only in infected cells.

The objective of this study is to explore whether intrinsic pathway of apoptosis induced by H5N1 NS1 protein was activated. NS1 protein of influenza A/Jiangsu/1/2007 virus, a highly pathogenic H5N1 strain isolated from an infected human in Nanjing, was cloned to pXJ40-HA vector to construct the plasmid of pXJ40-HA-NS1. pXJ40-HA-NS1 was transfected to human lung epithelial cell line (NCI-H292) with or without apoptosis inducer (staurosporine). The localization of NS1 protein in H1299 cells was detected by immunofluorescence (IF). The apoptosis effects were detected by MTT assay, flow cytometric assay and western blot analyses. The result of IF shows NS1 protein mainly

localizes in cell nucleus (Fig.1). NS1 protein could induce apoptosis in human lung epithelial cell line (NCI-H292) (Figs 2 and 3). Cytochrome C release could be observed dramatically in NS1 transfected cells and the effect was enhanced by apoptosis inducer (Fig. 4). Taken together, these data indicate that influenza A virus NS1 protein serves as a strong inducer of apoptosis in human lung epithelial cells and triggers apoptosis could be via mitochondria-dependant intrinsic pathway.

Fig. 1. Analysis the expression and localization of NS1 protein in H1299 cell line by immunofluorescence and confocal assay.

The pXJ40-HA-NS1 transfected H1299 cell staining with anti-HA serum and Alexa488 conjugated secondary antibody (A), anti-Cytochrome C MAb and Alexa555 conjugated secondary antibody (B), DAPI dye (C), respectively; Merged image (D).

Fig. 2. Cytotoxicity detection by MTT assay on NCI-H292 cells transfected by pXJ40-HA-NS1 for 24h. A:vector;B: STS 0.025 nmol;C: NS1;D: NS1 + STS 0.025 nmol.

Fig. 3. Identification of apoptosis by FCM assay of Annexin-V/PI double staining.

A:vector;B: NS1;C: STS0.025 nmol;D: NS1 + STS0.025 nmol.

Fig. 4. Cytochrome C release detection by WB assay in NCI-H292 cells transfected by pXJ40-HA-NS1 and induced by STS (0.025 nmol) for 24 hour.

### P873 Herpes simplex virus in the testis of prepuberal and adult mice: in vivo and in vitro models

Y.A. Tyulenev\*, O.V. Masalova, V.A. Naumenko, L.V. Shileyko, R.R. Klimova, L.F. Kurilo, A.A. Kushch (Moscow, RU)

**Objectives:** Although herpes simplex virus (HSV) is associated with male infertility, the mechanisms of its interactions with germ cells and the role of hematotesticular barrier (HTB) are poorly understood. The aim of the present study was to compare germ cells susceptibility to HSV in the testis of prepubertal and adult mice after in vivo and in vitro infection.

**Methods:** Pups 7-day-old (Group I) and 5-month-old (Group II) mice were used to model HSV-infection before and after HTB formation, respectively. Testis organotypic culture was used as in vitro model. It was infected and incubated for 6 days. In vivo infection was performed by intraperitoneal injection of virus. HSV markers in testicular cells were analyzed by PCR, culture method and immunostaining.

**Results:** In culture, HSV-DNA load reached the maximum on day 4 post infection:  $3.5 \times 10^8$  copies/mL in Group I and  $3.4 \times 10^7$  copies/mL in Group II. The content of infectious virus increased till day 6, reaching  $5 \times 10^3$  and 20 plaque forming units (PFU)/mL in groups I and II, respectively. In pup testis 90% of spermatogonia and Sertoli cells contained viral antigen compared with 5% germ cells in adult mice.

In vivo, high levels of HSV DNA ( $1.5 \times 10^5$  copies/mL), infectious virus (140 PFU/mL) and viral antigens (45% of cells) were detected in pups testis. However, no HSV markers were identified in testis of adult mice.

**Conclusion:** Both in vitro and in vivo studies show that testicular cells of mouse pups are more sensitive to viral infection than those of adult mice. These results suggest that HSV-infection of mice in the early neonatal period before HTB formation leads to germ cells infection that can be one of the possible causes of male fertility disorders.

### P874 Post exposure efficacy of AVI-7100 against influenza A in mouse and ferret infection models

P. Iversen\*, F. Schnell, S. Crumley, D. Mourich, T. Voss (Bothell, New Orleans, US)

**Objective:** AVI-7100 is a phosphorodiamidate morpholino oligomer containing three modified linkages (PMOplus) that is designed to interfere with expression of the M1 and M2 genes of influenza A virus. The objective was to evaluate the therapeutic utility of AVI-7100 up to one day post viral exposure.

**Methods:** A single 0.1 mg intranasal (i.n.) dose of AVI-7100 was administered to female BALB/c mice (n = 10/group) either 4 hours prior to or 4 hours after viral challenge with with  $5 \times 10^5$  pfu of A/Port Chalmers/1/73 (H3N2). Lung viral load was determined on day 6 post infection. A similar efficacy study in outbred ferrets (*Mustela putorius furo*; n = 7/group) were administered AVI-7100 as a single i.n. dose 4 hours prior to or 1 day post insufflation viral challenge with  $5 \times 10^5$  pfu H1N1 A/Hong Kong/2369/09 per ferret. Negative control groups were treated with saline and positive controls were administered oseltamivir at 10 mg/kg p.o. every other day beginning 7 days prior to infection. A plasma pharmacokinetic study with 16 ferrets (four groups of four ferrets/group) in which a 10 mg/kg or 30 mg/kg i.v. dose was evaluated prior to and three days post viral challenge with H1N1 strain A/Mexico/4108/09 or H5N1 strain A/Vietnam/1203/04.

**Results:** A single intranasal dose of AVI-7100 (0.1 mg/mouse) administered either 4 hours prior to or 4 hours after infection with A/Port Chalmers/1/73 (H3N2) significantly ( $p < 0.05$ ) reduced lung viral titers in each group compared to vehicle controls and oseltamivir treated mice. In the ferret, a single i.n. dose of AVI-7100 administered 4 hours prior to exposure or 1 day after exposure with A/Hong Kong/2369/09 (an oseltamivir resistant pH1N1) significantly ( $p < 0.05$ ) reduced cumulative viral load in nasal wash and in lung bronchiolar lavage compared to saline controls and oseltamivir treated ferrets. A plasma pharmacokinetic study revealed no differences between infected and uninfected ferrets.

**Conclusions:** AVI-7100 is effective against influenza A (H1N1 and H3N2) and in both mouse and ferrets when administered as a single intranasal dose for greater than one day post viral exposure. Post-exposure efficacy data indicate robust antiviral and symptom benefit can be provided by AVI-7100. Infection does not significantly alter plasma pharmacokinetics relative to uninfected ferrets. These data provide a rationale for a therapeutic use of AVI-7100 following influenza exposure.

### P875 Presence of dengue virus genome in kidney tissue of adults without recent dengue infection: another piece of evidence of in vivo persistence of the virus

R. Plongla\*, K. Songchareon, K. Arunyimgongkol, K. Tantiwongse, W. Kulwichit (Bangkok, TH)

**Objectives:** Dengue is the most rapidly spreading mosquito-borne viral disease on a global scale and causes a major public health problem in Thailand. Serosurveillance indicates that almost all Thai adults have been infected, mostly asymptotically. Even though dengue virus is thought to cause only acute infection, some of its peer flaviviruses cause persistent infections in the hosts. Our prior studies revealed that dengue

viral genome could be detected in the bone marrows and the lymph nodes of the patients without evidence of acute or recent infections. Similarly, West Nile virus could be detected in urine for many years after infection in both animal and human hosts. Here, we conduct a study to demonstrate evidence of dengue virus persistence in the kidneys from adults with remote infections.

**Methods:** We enrolled the adults who had an indication for elective nephrectomy and autopsied cases at King Chulalongkorn Memorial Hospital, Bangkok, Thailand from March 2010 to March 2011. Demographic data, especially for the history of recent febrile illness, and laboratory data were recorded. We performed reverse transcription polymerase chain reaction (RT-PCR) using dengue specific primers targeting conserved sequences within the envelope and 3'-untranslated region on the kidney tissues. To confirm that there were no acute or recent infections, paired sera were collected before and 1–4 weeks after surgery for anti-dengue IgM and IgG by standard enzyme-linked immunosorbent assay (ELISA), and were interpreted according to standard criteria.

**Results:** Forty-four surgical cases and five autopsied cases were enrolled. Neoplasm of the urinary system was the most common indication for nephrectomy at almost 50%. Dengue genome was detected in 7 of 49 cases using RT-PCR (table) which was the prevalence of 14.29%. All these seven cases had no prior history of recent febrile illness and there was no evidence of acute or recent infection detected by dengue-ELISA of patients' paired sera.

Patient# & pathological diagnosis	Age (yr) & Gender	ELISA:	
		1st, 2nd IgM & 1st, 2nd IgG	
1. Renal cell carcinoma, unremarkable renal parenchyma	87 M	0, 0 & 0, 0	
2. Infiltrating urothelial carcinoma of urinary bladder, no tumor involving kidney	39 F	11, 14 & 18, 14	
3. Infiltrating urothelial carcinoma, chronic change of renal parenchyma	79 M	4, 0 & 30, 22	
4. High grade infiltrating urothelial carcinoma, chronic pyelonephritis	76 F	8, 0 & 0, 0	
5. Low grade papillary urothelial carcinoma, hydronephrosis of renal parenchyma	58 M	1, 0 & 2, 4	
6. Autopsy: Chronic pyelonephritis with acute tubular necrosis	69 F	0, 13 & NA, NA	
7. Autopsy: Diffuse proliferative glomerulonephritis (LN class IV), bilateral renal infarction, invasive aspergillosis of both kidneys	41 F	0, 6 & NA, NA	

Abbreviations: RT-PCR, reverse transcription polymerase chain reaction; LN, lupus nephritis; M, male; F, female; NA, data not available.

**Conclusions:** This study showed that dengue virus could be detected in kidney tissues more than previous expectation. These findings have implications for dengue pathogenesis and for public health. Persistence of dengue virus genome in the kidney is another step to understand pathogenesis of dengue virus infection. As for public health, a urine-mosquito connection may be another potential route of dengue transmission.

#### P876 Human papillomavirus subtype distribution among women in Singapore: a cross-sectional study

L.L.E. Oon\*, S.L. Chen, P.Z. Ong, T.H. Yeo, S.K. Tay (Singapore, SG)

**Objectives:** Human papillomavirus is the causative agent of the vast majority of cases of cervical cancer, which is the second leading cancer among women worldwide. There are more than 100 human papillomavirus (HPV) subtypes known, with at least 15 subtypes being "high-risk" which will lead to cervical cancer. Epidemiological studies have revealed significant differences in geographical distribution of HPV subtypes across the world. Information on the prevalence of different subtypes of HPV in Singapore is limited to surveys of a small number of HPV subtypes in neoplastic tissues. This study aimed to investigate the HPV prevalence among the different age and ethnic groups of healthy women in Singapore, and study the HPV type-specific distribution to identify the most prevalent HPV subtypes present locally. Such information is important for evaluating the use of anti-HPV vaccines as a public measure in controlling the burden of cervical cancer in Singapore.

**Methods:** A prospective cross-sectional study of 971 healthy women between the ages of 13–82 years was carried out. Informed consent is obtained. Socio-demographic data including age and racial group were obtained. A routine cervical smear (or a vaginal lavage in virginal girls) was obtained from each participant for cytological evaluation. These were collected in liquid-based preservative for HPV DNA analysis. HPV detection and typing was performed using the Roche LINEAR ARRAY HPV (Human Papilloma Virus) Genotyping Test (Roche Diagnostics, Germany) which detects 37 anogenital HPV DNA genotypes.

**Results:** Of the 971 women surveyed, 890 (91.7%) had valid samples. Among the valid cases from 890 women, 83 (9.3%) of the cases had HPV detected. The highest prevalence of HPV and high-risk HPV (HR-HPV) infections were noted in the study population aged 29 years old and below. However, no significant difference was observed in the HPV prevalence of different ethnic groups. Unlike other international studies, HR-HPV subtypes 51, 52 and 58 were significantly more prevalent in the HPV positive cases of normal healthy women in Singapore.

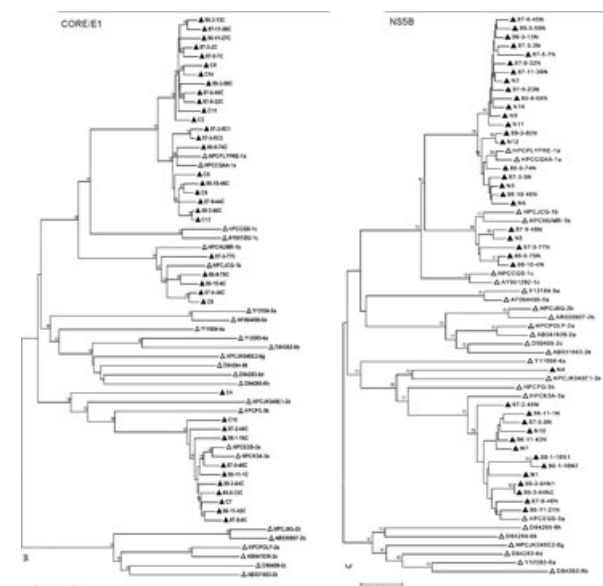

**Conclusions:** The subtype distribution of HPV in Singapore differs from studies conducted in Europe and USA. Findings of this study will be useful in evaluating the cost-effectiveness of HPV vaccine implementation as a national programme in the prevention of cervical cancer.

#### P877 A new and rare subtype of HCV genotype 3 in Iran: phylogenetic analysis of NS5b and Core/E1 gene regions

S.A. Nadjji\*, A. Babaie, P. Tabarsi, P. Momeni, R. Haj-Hosseini, A.A. Velayati (Tehran, IR)

**Objectives:** Hepatitis caused by HCV is a serious disease affecting more than 170 million people worldwide. HCV genome is highly variable and based on genetic distances and phylogenetic analyses, all isolates are grouped into six genotypes and many different subtypes. During a research on HCV molecular epidemiology among HIV-HCV dually infected patients admitted to Masih Daneshvari Hospital in Tehran, we found a new variant of HCV genotype 3.

**Methods:** A serum sample from a 41Y/O patient (TB/HIV/HCV infected) was obtained as part of an HCV molecular epidemiology study in the Virology Research Center. The partial genome sequences, including both the core/E1 region and the NS5B region (GenBank accession number JN129985 and JN129986) from this patient's plasma were obtained. Phylogenetic analysis of these partial genome sequences was conducted using MEGA version 4.0 along with representatives of the six HCV genotypes described previously.

**Results:** Neighbour-joining phylogenetic reconstructions revealed that the new sequence placed in HCV genotype 3 sequences, but grouped separately from any of the subtypes described for this genotype in the both gene regions. Genetic distances showed that compared with representatives of the confirmed subtypes of genotype 3, the NS5B and Core/E1 sequences displayed 25.5–35.2% and 41.8–45.4% nucleotide differences, respectively.

**Conclusion:** In this study, we have revealed the existence of a new and distinct variant of HCV genotype 3 from Iran by sequencing and analyzing of partial genome sequences. This genome is as divergent from representative variants of confirmed genotype 3 subtypes. In consequence, we have provided evidence that this isolate could be a truly new subtype. The presence of the new variant in Iran is mostly proven by finding another sequence during BLAST search (isolate 943, GenBank accession number AY654000) with 95.35% similarities in the NS5B region. The variant was also from a dialysis patient in Tehran and reported by Samimi-Rad et al. in 2004. Due to possibly some mistakes, the 943 variant was classified as HCV genotype 5. It is clearly the same genotype as the one we have identified. The rarity and restriction of our new HCV variant to Iran is rather interesting, and might justify some further screening-genotyping of other HCV infected patients.

#### **P878** Vaccine poliovirus associated encephalitis in OPV vaccinated children

A. Kumar\*, D. Shukla, R. Kumar, M.Z. Idris, T.N. Dhole (Lucknow, IN)

**Objectives:** The inheritant problem of Poliovirus genome is subjected to mutation, recombination and may revert back to neurovirulent strain. These neurovirulent strains might cause rare serious disease like vaccine-associated paralytic poliomyelitis in primary vaccine recipients and their contacts. As wild poliovirus is in the last stage of eradication, the characterization of oral polio vaccine (OPV) like strain from central nervous system disease is necessary to completely achieve the goal of poliomyelitis free world and future planning. The aim of the present study was to characterize the OPV like strains associated with encephalitis in children from northern India.

**Methods:** A total of 75 cerebrospinal fluid (CSF) specimen were collected between January and December 2010 from children (age <5 years) with symptoms of acute encephalitis syndrome admitted to the department of Paediatrics, Chhatrapati Shauji Maharaj Medical University Lucknow. Viral RNA was extracted from CSF using a QIAamp Viral RNA mini kit. Enterovirus serotypes were determined by semi-nested RT-PCR and sequencing of partial VP1 region. The categorization of poliovirus into OPV like, vaccine derived poliovirus and wild polio virus was performed according to WHO criteria. The neurovirulence of OPV like strain was done by amplification and sequencing of poliovirus 5' untranslated region (UTR).

**Results:** Out of 75 CSF, 19 (25.33%) were positive for enterovirus, 10 (13.33%) for Japanese encephalitis virus and 8 (10.66%) for chikungunya virus. Out of 19 enteroviruses, type 3 vaccine poliovirus was identified in three encephalitis cases which were vaccinated with OPV. Sequence analysis of 5'UTR region confirms mutation at 472 nucleotide position which is responsible for increased neurovirulence.

**Conclusions:** All three cases were identified as type 3 polio virus probably derived from type 3 OPV strain. The detection of neurovirulent OPV like strain in this highly populated and endemic area of poliomyelitis suggest enhanced molecular surveillance in cases of encephalitis. However, this is the time to debate on the role of emerging oral vaccine poliovirus in central nervous system disease.

#### **P880** The herpes simplex virus type 1 late associated transcript derived miR-H2 drastically reduced SMAD4 expression

E. Arefian\*, T. Bamdad, M. Soleimani, S.H. Aghae-Bakhtiari (Tehran, IR)

**Objectives:** The Herpes Simplex Virus type 1 (HSV-1) naturally establishes latency in ganglions of sensory neuron cells. The late

associated transcript (LAT) is a spliced noncoding RNA that is transcribed in HSV-1 infected neuron cells. The LAT produces six microRNAs that are able to affect the host cell or viral genes expression. The recent study showed that miR-H2, one of the LAT derived microRNAs, arrests the HSV-1 immediate early ICP0 gene expression. The transforming growth factor-beta (TGF-B) signaling is a critical pathway that regulates cellular process like apoptosis, cell differentiation and growth. The SMAD family member 4 (SMAD4) is crucial protein in TGF-B signaling that in response to TGF-B receptors signals bind to SMAD1 and SMAD2 and as a transcription factor complex regulates gene expression. In this study, we assessed effects of miR-H2 on Smad4 expression.

**Methods:** To prediction of miR-H2 targeting genes the bioinformatical studies were implemented by two software. The targets can and RNA22 with different algorithms were used in forecasting of genes that targeted by miR-H2. The plasmid including miR-H2 was transfected to human neuroblastoma cells [BE-2(c)] by lipofectamine 2000 (Invitrogen) according to manufacture protocol. The expression of miR-H2 was assayed by Real Time PCR. The effects of miR-H2 on Smad4 and its downstream genes were evaluated.

**Results:** The bioinformatical analysis of Targets can predicts that miR-H2 target Smad4 by a site with 8mer seed and RNA22 algorithm forecast two sites with -33 Kcal/mol folding energy. The Real Time PCR assays 48 hours after miR-H2 transfection showed that along with expression of miR-H2 in BE-2(c) cells the Smad4 was drastically reduced.

**Conclusion:** The Real Time PCR results revealed that the SMAD4 expression was reduced in response to miR-H2 overexpression in neuroblastoma cells when bioinformatical studies predicted SMAD4 targeting by miR-H2. Considering TGF-B pathway plays critical roles in many cellular disorders and disease, regulation of SMAD4 as an important protein in this path by miR-H2 could be useful in future investigation on gene therapy.

#### **P881** Genotype variability and clinical features of human metapneumovirus Isolated from Korean children, 2007–2010

M.K. Lee\*, H.R. Kim, T.H. Kim, B.S. Shim (Seoul, KR)

**Objectives:** Human metapneumovirus (hMPV) has been divided into five subgroups based on variations of the hMPV F gene. This study was undertaken to determine the genotype variability of hMPV, its circulation pattern in over a 3.5 year period, and to evaluate its clinical characteristics in Korean children.

**Methods:** We investigated 325 of 4599 pediatric patients with a positive nasopharyngeal aspirate that were referred for a routine respiratory virus test for hMPV by RT-PCR. HMPV genotype analyses were performed using a nested PCR-restriction fragment length polymorphism (PCR-RFLP) assay. Clinical and laboratory data obtained from medical records were reviewed retrospectively.

**Results:** Three hundred and twenty-five (7.1%) of the 4599 samples tested were positive for hMPV, and the co-infection rate among these 325 was 16%. Nested PCR-RFLP analysis clearly identified four of the five previously described hMPV genotypes (A2a, A2b, B1 and B2) in 97.8%. The predominant genotype of hMPV changed over the 3.5-year study period from genotype A2a to B2 and then back to A2a. The most common genotype was A2a (214/325, 65.8%). Evidence of recurrent infection was obtained in one child only. Lymphocytosis was more frequent in children with a co-infection, but sputum was less frequent than in children with a single infection ( $p < 0.05$ ). In genotype A2a hMPV infected-children, sneezing and neutrophilia were more frequent than in genotype B1 or B2 hMPV-infected children.

**Conclusion:** This 3.5-year study broadens knowledge regarding the prevalence, the seasonal incidence, the occurrences of co-infection and re-infection, and the genotype diversity of hMPV in Korea.

**P882** “Moderate” concordance between “modified” Abbott real-time HIV-1 assay and Roche Cobas/Taqman HIV-1 v2.0 procedure for the quantification of human immunodeficiency virus type 1 (HIV-1) RNA at low level of viral load (BELOW 600CP/ML)

A. Amendola\*, P. Marsella, M. Bloisi, C. Angeletti, M.R. Capobianchi (Rome, IT)

**Objectives:** The suppression of HIV RNA below 50 cp/mL is commonly achieved in most patients undergoing current therapeutic approaches. When viremia is reduced below the limit of detection (LOD) of commercial diagnostic tests, residual viremia (RV) can still be detected. The assessment of RV is proving increasingly useful in monitoring viral suppression to determine the relative effectiveness of different regimens, but concordance between commercial assays is weak at low viremia. We compared performances of “modified” procedure of Abbott Real-time HIV-1 assay and standard protocol of Roche COBAS/TaqMan HIV-1 v2.0 for quantification of HIV RNA low levels (<600 cp/mL). The “modified” Abbott assay reaches a LOD of 19 cp/mL (Amendola A. et al. J Clin Virol 2011); the Roche standard procedure shows LOD of 20 cp/mL.

**Methods:** The comparison was performed using: (i) 153 clinical samples chosen with viral load values ranging from “not-detected” to 600 cp/mL with Abbott standard protocol and (ii) the Working Reagent (WR) for NAT assays (NIBSC) as a standard, diluted to 128, 64, 32 and 16 cp/mL (seven replicates/dilution). Quantitative results were compared using correlation, linear regression and Bland and Altman analyses. Concordance on qualitative results (namely “detected” vs “not-detected”) was measured by Cohen’s kappa statistic. Probit analysis of both assays was performed with WR.

**Results:** 1 A good correlation between assays was observed in clinical samples with viral load values ranging from 20 to 600 cp/mL (Pearson  $r = 0.7468$ ); Bland&Altman analysis showed a mean difference of measurement equal to 0.170 log<sub>10</sub> cp/mL. Below 20 cp/mL, the degree of concordance between the two assays for samples given as “detected” vs “not-detected” was “moderate”, with Cohen’s kappa-statistic of 0.450 and an agreement proportion of 0.730.

2 The difference in viral load quantification at low levels was also observed using the WR standard. The Roche assay provided, with high reproducibility, results that were, on average, 3.45 times higher than expected values (equal to +0.52 log<sub>10</sub> cp/mL) at all dilution levels, whilst the Abbott “modified” procedure produced the expected values.

**Conclusions:** Overall, the two diagnostic systems show some differences in the quantification of HIV-1 viral load at low levels and a degree of concordance “moderate”. By probit analysis, performed with WR standard, we observed that Roche procedure is more sensitive, but Abbott “modified” is more precise and accurate.

**P883** Genetic diversity of hepatitis E virus isolates originating from human patients and animals in the Czech Republic

P. Vasickova\*, P. Kralik, J. Lamka, P. Chalupa, R. Svoboda, M. Holub, I. Pavlik (Brno, Hradec Kralove, Prague, Prague, CZ)

**Objective:** Hepatitis E virus (HEV) causes an important public health problem in many countries worldwide and its zoonotic potential was recognized recently. Due to high prevalence of HEV in domestic pigs and wild boars, these animals were considered as a reservoir of the virus. According to phylogenetic analysis HEV strains segregate into four major genotypes and their subtypes. Genotypes 1 and 2 correspond to primary circulation within humans, whilst diversity of genotypes 3 and 4 is related to zoonotic origin. Each genotype (even subtype) is dominant in reported geographical areas, which could be used in epidemiological studies. The aim of the study was to perform sequence comparison and phylogenetic analysis of Czech HEV isolates of human and animal origin and thus to find out their possible relation.

**Methods:** Stool and serum from 56 patients with serologically confirmed hepatitis E (HE) and bile, liver and faecal samples from domestic pigs and wild boars were tested for presence of HEV RNA by triplex real time reverse transcriptase PCR. Specific part of HEV genome (242 nt) originating from detected isolates was subjected to sequencing. The sequences were analysed by MEGA 5.05 and compared with the sequences in GenBank. Neighbor-joining method was used for phylogenetic analysis.

**Results:** Comparison of the sequences with GenBank failed to find any 100% identical HEV isolate. The sequence analysis revealed that one human and two swine isolates shared 99.6% (a single nucleotide difference) homology with each other and sequences of two human isolates were 100% identical. Phylogenetic analysis showed that all Czech isolates belonged to genotype 3 subtypes: human isolates 3e, 3f, 3g, 3i and 3g and animal isolates 3f and 3g.

**Conclusions:** Consumption of raw or undercooked meat and meat products or direct contact with infected animals is possible source a HEV infection. Phylogenetic analysis of found HEV isolates revealed presence of subtype 3g and 3f in HE patients and domestic pigs and subtype 3g in HE patients, domestic pigs and wild boars in the Czech Republic. A single nucleotide difference of 242 nt long sequences of human and swine HEV isolates together with HE patients’ anamnestic data support interspecies transmission of HEV in the Czech Republic and zoonotic potential of the virus.

**Acknowledgement:** This work was supported by the Min. Agr. (No. MZE0002716202) and the Min. Edu., Youth and Sports of Czech R. (AdmireVet CZ 1.05/2.1.00/01.0006-ED0006/01/01).

**P884** Multiplex respiratory virus PCR: a comparison of the FilmArray® and xTAG® respiratory panels on bronchoalveolar lavage and other respiratory specimens

J.M. Balada-Llasat\*, C. Kelly, W. Zhang, H. LaRue, P. Pancholi (Columbus, US)

**Objectives:** The clinical presentation of respiratory viral infections may be similar, therefore identification of the causative agent(s) aids in the selection of appropriate treatment and infection control measures. Several multiplex PCR assays have been developed for the detection of respiratory viruses. Among these are the FilmArray® (Idaho Technology Inc.) and the xTAG® (Luminex) assays. We evaluated the performance of the FilmArray compared to the xTAG for the detection of respiratory viruses from various respiratory specimens including Bronchoalveolar lavage (BAL).

**Methods:** Two hundred and sixty-nine respiratory specimens (nares, nasopharynx, throat, sputum, BAL, lung, pleural fluid) were collected from hospitalized patients during the winter of 2010–2011. One aliquot was processed with the xTAG and a second previously frozen aliquot was tested by the FilmArray assay. For the xTAG assay viral nucleic acid was extracted using the EasyMag, reverse transcribed, amplified, and analyzed with Luminex® technology. For the FilmArray, respiratory specimens were processed in a closed RT PCR system that isolates, amplifies, and detects the viral targets. Both assays detect influenza A (Flu A; seasonal H1 and H3) and influenza B (Flu B), adenovirus, parainfluenza 1–3 (Para 1–3), respiratory syncytial virus (RSV), human metapneumovirus (HMPV) and human rhinovirus/enterovirus (HRV/E). The FilmArray additionally detects coronaviruses (NL63 and HKU1), Para 4, and Flu A subtype 2009 H1. The xTAG also differentiates RSV A and RSV B. For discrepant analysis, both assays were repeated on the frozen aliquot. Additionally, sequencing was performed.

**Results:** Of the 269 specimens tested, both assays agreed on 109 negative and 150 positive respiratory specimens. When compared to the xTAG, the FilmArray showed a 95% sensitivity and 98% specificity.

**Conclusions:** The FilmArray was useful for detecting a wide range of viruses in various sample types including BALs. The FilmArray additionally detected coronaviruses. The xTAG requires 6–7 hour with 2.5–3 hour of hands-on time, while the FilmArray takes about an hour with 3–5 minute of hands-on time, making it much easier to perform.

However the FilmArray processes only one sample at a time that can limit its utility in moderate-to high-volume laboratories.

**P885** **Quantification of human cytomegalovirus DNA in transplant recipients by the Abbott real-time HCMV assay**

V. Rognoni\*, M. Furione, E. Cabano, R. Restivo, R. Moriconi, R. Pulvirenti, K. Pfeifer, J. Yu, F. Baldanti (Pavia, Rome, IT; Wiesbaden, DE; DesPlaines, Chicago, US)

**Objectives:** Human Cytomegalovirus (HCMV) infection/disease is the major infectious viral complication in the post-transplant period for hematopoietic stem cell (HSCTR) and solid organ transplant recipients (SOTR). Standardization of protocols for monitoring HCMV infection is a priority in the management of transplanted patients receiving pre-emptive therapy.

**Methods:** The kinetics of HCMV disseminated infections was retrospectively evaluated in surplus whole blood samples of 20 paediatric HSCTR and 17 adult SOTR enrolled in two prospective studies at the IRCCS Policlinico San Matteo, Pavia, Italy aimed at the clinical validation of HCMV DNA cut-off values for preemptive treatment (Gerna et al., *Antivir Ther* 2007; Lilleri et al., *Blood* 2008). All patients had been prospectively tested once a week using an in house developed Real-Time PC (PV assay). HCMV infection was treated preemptively on the basis of two HCMV DNA cut-off values in whole blood: 30 000 copies/mL for HSCTR and 300 000 copies/mL for SOTR.

**Results:** Overall, 266 sequential whole blood samples from 20 HSCTR patients and 247 specimens from 17 SOTR patients were analyzed. HCMV disseminated infection was confirmed by both assays in 18/20 HSCTRs and 15/17 SOTRs, whereas HCMV infection was excluded by both methods in 2/20 HSCTRs and in 2/17 SOTRs. In particular, 352/513 samples resulted concordant positive and 42/513 were concordant negative. 119/513 samples were discordant (Abbott-positive and negative by the PV assay). These samples were restricted to the initial and conclusive phases of infection and were scored as positive by the Abbott assay and as containing <100 copies/mL by the PV assay. A significant correlation was observed between concordant positive samples ( $r = 0.89$ ). Following dilution in whole blood of the WHO international standard for HCMV DNA quantification, a copies/mL to IU/mL conversion factor of 5.04 and 9.83 was calculated for the PV assay and the Abbott assay, respectively. A better concordance between the PV assay and the Abbott assay to score the patients' eligibility to treatment was observed following translation of results in IU/mL, than using the copies/mL readout.

**Conclusions:** (i) the Abbott assay showed greater analytical sensitivity, a characteristic to be taken into account for treatment interruption; (ii) normalization of quantitative results expressed by UI/mL could be useful in order to safely export and use clinical cut-offs for pre-emptive antiviral therapy.

**P886** **Type distribution of human papillomaviruses in cervical samples of women with cytological abnormalities from Primorsko-Goranska county, Croatia**

T. Rukavina\*, B. Ticac (Rijeka, HR)

**Objective:** Cervical cancer is the second most common cancer in women. Most of the cases are caused by infection with HPVs. Certain HPV types have strong oncogenic potential and are considered high-risk (HRT), while certain are considered low-risk (LRT) since their infection results in formation of benign genital warts. Currently, two vaccines for the prevention of these infections are available. Two HRTs (16 and 18) included in vaccines are considered responsible for more than 2/3 of cases of cervical cancer. Several studies from Croatia reported that these two types are less frequent in our female population. Therefore, we decided to determine the HPV types in cervical samples

of women with cytological abnormalities from Primorsko-Goranska County in Croatia.

**Methods:** We have analyzed 108 consecutive HPV-positive samples of women with proven cytological abnormalities. Samples are processed in the Laboratory for Molecular Diagnostics of the Teaching Institute of Public Health of Primorsko-Goranska County, Rijeka, Croatia. They were analyzed by PCR method using commercial kits with electrophoretic detection: HPV6/11; HPV High Risk Screen; and HPV High Risk Typing (Sacace Biotechnologies, Italy). The kits enable detection of LRTs HPV6 and 11 and HRTs HPV16, 18, 31, 33, 35, 39, 45, 52, 53, 56, 58, 59, 66 and 70.

**Results:** Fifty-three of 108 analyzed samples (49.1%) contained 1 type of HPV; while more than 1 (up to 5) HPV types were detected in 51 samples (47.2%). In four samples (3.7%) the HRT detection was positive but the typing was not successful, so we considered them HRT positive, nontypeable. Four samples (3.7%) contained only 1 LRT while all the other samples contained HRTs. The most frequent HRT was HPV16 that was detected in 33 samples (17.2%), followed by HPV31, 52 and 18 that were detected in 25 (13.0%), 21 (10.9%) and 18 (9.4%) samples, respectively. HPV16 and 18 that are considered responsible for more than 2/3 of cases of cervical cancer were found in 48 analyzed samples (44.4%).

**Conclusions:** Most of the women with cytological abnormalities included in study were infected with HRTs (104 out of 108). HPV16 was the most commonly found, followed by HPV31, 52 and 18. The two HRTs covered by currently available HPV vaccines were detected in 44.4% of analyzed samples. This fact should be taken into account during planning of future preventive public health activities.

**P887** **Comparison of Cobas AmpliPrep/Cobas TaqMan Docking Station vs. Cobas AmpliPrep/Cobas TaqMan 48, Nuclisens EasyMag/EasyQ System and System 340 bDNA Analyzer for quantification of HCV, HIV-1 and HBV in plasma**

M.J. Munoz-Davila\*, A. Moreno, D. Montero, T. Ramos, M. Segovia (Murcia, Madrid, Barcelona, ES)

**Objective:** Comparative evaluation of correlation rates and management of the Cobas AmpliPrep/Cobas TaqMan Docking Station (CAP/CTM DS) vs. the routine assays (Cobas AmpliPrep/Cobas TaqMan 48 [CAP/CTM 48], Nuclisens EasyMag/EasyQ System [NEQ/NEM] and System 340 bDNA Analyzer [S340bDNA]) used for human plasma or serum measurement of HBV, HCV and HIV-1 in the two laboratories included in the study center (University Hospital Virgen de la Arrixaca [UHVA] and University Hospital La Paz [UHP], Spain).

**Methods:** All samples included in this comparative evaluation were processed on three consecutive days. All tests were performed strictly according to the manufacturer's instructions. Patient samples received at the virology units for viral load quantification of HBV DNA, HCV RNA and HIV-1 RNA were performed in parallel by the routine method and by the CAP/CTM DS at the two hospitals included in the study. Patient samples collected on three consecutive days included positive results in a wide range of quantifications and also samples resulting in target not detected. The patient samples were randomly selected according the order in which they were received at the laboratory, until a statistically significant number was reached. Workflow, throughput, and minimum user time was collected for each assay studied. Statistical analyses: The Passing-Bablok method was used to judge the relationship of the assays to one another. Bland-Altman plots were constructed.

**Results:** The percentages of correlation coefficient of the CAP/CTM DS vs. CAP/CTM 48 were 99.7% and 87.2% for HCV and HIV-1 respectively, at the UHVA. These percentages of correlation coefficient were quite similar to those obtained by the UHP, namely 98.7% for the CAP/CTM DS vs. CAP/CTM 48 for HCV, 86.6% for CAP/CTM DS vs. NEQ/NEM for HIV-1 and 94.2% for CAP/CTM DS vs. S340bDNA for HBV. Linear regression analyses represented by scatter plots are

shown in Figure 1. The specimen throughput for a batch size of 24 was consistently lower for the CAP/CTM DS in all cases except when it was compared with NEM/NEQ for viral load quantification of HIV-1 at the UHP. Importantly, CAP/CTM DS exhibited substantially reduced hands-on-time when compared with the rest of the assays.

**Conclusion:** When compared with these systems, the CAP/CTM DS assay yielded excellent correlation results and improved hands-on time in all cases. Total processing time for 24 samples was also reduced in most cases.

#### **P888** Evaluation of sample collection and handling conditions for the Versant HCV RNA 1.0 assay (kPCR)

W. Lin\*, L. Cheng, P. Lau, S. Ho, J. Canchola, G. Gorrin (Berkeley, US)

**Objectives:** The VERSANT® HCV RNA 1.0 Assay (kPCR)\* (Siemens Healthcare Diagnostics Inc., Tarrytown, NY, USA) is an in vitro nucleic acid amplification assay for the quantitation of hepatitis C virus (HCV) RNA in serum or plasma of HCV-infected individuals over the range of 15–1.0E8 IU/mL using the VERSANT® kPCR Molecular System.\*A study was performed to investigate the effect of multiple sample collection tubes and associated processing parameters on viral quantitation in the VERSANT HCV kPCR Assay.

**Methods:** Sixty unique HCV-infected donors were divided among six donor sample sets that were used to evaluate BD VACUTAINER ACD, K2EDTA, PPT, (plasma) and SST (serum) blood collection tubes. Sample hold times before collection tube processing (up to 6 hours at ambient temperature or 24 hours at 2–8°C) and after (24 hours at ambient temperature and up to 72 hours at 2–8°C) were evaluated. In addition, long-term sample storage at –20°C and –80°C plus multiple freeze-thaw cycles at –20°C and –80°C were assessed. Twenty additional patient samples were collected to study the effect of fresh vs. frozen samples on viral quantitation in the four tube types, and primary tubes vs. aliquots in PPT and SST tubes. Results were considered acceptable if the average difference between test and control conditions was within  $\pm 0.2$  log IU/mL.

**Results:** There were no significant differences between the four tube types tested. Serum and plasma were found to be equivalent matrices, as quantitation in serum (SST) was within  $\pm 0.2$  log of quantitation in plasma (K2EDTA, PPT, and ACD). The varying hold times before and after collection tube processing also did not have a significant effect. Long-term sample storage for up to 4 months at –20°C proved to be no different from storage at –80°C for all tube types tested, and samples were stable for up to four freeze-thaw cycles at –20°C and –80°C. Results from the additional twenty patient samples demonstrated that either fresh or frozen samples can be used, (all quantitation differences within the  $\pm 0.2$  log IU/mL). There were also no significant differences in quantitation between primary tubes and aliquots.

**Conclusion:** This study found no significant difference in quantitation between test and reference conditions for all parameters evaluated.

These data demonstrate that the VERSANT HCV RNA 1.0 Assay (kPCR) provides flexibility in sample collection and processing.

\*CE marked. Not available for sale in the US.

#### **P889** Method comparison between the VERSANT HCV RNA 1.0 assay (kPCR), Abbott RealTime HCV, Roche COBAS AmpliPrep/COBAS TaqMan HCV Test, and VERSANT HCV RNA 3.0 assay (bDNA)

H. Huang\*, W. Lin, S. Ho, J. Brooks, P. Lau, J. Surtihadi, J. Canchola, L. Cheng, G. Gorrin (Berkeley, US)

**Objectives:** The VERSANT® HCV RNA 1.0 Assay (kPCR)\* (VERSANT kPCR; Siemens Healthcare Diagnostics Inc., Tarrytown, NY, USA) is an in vitro nucleic acid amplification assay for the quantitation of hepatitis C virus (HCV) RNA in serum or plasma of HCV-infected individuals over the range of 15–1.0E8 IU/mL using the VERSANT® kPCR Molecular System.\*Method comparisons were conducted between VERSANT kPCR and Abbott RealTime HCV (ART; Abbott Molecular, Inc., Des Plaines, IL, USA), Roche COBAS® AmpliPrep/COBAS® TaqMan® HCV Test (CAP/CTM; Roche Molecular Systems, Pleasanton, CA, USA) and VERSANT HCV RNA 3.0 Assay (bDNA) (bDNA; Siemens Healthcare Diagnostics Inc.).

**Methods:** In all, 155 samples were tested: 116 HCV-infected serum and plasma samples, collected with IRB approval at BioCollections Worldwide, Inc. (Miami, FL, USA); and 39 samples from HCV genotype panels, purchased from SeraCare (Milford, MA, USA), to ensure all common HCV genotypes were included. Each sample was tested with the VERSANT kPCR Molecular System, which consists of a Sample Prep module and an Amplification/Detection module (Siemens, Berkeley, CA, USA), as well as with bDNA, at Siemens Clinical Laboratory, Berkeley, CA; with Roche CAP/CTM at John Muir Hospital Lab, Walnut Creek, CA; and with Abbott ART at BioCollections Worldwide. Testing was done in singlicate by each of the methods, and results were compared for all samples with paired quantitations within the reporting ranges of each pair of methods. Deming regression was used to determine if methods had a linear relationship (slope within 0.9–1.1). Quantitative equivalence was considered acceptable if the average log difference was within  $\pm 0.5$  log IU/mL.

**Results:** The Deming regression slopes for all paired comparisons were between 0.98 and 1.01, indicating that the VERSANT kPCR has a linear relationship with all of the comparator methods. The average log difference between the VERSANT kPCR and the comparator methods was within 0.38 log IU/mL for Abbott, within 0.13 log IU/mL for Roche, and within 0.31 log IU/mL for bDNA.

**Conclusions:** The results demonstrate a linear relationship and quantitative equivalence between VERSANT HCV RNA 1.0 Assay (kPCR) and the comparator methods:

- 1 Roche COBAS AmpliPrep/COBAS TaqMan HCV Test,
- 2 Abbott RealTime HCV Assay, and
- 3 VERSANT HCV RNA 3.0 Assay (bDNA).

#### **P890** Multiplex PCR assays for RSV-A, RSV-B and human metapneumovirus diagnosis in acute bronchiolitis

A. Tenorio-Abreu, J. Gil-Tomás\*, A. Burgos-Teruel, B. Gómez-Alonso, O. Martínez Macías, M. Borrás Mñez, J. Colomina Rodríguez, A. Guerrero Espejo (Alzira, La Laguna, ES)

**Objectives:** Design and optimization of multiplex real-time RT-PCR for RSV-A, RSV-B and human metapneumovirus diagnosis in acute bronchiolitis in pediatric population.

**Material and Methods:** Three sets of TaqMan primers-probes (Applied Biosystems, USA) were devised for detection of respiratory syncytial virus type A (RSV-A), RSV-B and human metapneumovirus, which are the main causal agents of neonatal and unweaned baby

bronchiolitis. A 7500 Fast real-time thermocycler system (Applied Biosystems, USA) was used to carry out RT-PCR in <1.5 hour. Sequencing of the resulting amplicons using every set of primers and mixtures of the three viruses was made to establish the technique specificity. Sensitivity was determined using serial dilutions of decreasing and known DNA concentrations. Finally, the test yield was proved by means of application of the procedure to 121 nasal aspirate samples from children with clinical findings of bronchiolitis. A rapid detection RSV test (BinaxNow) and a NASBA (Nucleic acid sequence based amplification) technique (EasyQ, Biomerieux, Spain S.A.) for metapneumovirus detection, were previously performed to these samples.

**Results:** Sequencing of the three resulting amplicons compared to sequences from GeneBank database proved an absolute specificity. Also, the technique allows for proper simultaneous differentiation of each virus in a mixture containing the above mentioned viruses. The sensitivity limit showed a PCR able to detect between 1 and 10 DNA copies/ $\mu$ L. The comparison results with the rapid detection RSV test and NASBA technique were as follows: the proportion of positive results for RSV detection by the rapid test was 53/121 (43.8%); 1/121 (0.8%) was positive for metapneumovirus by NASBA technique; 66/121 (54.5%) were positive to RSV (34 type A and 32 type B) and 3/121 (2.5%) to metapneumovirus using multiplex RT-PCR. The operating features of both techniques compared to multiplex RT-PCR are shown in the table.

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
RSV	80,3	100	100	80,9
Metapneumovirus	33,3	100	100	98,3

**Conclusions:** Multiplex real-time RT-PCR has proved both high specificity and sensitivity. Regarding other diagnosis techniques, this PCR procedure has shown a high superior sensitivity. All these advantages, coupled to the high rate and simplicity of the method make this technique very useful in a daily clinical practise for acute bronchiolitis virological diagnosis.

**P891 Multi centre study to evaluate the influence of pre-analytical storage conditions on the RNA concentration of hepatitis C virus**

B. Vanmassenhove\*, S. Lambin, F. Hillen, K. Pieters, P. Descheemaeker, M. Boudewijns, M. Raymaekers, K. Martens, D. Vaira, N. Hougardy, D. Ursi, K. Beuselincx, W. Verstrepen, S. Franke on behalf of MolecularDiagnostics.be

**Objectives:** Several studies have claimed that hepatitis C virus (HCV) RNA levels are stable in samples when stored at 4°C for 3 up to 7 days. The stability of HCV RNA levels at room temperature (RT) is less clear. Some studies stated that HCV RNA is unstable at RT (18–25°C) whereas others demonstrated that EDTA blood or serum may be stored at 25°C for 4 up to 5 days without significant loss in HCV RNA. In this multi-centre study (10 laboratories) we tested the HCV RNA stability of 15 samples (eight serum samples and seven plasma samples) by storing the samples at RT for 0, 1, 3 and 7 days before analysis.

**Methods:** Laboratories analysing HCV on serum, divided a fresh serum sample in four aliquots, left these aliquots at RT and stored the aliquots below –20°C at day 0, 1, 3 and 7. Laboratories analysing HCV on EDTA plasma, divided an EDTA blood sample in 4 aliquots. The different aliquots were left for 0, 1, 3 and 7 days at RT before centrifugation and immediately stored below –20°C. The RNA extraction and HCV qPCR was done for all aliquots in the same run (avoiding inter-run differences). The concentrations (IU/mL) of the samples at day 0, 1, 3 and 7 were expressed as Log10 values. A Log10 difference >0.5 was considered as a clinical significant difference.

**Results:** One sample was excluded for further analysis because the centre did not determine the RNA level on day 0. One result on day 1 was excluded because of a statistical outlier. The Log10 differences from all samples for the different time points indicate an similar trend:

the HCV concentration decreases over time. For 2 out of 14 samples (14%), a Log10 difference >0.5 was observed at day 3. For 5 out of 12 samples, a Log10 difference >0.5 was observed at day 7. The mean Log10 difference stayed within the 0.5 limit at all days. However at day 7, the mean Log10 difference was  $-0.45 \pm 0.34$ , which demonstrates a significant decrease in HCV concentration for several samples. No statistical difference was observed between serum and plasma samples.

**Conclusion:** Although it is clear that it is the best procedure to store samples as soon as possible at <–20°C is, we can conclude that most samples stored at RT for 3 days do not exhibit a significant loss in measured HCV RNA levels. However, storage for more than 3 days at RT will lead to an underestimation of HCV RNA concentrations or false-negative results in the detection of HCV RNA in serum and plasma.

**P892 Rabies outbreak among wild and domestic animals in Republic of Buryatia, Russia**

R. Adelshin, O. Melnikova, E. Andaev, A. Botvinkin, S. Balakhonov\* (Irkutsk, RU)

**Objectives:** Rabies is a zoonotic viral disease which infects domestic and wild animals and it is fatal for animals and human. The aim of our study was to determine the molecular characteristics of rabies virus (RABV) outbreak in the Republic of Buryatia (Russia).

**Methods:** We examined three domestic and six wild animals' brain samples on RABV presence. For this goal we have used biological (bioassay), serological (fluoroimmunoassay) and molecular genetic (RT-PCR and sequencing) methods. Several smears on ground slides were prepared from the received material, which were labeled with fluorescent antirabic globulin (Federal Center for Toxic and Radiation Safety of Animals, Russia) after acetone fixation during 2–4 hour. Laboratory not pedigree white mice were infected according to method recommended by WHO. Total RNA was extracted directly from brain tissue (10% suspension in saline) using Riboprep kit (ILS Ltd., Russia). Amplification of nucleocapsid (N) gene was carried out with Amplisens kit (ILS Ltd., Russia). PCR products were sequenced with ABI Prism Big Dye Terminator v.1.1 Cycle Sequencing Kit and Genetic Analyzer 3130 (Applied Biosystems). Sequencing results (1353 bp) were analyzed by BioEdit v.7.0.5.3. software. Phylogenetic analysis was performed by MEGA 5 program using Maximum Likelihood method.

**Results:** The intensity of the granules fluorescence in preparations from the native samples was as much as ++ – +++, the intensity in preparations from the laboratory died mice' samples was as much as +++ – +++. Bioassay samples' nucleotide sequences had 100% of

homology with isolate's sequences. Phylogenetic analysis shows that RABV isolates from Republic of Buryatia (Russia) follows into the clade with RABV strains from Mongolia isolated from domestic and wild animals some years ago. The identity of nucleotide sequences of these strains and Buryat isolates is 98.9–99.2%.

**Conclusion:** Our results show the presence of rabies outbreak among wild animals and cattle on the territory of Republic of Buryatia (Russia). Phylogenetic analysis allows to suggest possible import of rabies virus by wild animals from Mongolia.

#### **P893** Tropism testing using an adaptation of the Trugene assay in plasma, CSF and cell extract (proviral)

A. Cox\*, P. Pantelidis, M. Atkins, P. Kelleher (London, UK)

**Objectives:** To adapt an existing rapid HIV drug resistance sequencing test for HIV-1 envelope co-receptor usage detection for plasma, proviral and CSF samples.

**Background:** Knowledge of HIV-1 envelope V3 gene tropism is essential to select most appropriate patients for treatment with the anti-HIV CCR5 drug inhibitors such as Maraviroc. Determination of V3 co-receptor usage is performed primarily by molecular assays which have can be time consuming and involves viral RNA extraction, RT-PCR, sequencing and bioinformatics prediction of HIV coreceptor usage (geno2pheno; Max Planck Institute). There is increasing clinical demand for assessment of V3 tropism in plasma, peripheral blood mononuclear cells and cerebro-spinal fluid (CSF) samples. Here, we describe an adaptation of the Siemens Core Reagent assay which provides a quick and easy method to determine likely co-receptor usage in plasma (Viral RNA), cell extract (proviral DNA) and CSF.

**Method:** RNA was extracted from plasma or CSF using the Qiagen RNA extraction kit and DNA was extracted using the Qiagen DNA miniKit. V3 tropism was assessed using a single approach for all samples with an adaptation of the Siemens Core Reagent method for first round PCR, followed by an in-house nested PCR protocol utilizing a proof-reading enzyme cocktail. PCR products were subsequently directly sequenced using the Siemens Clip Assay and data were analysed online with geno2pheno bioinformatics prediction program. Clade types in V3 samples were compared with Clade types obtained for protease and reverse transcriptase resistance (Pr/RT) typing.

**Results:** The methodology used was found to be equally applicable for the detection of HIV coreceptor usage in viral RNA (plasma/CSF) and proviral (DNA) samples. The Clade types obtained by V3 samples were found to be 95% concordant with the Clade types obtained by Pr/RT resistance typing with discrepancies being confirmed by repeat testing and as such likely to be due to recombination. The majority of samples tested were Clade B (69.8%), followed by Clade A/AG (17.0%), Clade C (9.4%) and Clade G (3.8%). In a small number of samples with both plasma and proviral sequencing data, there was a good concordance between plasma and proviral sequences.

**Conclusion:** Using a single approach, as described here, co-receptor usage can be determined for RNA and proviral DNA samples with equal success.

#### **P894** Design and efficacy of a real-time genome amplification (RT-PCR) for human herpesvirus type 6A/B and 7

I. Hernández-Cáceres, M.E. Álvarez-Argüelles, J.A. Boga-Riveiro, S. Rojo-Alba, Ó. Martínez-Expósito, J. Fernández-Domínguez, S. Melón-García, M. Oña-Navarro\* (Santa Cruz de Tenerife, Ovedo, ES)

**Objectives:** Human Herpesvirus type 6A/B (HHV6A/B) and Human Herpesvirus type 7 (HHV7) are involved in multiple symptoms, specially in immunosuppressed patients, where a rapid diagnosis of the infection is necessary. Both viruses grow poorly in conventional cell culture, so molecular biology techniques constitute the diagnostic method of choice. Our objective was to design a rapid test based on

real-time amplification (RT-PCR) to detect HHV6A/B and HHV7 genomes, and to check its efficacy in clinical samples.

**Methods:** Two different pairs of primers targeted to the U20 gene from HHV6A/B, and to a non-coding fragment (117250–117350 bp) from HHV7 were designed using Primer Express v.3 software (Applied Biosystems, USA). A RT-PCR was performed with LightCycler FastStart DNA Master<sup>PLUS</sup> SYBR Green I (Roche Diagnostics, Switzerland) according to the manufacturer's protocols. Specificity was determined by melting temperature (T<sub>m</sub>) in positive controls for both viruses (quantitated plasmid dilutions for HHV6A/B, and serial dilutions of positive samples for HHV7). In 60 samples for HHV6A/B, and 38 samples for HHV7, results of RT-PCR were contrasted with the results of the multiplex-nested-PCR performed routinely in the laboratory, using primers directed against the same target genes (see Table 1).

**Results:** RT-PCR detected between 50–500 copies of HHV6A/B DNA, and a 10<sup>-6</sup> dilution of a HHV7-positive clinical sample. The T<sub>m</sub> for HHV6A/B was 80.5°C, and for HHV7 was 84.9°C. In 60 samples assayed for HHV6A/B, RT-PCR was positive in 1 (1.6%), whereas nested-PCR was positive in 8 (13%) (p = 0.03). On the other hand, RT-PCR detected 12 positives of 38 samples assayed (31.5%) for HHV7 DNA, and nested-PCR detected nine positives (23.7%).

	RT-PCR primers	Nested-PCR	
		External primers	Internal primers
HHV6 A/B	5'-GTGTATGCTCAAGCTCTACTCAA-2' 5'-TTCAGATGACATAGACTACAGAT-3'	5'-CRTCTCTCGGATTCCTCA-2' 5'-CTCTARAGACGCTCTCTC-3'	5'-TCTCTGTAAAGAGCTGG-3' 5'-AGAGAGACAGGTTTCTCTC-3'
HHV7	5'-TTCATGTATGATCCGGGCTTT-3' 5'-AACGGTTTACTTCCGCGAATTT-3'	5'-CAGACATCGATGACAGATTTGA-2' 5'-ATTCCGGAAATGATACCAACA-3'	5'-TTCATGTATGATCCGGGCTTT-3' 5'-TAACGGTTTACTTCCGCGAATTT-3'

**Conclusions:** Although the RT-PCR designed for HHV6A/B could detect few DNA copies of a specific plasmid, the poor performance in clinical samples suggest redesigning the conditions of the experiment. RT-PCR protocol for HHV7 is a good alternative to a classic nested-PCR, reducing working time and laboriousness. It also could be possible to simultaneously detect HHV6A/B in a multiplex-PCR with HHV7 because of their different melting temperatures.

#### **P895** Evaluation of Versant<sup>®</sup> HCV RNA 1.0 Assay (kPCR). A new automated kinetic PCR assay for quantification of HCV RNA in plasma

D. Martin\*, J. Costa, T. Pumarola (Madrid, Barcelona, ES)

**Objectives:** To assess performance characteristics of the new VERSANT<sup>®</sup> HCV RNA 1.0 Assay (kPCR) (VERSANT kPCR; Siemens Healthcare Diagnostics) and to compare VERSANT kPCR viral load results with those of the VERSANT HCV RNA 3.0 Assay (bDNA) (VERSANT bDNA; Siemens Healthcare Diagnostics).

**Methods:** Plasma specimens were collected from 451 anti-HCV-positive individuals monitored at two hospitals in Madrid and Barcelona, Spain. Samples having viral loads within the common quantification range of the two assays were aliquoted and stored at -80°C. HCV genotype and subtype were assessed using VERSANT HCV Genotype 2.0 Assay (LiPA). The distribution of HCV genotypes corresponds to the local prevalence. HCV viral loads were tested using VERSANT kPCR and VERSANT bDNA assays, following the manufacturer's instructions. Eight serial dilutions of an HCV concentrated stock provided by Siemens (ranging from 96 969 125 to 48 IU/mL) were used to evaluate precision and linearity. Specificity was evaluated by testing 89 anti-HCV antibody-negative samples from normal blood donors. Statistical analysis was performed using Deming regression and Bland-Altman methods.

**Results:** The slope of the Deming regression for the 256 samples that quantified within the overlapping range of the two assays was 0.95 (R<sup>2</sup> = 0.89) indicating that the two assays have a linear relationship. The Deming regression slopes were 0.98 for Madrid (n = 106), and

0.91 for Barcelona (n = 150). The average log difference between the two assays (kPCR – bDNA) was 0.09 log (95%CI: 0.05–0.14 log). 87.9% of the samples quantified within  $\pm 0.5$  log for the two methods. The mean log difference between assays was also within  $\pm 0.5$  log for all genotypes tested.

A high correlation ( $R^2 = 0.99$ ) was observed between the expected and observed values for quantification of HCV RNA in serial dilutions indicating that the VERSANT kPCR assay has a linear response. Specificity of the VERSANT kPCR assay was 100% (0/89 detected).

**Conclusions:** The VERSANT HCV RNA 1.0 Assay (kPCR) showed excellent specificity, good linearity and genotype inclusivity. This study demonstrated that the VERSANT HCV RNA 1.0 Assay (kPCR) and VERSANT HCV RNA 3.0 Assay (bDNA) have a linear relationship with good concordance. The new VERSANT HCV-1 RNA 1.0 Assay (kPCR) is suitable for monitoring HCV patients following current medical guidelines.

#### **P896** Evaluation of the QIASymphony® RGQ system for the quantification of different BK virus genotypes in biological samples

C. Brunet, G. Wall, S. Burrell, N. Hamm, E. Gay, H. Agut, D. Boutolleau\* (Paris, FR; Hilden, DE)

**Objectives:** BK virus (BKV) is a ubiquitous human polyomavirus classified into four different genotypes (I to IV) which constitutes an important pathogen among kidney and haematopoietic stem cell transplant recipients. BKV infection monitoring in patients requires the accurate quantification of the BKV genome in biological samples using real-time PCR methods. The aim of this study was to perform a clinical evaluation of the artus® BK Virus QS-RGQ Kit on the QIASymphony® RGQ system.

**Methods:** One hundred and eleven whole blood and 17 urine samples, collected from transplant recipients and stored at  $-80^{\circ}\text{C}$ , were retrospectively selected in order to obtain a broad range of BKV loads. BKV genotype was determined for 71 samples by the sequencing of VP1 gene. BKV load was measured using the QIASymphony® RGQ system according to the manufacturer's instructions (whole blood samples were tested in an off-label capacity). The results were compared to those obtained with the laboratory-developed BKV real-time PCR assay currently used for virological diagnosis.

**Results:** The interassay variation for the four quantitative standards of the kit tested in four consecutive runs was low (CVs ranging from 1.0 to 2.3%). No cross-contamination was observed. The internal control (IC) was detected in all samples apart from seven urines for which BKV load was high (over 7 log). For the 121 remaining samples, the IC mean Ct value (SD) was 26.70 (1.78). For the 128 samples tested, the overall agreement between the laboratory assay and the artus® BKV assay was 96.9%. The four discrepant results corresponded to low BKV loads, below 3 log. The comparison of the 113 paired positive results evidenced a significant correlation (Spearman correlation coefficient: 0.87 [ $p < 0.0001$ ]), and the Bland-Altman analysis showed no significant shift between both assays (bias artus® BKV/laboratory:  $-0.38$  [ $\pm 1.96$  SD:  $-1.35$  to  $0.59$ ]). The comparative analysis of the BKV loads obtained with the QIASymphony® RGQ system evidenced no difference according to BKV genotype, with BKV load differences ranging from  $-0.29$  to  $-0.40$ .

**Conclusion:** This study showed a very good agreement and a high correlation between the artus® BKV and the laboratory-developed assays for whole blood and urine samples. Moreover, the performance of the artus® BKV assay was similar regarding the quantification of all 4 BKV genotypes. In conclusion, the QIASymphony® RGQ system constitutes a suitable and versatile tool in a routine virological laboratory setting.

#### **P897** Comparison of xTAG-Fast respiratory virus panel and CLART PneumoVir for detecting respiratory viruses in nasopharyngeal samples

M. Rodriguez-Dominguez\*, J.M. Gonzalez-Alba, R. Cantón, J.C. Galán (Madrid, ES)

**Objective:** Several molecular technologies have been recently developed to detect simultaneously the presence of a broader panel of viruses in infections of lower respiratory tract. We compare xTAG-fast viral respiratory panel (Abbott Molecular diagnostics) based on target-specific primer extension technology and CLART PneumoVir (Zeltia Genomica) based on low density array. This comparison has not been previously analyzed.

**Methods:** Forty nasopharyngeal swabs from hospitalized patients to the Ramon y Cajal Hospital, Madrid, Spain with severe respiratory illness were collected between January to October-2011. The swabs were inoculated into 3 mL of Universal Transport Medium (COPAN Diagnosis, Murrieta, USA) to conserve the sample. Nucleic acids were automatically extracted using NucliSens easyMAG system (Biomerieux, France) from two hundred  $\mu\text{L}$  samples and eluted in 35  $\mu\text{L}$ . These platforms can discriminate between 10 families of viruses. The main differences were CLART was able to discriminate between Enterovirus and Rhinovirus and detect fluA(H1N1)2009 and flu-C. xTAG-fast can detect flu-A (H5N1) and four different strains of coronavirus.

**Results:** Twenty-eight samples lead a positive result at least for one method (71%). Concordance ranged between 76.5% and 42.8% when single and mixed viral infections were compared. The low value of concordance in mixed infection (42.8%) was due to xTAG-fast was not able to detect simultaneously more than two viruses in the same sample. Two samples from ICU patients were negative using xTAG-fast but parainfluenza-4 virus and bocavirus were detected by Clart PneumoVir; moreover parainfluenza-3 virus, respiratory syncytial virus and bocavirus were not detected in mixed infections using xTAG-fast. On the other hand, Clart PneumoVir was not able to detect single infections produced by coronavirus CoV-OC43 and enterovirus/rhinovirus. The xTAG-fast requires around 4 hours whereas Clart PneumoVir takes about 7 hours.

**Conclusions:** Clart PneumoVir seems to be more sensitive to detect multiple viruses in the same sample, although the role of coinfections is not clear. Major differences were observed in the detection of bocavirus and parainfluenza viruses; the first was detected 40% lower with xTAG-fast than Clart PneumoVir and the second was detected 30% lower with xTAG-fast respect to Clart PneumoVir. The observed failures using xTAG-fast are coincident with the target not-approved by US-IVD although they were accepted by CE-IVD Europe.

#### **P898** Evaluation of an automated sample preparation system for detection of human cytomegalovirus in whole blood

S. Wang\*, H. Sidhu, H. Beas, B. Maier, M. Vignoles, M. Joannes, T. Battersby (Berkeley, US; Graz, AT; Verniolle, FR)

**Objectives:** The VERSANT® Sample Preparation 1.2 (SP1.2) reagents kit\*, which can extract DNA from up to 96 whole blood samples on the automated VERSANT® kPCR Molecular System, was used with the R-gene™ CMV assay to detect human cytomegalovirus (CMV) in whole blood. Analytical performance characteristics of the assay were evaluated.

**Methods:** CMV viral DNA was extracted and captured from panels or patient specimens using VERSANT SP1.2 reagents on the SP module of the VERSANT kPCR Molecular System. The purified DNA target was amplified and detected using the R-gene CMV assay on the Amplification/Detection (AD) Module of the VERSANT kPCR Molecular System. Assay sensitivity, linearity, and precision were determined by testing serial dilution panels prepared with live CMV virus spiked into whole blood. DNA extraction efficiency on the VERSANT SP module using VERSANT SP1.2 reagents was compared

against that of three other automated sample preparation platforms—NucliSens easyMAG (bioMérieux), QIA Symphony (Qiagen), and MagNA Pure LC 2.0 (Roche Diagnostics)—using whole blood samples obtained from patients. A method comparison between the VERSANT kPCR molecular system and the NucliSens easyMAG system was performed using 31 whole blood patient specimens and the R-gene CMV assay.

**Results:** The R-gene CMV assay used with the VERSANT SP1.2 reagents yielded quantitative results for the CMV target in whole blood. Detection limit for CMV was 744 copies/mL with 200 µL whole blood input and 10 µL eluate used in the kPCR reaction. Linearity of the assay was between 2280 and 1E7 copies/mL. Precision results showed a variation of the base-10 logarithm of viral load quantitation of <0.5 at above 1E4 copies/mL. With the R-gene CMV assay as the AD method, the VERSANT SP system in conjunction with the SP1.2 reagents consistently yielded a higher viral load for the same clinical sample than the other three automated sample preparation platforms.

**Conclusion:** Preliminary analytical and clinical data demonstrated that the SP1.2 kit—together with the VERSANT SP module—is an efficient automated method for isolating DNA from whole blood samples. The VERSANT kPCR Molecular System in combination with the VERSANT SP1.2 Reagents kit and the R-gene CMV kit provide an automated method for measuring CMV viral load in whole blood samples.

\*As of November 2011, the VERSANT Sample Preparation 1.2 reagents kit is not yet commercially available. Siemens Reference Number: A91DX-MM-110163-GC1-4A00

#### **P899** Evaluation of the performance of the ProbeTec Qx assay for detection of herpes simplex 1 and 2 using the VIPER platform

*C.F. Pope, R.V.N. Karunaranan\*, K. Capaldi, T. Planche (London, UK)*

**Objectives:** Molecular assays are routinely used to detect Herpes simplex and are known to be more sensitive than cell culture. Our aim was to determine the performance of the new Becton Dickinson ProbeTec HSV 1 and 2 Qx assay on the VIPER platform in extracted mode. Assay results were compared to cell culture and to an in house HSV 1 and 2 multiplex real time PCR on the BD Max platform. The BD MAX (BD, NJ, USA) is a new flexible platform for performing automated extraction and real time polymerase chain reaction (PCR) on a range of patient specimens.

**Methods:** Six hundred and forty-two virology swabs submitted routinely for herpes simplex 1 and 2 cell culture from patients with genital lesions were included. These were tested by cell culture, anonymised, aliquoted and stored at -80°C until molecular testing was performed. Swabs were expressed in Hanks cell culture media and inoculated onto a monolayer of HEL cells. Cells were examined for a characteristic cytopathic effect (CPE) on a daily basis for a week. Immunofluorescence was performed on all monolayers exhibiting a CPE to differentiate between HSV 1 and HSV 2. Stored aliquots were tested in the BD ProbeTec HSV 1 and 2 Qx assay on the VIPER. Aliquots were then tested using an in house real time multiplex HSV1/HSV 2 PCR assay which has been adapted for use on the BD Max platform

**Results:** 56/642 (8.72%) samples were positive by cell culture for HSV 1 and 103/642 (16.04%) were positive for HSV 2. Using the ProbeTec HSV1 and 2 Qx assay, 73/642 samples tested as positive for HSV 1 and 171/642 tested as positive for HSV 2. The VIPER assay detected 30.4% extra HSV 1 results and 66.0% extra HSV 2 results.

**Conclusions:** The ProbeTec Qx HSV 1 and 2 assay detects more HSV infections than cell culture. Sensitivity and specificity will be determined by comparison to the in house assay using the in house real time multiplex PCR on the BD Max.

#### **P900** Molecular characterisation of clinical enterovirus 71 strains in Greece

*N. Siafakas\*, G. Stanway, L. Zerva (Athens, GR; Colchester, UK)*

**Objectives:** Six EV-71 strains were recently detected for a first time in Greece in children with hand-foot-and-mouth disease or exanthematous disease with diarrhoea and fever. All these strains were detected within a period of 7 months amongst patients admitted to the same hospital. The present study attempted characterization of almost complete genomic sequences of these strains, in an attempt to elucidate their epidemic association with other EV-71 strains circulating elsewhere in the world and identify possible recombination events which underlie enterovirus evolution and virulence.

**Methods:** RT-PCR assays using primers that specifically amplify the entire genome of all EV-71 strains were employed. Genomic sequences of enteroviruses belonging to Human Enterovirus Species A (HEV-A) were retrieved from GenBank and used for comparison with the partial 5'-UTR, P1, P2 and P3 region sequences of the EV-71 strains obtained during the present study. Multiple alignment of all sequences was made with the aid of ClustalW2 computer software. Genotypic relatedness between the strains identified in the present study and other, previously or currently circulating clinical strains was investigated by construction of the appropriate phylogenetic dendrogram. Finally, all sequences were screened for the presence of recombination events using the SimPlot software.

**Results:** The partial genomic sequences obtained from the six EV-71 strains revealed that they were highly similar (97–99%) to strains isolated from CSF in UK and the Netherlands during 2007 and 2008, belonged to the C2 genetic cluster and were closely related with strains responsible for significant epidemic activity in the Western Pacific Region. No significant genetic recombination events with other HEV-A strains were observed.

**Conclusion:** Molecular characterization of EV-71 strains detected and identified for a first time in Greece revealed the close association of these strains with highly virulent strains that circulated in Europe. Despite the fact that genetic recombination may play a significant role in the evolution of certain genetic groups of EV-71 strains, the lack of such recombination events in the partial sequences of the C2 sub-genogroup strains of the present study comes in accordance with previous studies regarding C1 and C2 sub-genogroups. The complete genomic sequences will have to be obtained first in order to address this issue with certainty.

#### **P901** Performance of the Abbott PLEX-ID viral IC spectrum assay on the PLEX-ID analyser system

*K. Ray\*, L. Blyn, D. Drapp, J. Goveia, R. Ofsaiof, D. Baynes, R. Lovari, D. Metzgar, R. Sampath, G. Schneider, M. Stemler, R. Vijesurier, J. Welk (Des Plaines, Carlsbad, US)*

**Objective:** The PLEX-ID Viral IC Spectrum assay is an in vitro test used for the detection and identification of human herpes viruses 1–5 and 8, BK and JC polyomaviruses, parvovirus B19, human enterovirus, and human adenovirus in human plasma. The purpose of these studies was to evaluate the analytical performance of the assay.

**Methods:** The PLEX-ID system couples nucleic acid amplification by PCR and analysis of reaction products by mass spectrometry. Nucleic acids are extracted from plasma samples and amplified by PCR. The reaction products are desalted and then injected into the mass spectrometer for analysis. The base compositions of the products are determined and matched against a reference database to identify any viral nucleic acids in the sample. The Limit of Detection (LOD) of the PLEX-ID Viral IC Spectrum assay was established by analysis of dilute samples (quantified by PCR) of the eleven target organisms. Assay reproducibility was assessed using three assay lots runs over five days, with three different operators using three different instruments. A panel of all 11 target viruses was used. Specificity of the assay was evaluated by testing 100 plasma EDTA specimens from apparently healthy subjects. Sensitivity of the PLEX-ID Viral IC Spectrum assay was

evaluated by testing 133 plasma EDTA specimens with an initial PCR test result positive for 1 of the 11 viruses detected by the assay. All specimens were retested by PCR.

**Results:** LOD: The LOD was defined as the lowest concentration at which  $\geq 95\%$  of replicates tested positive. Reproducibility: At both low (3 X LOD) and moderate (10 X LOD) concentrations, 45/45 (100%) of the sample replicates were detected for each sample virus. Specificity: The specificity rate was 100% (99/99). No viruses were detected in 99 specimens by PLEX-ID. One specimen tested positive by PLEX-ID for Parvovirus B19. This positive result was confirmed by PCR testing and considered a true positive. Sensitivity: The overall sensitivity rate was 94% (123/131 matching results). Thirty-three samples were positive for multiple viruses and further evaluated with additional PCR testing.

**Conclusions:** The PLEX-ID Viral IC Spectrum assay compares favorably to rtPCR detection methods for the viruses studied here. Sensitivity testing results demonstrate the multiplex detection capabilities of the PLEX-ID Viral IC Spectrum assay.

#### **P902** Characterisation of influenza viruses circulating in Latvia in 2010/2011 season

*T. Kolupajeva\*, S. Cvetkova, M. Petrova, E. Bleidele, A. Aniscenko, G. Rjazanceva, N. Zamjatina, J. Storozenko, B. Rozentale (Riga, LV)*

**Objectives:** To characterise influenza viruses circulating in Latvia in 2010/2011 season comparing to 2009/2010 season and evaluate a likelihood of antiviral resistance and virulence mutations.

**Methods:** Influenza viruses RNA was detected using real-time RT-PCR according to WHO/CDC protocol. Both the neuraminidase (NA) and hemagglutinin (HA) genes were sequenced. Phylogenetic tree was constructed using neighbour-join in MEGA 5. Cell line MDCK was used for isolation of influenza virus strains. Antigenic characterisation based on hemagglutination inhibition test performed using a panel of reference ferret antisera from NIMR, UK. We analyzed 23 sequences of (H1N1)pdm09 viruses from patients hospitalized in 2010/2011 season mostly with pneumonias including severe cases with death (13 cases) and six sequences of B influenza viruses (one lethal case). Sixteen A(H1N1)pdm09 viruses from 2009/2010 season were sequenced in NIMR.

**Results:** All 227 typed A(H1N1)pdm09 viruses from 2010/2011 season showed antigenic similarity to the currently recommended vaccine virus A/California/7/2009. In most (14/16) sequences from 2009/2010 season and in all sequences from 2010/2011 season mutation S203T in HA gen Ca1 antigen region was found. The specific NA gene mutation associated with oseltamivir resistance (H275Y) was not observed in the 2010/2011 nor in the 2009/2010 seasons. Virulence-associated amino acid substitution from aspartic acid to glycine at position 222 (D222G) of the HA1 subunit of HA were detected in two sequences from 2009/2010 season, one of them in fatal case. Other mutation at this amino acid, D222E was found in three sequences, two of them from fatal cases. In 2010/2011 season D222G was observed in one sequence from fatal case and in one sequence other substitution at this position D222N was found. Most of 2010/2011 season circulating A(H1N1)pdm09 viruses belonged to A/StPetersburg/27/2011 group. Influenza B viruses of the B/Victoria/2/87 lineage predominated (164/167) over those of the B/Yamagata/16/88 lineage (3/167) as in other European countries.

**Conclusion:** A(H1N1)pdm09 and B type influenza viruses circulated in Latvia in 2010/2011 season showed the same antigenic profile as viruses circulated in other European countries. The specific NA gene mutation associated with oseltamivir resistance (H275Y) was not found. Virulence-associated amino acid substitution D222G of the HA1 subunit of HA were identified in some sequences from both 2009/2010 and 2010/2011 seasons.

#### **P903** The QIAGEN artus HIV-1 QS-RGQ viral load assay shows high concordance to the Abbott m2000rt HIV-1 viral load and the Roche CAP/CTM HIV-1 test v2.0 assay

*M. Obermeier\*, A. Moritz, U. Küsters, G. Wall, T. Berg (Berlin, Hilden, DE)*

**Objectives:** Quantitative measurement of viral load is one of the major parameters for therapy monitoring in HIV infected patients. The newly available artus HIV-1 QS-RGQ viral load assay provides a complete workflow of sample preparation, PCR setup, amplification and detection as a CE-IVD compliant workflow, whilst remaining highly flexible. As all three platforms employ different target regions for the PCR amplification, with Abbott using Integrase, QIAGEN using LTR and Roche using LTR and gag regions, we analysed clinical routine samples with all three assays in parallel to test for concordance of results. As HIV-1 shows a high genetic diversity we also compared the viral load results from selected non-B-subtype samples between the Abbott and the QIAGEN assay.

**Material and methods:** HIV-1 viral load was determined in 53 routine diagnostic samples using the artus HIV-1 QS-RGQ viral load assay, the Abbott m2000rt HIV-1 viral load assay and the Roche CAP/CTM HIV-1 test v 2.0 assay. All three assays were compared by linear regression analysis and Bland-Altman plotting. In addition to 19 non-B-subtype samples (five subtype A, 3 C, 1 D, 1 F, 1 G, 1 CRF01\_AE, 6 CRF02\_AG, 1 CRF06\_cpx) from clinical routine testing, eight samples from the NIBSC panel were analysed with the QIAGEN and the Abbott assay.

**Results:** Comparison of the QIAGEN assay against the Abbott assay showed a coefficient of determination (R<sup>2</sup>) of 0.9 (QIAGEN vs. Roche also 0.9, Abbott vs. Roche also 0.9). Analysis of Bland-Altman plots showed a slight tendency for higher quantification of 0.2 log<sub>10</sub> c/mL by the QIAGEN and the Roche assays compared to the Abbott assay, while no such difference could be seen between the QIAGEN and the Roche assays. The high coefficient of determination (R<sup>2</sup>) of 0.9 between the QIAGEN assay and Abbott assay could also be confirmed for the non-B subtype samples.

**Conclusions:** All three assays showed a high concordance of results, which could also be confirmed for non-B-subtype viruses for the QIAGEN and the Abbott assay. Although different target regions are used for HIV-1 quantification, standardisation of the assays to the WHO standard material by the manufacturers allows for interchanging these assays in routine diagnostics. The QIAGEN and the Roche assay show a trend for higher quantification compared to the Abbott assay. As the average of the results are only slightly higher there is no risk for falsely classifying these differences as significantly relevant for the patients.

#### **P904** Validation of a real-time multiplex PCR protocol for diagnosis of viral gastroenteritis

*M.J. Hopkins\*, J.A. Booth, N.A. Cunliffe, I.J. Hart (Liverpool, UK)*

**Objectives:** Highly sensitive molecular methods are commonly employed for detection of norovirus in infection control protocols. Molecular techniques are increasingly being used for diagnosis of other causes of viral gastroenteritis, although enzyme immunoassay (EIA) results may correlate better with symptomatic disease. Thus, a cut-off in line with EIA detection limits has been recommended to distinguish sub-clinical rotavirus infection. Here we validate a multiplex PCR for detection of rotavirus, adenovirus, astrovirus and sapovirus which can be used alongside a norovirus PCR to provide a comprehensive viral gastroenteritis screen.

**Methods:** One hundred and thirty-six electron microscopy (EM) screened community stool samples plus 175 paediatric samples previously screened by rotavirus EIA, and a norovirus QCMD EQA panel were included in the evaluation. All samples were blinded and anonymised. Nucleic acid was extracted using the Qiasymphony virus/bacteria kit. Published assays for rotavirus, adenovirus, astrovirus and sapovirus were combined in a single multiplex PCR. An internally controlled norovirus PCR as described previously was run in parallel.

Quantified RNA transcripts were used as positive controls and a PCR targeting VP7 was used to confirm discrepant rotavirus results.

**Results:** The multiplex PCR had detection limits of 4, 45, 5, and 45 RNA copies/ $\mu$ L for rotavirus, adenovirus, astrovirus, and sapovirus, respectively. Low-level RNA could be detected in the presence of higher amounts of the other viral target nucleic acid. Of all 323 samples tested, the multiplex PCR detected rotavirus, adenovirus, astrovirus, and sapovirus nucleic acid in 145, 58, 13, and 13 samples, respectively. Multiple viruses were detected in 60/323 (19%) of samples. No false-negative PCR results were observed in relation to EM and EIA data. One hundred and forty-three of the 145 rotavirus positives were confirmed positive by alternative methods (sensitivity 100%, specificity 98.9%). Receiver operating characteristic analysis identified a cycle threshold cut-off  $\leq 29.07$  for rotavirus EIA positive results in the paediatric samples. A cut-off of 30 was also applied to astrovirus PCR results to avoid false-positives.

**Conclusions:** The multiplex PCR proved a sensitive and specific adjunct to norovirus PCR for detection of additional causes of viral gastroenteritis. A cut-off  $\leq 29$  cycles can be applied to the rotavirus multiplex PCR results if correlation with EIA positive results is required.

**P905** **Cross-sectional study on the performance of quantitative cytomegalovirus (CMV) PCR in stool as a non-invasive diagnostic tool for CMV intestinal disease in comparison to the quantification of CMV-DNA levels in gut biopsies**

*T. Ganzenmueller\*, J. Kluba, J.-U. Becker, C. Schmitt, A. Heim (Hannover, DE)*

**Objectives:** Cytomegalovirus intestinal disease (CMV-ID), a serious complication in immunocompromised patients, is diagnosed by clinical and endoscopic findings and analysing gut biopsies by histopathology and CMV PCR. As endoscopic procedures are rather invasive, CMV PCR from stool samples has been proposed as additional method to identify CMV-ID, but its diagnostic significance has not been studied in detail.

**Methods:** This cross-sectional study included 53 immunocompromised patients with suspected CMV-ID, from whom a lower intestinal tract biopsy and a stool sample was sent to our diagnostic routine laboratory. Biopsy and stool were analysed in parallel by quantitative real time CMV PCR. The aetiology for intestinal disease was classified into "CMV-ID", "Non-CMV" or "unclear" based on thresholds for the CMV-DNA levels in biopsies [quantified as CMV copies/cell by PCR as published previously (J Clin Virol, 2009, 46, pp.254-8)]:  $>0.14$  copies/cell were considered as indicative for CMV-ID,  $>0.01$  as suspicious. Additionally, histopathological, endoscopic and clinical findings were considered to define the diagnosis.

**Results:** 14/53 patients had the diagnosis "CMV-ID" (median 3.96, range 0.05–46.1 CMV copies/cell in biopsies). Thirty-three patients had "Non-CMV" aetiologies of intestinal disease, e.g. graft vs. host disease (3/33 biopsies weakly CMV positive). In 6 "unclear" cases (five CMV positive biopsies; with one exception  $<0.14$  copies/cell) CMV-ID could not be excluded completely.

CMV-DNA was detected in 9/53 stool samples (detection limit of the PCR 500 copies/mL): in 8/14 CMV-ID patients and 1/6 with "unclear" diagnosis. The latter had a negative colon biopsy but subsequently developed CMV duodenitis. None of the 33 patients with "Non-CMV" aetiology had CMV detectable in stool, indicating a very high specificity of the CMV PCR. CMV loads observed in stool samples were relatively low in all cases (range 1000–11 000 copies/mL).

**Conclusions:** CMV-DNA detection from stool samples showed an excellent specificity for diagnosing CMV-ID and might be less prone to sampling errors than biopsies as shown by the CMV duodenitis case. However, compared to analysing biopsies, the sensitivity in stool is low (6/14 CMV-ID cases would have been missed). As the CMV concentrations shed in stool were low, the use of highly sensitive PCR protocols for stool samples requires evaluation. Nevertheless, if

endoscopy is not possible, CMV PCR from stool might be a non-invasive alternative.

**P906** **Aetiology and epidemiology of viral respiratory tract infections in hospitalised and non-hospitalised children using a microarrays platform**

*S. Koumi\*, P. Karakitsos, K. Chranioti, M. Theodoridou Papagrorgiou, A. Michos (Athens, GR)*

**Objectives:** To study the etiology of respiratory viral infections (RVI) using a microarrays platform.

**Methods:** Rhinopharyngeal washes were taken from children (1 month–14 years) who were treated as outpatients or hospitalized for upper (URTI) or lower respiratory tract infections (LRTI), from 6/2010 to 6/2011. A microarrays assay (CLART<sup>®</sup> Pneumovir kit – GENOMICA, Spain), that detects 17 different viruses or subtypes simultaneously, was performed to diagnose the etiology of RVI.

**Results:** Samples were taken from 611 children, 299 who were treated as outpatients and 312 who were hospitalized. Two hundred and thirty-five (38%) children were diagnosed with URTI, 320 (53%) with LRTI and 54 (9%) with URTI and LRTI. LRTI was diagnosed more often in hospitalized children and URTI in outpatients ( $p = 0.001$ ). Single infection was found in 228 cases (37.3%), viral coinfections in 169 (25.6%) and no result in 214 (35%). The most prevalent viruses among children with positive samples (397) were Respiratory Syncytial Virus (RSV) in 225 (56.6%) children, Parainfluenza viruses (PIV) in 118 (29.7%), Rhinoviruses (RV) in 73 (18.4%), Influenza viruses (INFL) in 56 (14.1%), Adenoviruses (AD) in 31 (7.8%), Human Bocavirus (HBoV) in 25 (6.3%) and Human Metapneumovirus (HMPV) in 15 (3.7%). No cases of Echovirus infections were detected in our study population. Most common coinfections were RSV-A-RSV-B in 46 (27.2%) children, RSV- INFL in 20 (11.8%), RSV- Rhinovirus in 18 (10.6%), PIV-INFL-RSV in 9 (5.3%), RSV-PIV in 8 (4.7%), RSV-Bocavirus in 5 (3%), PIV-RSV-Adenovirus in 5 (3%). No statistically significant association of viral coinfections with age, LRTI or need of hospitalization was found.

**Conclusions:** Viral coinfections and recently discovered viruses are involved in a significant percentage of acute RVI. Microarray assays could be useful for simultaneous detection of the most common viral respiratory pathogens.

**P908** **Multicentre performance evaluation of the Cobas AmpliPrep/Cobas TaqMan Docking Station**

*M.J. Munoz-Davila\*, A. Moreno, D. Montero, T. Ramos, M. Segovia (Murcia, ES)*

**Objective:** Bi-center (University Hospital Virgen de la Arrixaca and University Hospital La Paz, Spain) assessment of reproducibility, limit of detection and workflow of the Cobas AmpliPrep/Cobas TaqMan Docking Station for the viral load quantification of HBV, HCV and HIV-1.

**Methods:** (i) Reproducibility analysis of the system. Analytical standards. OptiQuant HIV-1 and HCV RNA quantification panels and OptiQuant HBV DNA quantification panels (AcroMetrix Corp., Benicia, CA) (Table 1) were used for analytical evaluation of the CAP/CTM DS. (ii) Limit of detection analysis of the system. In this study, we used dilution panels from the international standards recommended by the World Health Organization (WHO). Six serial dilutions were prepared with human plasma/serum for HBV, HCV and HIV-1. (iii) Workflow analysis. Total time required, time required for reporting results, hands-on time and hands-off time were studied.

Statistical analyses: Assay variability was expressed as SD and coefficient of variation (CV), both based on mean log<sub>10</sub>-transformed concentrations. The limit of detection was determined as the 95% probability of obtaining a positive result.

**Results:** (i) Reproducibility analysis: The CAP/CTM DS system was found to be precise within the assay quantitative range of  $2 \times 10^2$  to

2 × 107 UI/mL for HBV (total CV ≤3.36), 5 × 101–5 × 106 UI/mL for HCV (total CV ≤7.02) and 5 × 101–5 × 106 copies/mL for HIV-1 (total CV ≤6.5), which are within the ranges of reproducibility data provided in the respective reagents insert (Table 1). (ii) Sensitivity analysis: The analytical sensitivities of the CAP/CTM DS were also determined to be ≤12.4 UI/mL (95% CI) for HBV, ≤94.02 UI/mL for HCV (95% CI) and ≤26.88 copies/mL (95% CI) for HIV-1 viral load quantification, closely approximating the lower limits of quantification set by the manufacturer of the three assays. (iii) Workflow analysis: The CAP/CTM DS allows emission of 96 results in eight hours.

**Conclusion:** In this study, we report the results of a two-hospital multicenter evaluation of the CAP/CTM DS assay which yielded very good reproducibility results and an accurate limit of detection for HBV, HCV and HIV-1 viral load quantification. Regarding the new system's workflow, its extraordinary automation and the possibility of 96 results of viral load quantification of the three kinds of virus in an eight-hour workshift are certainly remarkable.

**P909** Frequency of hepatitis D virus infection in HIV-positive and haemodialysis patients in Iran

A. Ramezani\*, M. Aghasadeghi, G. Bahramali, A. Aghakhani, M. Banifazl, S. Sadat, M. Foroughi, R. Vahabpour, A. Eslamifaz, S. Siadat, M. Mohraz (Tehran, IR)

**Objectives:** Hepatitis D virus (HDV) is a defective RNA virus dependent on hepatitis B virus (HBV) infection for its replication and expression. It is known that coexistent infection with HDV tends to aggravate the course of HBV-associated liver disease. HDV is a major public health issue in Iran. Studies from different areas of the country show varied prevalence rates. This study was carried out to determine the frequency of HDV infection among HIV positive and hemodialysis patients with HBsAg in Iran.

**Methods:** A total of 720 individuals were enrolled in this study, including 120 hemodialysis (HD) and 600 HIV-infected patients. HBsAg were tested in all subjects. All HBsAg positive cases were evaluated for the presence of anti-HDV antibodies using commercially available enzyme-linked immunosorbent assay kits. Finally anti-HDV and HBsAg positive coinfecting samples were used for HDV active RNA confirmation using nested polymerase chain reaction (PCR). PCR products were sequenced, and the genotype of HDV samples was determined.

**Results:** Out of 120 HD patients, 9 (7.5%) and out of 600 HIV-infected patients 9 (1.5%) were HBsAg positive. Three (33.3%) of HBsAg positive HD samples and 5 (55.5%) of HBsAg positive HIV infected cases, were anti-HDV positive which were then subjected to nested PCR. The amplification results confirmed 3 (37.5%) samples to be HDV-RNA positive. Two of them were HD patients and one was HIV infected case. HDV infection was more common in male than

female patients. All of the HIV-HDV co-infected subjects were intravenous drug users and were co-infected with HCV. Genotypes of HDV samples will be reported in the congress.

**Conclusion:** Our results suggest that the prevalence of HBV/HDV co-infection is relatively high in HIV and HD patients in Iran. Therefore, practitioners and health care managers should be made aware of the risk of dual infection with HBV and HDV especially in high risk patients.

**P910** Molecular epidemiology of non-polio enterovirus circulating in highly endemic areas of central nervous system disease

T.N. Dhole\*, A. Kumar, D. Shukla, S. Srivastava (Lucknow, IN)

**Objectives:** Human enterovirus (HEV) causes asymptomatic infections to a wide range of clinical disease like aseptic meningitis, encephalitis and myocarditis. HEV serotype identification is necessary for their

clinical presentation, emergence of variants and epidemiological surveillance. In northern India, enteroviruses are a significant cause of central nervous system infection presenting either in endemic or epidemic forms. The aim of the present study was identification of enterovirus circulation by molecular method in direct clinical specimen to determine their prevalence in the community.

**Methods:** A total of 320 clinical specimens were collected between January 2009 to December 2010 from children (age <15 years) with suspected enterovirus infection and healthy controls in northern India. Reverse – transcription real time PCR (r-RT-PCR) and semi nested RT-PCR targeting the 5' untranslated region and VP1 region was used for the detection and identification of enterovirus serotypes.

**Results:** HEV genome was detected in 79 (24.7%) of 320 clinical specimens by real time PCR. Central nervous system syndrome (CNS) was the most common clinical manifestations (n = 32, 62.74%) followed by respiratory tract infection (n = 8, 15.69%), acute febrile illness (n = 7, 13.73%) and gastrointestinal disease (n = 4, 7.84%). A total of 32 different serotypes were identified: mainly coxsackievirus (CV) B5 and echovirus (ECV) 6 (11.4% each) followed by CV B3 (6.3%), CV A13, CB6, ECV 3, ECV 20 and ECV 29 (5.1% each), ECV11, ECV24, EV 75 (3.8% each). Phylogenetic analysis of partial VP1 gene sequences from this study showed that many HEV serotypes were showing good similarity with strains from American and European country in comparison to the neighbouring Asian country.

**Conclusions:** High frequency of HEV B species circulation may be an important cause of CNS infection in the children of this region.

#### **P911** A molecular epidemiological survey of viral respiratory tract infections in children

*M.L. Modolo, R. De Rosa, A. Camporese\* (Pordenone, IT)*

**Objectives.** Respiratory viruses are known to cause acute respiratory tract infections, including the common cold, bronchiolitis, and pneumonia. The objective of this study was to employ the multiplex Seplex DPO molecular technology (Seegene) to study the epidemiology of respiratory virus infections, the virus-specific positivity rates, and seasonality for respiratory virus infections over a 21 months period in an area of the North East of Italy.

**Methods:** Five hundred and eighty nasopharyngeal specimens were obtained from symptomatic pediatric inpatients between February '10 and October '11. Each specimen was collected with a Copan flocced swab and a liquid universal transport medium. Total nucleic acid was extracted using the easyMAG system (bioMerieux). From February '10 to December '10, 324 samples were assayed by the Seplex RV12, that allows simultaneously detection of Metapneumovirus (MPV), Adenovirus (AD) A/B/C/D/E, Coronavirus (COR) 229E/NL63, Parainfluenza virus (PIV) 1/2/3, Influenza virus A/B (IA/IB), RSV A/B, Rhinovirus (RV) A/B and Coronavirus (COR) OC43. Because Seegene developed a second-generation system, RV15, which allows detection of other additional viruses (Bocavirus 1/2/3/4, Parainfluenza virus 4, RV C, Enterovirus), from January '11 to October '11 respiratory samples were assayed with RV15.

**Results:** Of the 580 specimens tested, 325 (56%) were positive for at least one respiratory virus, including 161 (27.8%) RSV (A or B), 75 (12.9%) RV, 29 (5.0%) PIV, 27 (4.7%) AD, 18 (3.1%) MPV, 17 (2.9%) IA, 14 (2.4%) COR, 9 (1.4%) BOCA, 8 (1.4%) IB and 0/580 Enterovirus. We revealed 22 dual respiratory virus infections (3.8%), and only two triple virus infections. During '11, RV15 allows detection of 8 Bocavirus infections. Most of viruses were distributed across the majority of months, with some peaks: RVs (February/March '10, September/October '10, December 10/March '11, August/September '11), MPV (February/April '10 and December/May '11), PIVs (spring and late summer/autumn). IA/B had an "atypical" distribution during 2010, and a peak from January/March '11, with a prevalence of A/H1N1.

**Conclusion:** RV12 and RV15 increased our understanding of the epidemiology of respiratory viral infections and assist us in the diagnosing the etiology of respiratory tract infections in individual and

in outbreak situation. The high throughput capabilities and potential lower technical requirements afforded by the Seplex system, within easyMAG automated platform, allow a very significant reduction in the turnaround time of viral respiratory tract infections (RTIs) diagnosis.

#### **P912** A novel nucleic acid amplification/signal generation platform with implications as a cost-effective detection system for infectious organisms

*W. Cheng, D. Liu, M. Mitchell, E. Rabbani, J. Donegan, B. Taillon\* (New York, US)*

**Objective:** Enzo Biochem set out to develop a low cost, high sensitivity, real-time platform for specific detection of any nucleic acid target.

**Methods:** Primers for the amplification and quantification of HCV RNA were developed as an initial demonstration of utility in infectious disease research. This HCV assay was retrospectively validated against clinical samples.

The Enzo system is designed to amplify a very short target segment which incorporates the primers in close proximity. The primers are manufactured to contain energy transfer dyes such that one primer (eg forward primer) contains an energy donor dye while the other primer (eg reverse primer) contains an energy acceptor dye. When proper amplification occurs the energy transfer dyes are in close proximity and, when exposed to the proper wavelength of light, generate signal that is directly related to the amount of amplicon generated. The Enzo system has very high specificity and low background because the only manner in which signal can be generated is by proper amplicon generation. As such, even after 60 cycles of amplification without target template, there is a lack of any signal generation.

**Results:** The results show a high degree of correlation for the presence or absence of virus as well as the relative quantity of HCV in clinical samples compare to standard clinical methodology. Furthermore, we found a direct correlation between methodologies with smaller sample amount and smaller reaction volumes.

**Conclusion:** We believe this new platform can provide a superior testing methodology through improvement of operational efficiency and reduction of costs. One of the major cost drivers in molecular testing is sample preparation. The Enzo technology requires less sample input and therefore allows paneling or multiplexing of tests per sample preparation. Paneling or multiplexing will reduce the cost of sample preparation per test. Similarly, our technology is highly efficient, requiring less reaction volume and thereby imparting overall cost savings in reagents. We will describe in details the methodology as well as demonstrate its utility in the detection of infectious agents including HCV.

#### **P913** Frequent isolation of Epstein-Barr virus in the intestine of patients with inflammatory bowel disease: a case-control study

*E. Dimitroulia, N. Spanakis, V. Pitiriga, E.T. Piperaki, A. Konstandinidou, A. Tsakris\* (Athens, GR)*

**Background:** Although Epstein-Barr (EBV) infection has been linked to the pathogenesis of inflammatory bowel disease (IBD), the strength of the association is still debatable. The aim of this case-control study was to estimate the frequency of EBV in patients with ulcerative colitis and Crohn's disease and to elucidate the clinical significance of EBV infection in the course of disease.

**Methods:** Ninety four IBD patients-63 with ulcerative colitis (UC) and 31 with Crohn's disease (CD)-and 45 controls with non-inflammatory disease selected from two adult gastrointestinal referral centers in Athens, Greece, were included in the study. The presence of EBV was examined in blood and intestinal tissue samples by molecular assays and comparisons were made among IBD patients and controls. Demographic and clinical characteristics of all participants were also recorded.

**Results:** The mean age of each of the three groups was 47.7 ± 18.3 for patients with UC, 48.1 ± 19.25 for patients with CD and 64.2 ± 14.38 for the control group. UC location was proctitis (n = 6, 9.5%), left-side colitis (n = 36, 57.1%), and pancolitis (n = 21, 33.3%). CD location was small bowel and colon (n = 22, 70.9%), colon only n = 5 (16.1%), and small bowel only n = 4 (12.9%).

The EBV genome in intestine biopsies was detected in 14 (45.2%) CD patients and in 6 (12%) controls (p = 0.001). In blood the EBV genome was detected in 4 (12.9%) CD patients and in 9 (18%) controls (p = 0.3). Regarding UC patients, EBV genome in intestine biopsies was detected in 30 (47.6%) of them and in 6 (12%) controls (p = 0.001). In blood, the EBV genome was detected in 20 (31.7%) UC patients and in 9 (18%) controls (p = 0.07). No differences in demographic and clinical parameters were observed between EBV infected and EBV non-infected patients of both UC and CD. Similarly, no difference in prevalence of EBV genome in blood was indicated among all groups.

**Conclusion:** Higher prevalence of EBV detection in intestinal tissues of IBD patients comparing to healthy controls was observed. In addition, an indication of more frequent EBV detection in blood was established between UC patients and controls. Although a definite causative role of EBV cannot be supported, our findings suggest further investigations on the potential efficacy of antiviral therapy against EBV infection in IBD patients.

**P914** Characterisation of rotavirus circulating in Pakistan

T. Ifrikhar\*, C. Donato, N. Bogdanovic-Sakran, A. Haque, C. Kirkwood (Faisalabad, PK; Melbourne, AU)

**Objective:** The objectives are: To identify G and P genotypes based on molecular typing of rotavirus in children with acute gastroenteritis Sequencing and phylogenetic analysis and to the elucidation of rotavirus evolution Comparison of amino acids sequence Genbank sequence submission

**Methods:** Sixty-six samples were characterised for G and P genotype RT-PCR assay. Viral RNA-PAGE was done to determine the electropherotype on a 10% polyacrylamide gel. The stronger amplicon for sequencing is obtained by the full length amplification of VP7, VP8\* and NSP4. Prepared samples were sent to AGRF c/o The Walter and Eliza Hall Institute of Medical Research, Melbourne. Phylogenetic analysis of rotavirus genotypes was performed with MEGA software, version 5. The nucleotide sequence in this study has been deposited in the gene bank database. The accession numbers was assigned for the VP7, VP4 and NSP4 sequences.

**Results:** The 16 samples analysed possessed different electropherotype patterns, each sample contains 11 segments of dsRNA either possessing "short pattern" or "long pattern". Twenty-six samples were genotyped as G1. Prevalence of other genotypes, 2 were genotyped as G2, 8 were

typed as G9, 1 was typed as G3 and. Mixed infection was seen in 16 samples of which 3 were G1/G3, 1 was G1/G8, 7 were G1/G9, 1 was G1/G2/G9, 4 were G1/G3/G9. Twenty-six samples were genotyped as P[8]. Prevalence of other genotypes, 1 was typed as P[4] and 3 were genotyped as P[6]. Mixed infection of P[4] P [8] was seen in 26 samples. The most common genotype combination was G1P[8] at 25.75% followed by mixed infection of G1P[4]P[8] at 9.09%, G9P[4]P[8] at 7.57%, G1/G9P[8] at 6.0%, G1/G3/G9P[8]P[4] at 6.0%, G1/G3P[8]P[4] at 6.0%, G9 P[8] at 4.54%, G1/G9P[8]P [4] at 4.54%, G2P[6] at 3.0%, G12P[8] at 3.0%, G3/G9P[8]P[4] at 1.5%, G3/G9/P[8]P [4] at 1.5%. Sequencing and deduced amino acids analysis of VP4, VP7 and NSP4 were found to be closely related to globally circulated rotavirus strains. Comparison between Faisalabad samples and globally circulating strains identified different amino acids substitutions in variable regions at different positions.

**Conclusion:** The rotavirus strains originating in Faisalabad, Pakistan are globally circulating strains. Some noticeable mutations were detected in regions known to increase pathogenicity, the amino acids substitutions present may have contributed to the emergence of the new strains.

**P915** Development and evaluation of a multiplex real-time assay to detect herpes simplex virus types 1 and 2, and varicella-zoster virus

M. de Oña Navarro\*, C. Balado Cabana, M. Alvarez-Argüelles, R. Rico Rico, R. Carballo Fernandez, J. Boga Riveiro, S. Melón García (Oviedo, ES)

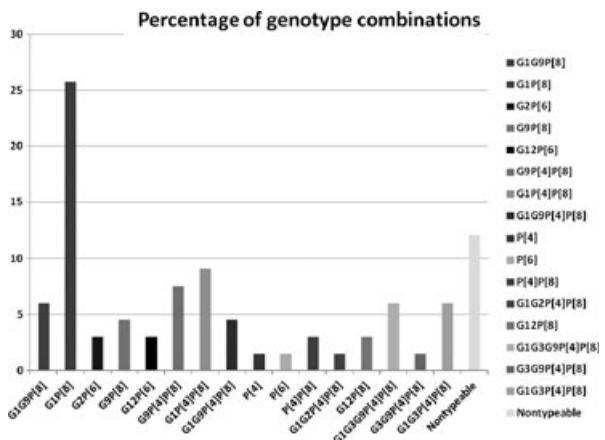

**Introduction:** Herpes simplex virus types 1 and 2 (HSV-1, HSV-2), and Varicella-Zoster virus (VZV) are implicated in multiples types of infections, some of them as important as encephalitis. Real-time PCR is a significant improvement over viral isolation and immunofluorescence for routinely detecting viruses in order to management the infection.

**Objective:** To check the efficacy of a multiplex Real-Time PCR (RT-PCR) designed to detect simultaneously HSV-1, HSV-2, and VZV infections in different types of samples.

**Methods and samples:** primers and labeled-probes against different regions of HSV-1, HSV-2, and VZV were designed using Prime3 software (ABI, USA) (table 1). The assay was developed with Fast- 1-Step Mix (ABI, USA), according manufacturer protocol.

From february, 15th and july 15th, 463 different samples (97 respiratory swabs, 95 genital swabs, 72 skin samples, 18 conjuntival swabs, 135 CNS, and 41 biopsies) belonging to 438 patients were processed by new multiplex RT- PCR, and conventional multiplex nested PCR with primers located in same regions (table 1). In 268 samples, immunofluorescence and viral culture were also performed.

**Results:** Viruses were presented in 109 (24.88%) individuals. In 102 (93.5%) were detected by classical multiplex PCR, and in 98 (89.9%) by new multiplex RT-PCR. HSV-1 was found in 62 samples: 58 (93.5%) by nested-PCR and 52 (83.8%) by RT-PCR. HSV-2 was found in 30 samples: 29 (97%) by nested-PCR, and 30 (100%) by RT-PCR. VZV was detected in 17 samples: 15 (88.2%) by nested-PCR, and 17 (100%) by RT-PCR. In 268 samples which other methods were assayed, genomic amplification (RT-PCR or nested PCR) was positive in 91 (34%), immunofluorescence in 22/250 (8.8%), and culture in 67/265 (25.3%). RT-PCR was positive in seven CNS, and nested-PCR in 3. In the opposite, RT-PCR found viruses in three biopsies and nested-PCR in 8. RT-PCR was able to detect 50 copies in HSV-1, and VZV. Nested-PCR detected 50 copies in HSV-1, and 500 copies in VZV. No quantitative control for HSV-2 was available.

Region	Primer	RT-PCR		nested PCR	
		probe	External primers	Internal primers	
HSV1	GPO	g1g9p[8]	g1g9p[8]f	g1g9p[8]i	g1g9p[8]i
		g1p[8]	g1p[8]f	g1p[8]i	g1p[8]i
		g2p[6]	g2p[6]f	g2p[6]i	g2p[6]i
HSV2	GPO	g1g9p[8]	g1g9p[8]f	g1g9p[8]i	g1g9p[8]i
		g1p[8]	g1p[8]f	g1p[8]i	g1p[8]i
		g2p[6]	g2p[6]f	g2p[6]i	g2p[6]i
VZV	HEE	g1g9p[8]	g1g9p[8]f	g1g9p[8]i	g1g9p[8]i
		g1p[8]	g1p[8]f	g1p[8]i	g1p[8]i

**Conclusions:** Multiplex RT-PCR provides a rapid, sensitive, specific and simultaneous detection of HSV-1, HSV-2, VZV in clinical samples even with a low viral load, making it as a useful tool for diagnosis of these viruses, reducing laborious and time-work consuming.

#### **P916** The effect of interpretation method for quantitation of cytomegalovirus by real-time PCR

*B.R. Jeon\*, Y.W. Lee, H.B. Shin, Y.K. Lee (Bucheon, KR)*

**Objectives:** The real-time PCR using Ct value and standard curve is well established quantitation method assuming the equal efficiency between unknown specimen and standard materials. However, in the presence of inhibitory agents, amplification efficiency difference could cause significant inaccuracy and numerous methods have been proposed to correct this problem. In order to know the actual effect in clinical practice, we compared Ct method with Cy0 and maxRatio method.

**Methods:** A total of 93 batch run data including 610 clinical specimen from Jan 2010 to Sep 2011 are analysed; Each batch includes four quantitation standard material equivalent 10000, 1000, 100, 10 copies/ $\mu$ L and one negative control (ntc). QIAcube with QIAmp blood DNA mini kit (Qiagen) was used for sample preparation and Rotor-Gene Q with Artus CMV RG PCR Kit (Qiagen) was used for real-time PCR experiments. Threshold for Ct method were determined by Rotor-Gene Q – Pure Detection Software version 2.0.2 below 0.05 (AutoCt). Cy0, maxRatio method were analyzed by qpcR package in R version 2.13.1 (R Foundation for Statistical Computing).

**Results:** In analysis of standard material, autoCt method shows best coincidence in the point of mean CMV copies and also showed least CV. In NTC sample results, autoCt method showed 1.72 copies/ $\mu$ L in one sample and negative for other samples; Cy0 method couldn't calculate 12 samples and showed above 1000 copies/ $\mu$ L in 81 samples; MaxRatio method couldn't calculate 11 samples and showed three samples below 100 copies/ $\mu$ L and 79 samples above 20 000 copies/ $\mu$ L, however, in maxRatio method, MR were <0.1 in 80 sample and only two sample were above 0.1 which suggest false elevation. In clinical samples, 25 samples between 10 and 100 copies/ $\mu$ L, seven samples between 100 and 1000 copies/ $\mu$ L, and four samples between 1000 and 10 000 copies/ $\mu$ L in autoCt method coincided with Cy0 and maxRatio method. In 203 samples showing <10 copies/ $\mu$ L in autoCt method, Cy0 method showed one sample above 1000 copies/ $\mu$ L and maxRatio method showed two samples above 10 000 copies/ $\mu$ L with low MR. Efficiency calculated by Cy0 method were between 1.016 and 1.149 in standard samples and seven clinical samples were out of that range.

**Conclusion:** Although Cy0 and maxRatio method could be helpful in samples with reduced efficiency, care must be taken and individual amplification curve or supplementary index should be examined for proper evaluation especially when interpret low concentration samples.

#### **P917** Outbreak of acute enterovirus intestinal infection in Sakhalin region in August 2010

*A. Demina\*, V. Ternovoi, B. Darizhapov, T. Yakubich, A. Sementsova, O. Demina, E. Protopopova, V. Loktev, A. Agafonov, S. Netesov (Novosibirsk, Yuzhno-Sakhalinsk, RU)*

**Introduction:** Enterovirus diarrhea (gastroenteritis) is an acute febrile illness with lesions of the gastrointestinal tract. Outbreaks of enterovirus gastroenteritis usually are local. Large epidemics occur extremely rare.

**Objectives:** To investigate cases of acute intestinal infections in the Sakhalin region in August 2010, the identification of the causative agent.

**Methods:** We analyzed 102 samples of faeces received from the Sakhalin region from patients with acute intestinal infection. Isolation of RNA/DNA from the test material was carried out using a reagent kit "Ribo-Sorb" (AmpliSens, Russia), reverse transcription reactions –

using the reagent kit "Reverte-L" (AmpliSens, Russia). All samples were analyzed for the presence of adeno-, noro-, astro-, rota-, enteroviruses, *Yersinia enterocolitica* and *Listeria monocytogenes* sets of (AmpliSens, Russia). All samples were additionally tested for enterovirus by PCR with primers for genotyping on the 5'UTR (Demina A.V. et al., 2011) Determination of nucleotide sequences was performed using an automatic sequencer ABI Prism 3130xl. The nucleotide sequences were analyzed using Lasergene 7 and compared with nucleotide sequences database GenBank.

**Results:** The study showed that in these clinical samples, genetic material (viral RNA or DNA), adeno-, noro-, astro-, rotavirus, as well as DNA *Yersinia enterocolitica* and *Listeria monocytogenes* is absent. In 93 fecal samples there were detected RNA enteroviruses. After determining the nucleotide sequences of DNA fragments in the positive samples there were identified enteroviruses: Coxsackie A2–42 samples (45%), Coxsackie A4–31 sample (34%), Enterovirus 71 – six samples (6.5%), coxsackievirus B5 – six samples (6.5%), coxsackievirus B3 – four samples (4%) and Coxsackie B1 – four samples (4%). Phylogenetic analysis showed that the closest prototype of nucleotide sequences of these genotypes were previously identified in Japan (AB126199, AB126200, AB550333), China (GU109481) and Korea (AY875692) in 2000–2010.

**Conclusion:** A molecular epidemiological investigation of outbreak of acute intestinal infection in the Sakhalin region in August 2010, the etiologic agents that caused diseases, are enteroviruses of different serotypes. Specific nucleotide sequences (fragments of the 5'UTR) were deposited by us in GenBank (23.08.2011: JN603367 – JN603368).

#### **P918** Usefulness of herpes consensus PCR methodology in the diagnosis of herpesvirus ocular infections

*C. Gartzonika, C.D. Kalogeropoulos, G. Vrioni, E. Priavali, N. Zotos, E. Papapetrou, I. Margelis, S. Levidiotou\* (Ioannina, Athens, GR)*

**Objectives:** Herpetic eye diseases exhibit various clinical manifestations making a diagnosis difficult in some patients. Molecular techniques are most useful in such instances for an accurate and rapid diagnosis since conventional methods are less sensitive. The purpose of this study was to assess the usefulness of simultaneously amplifying herpeviruses DNA in various ocular samples by using a multiplex polymerase chain reaction (PCR) assay.

**Methods:** A total of 278 samples (aqueous fluid-160, eye swabs and tears-102, corneal scrapings-9, vitreous fluid-7) from consecutive patients with keratoconjunctivitis, hypertensive iridocyclitis, retinitis and uveitis were tested using the Herpes Consensus PCR methodology which is based on gene amplification to search for the six main human viruses: herpes simplex virus 1 and 2 (HSV-1 and HSV-2), varicella-zoster virus (VZV), cytomegalovirus (CMV), Epstein–Barr (EBV) and human herpesvirus 6 (HHV-6).

**Results:** Thirty-five out of 278 ocular specimens (13%) tested positive and most of them were obtained from adults. HSV-1 DNA was detected in majority of the clinical samples (80%), most frequent being eye swabs (60.7%) and aqueous fluid (32.2%). Comparatively, HSV-2, VZV and CMV infections were detected in small number of specimens (2.86%, 14.28% and 2.86% respectively). No sample was positive for EBV and HHV-6 DNA or more than one herpesvirus. The patients with detectable HSV-1 and VZV DNA in aqueous fluid experienced in their majority (eight out of nine and three out of five respectively) hypertensive iridocyclitis. In four patients with acute retinal necrosis syndrome (ARNS), VZV was detected in aqueous tap in two cases, HSV-1 in one case and HSV-2 in one case.

**Conclusion:** According to our experience, Herpes Consensus PCR assay can be useful to facilitate the routine diagnosis of herpetic ocular infections- especially in difficult clinical cases as hypertensive iridocyclitis or ARNS- within a single assay, thereby allowing earlier and prompt administration of a specific antiviral treatment and better clinical management.

**P919** Evaluation of suitability of various novel swab devices for the molecular detection of influenza A from surveillance samples in France

M. Valette\*, R. Fanget, G. Burfin, D. Shedden, B. Lina (Bron, FR; Corsham, UK)

In France, the influenza surveillance in the general population is carried out with the GROG network that includes general practitioners and paediatricians. These practitioners collect clinical samples (nasal swabs) with Sigma-virocult®. The samples are sent to the laboratory by post with an average delay of 4 days.

**Objective:** In this study, we compared the performance of four different swab collection devices over 4 days for the detection of the pandemic A/California/7/2009 virus using an in-house RT-PCR technique. The devices used were Sigma-Virocult® with polyurethane foam bud swab (SVP), Sigma-Virocult® with Hydraflock Swab (SVH), Sigma-VCM™ with Hydraflock Swab (VCH) and Copan UTM® with Flocked Swab (CU).

**Methods:** Briefly, a titrated suspension of influenza A(H1N1pdm)09 prepared on MDCK cells was used as infectious material to be seeded on different swabs. In this protocol, 10-fold dilutions of the virus suspension (ranging from 10.3 to 10.5) were seeded and subsequently tested at Day 0 and Day 4 post-seeding by RT-PCR. For the latter point, seeded swabs were stored at room temperature, to mimic postal transportation of a GROG specimen.

**Results:** The results showed a high stability of the detection of the virus by RT-PCR in the 4 transport devices up to 4 days. The performance of the foam bud device (SVP) is similar to the 3 hydraflock swabs whatever the concentration of the virus.

**Conclusion:** From this study, we confirm that both foam and flocked swabs are suitable for molecular diagnostic of pandemic influenza from surveillance samples.

**P920** Association of mutation in HCV core region and response to interferon therapy in patients from Rawalpind, Pakistan

S. Kanwal\*, T. Mahmood (Islamabad, PK)

**Objectives:** The global prevalence of Hepatitis C Virus (HCV) infection corresponds to about 130 million HCV positive patients worldwide. The only drug that effectively reduces viral load is interferon-alpha (IFN-alpha) and currently combination of IFN and ribavirin is the choice for treatment. HCV variants with mutations within the core protein appeared to be more sensitive to therapy, suggesting that core protein played a role in conferring IFN-resistance. The present study is aimed to resolve the genotypes that affect the response to interferon therapy.

**Methodology:** To achieve the objectives seven HCV ELISA positive subjects who have completed IFN treatment were randomly selected. All patients received injections of pegylated-IFN-alpha once each week plus oral ribavirin daily for 48 weeks. Nested RT-PCR was performed after reverse transcribing the viral RNA. Sequencing of the purified PCR samples was carried out to assign the genotypes; core region was the target site for direct sequencing. Neighbor Joining (NJ) method was used to study the evolutionary relationship among the studied samples and HCV strains reported from different geographical regions of the world.

**Results:** Four different genotypes were revealed out of which two samples could not be typed. Two new genotypes have been reported for the first time: 4a from sub urban region of Rawalpindi and 6e from all over the Pakistan in addition to HCV genotype 3 (3a and 3b).

**Conclusion:** The emergence of new genotypes, untypable genotypes and new quasispecies is due to mutations that emerged during therapy due to drugs resistance. Rapid emergence of new resistant strains/quasi-species occurs in a population of viruses already present, allowing the new/resistant virus to become the leading strain, therefore, further understanding of the complex mechanism involved in disrupting the

viral response to therapy would facilitate the development of more effective therapeutic regimens.

**P921** Molecular detection and identification of enteroviruses and parechoviruses in hospitalised children

N. Siafakas\*, G. Stanway, A. Attilakos, E. Stefos, P. Nikolaidou, L. Zerva (Athens, GR; Colchester, UK)

**Objectives:** The present study attempted the prospective molecular detection and identification of human enteroviruses and parechoviruses in children admitted to a university hospital with signs and symptoms suggestive of enterovirus or parechovirus infection, as well as the investigation of their possible epidemic association with virulent strains.

**Methods:** During a period of 3 years, 220 consecutive samples [189 stool, 20 cerebrospinal fluid (CSF), 7 whole blood, 2 throat swabs and 2 vesicular fluid swabs] were collected from 188 patients. Clinical presentation included febrile illness variably accompanied by gastrointestinal disorders, possible viral meningitis, exanthematous disease and hand-foot-and-mouth disease. An one-step Real-Time RT-PCR protocol targeting the 5-UTR was used as a screening method for rapid, simultaneous detection of enteroviruses and parechoviruses. Genotypic identification of the different serotypes was performed by sequencing of the VP1-coding region.

**Results:** Twenty-seven enterovirus strains were detected and identified in 25 stool samples, one CSF, one whole blood sample, one throat swab and two vesicular fluid swabs from 27 out of 188 examined patients (14.4%). In contrast, only two parechoviruses were detected in stool samples from two different patients, which were identified as human parechovirus type 1 (HPeV-1) and HPeV-3 respectively. Fourteen enterovirus strains (eight serotypes) belonged to Human Enterovirus Species B (HEV-B) and 13 (five serotypes) to HEV-A. HPeV-1, coxsackieviruses A2, A4, A6, A10 and particularly, the emerging enterovirus 71 and the potentially neurovirulent for neonates HPeV-3 were detected for the first time in Greece. All enterovirus 71 strains were detected within a period of 7 months, indicating a possible epidemic outbreak in the community. Phylogenetic analysis confirmed that most of the strains were closely associated with virulent strains circulating in Europe and elsewhere, but not with strains identified in Greece during the previous years.

**Conclusion:** The present study showed the simultaneous circulation of different enterovirus serotypes and elucidated the epidemic association of these strains with other virulent strains that circulate globally. Most notably, detection of enterovirus 71 for the first time in Greece is particularly alarming and further emphasizes the significance of applying informative molecular assays to improve surveillance for emerging strains with increased virulence.

**P922** Molecular epidemiology of human rhinovirus in general population in Catalonia during 2010

A. Antón\*, G. Tudó, N. Torner, R. Isanta, A. Martinez, T. Pumarola, M.A. Marcos (Barcelona, ES)

**Objective:** To determine the prevalence of infections by the three human rhinovirus (HRV) species in general population with upper respiratory disease in Catalonia (Spain) during 2010.

**Methods:** Nasopharyngeal specimens were collected from patients with mild upper respiratory tract infection through sentinel surveillance network in Catalonia during last year. HRV and the most common human pathogenic respiratory viruses were detected using two nested-PCR. In laboratory-confirmed samples of single HRV infection, nucleotide VP4/2 region was used for phylogenetic analysis to establish the HRV specie (HRV-A, HRV-B or HRV-C).

**Results:** HRV infection was laboratory-confirmed in 241 (24%) samples out of 1009 respiratory specimens collected during 2010, of which 188 (78%) positive samples were in single infection. The prevalence of rhinovirus in general population in Catalonia was high

during late winter (weeks 3–10) and early autumn (weeks 41–48). The incidence was especially high in children between 2 and 6 years old. Phylogenetic analysis of nucleotide sequences VP4/2 region obtained from 154 (82%) HRV positive samples identified: 94 (61%) HRV-A, 19 (12%) HRV-B and 41 (27%) HRV-C.

**Conclusion:** High prevalence of HRV infection and co-circulation of the three HRV (A, B and C) species in general population with mild upper respiratory illness in Catalonia was shown. Interestingly highest incidence of HRV was observed in youngest children. HRV-A was the most predominant rhinovirus specie. Better acknowledgment of molecular epidemiology of circulating HRV among general population in Catalonia is good for further studies in hospitalized population.

#### **P923** Use of real-time PCR for the detection of EBV in rare clinical manifestations

G. Terhes\*, B. Kele, O. Szakáll, C. Bereczki, A. Annaházi, R. Róka, L. Tiszlavicz, J. Kóbor, K. Rácz, J. Deák (Szeged, HU)

**Objectives:** Herpesviruses may cause wide range of infections which manifest with various and often non-specific symptoms and signs, because specific therapy is available in certain cases, rapid and accurate diagnosis is essential. In our laboratory, real-time quantitative PCRs are generally used for the detection of CMV, HSV-1/2, and EBV in immunocompromised patients and in patients with central nervous system infections. Our aims were to retrospectively analyze the results of real-time EBV PCR and to show three, rare clinical presentations of EBV infection.

**Methods:** We analyzed the results of real-time EBV PCR (artus<sup>®</sup> EBV LC PCR; Qiagen) given during the last 36 months. Clinical specimens (plasma, cerebrospinal fluid, biopsy, urine and other specimens) were sent to the laboratory from mainly inpatients treated in the local university hospitals.

**Results:** During 36 months, 349 specimens were set up for EBV real-time PCR from 273 patients. Thirty-four samples collected from 20 patients proved to be positive for EBV. Positive PCR results were given in the case of 16 plasma, six biopsy, nine CSF and three other specimens. Three unusual manifestations of EBV infection were selected from positive cases. In one patient after 4 years of renal transplantation, on the basis of brain MRI, and histological examination the possibility of PTLD has been arisen, this was confirmed by EBV PCR positivity from brain biopsy, CSF and plasma specimens. The patient was successfully treated with ganciclovir, rituximab, mycophenolate acid, and everolimus and lesions in the brain on MRI were completely resolved. The second case was an EBV-associated oesophagitis in an immunocompetent patient, in this case after acyclovir treatment, the patient were symptom-free for 1 year until 1 month ago that he developed relapse. In the case of a 15-year-old girl real-time EBV PCR and serology revealed cerebellitis with concomitant hydrocephalus. Treatment consisted of acyclovir, mannitol, furosemide and ceftriaxone and ventriculostomy. Nine days after ventriculostomy catheter insertion control MRI showed regression and the catheter was removed.

**Discussion:** Because of the importance of early recognition of PTLD in transplant patients, and rare manifestations of EBV infection in some patients, besides serology the use of molecular methods may give rapid and reliable results to set up the clinical diagnosis.

#### **P924** Evaluation of GeneXpert enterovirus assay for detection of enteroviral RNA in paediatric cerebral spinal fluid

J. Lin\*, C. Lin, T. Liao (Changhua, TW)

**Background:** Traditional viral culture for detection of enteroviruses in cerebral spinal fluid (CSF) is time-consuming and less sensitive when compared with clinical impression. The molecular assay directly detects enteroviral RNA in CSF may help physicians to act in a timely manner especially when encountering a catastrophic condition.

**Objectives:** The Cepheid GeneXpert EV assay is a commercial and in-vitro diagnostic reagent performed on an automated GeneXpert system. This study was to evaluate the performance of GeneXpert enterovirus (GEV) assay for detection of enteroviral RNA in pediatric CSF.

**Methods:**

CSF specimens submitted to viral culture that obtained from unrelated pediatric patients under clinical impression of enteroviral infection with CNS involvement were investigated. After inoculation, CSF was appropriately frozen until analysis for enteroviral RNA using GEV assay. The results were compared and sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated.

**Results:** A total of 42 CSF specimens were enrolled. Ten and 32 were positive and negative for CSF culture, respectively. Among 32 patients having negative CSF culture, 20 had a positive throat/rectal culture for enteroviruses in the same course. When GEV assay was compared with CSF culture, the sensitivity and specificity for GEV assay were 90.0% (9/10) and 87.5% (28/32), respectively. When adding other culture results in addition to CSF culture as laboratory evidence of enteroviral infection, PPV and NPV of GEV assay for diagnosis of CNS enteroviral infection were 92.3% (12/13) and 96.6% (28/29), respectively.

**Conclusions:** The GEV assay was demonstrated as a useful tool for its good performance for rapid detection (2.5 hours) of enteroviral RNA in CSF of pediatric patients under impression of enteroviral infection with CNS involvement.

#### **P925** A clinical laboratory evaluation of the Luminex xTAG respiratory viral panel FAST version 2.0

J. Bible\*, E. Halligan (London, UK)

The Luminex xTAG respiratory viral panel FAST version 2.0 (RVP FASTv2.0) is an updated assay which detects 19 human respiratory virus strains per single well test, including identification of the 2009 Pandemic H1N1 Influenza strain. This assay was run on new MAGPIX platform. We studied RVP FAST 2.0 efficacy in detecting respiratory viruses from 121 Nasopharyngeal Aspirates (NPA) samples collected from patients with acute respiratory infection during the winter 2010–2011 season and compared RVP FASTv2.0 results to those obtained with the RVP FASTv1.0. Considering the 2009 pandemic Influenza strain RVP FAST v1.0 detected 41 of 48 isolates as matrix positive, whilst RVP FASTv2.0 detected all 42 as matrix positive and Hemagglutinin (HA) positive with three other isolates as HA positive but with no matrix signal. A secondary real-time PCR was used to confirm all pandemic positive results. Findings for all other respiratory viruses indicate equal sensitivity and specificity between the two assay formulations using our clinical specimens.

In addition, a significant difference between the assays occurred when the QCMD RSV 2011 panel for was tested. The RVP FASTv2.0 assay comprehensively detects all the clinically significant viruses in a single measurement making it a useful application for detecting respiratory tract viral infections. Use of RVP FAST v2.0 would be a significant advantage over RVP FAST v1.0 in simplifying and organising laboratory workflow and increasing speed to result over current reflex testing of untypable influenza positives.

#### **P926** Evaluation of three molecular assays for detection of respiratory virus

K. Rodrigues, A.C. Mendes\*, S. Fernandes, C. Santos, A. Castro, H. Ramos (Porto, PT)

**Objective:** To evaluate three molecular methods for detection of respiratory viruses. After comparison of different kits, to implement a molecular method suitable for routine laboratory analysis, evaluating cost, speed and ease of technical implementation.

**Methods:** For comparison purposes, we studied 58 samples (nasopharyngeal lavage) collected between July 2009 and June 2010,

mostly from children under the age of five, with respiratory disease. Results were compared with IF (Biotrin<sup>®</sup>, Diagnostics Hibrids<sup>®</sup>). The molecular analysis included nucleic acid extraction, amplification and detection of respiratory viruses by three different kits: RV15 ACE Detection, Seegene; Pneumovir CLART<sup>®</sup>, Genomica, Magicplex<sup>™</sup>RVPanelReal-TimeTest, Seegene.

After implementation of Magicplex<sup>™</sup> RV Panel in laboratory routine, 263 samples were studied between February and August 2011, mostly from Pediatric ward and emergency.

**Results:** Considering only the virus detected by IF and PCR, positivity rate was 26% and 64% respectively. In the comparative molecular study, the number of viruses detected by the three techniques was different (RV15-68; Pneumovir-76; Magicplex-87), the most commonly detected virus was RhV (RV15-34%, n = 23; Pneumovir-28%, n = 21; Magicplex-33%, n = 29) followed by VSR (RV15-28%, n = 19; Pneumovir-25%, n = 19; Magicplex-26%, n = 23). The three techniques allowed identification of co-detections (RV15-17; Pneumovir-19; Magicplex-21) the most common being the association AdV/RhV (Pneumovir 38%, n = 5; Magicplex 33%, n = 4) and VSR/RhV (RV15-43%, n = 6).

After implementation of Magicplex<sup>™</sup> RV Panel, of 263 samples studied, 210 were positive and 53 negative for the detection of respiratory viruses. The most commonly detected virus was AdV (57%, n = 120) followed by RhV (35%, n = 74). In 90 double detections, the most frequent association was AdV/RSV (22%, n = 20).

**Conclusion:** The comparative study demonstrated the superior sensitivity of molecular methods, which lead us to choose the kit Magicplex<sup>™</sup> RV Panel Real-Time Test, since it showed a better cost/benefit ratio, as well as better suitability for laboratory implementation. The results after 6 months of implementation in the routine laboratory, revealed a high number of co-detections, as well as the difficulty in clinical interpretation of these results. Thus, the use of complementary methodologies, as well as viral load quantitation, may be the next steps in completing this work.

#### **P927** Clinical performance of the xTAG<sup>®</sup> respiratory viral panel FAST v2 with subtyping capability of influenza A 2009 H1N1 non-seasonal variant

*E. Lopes, F. Merante, D. Himsforth, C. Ginocchio, Y. Qian, J. Liu\* (Toronto, CA; New York, US; Beijing, CN)*

**Objectives:** Since the 2009 pandemic, FluA 2009H1N1 strain has become a predominant strain of influenza A H1 virus worldwide. The xTAG<sup>®</sup> Respiratory Viral Panel FAST v2 (RVP FAST v2) is a qualitative nucleic acid multiplex test intended for the simultaneous detection and identification of multiple respiratory viruses including the 2009H1N1 strain in NP swabs, nasal aspirates and BALs from individuals suspected of respiratory tract infections. The viruses and subtypes detected by the assay are: FluA, FluA subtype H1, FluA 2009H1N1 (pandemic variant), FluA subtype H3, FluB, RSV, hMPV, HRV, Adenovirus, HPIV-1, HPIV-2, HPIV-3, HPIV-4, HCoV-229E, HCoV-OC43, HCoV-HKU1, HCoV-NL63, and HBoV. Here we describe the clinical performance of RVP FAST v2 for all viral targets probed by the assay.

**Methods:** Diagnostic accuracy of RVP FAST v2 for FluA 2009H1N1 was evaluated using clinical specimens that tested positive or negative for FluA 2009H1N1 by real-time RT-PCR assay or bidirectional sequencing. Clinical performance of RVP FAST v2 for all other targets was evaluated using clinical specimens that tested positive or negative by xTAG<sup>®</sup> RVP FAST. Clinical specimens were collected from multiple sites in the US, Canada and China. All specimens tested were run on both the Luminex<sup>®</sup> 100/200 and MAGPIX<sup>®</sup> systems.

**Results:** A total of 179 clinical specimens were tested to establish the diagnostic sensitivity and specificity of RVP FAST v2 for FluA 2009H1N1. Diagnostic sensitivity and specificity of RVP FAST v2 for FluA 2009H1N1 were 98.10% (95% CI: 93.3–99.8%) and 100% (95% CI: 95.1–100%) respectively. A total of 329 clinical specimens were tested by both RVP FAST and RVP FAST v2 in order to assess

equivalence for analytes probed by both assays, all of which were represented in this sample set. Overall agreement between the two assays for common analytes was 100% for positive calls (95% CI: 99.0–100%) and 99.1% (95% CI: 98.8–99.3%) for negative calls. Results were comparable between the Luminex<sup>®</sup> 100/200 and MAGPIX<sup>®</sup> systems.

**Conclusion:** This evaluation shows that RVP FAST and RVP FAST v2 are substantially equivalent in terms of clinical performance and that RVP FAST v2 is well suited for diagnosis of respiratory viruses including subtyping of FluA 2009H1N1 non-seasonal variant. Additionally the study demonstrated clinical utility of the MAGPIX<sup>®</sup> system for molecular diagnostic tests used as an aid in the diagnosis of respiratory tract infections.

#### **P928** Evaluation of a new real-time PCR for the detection of HSV1, -2 and VZV in CSF and lesion scrapings

*A.K Petrich\*, F. Gharabaghi, S.E. Richardson (Toronto, CA)*

**Objectives:** Nucleic acid amplification testing has greatly facilitated the detection of herpes simplex viruses (HSV-1, -2) and varicella-zoster virus (VZV) in CSF. The goal of this study was to evaluate a new multiplex real-time PCR assay that detects and identifies HSV1 and -2 and VZV (Altona Diagnostics, Hamburg, Germany) in CSF and lesion scrapings.

**Methods:** Ten-fold dilutions of culture lysates of HSV-1, -2, and VZV were used to spike pooled CSF and CSF shunt fluid. Five hundred microlitre of mock sample was extracted into 110 µL using the easyMag (biomérieux, France). Reactions were run in triplicate near the detection limit to compare the sensitivity of two conventional in-house PCR assays (HSV-1/2 and VZV, modified from Johnson et al., 2000) and the RealStar<sup>®</sup> alpha Herpesvirus real-time PCR assay (Altona Diagnostics). Ten microlitre of extracted nucleic acid was added to each reaction mix. Detection of the conventional PCR products was performed by gel electrophoresis with visualization using ethidium bromide. Fifty nine left-over CSF specimens (100 µL) from pediatric and adult patients were extracted and tested using the in-house conventional PCR assays and the real-time assay (19 pos. and 40 neg). Discordant results were repeated with the conventional and real-time assays. The real-time PCR assay was also evaluated with material from 22 known positive lesion scrapings extracted using a manual guanidine thiocyanate method and compared to the conventional PCR (modification of Johnson et al., 2000) for detection and characterization of the three viruses.

**Results:** The RealStar<sup>®</sup> alpha Herpesvirus assay was significantly more sensitive than the conventional PCR for all three targets; HSV1 (2–3 logs difference), HSV2 (1–2 logs difference), and VZV (2–3 logs difference) using end-point analysis on mock CSF and CSF shunt fluid samples. The RealStar<sup>®</sup> alpha Herpesvirus assay detected 19/19 (sensitivity 100%) known positive clinical CSF specimens and was negative for 40/40 known negatives (specificity 100%) For the lesion scrapings, both assays detected and identified 6 VZV, 12 HSV-1 and 4 HSV2 in 22 known positive lesion scrapings.

**Conclusion:** The new RealStar<sup>®</sup> alpha Herpesvirus PCR kit is a multiplex assay capable of detecting and characterizing HSV-1, HSV-2 and VZV in CSF and lesion scrapings with high sensitivity and specificity. The assay was 1–3 logs more sensitive for all targets in mock CSF and shunt specimens than conventional PCR.

#### **P929** Multicentre performance evaluation of the VERSANT<sup>®</sup> HCV RNA 1.0 Assay (kPCR) in quantitative detection of hepatitis C viral RNA

*D. Muir, H. Mistry\*, P. Nutter, J. Yao, B. Digmann, M. Gartner, J. Bendel, J. Turczyn, J. Chen, M. Garris, M. Hennig, J. Surtihadi, V. Nguyen (London, UK; Rochester, Berkeley, US)*

**Objectives:** The VERSANT HCV RNA 1.0 Assay (kPCR)\*\* (VERSANT assay) is a reverse transcription, kinetic polymerase chain reaction (kPCR) method for quantifying hepatitis C virus (HCV) RNA in human plasma and serum, using the VERSANT kPCR Molecular

System (System). This system combines a fully automated sample preparation module and a fully automated amplification and detection module. This study examined the performance characteristics of the assay, including a comparison between the VERSANT Assay and the Abbott RealTime HCV assay (Abbott assay).

**Methods:** Assay performance characteristics were evaluated at three laboratory sites, using two assay reagent lots and six Systems. Assay specificity was assessed using plasma and serum samples from 1054 HCV-seronegative individuals. A 14-member panel prepared from high-titer HCV RNA samples or HCV Armored-RNA, diluted in defibrinated human plasma basepool, was used to determine reproducibility (precision), linearity, accuracy, quantification range and analytical sensitivity (LoD). Panel concentrations range from 5 to 139 711 676 IU/mL. The VERSANT and Abbott assays were compared using 243 paired HCV RNA-positive clinical samples across the quantification range, with HCV genotypes 1 to 6 represented.

**Results:** The overall assay specificity was 100%. The estimated limit of detection (LoD) was 10.5 IU/mL, and the claimed LoD was 15 IU/mL. The claimed lower and upper limits of quantification were 15 IU/mL (LLOQ) and  $10^8$  IU/mL (ULOQ). Within this range, the assay showed good reproducibility (total log SD range: 0.10–0.37), linearity (log observed = 0.97 log expected + 0.20), and accuracy (log recovery range: -0.1 to 0.2). Deming regression analysis of log quantitative results obtained from VERSANT vs. Abbott assay showed good correlation ( $y = 1.1 \times -0.28$ ;  $R = 0.93$ ). On average VERSANT assay quantified 0.24 log IU/mL higher than Abbott assay, with 95% of the differences falling within the range of -0.51 to 0.99 log IU/mL.

**Conclusions:** The VERSANT HCV RNA 1.0 Assay using the VERSANT kPCR Molecular System is a reliable and accurate assay for the quantification of HCV RNA in plasma and serum from HCV infected individuals.

VERSANT is a registered trademark of Siemens and all other trademarks are the property of their respective owners.

\*\*CE marked in Europe; not available in the US.

### P930 Molecular genotyping of dengue serotype 2 in the Philippines

R. Destura\*, J.A. Petronio, R. Vinarao, K.M. Flores (Manila, PH)

**Objectives:** Dengue fever and dengue haemorrhagic fever (DF/DHF) have emerged as the most important arboviral diseases of mankind. The characterization of circulating dengue virus serotypes is important in surveillance, since the introduction of a new variant to areas affected by pre-existing serotypes constitutes a risk factor for DHF and Dengue Shock Syndrome (DSS). This study aims to determine the genotype of Dengue Virus (DENV) 2 using the capsid-premembrane (C-prM) gene junction sequence of isolates during the 2008–2010 outbreaks.

**Methodology:** De-identified serum samples positive for dengue infections were obtained from a tertiary hospital during outbreaks from 2008 to early 2010. Dengue virus serotyping was carried out by heminested RT-PCR targeting the C-prM gene junction. DNA sequencing was performed using an ABI PRISM BigDye<sup>®</sup> Terminator v1.1 Cycle Sequencing Kit on an automated sequencer. The C-prM gene was sequenced using the primers, mD1 and D2. Sequence alignments were performed using the ClustalW function of MEGA 4 (Molecular Evolutionary Genetics Analysis) software. Comparisons were made with DENV-2 reference strains. Phylogenetic trees were constructed by the neighbour-joining (NJ) method and reliability of neighbour-joined trees was estimated by bootstrap analysis.

**Results:** Nineteen DENV 2 were identified from nucleotide sequences generated from the C-prM gene junction and compared with ten other DENV 2 isolates with known genotypes. Alignments revealed eight point mutations distributed in different isolates, five of which were missense. Analysis using Maximum Composite Likelihood method showed that the number of substitutions per site of the nineteen isolates was 0.011. Seventy three out of the 386 base pairs in the final dataset were variable, 47 of which were parsimony informative and 26 are singletons. Phylogenetic tree was drawn including DENV 1, 3, and 4 as

outgroups. Isolates investigated claded in the cosmopolitan genotype and was supported by a bootstrap value of 91%.

**Conclusion:** Sequence analysis and phylogenetic data suggested that the Philippine DENV 2 isolates are primarily Cosmopolitan genotype. Constant monitoring of the DENV 2 genotypes is essential to detect possible shifts within the serotype in the future and in understanding phylodynamic patterns of disease outbreaks in the era of global warming and climate change.

### P931 Serum profile of T helper 1 and T helper 2 cytokines in HCV-infected patients

A. Ramezani\*, M. Sofian, A. Aghakhani, A. Farazi, M. Banifazl, A. Eslamifard, A. Velayati (Tehran, Arak, IR)

**Objectives:** T-helper (Th) lymphocyte cytokine production may be important in the immunopathogenesis of hepatitis C virus (HCV) infection. Th1 cytokines (interleukin [IL]-2, interferon gamma [IFN-gamma]) are necessary for host antiviral immune responses while Th2 cytokines (IL-4, IL-10) can inhibit the development of these effector mechanisms. The aim of the present study was to assess the serum profile of Th1 and Th2 cytokines in treated and non-treated HCV infected individuals.

**Methods:** This study was carried out in 63 HCV infected patients (31 under treatment and 32 untreated) and 32 matched HCV-seronegative healthy subjects. The serum samples were checked with enzyme-linked immunosorbent assay (ELISA) for IL-2, IL-4, IL-10 and IFN-gamma.

**Results:** Levels of circulating IL-2, IL-4, IL-10 and IFN-gamma were significantly elevated in HCV patients vs. normal controls ( $2822.6 \pm 1259.92$  vs.  $950.8 \pm 286.9$  pg/mL;  $1987 \pm 900.69$  vs.  $895.91 \pm 332.33$  pg/mL;  $1688.5 \pm 1405.1$  vs.  $519.03 \pm 177.64$  pg/mL and  $1501.9 \pm 1298$  vs.  $264.66 \pm 71.59$  pg/mL respectively;

$p < 0.001$ ). The serum levels of all cytokines were significantly lower in under treatment patients than those of untreated patients ( $p < 0.001$ ). **Conclusion:** On the basis of our data, the simultaneous increase of Th1 and Th2 related cytokines may indicate that both Th1 and Th2 cytokines have been involved in the pathogenesis of HCV infection. Besides, this activated T-cell response in HCV infected patients could be regulated by treatment.

#### P932 Molecular detection and sub-typing of human papillomavirus on Albanian women

A. Mitre\*, F. Bakiri, T. Bare, A. Xhani, R. Bajro (Tirana, AL)

Human Papillomavirus (HPV) is estimated to be the common sexually transmitted infection in the Albanian population. Genital HPV types are categorized according to their epidemiological association with cervical cancer. High-risk HPV types can cause cervical and other genital cancers. Here, we introduce a new broad HPV assay based on high-density DNA microarrays, with which single and multiple HPV infections are easily recognized, and the corresponding HPV types can be identified. With this format it is possible to detect and identify 35 HPV types and the assay has the ability to recognize multiple infections.

**Aim:** The use of DNA microarrays for detection and sub typing of the multitude of HPV types in endocervical samples.

**Materials and methods:** Cervicovaginal swab specimens were collected from the 111 females aged 18–50 years, during period of time 2009–2010. The patients were recommended from gynecologist of University Hospital “Mbretresha Geraldine”. The identification and subtyping of HPV was performed with high density AND microarray in “Intermedica” laboratory.

**Results:** In the studied population we observed 27.9% incidence of HPV infection, from which 70.9% with high risk. The following HPV types were encountered in our clinical sample collection: 51(h), 84(p), 6(l), 16(h), 39(h), 51(h), 6(l), 31(h), 59(h), 56(h), 18(h), 52(h), 53(h), 83(p), 81(l), 73(h), 35(h), 66(h). The percentage of serotypes are: High risk HPV: HPV-16 (10%), HPV-18 (4%), HPV-31 (14%), HPV-35 (2%), HPV-39 (2%), HPV-51 (4%), HPV-52 (4%), HPV-53 (6%), HPV-59 (4%), HPV-62 (2%), HPV 66 (2%), HPV 73 (2%). Low-risk HPV: HPV-6 (28%), HPV-81 (6%). Indeterminate-risk HPV: HPV-83 (2%), HPV-84 (2%), which were found only as co infections with HPV-high risk types. We have found 71.7% of the positive cases as co infections with other HPV types, from which 46.7% with two type, 14% with three and the 9.5% with four types of HPV.

**Conclusion:** The prevalence of high-risk HPV in female genital tract shows high level. DNA microarrays were a good method for detection and sub typing of the multitude of HPV types in endocervical samples.

#### P933 Activation of monocyte derived dendritic cells (MoDCs) by hepatitis C virus (HCV) glycoproteins

A. Abdulhaq\*, A.W. Tarr, L. Martinez-Pomares, W.L. Irving (Nottingham, UK)

Hepatitis C Virus causes a persistent, chronic infection in more than 80% of the estimated 170 million infections worldwide. Persistent infection can lead to complications such as cirrhosis and hepatocellular carcinoma. Around 20% of HCV infected patients are able to spontaneously clear the infection. Clearance is associated with the presence of broadly neutralizing antibodies. HCV glycoprotein E2 mediates HCV entry, and as such is the primary target for neutralizing antibodies. Dendritic cells have a critical role in priming the adaptive immune response to pathogens. This study aimed to investigate the recognition of HCV E2 envelope glycoproteins by dendritic cells. sE2 interacted with multiple receptors on the surface of MoDCs, including CD81 and DC-SIGN. These interactions resulted in moderate activation of MoDCs, but was associated with different profiles of cytokine release compared to cells stimulated with either LPS or Poly I:C. In both healthy donors and HCV positive patients similar expression of CD86 was observed following stimulation, either with sE2, LPS or Poly I:C. In contrast, expression of CD83 was significantly reduced in HCV infections, compared to healthy donors. MoDCs isolated from HCV infected individuals displayed a normal cytokine

#### (a) Healthy controls

#### (b) HCV infected

production compared to healthy donors. When MoDCs were activated with combinations of sE2661 with LPS or poly I:C, differences were observed in the phenotype and production of cytokines between MoDCs isolated from healthy controls and HCV infected patients. These results demonstrate that the HCV E2661 protein is recognised by some MoDCs, resulting in up-regulated expression of the DC maturation markers CD83 and CD86 and altered patterns of cytokine secretion, compared to un-stimulated cells. This activation is not similar to that achieved with LPS or poly I:C. HCV sE2661 does not possess the capacity to induce either Th1- or Th2-type immune responses in MoDCs from both healthy and HCV infected patients. However, this protein induced production of TNF-alpha from MoDCs isolated from some healthy donors, but not from MoDCs isolated from HCV-infected patients. In addition, sE2661 was found to influence MoDCs function when combined with TLR ligands. It is concluded that MoDCs from some HCV infected patients possess different in phenotypes to healthy controls. This may play a role in the inability to control HCV infection.

## Virology – diagnosis, epidemiology, prophylaxis and therapy

### P934 Prophylactic efficacy of AVI-7100 against influenza A in mouse and ferret infection models

*P. Iversen\*, F. Schnell, S. Crumley, D. Mourich, T. Voss (Bothell, New Orleans, US)*

**Objective:** AVI-7100 is a phosphorodiamidate morpholino oligomer containing three modified linkages (PMOplus) that is designed to interfere with expression of the M1 and M2 genes of influenza A virus. The objective was to evaluate the prophylactic therapeutic utility of AVI-7100.

**Methods:** A single 0.1 mg intranasal (i.n.) dose of AVI-7100 was administered to female BALB/c mice (n = 10/group) at 7 days, 3 days or 4 hours prior to viral challenge with  $5 \times 10^5$  pfu of A/Port Chalmers/1/73 (H3N2). Lung viral load was determined on day 6 post infection. In a separate study, a single i.n. dose was administered to mice infected with A/PR/8 (H1N1) and plasma and lung oligomer concentrations were determined. Outbred ferrets (*Mustela putorius furo*; n = 7/group) were administered AVI-7100 as a single i.n. dose at 7 days, 5 days, 3 days or 4 hours prior to insufflation viral challenge with  $5 \times 10^5$  pfu H1N1 A/Hong Kong/2369/09 per ferret. Negative control groups were treated with saline and positive controls were administered oseltamivir at 10 mg/kg p.o. every other day beginning 7 days prior to infection.

**Results:** A single intranasal dose of AVI-7100 (0.1 mg/mouse) administered 7, 3 days or 4 hours prior to infection with A/Port Chalmers/1/73 (H3N2) significantly ( $p < 0.05$ ) reduced lung viral titers in each group compared to vehicle controls and oseltamivir treated mice. PMOplus concentrations in the lungs of mice following a single insufflation dose follow zero order elimination and tissue concentrations above the AVI-7100 EC50 are maintained for >3 days. In the ferret, a single i.n. dose of AVI-7100 administered 7 Days, 5 days, 3 days or 4 hours prior to exposure with A/Hong Kong/2369/09 (an oseltamivir resistant pH1N1) significantly ( $p < 0.05$ ) reduced cumulative viral load in nasal wash and in lung bronchiolar lavage compared to saline controls and oseltamivir treated ferrets. The decrease in viral load in nasal wash samples was directly proportional to the interval of time between prophylactic treatment and viral exposure (a zero order reduction in activity).

**Conclusions:** AVI-7100 is effective against influenza A (H1N1 and H3N2) and in both mouse and ferrets after a single intranasal dose up to seven days prior to viral exposure. Zero order elimination of AVI-7100 from the lung was observed. These observations support the prophylactic use of AVI-7100 in preventing influenza A infection.

### P935 The usefulness of mice monoclonal antibody in dengue virus diagnosis and research

*M. Pupo-Antunez\*, Y. Vazquez, N. Amin, S. Vazquez, Y. Caballero, L. Morier, L. Morier, V. Capó, G. Guzmán (Havana, CU)*

**Objective:** The aim of this work was to generate, characterize and mainly use mice monoclonal antibodies in serodiagnosis and dengue researches.

**Methods:** Mabs were generated by conventional technology of Kohler and Milstein. Mice immunizations were used dengue-2 virus (D-2V) New Guinea C and Cuban (A15) strains. Mabs were characterized to determine: immunoglobulin isotype, protein recognition, and biological characteristics. In some cases, they were used in different assays: serological diagnosis, passive protection, viral protein expression and used in the identification of dengue mimotopes by a phage display peptide library (pVIII-9aa).

**Results:** H3-6 Mab specific to D-2V New Guinea C strain showed IgG 2a isotype and was able to recognize E protein from four dengue serotypes by Immunofluorescence assays. This Mab was capable of detecting anti dengue IgA antibody by ELISA as a possible marker in early and recent dengue infection. From the biopanning process, three mimotope peptides were identified. These showed similarity in their amino acid sequences with E dengue protein. One peptide was synthesized containing E dengue mimotope which was recognized by anti dengue antibodies in sera from convalescent infected patients. 8H8 Mab was raised against core (C) dengue protein specific to D-2V A15 Cuban strain. It was the IgG1 isotype and it had no hemagglutination inhibition, neither complement fixation nor neutralization properties. 8H8 Mab followed kinetically C dengue protein expression in mosquito cells (from 6 to 96 hour post-inoculation) and immunolocalized in brain tissues from D-2V infected mice (from 24 to 78 hour post-inoculation). In preliminary studies, 8H8 Mab was competent to recognize the C dengue protein in viremic serum from infected patients which made possible the quantification of a C recombinant dengue protein.

**Conclusions:** Our results suggest that mice monoclonal antibodies continue being useful in Dengue diagnosis and research. Mabs can be used directly in serodiagnosis or indirectly through phage-displayed peptide library for the development of diagnostic systems and a potential vaccine against this pathogen. Murine Mabs with defined virus specificities were efficient analytic tools for detection and expression of dengue C protein in vivo and in vitro.

### P936 Development of a new method for BK polyomavirus genotyping: application to transplant recipients

*S. Burrel, M. Gits-Muselli, Z. Ait-Arkoub, S. Nguyen, N. Arzouk, H. Agut, D. Boutolleau\* (Paris, FR)*

**Objectives:** In immunocompromised patients, BK virus (BKV) reactivation may result in nephropathy in kidney transplant (KT) recipients or haemorrhagic cystitis in haematopoietic stem cell transplant (HSCT) recipients. BKV strains are classified into four different genotypes (I to IV). BKV genotyping has been historically based on the analysis a 327-bp variable region of the gene coding for the major capsid protein VP1. The aim of this work was to develop a new method for BKV genotyping based on the sequencing of the full-length gene coding for VP1 and to determine BKV genotypes among KT and HSCT recipients.

**Methods:** Primers were designed to amplify, by nested PCR, and to sequence the full-length VP1 coding region (1089 bp). Amplified products were analyzed with the automated sequencer ABI 3100 Genetic Analyzer (Applied Biosystems). This new method was applied to 52 EDTA whole blood specimens obtained from 40 KT and 12 HSCT recipients (34 men, 18 women, median age: 48 years) experiencing BKV active infection (median BKV load in blood: 5.5 log). All nucleotide and amino acid VP1 sequences were aligned with SeqScape v2.5 software using BKV Dunlop strain as a reference (GenBank accession number V01108). A phylogenetic tree was

constructed by the neighbor-joining method using ClustalW program, including the VP1 sequences from the different reference BKV strains representing the main genotypes obtained from GenBank.

**Results:** The sensitivity of the VP1 nested PCR was 500 copies/mL. At the nucleotide level, the interstrain identity of VP1 gene ranged from 91.9% to 99.2%. At the amino acid level, a total of 45 amino acid changes were identified, that is 12.4% of the total codons of the protein. Each strain harboured a mean number of 8.8 amino acid changes. Seven amino acid changes were evidenced among at least 50% of the BKV strains. As a whole, the distribution of BKV genotypes among transplant recipients was as follows: I (81%), II (8%), III (0%), IV (12%). Among genotype I, BKV Ia, Ib1, Ib2, and Ic subgroups represented 5%, 31%, 64%, and 0%, respectively. Only BKV subgroups Ib1 and Ib2 were identified among HSCT recipients.

**Conclusion:** We report here the development of a new method for the sequencing of the full-length VP1 coding region allowing BKV genotyping. Our results evidenced the high variability of VP1. This method constitutes a useful tool for further studies on BKV pathogenicity according to the genotypes.

### **P937** Comparison of the INNO-LiPA genotyping extra and the Hybrid Capture 2 assays for detection of carcinogenic human papillomavirus genotypes

*L. Barzon, V. Militello\*, S. Pagni, G. Palù (Padua, IT)*

**Objectives:** The objective of this analysis was to compare the performance characteristics of two human papillomavirus (HPV) DNA detection assays, the Hybrid Capture 2 assay (HC2) and the INNO-LiPA Genotyping Extra assay (LiPA), for the detection of carcinogenic HPVs.

**Methods:** Cervical specimens collected from a total of 1184 consecutive women, attending our Unit for HPV testing and genotyping for opportunistic screening and investigation of HPV-related lesions, were analyzed by both HC2 and LiPA tests.

**Results:** Among the 1184 paired analyses, 559 (47.2%) specimens were negative by both tests, 418 (35.3%) were positive by HC2, while 638 (53.9%) were positive by LiPA, including 371 (31.3%) which were positive for carcinogenic HPV types (i.e., IARC groups 1 and 2A). Seventy nine specimens (6.7%) were HC2-positive but carcinogenic HPV type-negative by use of the SPF10-LiPA system. Similarly, 45 (3.8%) were carcinogenic HPV type-positive by use of the SPF10-LiPA system but HC2-negative. Agreement between the two assays for carcinogenic HPV type detection was 89.7%. HC2 identified as positive between 83% (HPV51) and 100% (HPV45, HPV56, and HPV59) of specimens with carcinogenic HPV types detected by LiPA. Ninety-two and ninety percent of the samples identified as HPV16- and HPV18-positive, respectively, by SPF10-LiPA were called positive by HC2. Among patients infected with a single HPV type detected by LiPA, HC2 positivity for carcinogenic HPV types ranged from 61.9% (HPV51) to 100% (HPV33, 35, 39, 45, 59), from 0% for HPV73 to 44% and 50% for the possibly carcinogenic IARC 2B HPV66 and HPV53, respectively, while non-carcinogenic HPVs were negative at HC2 assay, with the exception of same single HPV6 and HPV74 infections testing HC2 positive in 14.3% and 5.6% of cases, respectively. When carcinogenic HPV type detection by HC2 and the SPF10 system was stratified by cytology diagnosis, both HPV assays performed similarly for all cytology interpretations, except for women with low-grade squamous intraepithelial lesions. Discordant results were mainly due to infection with HC2 cross-reactive types HPV53 and HPV66.

**Conclusion:** A very good agreement was observed between HC2 and INNO-LiPA Genotyping Extra assays for carcinogenic HPV type detection. In addition, HC2 probes showed cross-reactivity with the possible carcinogenic HPV53 and HPV66.

### **P938** Prospective evaluation of a norovirus bedside test in unselected patients with gastroenteritis

*E. Weise\*, M. Vergoulidou, B. Friedrichs, S. Siedler, S. Pfaffenbach, J. Hofmann, R. Somasundaram, S. Schwartz (Berlin, DE)*

**Objectives:** Infections with Norovirus (NV) are highly contagious, requiring rapid identification of infected pts. However, NV-specific PCR testing, currently regarded as the diagnostic standard, is not always readily available and time consuming. We prospectively evaluated a Norovirus (NV) bedside test, which gives a result within 15 minutes, in unselected pts with gastroenteritis (GE).

**Methods:** Pts who presented with acute gastroenteritis (GE) were enrolled after written consent. Clinical details were recorded by a standardised questionnaire. The study was approved by the ethical committee. Stool specimens were investigated using a commercially available, immunochromatographic bedside test (RidaQuick NorovirusTM, R-Biopharm, Darmstadt, Germany) and in parallel by NV-specific, quantitative PCR.

**Results:** A total of 63 pts (33 male; age 20–96 year, median 70 year) were enrolled during the past winter season and eligible for a final analysis. Another 16 pts were excluded: no stool specimen 14, no consent 2. Eligible pts (63) were tested 0–19 (median 1) days after onset of symptoms, which were emesis (1), diarrhoea (26) or both (36). In all, 18 pts had a positive bedside test result and in 28 pts Norovirus (NV) GE was confirmed by NV-specific PCR. The sensitivity, specificity, positive predictive value and negative predictive value of the bedside test were 61%, 97%, 94% and 76%, respectively. The median ct-value of 17 pts with NV GE and correctly assigned by the bedside test was significantly lower compared to 11 pts with a false-negative bedside test (22.5 vs. 27.2,  $p = 0.03$ ). There was only a slight, not significant trend towards a higher median clinical severity score (Rockx, Clin Infect Dis 2001, 35:246) among 17 pts with Norovirus (NV) gastroenteritis (GE) and correctly assigned by the bedside test compared to 11 pts with a false-negative bedside test (10 vs. 8,  $p = 0.31$ ).

**Conclusion:** In this clinical study, we recorded a limited sensitivity but good specificity, which makes this test a useful adjunct diagnostic tool, particularly in NV outbreak settings. We found a trend towards false-negative bedside test results in pts with likely low replicative NV GE.

### **P939** Evaluation of interleukin-10 gene promoter polymorphisms and hepatitis B virus infection outcome

*M. Sofian, M. Banifazl, A. Aghakhani, N. Zarin far, A. Farazi, A. Ramezani\* (Arak, Tehran, IR)*

**Objectives:** Single nucleotide polymorphisms (SNP) in the promoter region of the interleukin (IL)-10 gene has been reported to have a role in determining of hepatitis B virus (HBV) infection outcome. The present study was undertaken to evaluate the association between HBV infection and SNP in the promoter region of the IL-10 gene in a central Iranian city.

**Methods:** A total of 127 cases including 32 patients with chronic hepatitis B infection and 34 healthy carriers collapsed as persistent group, 30 subjects who had spontaneously recovered from HBV infection and 31 healthy controls were enrolled in this study. The three biallelic (–819, –592, –1082) polymorphisms in the IL-10 gene promoter were analyzed by polymerase chain reaction and direct sequencing.

**Results:** No significant difference was found in frequencies of genotypes and haplotypes of IL-10 gene promoter region at position –1082, –819 and –592 among controls, individuals spontaneously recovering from HBV infection, carriers and patients with chronic hepatitis B infection. However, frequencies of A/A genotype at position –592 and T/T genotype at position –819 were higher in the HBV clearance group, while frequency of G/G genotype at position –1082 was higher in persistence group. GCC/GCC and GCC/ACC haplotypes were significantly more frequent in anti-HBe positive patients.

**Conclusion:** It seems that genetic polymorphisms of IL-10 promoter region are not associated with HBV infection outcome. However, patients with high and intermediate producer haplotypes of IL-10 had more ability to produce anti-HBe than those with low producer haplotypes.

**P940 Investigation of interleukin 28b gene polymorphism in patients with chronic hepatitis C**

Ü. Savasçi, Ö. Coskun\*, S. Kozan, A. Karakas, H. Gül, C. Eyiğün (Ankara, TR)

**Introduction:** The rate of response to treatment can be predicted by IL28B genotyping. Thus, decisions related to treatment can be tailored and the cost can be reduced. The frequency of IL28B polymorphism and the effect of this on response to treatment were investigated in patients with chronic hepatitis-C virus.

**Methods:** The study was planned as a study for the determination of attitude and DNA was isolated from the blood sample obtained from the patients with chronic hepatitis-C, using “spin column” method. In the analysis of rs12979860 polymorphism, Tetra primer amplification refractory mutation system method was used. In the analysis of rs12979860 polymorphism, a fast and cheap polymerase chain reaction method was developed.

**Results:** As a result of the analysis for the correlation of rs8099917 polymorphism with genotypes performed using chi-square test, TT genotype was found in 21 of 37 patients among responsive patients and in 4 of 16 patients among unresponsive patients. In the evaluation of the difference between rs8099917 polymorphism and other genotypes using logistic regression, we found that the presence of GG genotype increased the therapeutic response by three times compared to TG, but this difference was not statistically significant. The presence of TT genotype in the patient increased the therapeutic response by 5.25 times compared to TG and the difference was statistically significant.

**Conclusion:** Future studies should address to the explanation of the genetic mechanisms involved in IL28B. Correlation between IL28B polymorphism and the therapy will be of a great value for the drugs used in the treatment of hepatitis-C infection.

**P941 Detection of hepatitis C virus proteins in peripheral blood mononuclear cells of patients with chronic hepatitis C: correlation with activity and stage of hepatitis**

O.V Masalova\*, T.V. Vishnevskaya, A.V. Pichugin, S.V. Alkhovsky, T.V. Shkurko, R.I. Ataullakhanov, A.A. Kushch (Moscow, RU)

**Objectives:** To study hepatitis C virus (HCV) RNA and HCV protein expression in peripheral blood mononuclear cells (PBMC) of patients with chronic hepatitis C (CHC), and to determine the relationship between HCV replication in PBMC and the activity and stage of hepatitis C.

**Methods:** PBMC were isolated from peripheral blood of 83 patients with CHC in a Ficoll gradient. PBMC from 20 HCV-negative donors served as a control. HCV proteins (core, NS3, NS4A, NS4B and NS5A) in PBMC were identified by immunocytochemical staining (ICS) with 17 monoclonal antibodies (mAb). Intracellular expression of viral proteins was also studied by flow cytometry with FITC-conjugated mAb. Plus- and minus-strands HCV RNA in PBMC were detected by RT-PCR. Histological activity and hepatitis stage were determined by analysis of liver biopsy specimens.

**Results:** By ICS, HCV proteins in PBMC were detected by at least one Mab or mixtures of Mabs in 71 out of 83 (86%) CHC patients. NS5A had the highest detection rate (61%), those for other proteins varied from 35% to 44%. The proportion of antigen-positive (AG+) cells and the intensity of staining varied considerably from patient to patient, being different for individual proteins. The HCV proteins were located

in the cytoplasm of predominantly monocytes and rarely – of lymphocytes. Flow cytometry detected HCV proteins in 11 out of 21 (52.4%) patients, in four patients the proteins were located in lymphocytes and monocytes and in seven patients only in monocytes. The proportion of AG+ cells reached 32% of total population for monocytes and 5% for lymphocytes. Imbalance in the lymphocyte/monocyte ratio was typical of the majority of patients. HCV detection rate correlated with a decrease in the total count of mononuclear cells and lymphocytes:  $r = -0.66$ ,  $p = 0.001$  and  $r = -0.64$ ,  $p = 0.002$ , respectively. Plus-strand HCV RNA in PBMC was detected in 95% patients and minus-strand RNA in 51% patients. The presence of minus-strand RNA in PBMC correlated with expression of core and NS5A ( $p < 0.05$ ). The accumulation of HCV Core protein in PBMC positively correlated with histological activity and stage of hepatitis ( $p < 0.05$ ). Detection rate for HCV proteins was the highest for PBMC of patients with elevated alanine aminotransferase level ( $p < 0.05$ ).

**Conclusion:** PBMC are a site of active HCV replication and viral proteins accumulation, which may lead to immune disorders, aggravated biochemical and necro-inflammatory activity of liver disease and hepatitis stage.

**P942 Cloning and expression of HCV polytope-HBV surface antigen fusion protein under optimised condition in *E. coli* for vaccine study**

M. Gholizadeh\*, H. Khanahmad, F. Roohvand, M. Aghasadeghi, S. Sadat, A. Memarnejadian, A. Nazemi, M. Yazdanian, F. Motevalli (Tehran, Isfahan, Mazandaran, IR)

**Objective:** Hepatitis C virus (HCV) is a major cause of liver disease worldwide. HCV infection is associated with high morbidity and has become a major problem in public health. Until now, there has been no effective prophylactic or therapeutic vaccine for HCV. Cellular immune responses, specially cytotoxic T-lymphocytes (CTLs) play a critical role in immune response against HCV. Considering that polytope vaccine has the ability to stimulate the cellular immunity, the aim of this study is construction of a recombinant fusion protein as an HCV vaccine. This fusion protein contains HBs-antigen as an immunocarrier and five immunogenic epitops (polytope) of HCV to induce specific CTL responses.

**Materials and methods:** Five immunogenic epitops from core, E2 and NS3 antigens of HCV were selected based on evaluation with SYFPEITHI software. Coding sequence of this polytope was synthesized and fused to the HBsAg sequence by overlapping PCR. The product was digested by NcoI and XhoI enzyme and cloned in to pET-28a plasmid, which was sequence-confirmed and transformed to different *E. coli* strains of BL21 (DE3), Rozetta (DE3) and BL21 (DE3) pLysS and BL21-CodonPlus (DE3)-RIL. Expression of recombinant fusion protein was induced by addition of IPTG and evaluated using SDS-PAGE analysis and western blotting.

**Result:** The results of immunoinformatic survey led to the selection of five immunogenic epitops with high HLA-binding scores. Sequencing reactions confirmed the authenticity of final plasmid. Optimization of inducer concentration, host strains, induction time, temperature and media resulted in the expression of the highest level of recombinant protein, nearly up to 50% of total protein, and the corresponding protein band with the molecular weight of 32 kDa was detected on SDS-PAGE and confirmed using western blotting.

**Conclusion:** Recombinant protein containing the fusion of HCV polytope and HBsAg was efficiently produced in *E. coli* cells. Polytope vaccines are new approach to immunize host against pathogens. A polyepitope-based strategy combining of HCV epitops including conserved T-cell epitops of core, E2 and NS3, could impulse cellular immunity. The recombinant polytope fusion protein properties represented a good implication as a potential vaccine candidate and this guarantees the further investigations towards the assessment of its immunogenicity, which are currently under process.

**P943 A new tool to study ribavirin-induced haemolysis**

E. Brochot\*, C. Francois, S. Castelein, E. Nguyen-Khac, D. Capron, G. Duverlie (Amiens, FR)

**Background and aims:** Today's treatment of chronic hepatitis C is based on a synergistic combination of pegylated interferon and ribavirin with antiprotease inhibitors. Anemia, which is the major side effect of ribavirin disrupts ribavirin treatment compliance and vary significantly from one patient to another. There is an individual susceptibility to ribavirin hemolysis.

**Methods:** With a view to studying hemolysis and thus optimizing the treatment response, we developed an in vitro tool for analyzing the ribavirin-induced lysis of red blood cells.

**Results:** In this model, the degree of hemolysis depended on the ribavirin concentration used and could be inhibited by the addition of dipyridamole with an IC50 of 30  $\mu$ M. Intra- and inter-individual variability of the hemolysis test were evaluated and were about 5%. We observed a strong decrease in red blood cells hemolysis in the presence of the ribavirin prodrug viramidine (Taribavirin®). When testing the performance of this assay with blood from 24 patients, we obtained a strong correlation between in vitro hemolysis before treatment and in vivo hemoglobin levels decrease during subsequent treatment ( $p < 0.001$ ).

**Conclusions:** Thus, with this new tool, it seems now possible to better evaluate individual susceptibility to ribavirin-induced hemolysis before the start of treatment. In addition, the mechanism of anemia with ribavirin can be further explored, which allow then to screen and test in vitro molecules that could reduce ribavirin hemolysis. This approach could help optimize current and future therapeutic strategies involving ribavirin in the treatment of chronic hepatitis C.

**P944 A report on a large measles outbreak in Lyon area, France, 2010–2011**

C. Huoi\*, T. Bénét, A. Neuraz, Y. Mekki, G. Billaud, J. Casalegno, B. Lina, P. Vanhems (Lyon, Bron, FR)

**Objectives:** A large outbreak of measles has been occurring in France since 2008. The city of Lyon, located in Rhône-Alpes region (South-East of France) experienced one of the highest burden in Europe with a regional incidence of 94 cases/100 000 inhabitants between January and May 2011. The objective was to describe the cases of measles diagnosed in Lyon University Hospitals between 2010 and mid 2011.

**Methods:** A prospective surveillance of measles cases based on mandatory report and virological data was done in Lyon University Hospitals from 1/1/2010 to 8/7/2011. Healthcare practitioners had to report each suspected or confirmed case of measles. A standardized form with clinical signs, biologic confirmation and vaccinal status was completed for each case. A clinical case was defined as: fever  $\geq 38.5^{\circ}\text{C}$  and maculopapular rash and at least one of the following signs: conjunctivitis, coryza, cough, Koplik sign.

**Results:** Overall, 407 measles cases were diagnosed (Figure 1, Epidemic curve), the higher number of incident cases was observed in the populations under 1 year old ( $N = 129$ , 32%) and those aged

between 17 and 29 years old ( $N = 126$ , 31%). Totally, 72 (18%) had complications of measles: 51 (13%) had pneumonia, and 2 (1%) had encephalitis, no patient died. Among the measles cases, 224 (55%) were not vaccinated, 52 (13%) had received a single dose of measles vaccine whereas 11 (3%) had received two doses. For 120 (29%), information about vaccination status was not available. Overall, 2789 individuals were tested for serology and/or PCR because of clinical suspicion or exposure to a measles case: 1487 patients and 1302 healthcare workers (HCWs). Among patient, 235 (27%) had positive IgM, 648 (70%) had positive IgG, and 345 (61%) had positive PCR. Among HCWs, 8 (1%) had positive IgM, 1238 (95%) had positive IgG, and none had positive PCR. The proportion of patients aged  $\leq 30$  years without immunization was 36% vs. 12% in individuals aged  $>30$  years ( $p < 0.001$ ). The proportion of HCWs aged  $\leq 30$  years without immunization was 11% vs. 3% in individuals aged  $>30$  years ( $p < 0.001$ ).

**Conclusion:** A catch-up vaccination campaign must be implemented, focused on population under 30 years old who did not receive two doses of measles vaccine and on HCWs. Hospital-based surveillance of measles is relevant to estimate the rate of hospitalization related to measles during this outbreak and to help for early detection and control of nosocomial cases.

**P945 Surveillance of measles outbreaks in Veneto region, Italy, November 2010–October 2011**

M. Pacenti\*, L. Barzon, E. Franchin, R. Cusinato, G. Marcati, E. Lavezzo, L. Gottardello, G. Palù (Padua, IT)

**Objectives:** An enhanced surveillance programme was activated in Veneto Region since October 2010 to improve case investigation and laboratory confirmation of diagnosis.

**Methods:** For each suspected measles case, the local health authorities carried out epidemiological investigation and obtained specimens for laboratory confirmation and genotyping. Confirmed cases were notified to regional and national health authorities. In our regional reference lab, real-time RT-PCR was used to detect measles RNA from throat swabs and/or urine specimens. As recommended by the WHO, strains were genotyped by viral nucleoprotein sequencing.

**Results:** Out of a total of 185 possible cases reported in Veneto Region during the surveillance period, 105 (56.7%) were classified as laboratory-confirmed. Two incidence peaks of confirmed cases occurred in December 2010 and in April 2011, followed by a progressive decrease and no case reported in August–October 2011. All provinces of Veneto Region were involved, but incidence varied among municipalities. Children younger than 1 year and young adults aged 20–35 years were the most affected age groups. Overall, 70% of cases were unvaccinated, 8% had received only one dose of vaccine, 2% had received two doses, while information on vaccination was unavailable for 20% of cases. Measles virus was genotyped in all confirmed cases and D4G4 (53%), D8 (45%), and D4G3 (1%) genotypes were identified. D4G4 circulated in all Veneto Region until February 2011, when it was replaced by D8 genotype, which circulated in central and southern provinces. A new genetic cluster of D4G4 genotype appeared in April 2011, with a peak of cases in May 2011. Measles subtyping by sequencing the whole haemoagglutinating gene identified temporarily and geographically-related measles clusters. One case of D4G3 genotype was imported from France and one case of Edmonston A vaccine genotype was isolated in a recently vaccinated subject.

**Conclusions:** Like other Italian Regions and countries in the WHO European Region, Veneto Region did not meet the 2010 elimination target. An enhanced surveillance programme led to the identification of several measles cases in 2010 and 2011 and the determination of their circulation in the regional territory. Unvaccinated children and young adults were the most affected age groups, indicating the need to strengthen interventions to increase vaccination coverage.

**P946** Parallel epidemics with a range of globally appearing rhinovirus types – a 4-year molecular epidemiology study

M. Sansone\*, M. Andersson, R. Brittain-Long, L.M. Andersson, S. Olofsson, J. Westin, M. Lindh (Gothenburg, SE)

**Objectives:** Human rhinovirus (HRV) is a major cause of acute respiratory tract infections. HRV appears to have less seasonality than most other respiratory viruses. Our objective was to study the biodiversity of HRV strains circulating in Western Sweden over a period of four consecutive years and to evaluate their relationship with previously described strains.

**Methods:** One-hundred-seventy diagnostic respiratory samples positive for rhinovirus by real-time PCR collected during November 2006 through September 2010 were chosen for further analysis. Selection criteria were a Ct-value  $\leq 33$  indicating a relatively high viral load, and a dispersed distribution across seasons. These samples represent approximately 10% of the total amount of HRV-positive samples from the region during this time period. Sequencing of the VP4/VP2 region was used for typing and phylogenetic trees were constructed using neighbour-joining maximum distance matrix analysis of the amplified regions by MEGA 4 software.

**Results:** Typing was successful in 112 samples, of which 54 came from children (age  $\leq 18$ ). HRV-A was found in 62, HRV-B in 11 and HRV-C in 37 cases and 33 different HRV-A types, 9 HRV-B types and 21 HRV-C types were identified. The mean genetic distance between the HRV-A strains was 0.23 as compared with 0.38 between HRV-C strains, ( $p < 0.0001$ ). Enterovirus (CAV9 and EV68) were found in two cases. Twelve of the subtypes appeared during several seasons, in some cases with a span of 4 years. Six samples showed  $< 85\%$  similarity with reference sequences suggesting putative new subtypes. Comparison with published sequences in Genbank was made and revealed similarity with sequences distant in time and geographical location.

**Conclusion:** HRV-infections are highly globalised. Subtypes may prevail during several seasons and seem to circulate as parallel global epidemics. HRV-A and HRV-C represent dominant subtypes with a greater genetic diversity within subtype C. Our results raise new questions regarding HRV epidemiology, viral evolution and persistence. Further study of subtype or strain-specific circulation patterns is needed to reveal the dynamics of HRV diversification or association with clinical outcome.

**P947** Influenza admitted in intensive care units: a comparative study of seasonal and pandemic influenza A (H1N1) 2009

C. Hauw-Berlemont, T. Guy, D. Veyer, S. Minjolle, F. Uhel, P. Tattevin\*, Y. Le Tulzo (Rennes, FR)

**Objective:** Pandemic A (H1N1) 2009 influenza was associated with an unprecedented rate of admission in intensive care units (ICU), mostly due to acute respiratory distress syndrome (ARDS). Characteristics of these patients were described, but they have not been compared to patients with severe seasonal influenza.

**Methods:** We performed a retrospective study of all patients with documented influenza admitted in one medical ICU for influenza A between 1993 and March 2011. Patients were included if influenza was documented on respiratory samples by RT-PCR and/or immunofluorescence and/or cell culture and/or serology (complement fixation). A standardized questionnaire was used to extract data from medical charts, including demographics, comorbidities, influenza vaccination, date of 1st symptoms, hospital, and ICU admission, patients characteristics including body mass index and pregnancy, severity score (IGS-II), ARDS, treatment (including antivirals, corticosteroids, and mechanical ventilation), bacterial infection, and final outcome. Patients with influenza A (H1N1) 2009 were compared to patients with seasonal influenza, using nonparametric Mann Whitney test for quantitative variables, and Fisher exact test for categorical variables.

**Results:** Between 1993 and 2011, 35 patients with documented influenza were admitted in our ICU, including 18 patients with seasonal influenza (1993–2006), and 17 patients with pandemic influenza A (H1N1) 2009. Patients with pandemic influenza were younger than patients with seasonal influenza, with a median age of 41 years (IQR, 29–55) vs 56 (41–68), ( $p = 0.04$ ), more likely to be obese (41% vs 6%,  $p = 0.03$ ), and current smoker (65% vs 28%,  $p = 0.01$ ). Influenza-related symptoms, and complications, were not different between the two groups, including ARDS, bacterial infections, and in-ICU mortality (respectively, 18% for pandemic, and 33% for seasonal influenza). The diagnosis delay (time between admission and influenza documentation) was shorter for pandemic influenza patients (median 1 day vs 4,  $p = 0.01$ ). More patients with pandemic influenza were treated with oseltamivir (88% vs 11%,  $p < 0.01$ ).

**Conclusion:** As compared to severe seasonal influenza, severe pandemic influenza A (H1N1) 2009 affected younger patients, more frequently obese and smokers. Although pandemic influenza A (H1N1) 2009 was diagnosed faster, and more likely to be treated with oseltamivir, outcomes were no significantly different.

**P948** Sequencing of influenza A(H1N1) pdm viruses in the Philippines

B. Schwem\*, S.K. Ganchua, R. Destura, F. Heralde, G.B. Trinidad, M. Ma, M.L. Agmata, E. Tayag, J. Roque, M. Tazyon, C. Padilla, E.M. Salvana (Ermita, Manila, PH)

**Objective:** Few studies have been done on the genetic characteristics of influenza strains in the Philippines. Mutations for drug resistance in local influenza isolates have also not been widely studied. This study is part of a larger project in collaboration with the Department of Health and Department of Science and Technology to develop a web-based genomic library for the surveillance of influenza A in the Philippines. Our aim is to generate a genomic library and resistance profile of local influenza strains by sequencing the matrix (M), neuraminidase (NA) and haemagglutinin (HA) genes.

**Methods:** RNA extracts of confirmed influenza A (H1N1) and seasonal influenza A (H3N2) from 2009 to 2011 were obtained from a tertiary hospital, The Medical City, Pasig City, Philippines. Matrix 1 and 2 (M), neuraminidase (NA), and haemagglutinin (HA) genes of influenza A were amplified using gene-specific primers. The amplification products were electrophoresed to determine the presence of amplified product. The amplified products were then sequenced.

**Results:** Of the samples sequenced, 33 have been sent to Genbank. None of the neuraminidase genes tested showed mutations for resistance to oseltamivir. However, all of the matrix genes had resistance mutations for adamantanes. Phylogenetic analysis did not yield any distinct clades of influenza A. However, this may be due to the fact that only one site was involved in the pilot project.

**Conclusion:** The results indicate that resistance mutations for adamantane are likely to be widespread in the Philippines, and the drug should not be used to treat influenza. Resistance mutations for oseltamivir, on the other hand, are likely to be rare. The pilot project will now be scaled up and integrated into all influenza A surveillance specimens in the Philippines.

**P949** A 5-year retrospective review of patients with norovirus infection: factors associated with prolonged viral shedding

E. Trainor\*, R. Vivancos, I.J. Hart, M.B.J. Beadsworth, N.A. Cunliffe, N.J. Beeching (Liverpool, UK)

**Objectives:** Norovirus gastroenteritis is a leading infection control problem. Existing UK guidelines recommend isolation/cohorting of individuals for 48 hours after symptom resolution and ward closure for 72 hours after the last new case. Individuals with norovirus gastroenteritis continue to shed virus in their stool after acute infection, but the factors which determine the duration of shedding

are not established. We aim to determine which factors may be associated with prolonged viral shedding.

**Methods:** We retrospectively reviewed all patients with norovirus diagnosed by RT-PCR in stool or vomit at the Royal Liverpool University Hospital between 2006 and 2011. Inclusion criteria was the detection of norovirus in stool or vomit on >1 occasion >1 day apart to be able to assess duration of shedding. Discharge summaries and laboratory records were reviewed and key demographic details, past medical and medication histories were collated. To compare the duration of viral shedding depending on exposure to various factors (age, sex, past medical and medication history) we calculated incident rate ratios (IRR) using negative binomial regression. Significant factors on univariable analysis were included in a stepwise multivariable negative binomial regression model to determine which factors were independently associated with duration of viral shedding.

**Results:** Eight hundred and forty-nine cases were identified of which 53 met the inclusion criteria, 49% male, with a median age of 77 years (range 33–98). The median duration of viral shedding was 8 days (range 3–90), 50% of cases shed norovirus for <10 days, while 25% shed for >3 weeks. 29.8% were on immunosuppressant therapy. On univariable analysis younger age, immunosuppressant therapy and renal transplant were associated with prolonged viral shedding. However, on a multivariable regression model only immunosuppressant therapy and younger age remained significant factors.

**Conclusion:** Current guidelines may not be adequate to prevent secondary nosocomial norovirus infection due to extended viral shedding. Younger patients and those receiving immunosuppressive therapy may have delayed clearance of norovirus infection. The role of prolonged shedding in secondary transmission of norovirus requires further investigation. Limitations of this study include retrospective analysis and a strong bias towards cases with persistent symptoms.

#### **P950** No resistance detected to PMOplus antisense oligomers that protect nonhuman primates against marburgvirus

*P. Iversen\*, T. Warren, A. Shurtleff, J. Wells, N. Garza, L. Dong, D. Mourich, L. Hauck, J. Kugelmann, B. Breitzel, G. Palacios, S. Bavari (Bothell, Fredrick, US)*

**Objectives:** Marburgvirus (MARV) is highly virulent RNA virus of the family Filoviridae and a causative agent of viral hemorrhagic fever (VHF). The postexposure therapeutic efficacy of AVI-6003 [a PMOplus combination targeting MARV nucleoprotein (NP, AVI-7287) and VP24 (AVI-7288)] has reproducibly provided for 100% survival in nonhuman primate (NHP) MARV lethal challenge infections. The objective was to evaluate the viral sequence fidelity in viral genome regions targeted by AVI-6003 in nonhuman primates infected with MARV Musoke in treated vs. untreated groups.

**Methods:** Three independent studies were conducted in which cynomolgus macaques were infected with 1000 pfu of MARV Musoke. Five groups of infected NHPs included daily doses of AVI-6003, AVI-7287 alone, AVI-7288 alone, a negative-control PMOplus agent, and saline. Viral genomic RNA was obtained from infected animals immediately upon sample collection by mixing one volume of serum with three volumes of Triazol LS. Samples with >300 pfu/mL were amplified using random hexamer DNA primers and reverse transcriptase PCR amplification. Viral genome sequence was determined using dye-terminator (studies 1 and 2) and pyrosequencing (study 3) methods.

**Results:** The amplicon DNA sequence was determined to an average depth of up to 3300 for the NP site and 6700 for the VP24 site including an approximate 200 base flanking region. Determination of the entire viral genome sequence is currently in progress. The sequence observations encompass three independent studies, evaluating blood or serum samples from 35 different NHPs (29 treated at doses from 7.5 to 40 mg/kg/day and six saline controls), and samples were evaluated from days 8 to 30 post infection. The PMO targeted viral genome sites

were found to demonstrate high fidelity and show no sequence changes indicating no development of resistance to AVI-6003.

**Conclusions:** These results indicate viral resistance to AVI-6003 and its components is unlikely in the genome of this single-stranded RNA human pathogen and support the further development of PMOplus therapies for use in humans.

#### **P951** Respiratory viruses other than influenza as cause of severely respiratory infections in adult patients admitted to an intensive care unit during 2009/2010 influenza season

*A. Martin-Quiros\*, M. Romero-Gomez, J. Figueira, C. Prados, N. Martinez-Sanchez, M. Mora-Rillo, A. Rico Nieto, C. Navarro San Francisco, S. Caro Bragado, G. Ruiz-Carrasco, M. Quintana-Diaz, J. Paño-Pardo (Madrid, ES)*

**Objectives:** To evaluate the frequency of viral pathogens in adult patients with severe respiratory infections (SRI) requiring admission to an Intensive Care Unit (ICU).

**Design, setting and Patients:** A prospective single-center observational study including all consecutive patients admitted to ICU due to SRI between July 17th, 2009 and January 31st, 2010 was conducted. Clinical, microbiological and radiological variables were assessed. In addition to RT-PCR for 2009 A(H1N1) pandemic influenza which was performed prospectively in all patients admitted to ICU with SRI, respiratory samples were retrospectively studied for multiple respiratory virus (Respiratory Virus Panel [RVP]) assay on the CLART<sup>®</sup> PneumoVir. RVP targeted the following virus types and subtypes: Influenza A, Influenza B, Respiratory Syncytial Virus subtype A, Respiratory Syncytial Virus subtype B, Parainfluenza 1, 2, 3 and 4 virus, Human Metapneumovirus, Rhinovirus, Coronavirus and Adenovirus. Other microbiological work-up was performed upon clinician request.

**Results:** Forty-nine patients were included. The median age was 48 years-old and associated comorbid conditions were present in 26 patients (53.1%), being chronic lung disease the most commonly observed comorbidity (13 patients-26.5%). No solid-organ transplant nor hematological patients were admitted during the study period. Median APACHE II score was 14. Inotropic drugs were needed in 17 patients (34.7%). Pulmonary infiltrates consistent with pneumonia were found in 23 patients (45.1%). Nine patients died during ICU admission. Etiological diagnosis was reached in 30 patients (61.2%), being Influenza the most frequently documented agent: Influenza C was identified in one patient (2.04%) and nH1N1 in 16 (32.7%). Respiratory Syncytial Virus in five patients (10.24%), Rhinovirus in 4 (8.16%) and Parainfluenza virus in 1 (2.04%). Six patients had documented bacterial infections (4 *S. pneumoniae* and 2 Legionella).

**Conclusions:** Respiratory viruses other than Influenza, especially Respiratory Syncytial Virus and Rhinovirus are involved in adult patients with SRI requiring intensive care support.

#### **P952** A novel study on rapid molecular characterisation of group A rotavirus in Turkey using PCR-reverse line blot hybridisation

*M. Altindis\*, F. Ahsan, B. van Der Veer, K. Eryegen, M. Hacimustafaoglu, I. Ipek, S. Celebi, T. Apan, O. Ozdemir, M. Koopmans (Afyonkarahisar, TR; Rotterdam, Bilthoven, NL; Bursa, Istanbul, Kirikkale, TR)*

**Objectives:** Group A rotavirus related acute gastroenteritis in infants and young children has evolved a significant impact on morbidity and mortality not only in developing but also in developed countries. The study was done to determine the diversity of co-circulating rotavirus strains in Turkey, and to provide a baseline for future assessment of possible effects of vaccine implementation in selecting novel vs. common rotavirus strains. Detection and genotyping of rotavirus strains

from stool samples in children with gastroenteritis in Turkey were examined using polymerase chain reaction-reverse line blot hybridization (PCR-RLB). Compared to conventional RT-PCR, PCR-RLB has known to be more robust, cheap, time saving and suitable to be implemented in developing country.

**Methods:** Stool samples were collected from 495 paediatric patients with acute gastroenteritis and screened for rotavirus infection from several hospitals in Turkey. The samples were provided by different paediatric clinics in Anatolian regions of Turkey such as Afyon, Bursa, Istanbul, and Ankara from May 2010 through May 2011.

**Results:** Of 495 stool samples, 238 samples were rotavirus ELISA positive and subsequently characterized by PCR RLB. Most of strains (97%) belonged to genotypes G1–G4, and G9, associated with either P[8] or P[4], commonly found in humans worldwide. We found that the percentage of G1P[8] is a predominant strain of Rotavirus (43.3) and followed by G4P[8] (26.5), G9P[8] (19.3), G2P[4] (13), G2P[8] (1.7), G1P[4] (1.3), G12P[8] (1.3), G12P[4] (1.3), G9P[4] (0.8) and G4P[6] (0.4). In 22.1% of cases, viruses exhibited either a G or P type typical of animal viral strains (G9 and G12), suggesting gene reassortment events between rotaviruses of different origin. Novelty, this study has characterized G12 as a newly emerging genotype in Turkey. In addition, we detected 17 patients with mixed infection in RLB hybridization membrane. However, there were untypable G genotype in 30 patients and P genotype in six patients.

**Conclusion:** The numbers and genotypes of likely natural reassortants of common genotype rotaviruses were found to be correlated with the observed numbers and genotypes of mixed infections. Large variation in the relative frequency of different rotavirus genotypes was observed between different seasons and/or areas of Turkey, suggesting independent evolution or differential introduction of viral strains with respect to both time and space.

#### **P953** Presence of multiple dengue serotypes in various body compartments in different time points of single clinical episodes

*M. Sriprapun\*, C. Laosakul, S. Krajiw, K. Arunyimgongkol, P. Siritasatien, W. Kulwichit (Bangkok, TH)*

**Objectives:** Dengue is the most wide-spread arthropod-borne virus. The virus consists of four serotypes, DEN1-DEN4. Frequent concurrent multi-serotype infections in a single clinical specimen in hyperendemic areas is well documented. Here we demonstrate for the first time that multiple serotypes could also be present in various compartments during different time points of each clinical episode.

**Methods:** Plasma, peripheral blood mononuclear cells (PBMCs), saliva and urine collected during febrile and convalescent periods of 22 serologically-confirmed dengue patients were subjected to nested reverse transcription PCR (RT-PCR) using two envelope (E) gene specific PCRs (E1 and E2 protocols). E2 differentiates each serotype by product size. E1 PCR products were used for both direct sequencing and cloning. The 10–15 colonies of each sample were sequenced. Direct sequencing results were blasted with GenBank for serotyping. Sequence of each clone was also aligned with that of direct sequencing.

**Results:** All patients were of secondary infection (DHF II). One of three patients (N40) clearly showed mixed DEN1 and DEN2 infections. Plasma, PBMCs and urine during febrile period contained DEN1 whereas convalescent PBMCs showed DEN2 by serotype-specific RT-PCR. Interestingly, clones from convalescent PBMCs PCR product showed mixed populations of DEN1 and DEN2 (%DEN2 > %DEN1). While PCR product direct sequencing of the other two patients clearly presented single serotypes of DEN4 and DEN1, some clone sequences showed populations of mixed serotypes. In patient N33, febrile plasma, PBMCs, saliva and convalescent urine were of DEN4 whereas febrile urine was of mixed DEN4 and DEN2 (% DEN4 > % DEN2). In patient N34, febrile PBMCs, saliva and urine were of DEN1 while convalescent urine was of mixed DEN1 and DEN3 (% DEN1 >

Code	Clinical diagnosis	Days of fever	Febrile period				Convalescent period			
			Plasma	PBMCs	Saliva	Urine	Plasma	PBMCs	Saliva	Urine
N33	DHF II	6	DEN4 (100%) [7]	DEN4 (100%) [7]	DEN4 (100%) [7]	DEN4 (72.73%) DEN2 (27.27%) [7]	-	-	-	DEN4 (100%) [18]
N34	DHF II	6	-	DEN1 (100%) [8]	DEN1 (100%) [8]	DEN1 (100%) [8]	-	-	-	DEN1 (83.33%) DEN3 (16.67%) [14]
N40	DHF II	4	DEN1 (100%) [4]	DEN1 (100%) [4]	-	DEN1 (100%) [4]	-	DEN1 (83.33%) DEN2 (16.67%) [21]	-	-

- = negative result  
( ) = % of each serotype of DENV (total clones of each serotype of all selected clones)  
[ ] = the day of illness that each specimen was collected

DEN3). E2 PCR also confirmed multi-serotype infections in both patients.

**Conclusions:** The phenomena of multi-serotype dengue infections occur in a more sophisticated manner than previously described. All the studied patients, along with almost all adult dengue patients in hyperendemic regions, are re-infected cases from a different serotype from that of the first, earlier infectious episode. We are unable to tell if these three cases were concurrently multi-serotype-infected, or whether the prior-infected and hidden, persistent serotype was reactivated to join the other new one. Further investigations could add up to the incomplete jigsaw of dengue pathogenesis.

## Virology – non-HIV/non-hepatitis

### **P954** Respiratory viral infections during the 2009–2010 winter season in the West Midlands Region, UK: incidence and patterns of multiple virus co-infections

*H. Tanner\*, E. Boxall, H. Osman (Birmingham, UK)*

**Objectives:** Acute viral respiratory infections are the most common infections in humans. Co-infection with different respiratory viruses is well documented but not necessarily well understood. The aim of this study was to utilise laboratory data from the winter season following the 2009 Influenza A(H1N1) outbreak to investigate rates of respiratory virus co-infections.

**Methods:** The Health Protection Agency Public Health Laboratory Birmingham, UK routinely uses PCR to detect a range of common respiratory viruses: influenza A and B, respiratory syncytial virus (RSV), human metapneumovirus (HMPV), parainfluenza, rhinovirus and adenovirus. Results from all specimens received for respiratory virus investigations from late September 2009 to April 2010 were downloaded and multiple virus detections in single specimens were identified. For each virus, the differences between the expected prevalence (i.e. the prevalence in all specimens) and the observed prevalences in specimens positive for other viruses, were calculated. Poisson regression was employed in order to determine the statistical significance of any associations found between different pairs of co-detected viruses.

**Results:** A total of 4821 specimen results were analysed. Of these, 2447 (50.8%) had at least one respiratory virus detected. Three hundred and twenty three (13.2%) had co-detections of two viruses, 22 (0.9%) had three viruses and four (0.2%) had four viruses. Reciprocal patterns of positive or negative associations between different virus pairs were found. Statistical analysis confirmed the significance of negative associations between influenza A and HMPV (p value 0.013) and influenza A and rhinovirus (p value 0.026). Positive associations between parainfluenza and rhinovirus (p value 0.003) and rhinovirus and RSV (p value 0.003) were also significant.

**Conclusion:** This study found that that co-detection of different respiratory viruses is not random and most associations are reciprocal, either positively or negatively. The most striking association observed was the lower prevalence of influenza A(H1N1) in patients positive for adenovirus, RSV, parainfluenza, HMPV and rhinovirus and vice versa, which reached statistical significance with HMPV and RSV.

**P955** **Viral load relative quantification of influenza virus in paired lower respiratory tract and nose-throat swabs samples from patients admitted in intensive care units**

P. López Roa\*, B. Rodríguez Sánchez, P. Catalán, M. Giannella, B. Padilla, P. Muñoz, D. García de Viedma, E. Bouza on behalf of the CIBER de Enfermedades Respiratorias CIBERES, Spain

**Background:** Influenza is a well known cause of admission to intensive care units (ICU's). Nasopharyngeal aspirates or Nose-Throat Swabs (NTS) specimens are considered the specimens of choice for the detection of influenza although most of the data come from paediatric population and are based on viral culture as the reference. In many ICU patients Lower Respiratory Tract (LRT) samples are readily and available. The aim of the study was to compare the yield of NTS with LRT for detection of Influenza virus by real time RT-PCR in patients admitted to ICU's.

**Methods:** From December 2010 to February 2011, we performed a prospective comparative study to detect influenza virus by RT-PCR in diagnostic NTS and LRT specimens from adults admitted in ICU's with suspected influenza. Relative quantification of viral load was performed in paired samples from patients in whom both samples were positive for influenza.

**Results:** During the study period, we included 52 patients admitted to ICU's, with suspicion of influenza, with paired NPA and LRT specimens. In 21 patients influenza virus was detected in at least one sample. All but one (influenza B) viruses detected were influenza A (H1N1) 2009. In 13/21 (62%) patients the virus was detected in the NTS and in 19/21 (90.5%) patients in the LRT. In 11 (52.4%) patients the virus was detected in both specimens. The validity values of NTS and LRT were respectively as follows: Sensitivity (62%, 90.5%), and Negative Predictive Value (79.5%, 93.9%). We detected higher amount of virus in LRT than in NTS samples but the difference did not reach statistical significance (median LRT/NTS for paired samples: 2.025; IQR: 0.039–6.374;  $p = 0.638$ )

**Conclusion:** Influenza detection by RT-PCR was more efficient in LRT than in NTE. In ICU patients with clinical suspicion of influenza, a negative RT-PCR in NTS is insufficient to rule out the entity. We recommended to search for influenza virus both in NTS and LRT.

**P956** **Identification and complete genome analysis of a novel feline picornavirus from the domestic cat in Hong Kong**

Y. Wu\*, S.K.P. Lau, P.C.Y. Woo, C.C.Y. Yip, G. Choi, R. Bai, R.Y.Y. Fan, K.K.Y. Lai, K.-H. Chan, K.-Y. Yuen (Hong Kong, HK)

**Objectives:** Picornaviruses are known to infect human and various animals in which they can cause many diseases of varying severity. Since the role and existence of picornaviruses in cats have been largely unknown, we attempted to study the presence of previously undescribed picornaviruses in domestic cats in Hong Kong.

**Methods:** A cat surveillance study was conducted during a 39-month period, in which samples from 662 stray cats captured from 32 different locations in Hong Kong were collected. Viral RNA extracted from respiratory, fecal, urine and serum samples was used as the template for RT-PCR. Initial picornavirus screening was performed by RT-PCR of 3Dpol gene of picornaviruses using conserved primers. And subsequent screening of novel "feline picornavirus" ("FePV") was performed by RT-PCR of 2C gene using specific primers, which were designed from the sequence of the first positive sample detected in the initial screening. Five genomes of "FePV" were amplified and sequenced, and the sequences were compared to those of other picornaviruses.

**Results:** "FePV" was detected in fecal samples of 14 cats and urine samples of two cats by RT-PCR among 662 cats. Analysis of five "FePV" genomes revealed distinct phylogenetic position and genomic features. The five "FePV" strains formed a distinct group among known picornaviruses in all three phylogenetic trees constructed using the P1, P2 (excluding 2A) and P3 (excluding 3A) regions. While the high sequence similarity and similar genome organization of the five strains suggested a

single species of "FePV", two potential genotypes may exist based on phylogenetic analysis of VP1 sequences. "FePV" is most closely related to the recently described bat picornaviruses group 1–3 and the genus Sapelovirus, while analysis of G+C content and sequences of P1, P2 and P3 regions showed that it is more closely related to bat picornaviruses, especially bat picornavirus group 3, than to sapeloviruses. "FePV" also exhibited other unique genomic features, including a putative type IV IRES instead of type I IRES in bat picornavirus group 3, different protein cleavage sites and H-D-C catalytic triad in 3Cpro, and the shortest leader protein among picornaviruses.

**Conclusion:** In this study, we identified a novel feline picornavirus from the domestic cat in Hong Kong. Based on its distinct phylogenetic position and genomic features, we believe "FePV" may be more appropriately classified under a new genus separate from Sapelovirus.

**P957** **Group A human rotavirus types circulating over a 25-year period in Palermo, Italy: a single-centre surveillance study**

F. Bonura, A. Cascio\*, V. Rotolo, M.A. Platia, S. De Grazia, G.M. Giammanco (Palermo, Messina, IT)

**Objectives:** To analyze the molecular epidemiology of human rotavirus (HRVs) in Palermo (Italy) over a 25-year period.

**Methods:** Faecal samples from 5623 children aged <5 years hospitalized with gastroenteritis in Palermo, Italy, from 1985 to 2010 were screened for the presence of rotaviruses by EIA and/or RT-PCR. Positive specimens were G/P genotyped through multiplex nested RT-PCR.

**Results:** HRV infection was detected in 33.3% of the paediatric patients. Yearly rates of infection varied from 11% to 51.6%. Strains with G1–G4 specificities accounted for more than 90% of HRV infections until 1999, when HRVs of the G9 type emerged. HRV strains belonging to the G1 type were the most common and were constantly detected but their relative prevalence varied widely, from a maximum of 88.9% in 2010 to a minimum of 6.4% in 2006. G2 strains were epidemic in 1996–97 but otherwise displayed a low prevalence, except in 2003 and 2007 when they represented 22.6% and 14% of the strains, respectively. G3 rotavirus circulation was limited and accounted generally for no more than 6.1% of the HRV strains, but in 2003 and 2005 they were involved in 17% and 16.9% of the gastroenteritis episodes. G4 epidemics occurred in 1990–1993, 1999–2001 and 2003. G9 HRVs were introduced in Palermo in 1999 when they represented 31.4% of the strains detected. In the following years G9 circulation fluctuated, almost disappearing before raising again, in 2005–2006 and 2008, so that G9 became the second most common G-type in the last 12 years. Human/animal reassortant G3P[9] strains were detected in 1994 and 1996 and a G3P[3] canine rotavirus was isolated in 1997, while G6 strains of animal origin with either a P[9] or P[14] VP4 specificity were sporadically isolated from the late 1980s to 2003. G1P[4] and G2P[8] strains were also sporadically detected.

**Conclusion:** Over the 25-year surveillance period, the circulation of the most common HRV combinations, G1P[8], G2P[4], G3P[8], G4P[8] and G9P[8], was confirmed, but unusual G/P combinations were occasionally found. The prolonged surveillance of HRV infection performed in Palermo allowed to confirm the important role of HRVs as agents of enteritis in the Italian paediatric population and highlighted the dynamics of circulation of the different genotypes.

**P958** **Molecular epidemiology of rotavirus strains in Bulgaria without rotavirus mass vaccination, 2009–2010**

A. Dikova\*, A. Stoyanova, Z. Mladenova (Sofia, BG)

**Objectives:** Rotaviruses are a leading cause of infantile acute gastroenteritis worldwide responsible for a great morbidity and economic losses in developed countries and significant mortality in developing countries. The study aimed to investigate the rotavirus

epidemiology and strain diversity in Sofia-city and Sofia-region, before the introduction of rotavirus vaccination. Methods:

For the period of September 2008 to August 2010 a total of 600 stool samples from children 25 days–12 years old were tested and confirmed as rotavirus-antigen positive using immunoassays. All children were hospitalized exhibiting symptoms of diarrhoea and/or vomiting. The rotavirus strains detected were further characterized using molecular-based techniques—RT-PCR, sequence and phylogenetic analysis toward VP7 and VP4 genome segments.

**Results:** The results revealed that most affected of rotavirus gastroenteritis were children 1–24 months old (70.7%, 424/600). Year-round circulation of rotavirus strains were recorded with a clear winter peak (December–April) and a second peak emerging in August–September. Rotavirus-positive samples which contained a single rotavirus strain accounted for 79.5% of the samples. Of them, the pre-dominant strain was G4P[8] (36.0%, 216/600), followed by G2P[4] (25.0%, 150/600), G1P[8] (15.3%, 92/600), G9P[8] (2.5%, 15/600) and G3P[8] (0.7%, 4/600). Increased incidence of rotavirus human-human reassortants (22, 3.7%) and emergence of rare/uncommon or potentially zoonotic rotavirus strains was seen in the absence of rotavirus mass vaccination. Among rotavirus reassortants the prevalent were strains with G1P[4] (16 samples), followed by G9P[4] (three samples), G4P[4] (two samples) and G2P[8] (one sample). Unusual rotavirus strains with porcine or feline-like characteristics (G3P[9], G4P[6], G5P[6]) along with isolates with G6P[8], G6P[9], G8P[8], G8P[14] and G12P[8] specificity were detected in a single samples. Sequence and phylogenetic analysis revealed that rotaviruses with G1–G4 genotype circulating in Bulgaria were distantly related to G1–G4 strains included in rotavirus vaccines available. Conclusion: Rotavirus immunization would be an effective preventive tool against severe rotavirus gastroenteritis in Bulgaria. Active surveillance and investigations over the fluctuations in rotavirus epidemiology and strain diversity before and after the introduction of rotavirus vaccine will need as basis in attaining success of the rotavirus vaccination program.

**P959** **Norovirus can be detected by PCR in oral swab samples from patients with acute gastroenteritis**

T. Andreasson\*, L. Gustavsson, M. Lindh, J. Westin, LM. Andersson (Göteborg, SE)

**Objective:** Norovirus (NoV) can be detected by PCR in samples from stool or vomit in almost all patients with acute NoV-infection. In a recently published study NoV was detected by PCR in mouthwash samples in 24% of patients with acute NoV-enteritis. We have previously shown that rectal swab samples are comparable to traditional stool samples for diagnosis of acute NoV infection. The objective of this study was to investigate if NoV can be detected in oral flocculated swab samples from patients with acute gastroenteritis.

**Methods:** Between October 2010 and April 2011, eighty-six hospitalised patients with suspected viral gastroenteritis who were admitted to the Department of Infectious Diseases, Sahlgrenska University hospital, Göteborg, Sweden were prospectively included. One oral flocculated swab sample, obtained from the oral mucosa of both cheeks, and one rectal swab sample were taken from each patient. Clinical data and symptoms were registered. The samples were analysed with a previously described multiple real-time PCR detecting six different gastroenteritis viruses (NoV genogroup I and II, sapovirus, astrovirus, adenovirus and rotavirus).

**Results:** Forty-eight of the 86 included patients (56%) were positive for NoV genogroup II in the rectal swab sample, and were subsequently included in the analysis. Twenty-eight patients (58%) were female, the median age was 80 (IQR 64–88) years and the median duration of symptoms was 3 (IQR 2–4) days. Twelve out of 48 (25%) were positive in the oral swab sample, and 9 (75%) of these reported vomiting the day before sampling compared to 24 of 36 (67%) patients with negative oral swab samples (ns.). Only two patients reported vomiting on the day of sampling, none of which were positive in the oral swab sample. In the patients with a positive oral swab sample the cycle threshold (Ct) values

were significantly lower in the rectal swab samples than in the oral swab samples (the median (IQR) Ct value was 20.5 (17.9–22.6) and 35 (32.5–40.4), respectively,  $p < 0.001$ ), indicating that the amount of virus was higher in rectal swab samples.

**Conclusion:** NoV could be detected in oral flocculated swab samples in a quarter of patients with NoV-enteritis, which is in accordance with the detection frequency reported for mouthwash samples. The amount of virus in oral swab samples was low.

**P960** **The first, second and third wave of pandemic influenza A (H1N1) in North Denmark region, 2009–2011: a population-based study of hospitalisations**

I. Oersted\*, M. Moelvaadgaard, H. Nielsen, H. Nielsen (Aalborg, DK)

**Objectives:** A new Influenza A (H1N1) virus emerged in 2009, leading to a world-wide pandemic. We analysed the epidemiology and clinical characteristics of hospitalized patients in a defined population of North Denmark Region with a mixed urban and rural community of 579 000 inhabitants.

**Methods:** Review of medical records of all hospitalized patients with confirmed Influenza A from July 2009–February 2011.

**Results:** Two hundred and seventy three patients with a positive PCR test for pandemic Influenza A (H1N1) from respiratory tract samples were admitted to hospital: 111 children (0–14 years) and 162 adults (>15 years). The age-related population incidences of hospitalization were, 0–14 years: 111/100 000, 15–64 years: 39/100 000, and >65 years: 17/100 000. During the first wave (July 2009–August 2009) three patients were admitted – none received treatment in Intensive Care Units (ICUs), during the second wave (October 2009–January 2010) 158 patients were admitted – nine received treatment in ICUs, and during the third wave (December 2010–February 2011) 112 patients were admitted – 25 received treatment in ICUs.

The length of hospitalization for all patients was on average 8 days (4 days for children, 11 days for adults).

Thirty of 34 patients treated in ICUs (average of 22 days) received ventilator therapy (average of 19 days), and seven patients received dialysis (average of 19 days).

Eighteen of 111 children (16%) and 114 of 162 adults (70%) were treated with oral oseltamivir.

No children and 14 of 162 adults (9%) were treated with intravenous zanamivir due to clinical failure of oseltamivir. Only two cases of H275Y mutation were observed, and these were not related to therapeutic failure.

Thirty three patients were diagnosed with concomitant bacterial pneumonia, predominantly caused by *Streptococcus pneumoniae* (n = 10), *Haemophilus influenzae* (n = 7) and *Staphylococcus aureus* (n = 3).

Fourteen of 273 patients (5%) died within 30 days of diagnosis, one child (14 years old) and 13 adults (41–76 years).

**Conclusion:** Patients hospitalized with pandemic Influenza A (H1N1) were predominantly children and younger adults, and only a few patients were >65 years. The third wave was the most severe taking the number and percentage of patients admitted to ICUs and 30-day mortality into consideration. We find it remarkable, that the incidence of hospitalization as well as clinical severity among younger adults did not decline from the second to the third wave.

**P961** **Actinobaculum schaalii a part of the normal flora of the genital area**

A. Buchhave Olsen\*, P. Kræmer Andersen, S. Bank, K. Søby, L. Lund, J. Prag (Viborg, DK)

**Objective:** To study the habitat of *A. schaalii*, and if it is a uropathogen in patients with kidney or urethra stones.

**Method:** A quantitative real-time PCR assay was used to examine 38 urine samples, 38 groin swabs, 30 faecal samples and 19 vaginal swabs.

**Results:** *A. schaalii* was found by real-time PCR in 14 (37%) urine samples from the patients undergoing extracorporeal shock wave lithotripsy (ESWL). Five (36%) of the urine samples containing *A. schaalii* were stix positive for leukocytes compared to 2 (8%) from urine without *A. schaalii* ( $p = 0.10$ ). *A. schaalii* was found in 7 (18%) of the groin swabs and predominantly from females ( $p = 0.10$ ).

*A. schaalii* was not found in any of the faeces samples but 6 (32%) of the vaginal swabs contained *A. schaalii* predominately from females above 50 years ( $p = 0.06$ ).

**Conclusion:** This study indicates that *A. schaalii* is a commensal on skin in the genitals and can be a cause of UTI. When patients show clinical signs of urinary infection and with leukocytes in the urine but no growth by culture, *A. schaalii* and its requirement in growth medium should be considered.

**P962** **Virological tests on broncho-alveolar lavage fluid have a low yield except in immunocompromised patients with ground-glass attenuations on CT-scan**

J.S. Poineuf, S. Jouneau, S. Minjolle, P. Tattevin\*, A. Gacouin, R. Colimon, P. Delaval, B. Desrués (Rennes, FR)

**Objectives:** Broncho-alveolar lavage (BAL) is a major diagnostic tool in selected patients. Although viruses have been incriminated in a wide range of respiratory diseases, the diagnostic yield of virological tests on BAL fluid remains poorly characterized. We aimed to analyze the characteristics of patients in whom viruses were identified in BAL fluid, to better define indications for virological tests during BAL.

**Methods:** All patients who underwent virological analysis on BAL fluid at the Rennes University Hospital – a 1435 bed tertiary care center – during year 2008, were retrospectively studied. Data were extracted using a standardized questionnaire, through the review of medical charts, imaging studies (all with radiologist interpretation), and microbiology laboratory database. The following patients were classified as immunocompromised: (i) patients with chronic immunodeficiency, including HIV; (ii) patients on corticosteroids >10 mg/day for  $\geq 3$  weeks; (iii) patients on any immunosuppressive drugs. We compared characteristics of patients with positive vs negative BAL virological analysis, using nonparametric Student ( $n > 30$ ), or Mann–Whitney ( $n < 30$ ) test for quantitative variables, and Fisher exact test for categorical variables.

**Results:** In 2008, 232 BAL were tested for viruses, in 212 patients (mean age  $54.4 \pm 45.4$  years; female-to-male ratio 0.6). Of these 232 BAL, 70 (30%) were positive, yielding 84 viruses: herpes simplex virus 1 ( $n = 27$ ), cytomegalovirus ( $n = 23$ ), Epstein–Barr virus ( $n = 17$ ), human-herpes virus 6 ( $n = 12$ ), respiratory syncytial virus ( $n = 3$ ), rhinovirus ( $n = 1$ ), and adenovirus ( $n = 1$ ). Pneumonia in immunocompromised patients was the most common indication for virological tests on BAL (55%), with a diagnostic yield of 44% in this group, as compared to 0% in the 17 patients with diffuse infiltrative lung disease. Immunocompromised patients represented 83% of virus-positive BAL. On bivariate analysis, only immunosuppression (82.9% vs 46.9%,  $p < 0.0001$ ), and ground glass attenuations on chest CT-scan (65.6% vs 43.7%,  $p = 0.006$ ), were more common in patients with virus-positive BAL, as compared to patients with virus-negative BAL. There were no significant differences in demographic and clinical criteria (age, gender, fever, dyspnea, cough, hemoptysis).

**Conclusion:** Pneumonia in immunocompromised hosts is the only situation where virological analysis of BAL fluid is of value, especially when chest CT-scan demonstrates ground-glass attenuations.

**P963** **Discrepancies between rubella IgG results: which assay is right, which assay is wrong?**

M. Guillet, L. Grangeot-Keros, C. Vauloup-Fellous\* (Clamart, FR)

Rubella-specific IgG testing is performed either for epidemiological studies, determination of the immune status or confirmation of rubella infection (together with the detection of rubella-specific IgM). Many

techniques have been developed for the detection of rubella-specific IgG but today, enzyme and chemiluminescent automated immunoassays are those most commonly used.

For over 15 years, commercial immunoassays for Rubella-specific IgG have been calibrated with a WHO international standard, and results are reported in IU/mL. The positivity threshold varies according to the assays: 10 IU/mL (recommended in US) or 15 IU/mL (commonly used in Europe). However, expressing results in IU/mL should have improved the correlation between assays. Actually, the antigen(s) used in the assays (total virus, recombinant antigens), the conjugate, the assay format (indirect, sandwich, competition, capture...), differ from one kit to another one. Under these conditions, even though commercial assays are calibrated with the same international standard, large differences in the result(s) obtained may be observed when testing the same sample, depending on the assay used. This situation is very confusing for clinicians and biologists and lead to misinterpretations of serology.

Firstly, we report the results of 10 sub-national quality controls, concerning rubella-IgG, conducted in French laboratories during a 3-year period (2009–2011). Results show that, depending on the assay used, results can differ by a factor up to 10!

A second part of this work focused on discrepant results between Elecsys® rubella IgG assay (Roche) and other assays. Since 2007, 178 serum samples were referred to our laboratory, because of discrepant results between Elecsys® rubella IgG assay (Roche) and another assay. Specificity was controlled on 137 samples, which were positive with the Roche assay, by using an in-house Western-blot. Anti-E1 Rubella antibodies were detected in 133 (97%) samples proving that Elecsys® rubella IgG assay is specific but much more sensitive than many other commercial assays.

Rubella specific-IgG results are often discordant, depending on the assay used even though results are expressed in IU/mL. However, the most sensitive assays are specific, as proved by Western-blot. Due to these discrepancies, consecutive samples should always be tested in the same laboratory using the same assay. Finally, given these conditions, one may question the usefulness of expressing results in IU/mL!

**P964** **Evaluation of serum cytokine levels as severity criteria in CCHF patients**

G. Yilmaz\*, K. Aydin, H. Yilmaz, M. Sönmez, C. Karahan, I. Köksal (Trabzon, TR)

**Background:** Crimean–Congo hemorrhagic fever (CCHF) is a potentially fatal disease caused by a tick-borne virus from the Bunyaviridae family. Cytokines plays an important role in the pathogenesis of viral, bacterial, and immunologic diseases. This study aimed to evaluation of serum cytokine levels as severity criteria in CCHF patients.

**Study design:** Sixty patients with confirmed CCHF were recruited for this study. Patients were divided into two groups (severe group: Patients who exhibited hemorrhage during their hospital stay, and non-severe

	Severe CCHF n=22	Non-severe CCHF n=38	P
Age	47,9±19,7	48,8±16,9	0,860
Gender (male/female)	10/12	15/23	0,856
IL-1 alpha	2,12±0,5	2,17±0,6	0,731
IL-1 beta	1,7±0,5	1,8±0,8	0,799
IL-2	2,86±0,48	3,06±1,27	0,836
IL-4	6,4±2,7	8,6±3,7	0,021
IL-6	62,7±40,6	34,2±20,4	0,000
IL-10	6,8±2,6	5,8±0,9	0,024
IL-12	10,2±2,6	11,2±3,3	0,262
IL-15	60,8±96,8	40,9±83,7	0,634
IFN-gama	161,3±135,4	121,5±80,1	0,330
TNF-a Iffa	68,6±49,5	43,4±17,3	0,034
TGF-beta	4,93±2,04	6,54±2,83	0,025
WBC	3090±4100	2657±1119	0,124
PLT	58177±38956	110315±44876	0,000
CRP	3,02±2,9	1,4±1,7	0,032
ALT	228±278	104±98	0,059
AST	564±941	166±214	0,000
CPK	1374±1383	509±651	0,021
LDH	1334±1213	562±469	0,000

group: Patients who displayed no hemorrhage during their hospital stay). Demographic characteristics, laboratory tests on admission of all patients with CCHF were investigated, and serum cytokine levels were measured.

**Results:** A total of 60 patients with confirmed CCHF were investigated. Twenty-two (36.7%) of these patients were in the severe group. In patients with severe CCHF, significantly higher serum levels of IL-6 ( $62.7 \pm 40.6$ ;  $p = 0.000$ ), IL-10 ( $6.8 \pm 2.6$ ;  $p = 0.024$ ), TNF-alpha ( $68.6 \pm 49.5$ ;  $p = 0.034$ ), and significantly lower serum levels of IL-4 ( $6.4 \pm 2.7$ ;  $p = 0.021$ ), TGF-beta ( $4.93 \pm 2.04$ ;  $p = 0.025$ ), were detected, compared with cytokine levels in patients who non-severe CCHF (Table 1). No differences in serum IL-1 alpha, IL-1 beta, IL-2, IL-12, IL-15 and IFN-gama levels between patients who severe CCHF and those who non-severe CCHF were detected ( $p > 0.05$ ).

**Conclusions:** Cytokines, chemokines, and other inflammatory mediators function in a manner, acting on many different cell types to regulate the host's immune response. When cytokines present in high concentrations, they might toxic or even lethal effects. In accordance with this view, In accordance with this view, our study significantly changed serum levels of cytokines in the patients with severe CCHF.

#### **P965** HPV infection linked to increased risk of breast cancer in north of Iran

A. Sigaroodi, F. Naghshvar, S.A Nadji\* (Tehran, Sari, IR)

**Objectives:** Breast cancer is the most frequently diagnosed cancer and the leading cause of cancer deaths among women worldwide. Viruses including Human papillomavirus (HPV) have been related to the pathogenesis of breast cancer. In the present study, we conducted a case-control study of breast cancer patients and controls and tried to find a viral aetiology by detection of HPV genome, and to evaluate the possible relevance of this factor for breast cancer risk among north female Iranian population from Mazandaran province.

**Methods:** A total of 130 blocks of paraffin-embedded tissue including 79 samples diagnosed as breast carcinomas and 51 non-cancer samples as control were retrieved from archive of Imam Khomeini Hospital, Medicine faculty of Sari city, Mazandaran University of Medical Sciences, Iran between 2002 and 2009. Polymerase chain reaction method with three different primer sets was applied for detection of HPVs in formalin-fixed paraffin-embedded breast cancer and breast fibroadema as case and control tissues, respectively. HPV genotypes were determined by phylogenetic analysis of viral genome sequences.

Phylogenetic analysis of these partial genome sequences was conducted using MEGA version 4.0 along with representatives of the HPV genotypes described previously.

**Results:** Of the 58 DNA extraction quality confirmed breast cancer cases, 25.9% (15 isolates) had positive test results for HPV DNA in contrast to 2.4% of cases (1 out of 41) with non cancer status ( $p = 0.002$ ). The infection of HPV had an OR of 14.247 (95% CI 1.558–130.284;  $p = 0.019$ ). The HPV genotypes in samples of breast cancer patients were 26.67% for HPV-16 (four isolates) and HPV-18 (four isolates), 13.3% for HPV-23 (two isolates) and HPV-6 (two isolates), 6.67% for HPV-11 (one isolate), HPV-15 (one isolate) and HPV-124 (one isolate) and one isolate could not be genotyped compared to HPV reference sequences, while the sole detected HPV in control specimens was HPV-124.

**Conclusions:** Our study reveals that HPV infection and age are the risk factors in breast cancer development in the north part of Iran, Mazandaran province. Meanwhile, confirming an etiologic role for HPV in breast cancer may help develop vaccine strategies for combating this increasingly common cancer. The association between risk of breast cancer development and viral infection is open and deserves further investigation.

#### **P966** Rotavirus, norovirus and adenovirus gastroenteritis in hospitalised children, Turkey

M. Altindis\*, S. Yuksek, F. Alpay, R. Kalayci, Y. Yoldas (Afyonkarahisar, TR)

**Objectives:** This study aims to determine the prevalence and the distribution of Enteric viruses (especially rotavirus, norovirus and adenovirus) responsible for gastroenteritis in children.

**Methods:** A epidemiological study on common diarrheal viruses was conducted in Afyon City, Turkey between January and November 2009. One hundred and fifty faecal samples from children under 6 years of age (mean age,  $2.18 \pm SD 3.64$  years, range: 1–72 months) (negative for the presence of pathogenic bacteria by standard culture methods) were tested by ELISA (Ridascreen and Biomeriux) and RTPCR methods for detection of- Norovirus G1, G2. Stool samples positive for group A rotavirus by commercial enzyme immunoassay were subjected to reverse transcription-polymerase chain reaction based genotyping of the outer capsid antigens, VP7 and VP4, determining G and P type specificities, respectively.

**Results:** Norovirus were detected in 22.8% of 92 children (<6 years of age) and rotavirus and adenovirus were detected in 23.3% and 6% of 150 hospitalized for gastroenteritis in Afyonkarahisar, Turkey, during 2009, respectively; predominant genotypes were GGIIb/Hilversum and GGII.4 Hunter for norovirus. The most common rotavirus strain was G2P[4] ( $n = 16$ ), followed by G9P[8] ( $n = 7$ ). Other strains were G1P[8] ( $n = 3$ ), G2P[8] ( $n = 3$ ), G1 + 2P[8] ( $n = 2$ ), G9P[4] ( $n = 1$ ), G2 + 9P[8] ( $n = 1$ ), G4 + 9P[6] ( $n = 1$ ), and G2P[4 + 8] ( $n = 1$ ). Of children with viral enteritis, 6.5% had a mixed norovirus-rotavirus infection.

**Conclusions:** Rotavirus is still the most common cause for gastroenteritis. Norovirus might be a more frequent agent in patients with vomiting prominent. The severity of infection by norovirus was lower but an increase was observed with rotavirus co-infection.

#### **P967** Analysis of HPV 6 variability in cervical and anal clinical samples

F. Cannella\*, A.M. Degener, N. Recine, M. Indinnimeo, G. Antonelli, A. Pierangeli (Rome, IT)

**Objectives:** Human papillomavirus genotype 6 (HPV6) is the major causative agent of genital warts and the most frequent benign tumours in the anogenital region. HPV 6 is regarded as a low risk HPV genotype and has been included in the recently developed quadrivalent HPV vaccine. On the basis of nucleotide sequence comparisons, HPV6 isolates are usually grouped into prototype

HPV6b-related (prototypic) and HPV6a and HPV6vc-related (non-prototypic). Non-prototypic HPV6 genomic variants seem to predominate in genital warts. The level of genomic diversity has been well established for some of the high-risk HPV genotypes, identifying some viral variants that differ in pathogenicity, transmission, persistence and progression of the clinical disease. Similar knowledge about low-risk HPVs such as HPV6 is scarce and in Italy there are no published papers about variants of HPV6. In this work, we analyzed different isolates from ano-genital samples of HPV6 using nucleotide sequence alignments of L1 region amplified by primer MY09/MY11.

**Methods:** A total of 75 HPV6 positive samples were included in this study, and the variability of the genomic fragment obtained by MY09/MY11 PCR assay (nt 6764–7167), was analysed by sequencing. The identification of HPV 6 genomic variants analysis was done with the ClustalW Multiple alignment program of the BioEdit Sequence Alignment Editor v7.0.9.0 program package identified using the prototype HPV6b genome (GenBank accession no. X00203) as a reference genome.

**Results:** The sequences of 42 cervical samples presented nucleotide substitution from prototype HPV6b in 14% (6/42) of analyzed sequence whereas 33 anal samples presented nucleotide substitution in 27% (9/33). Aminoacid substitutions from the prototype HPV6b L1 sequence were five silent and nine missense (conservative and semi-conservative) mutations (see table).

HPV6	6764	6779	6790	6792	6829	6866	7003	7076	7079	7120	7121	7129	7145	7155	7158	7167

Prototype aa	F	D	R	S	S	K	P	K	E	V	N	K	E	Q	Y	G
Mutated aa	F	N	R	N	S	K	P	Q	Q	V	D	K	K	H	F	G

**Conclusion:** In the present study we have analyzed the nucleotide and amino acid sequence variability of L1 sequence amplified by MY09/MY11 primers, revealing a wider variability than previously reported. This study revealed 12 not previously reported locations where nucleotide substitutions occurred and 6 isolates presented more than one substitutions. Our results support the need analyze the different isolates of HPV6 and investigate about a possible correlation with tissue tropism and clinical disease.

### P968 Varicella-zoster disease of the central nervous system in adults in a university hospital

B. Catalán\*, J. Mòdol, A. Hernández, P. Tudela, D. Escudero, L. Matas, L. Mateu, C. García (Badalona, ES)

**Objective:** The presence of shingles is the clinical clue for suspicion of varicella-zoster virus (VZV) aetiology in CNS infections (CNSI). In the latest months we have observed a cluster of CNSI by VZV. Most of them did not have shingles.

The aim of this study was to know the clinical presentation of CNSI by VZV paying special interest in the presence of skin injuries.

**Methodology:** We have reviewed the clinical histories of all the cases of CNSI by VZV in adults from January 2006 to June 2011 in a university hospital that holds 600 beds. We performed a multiplex nested polymerase chain reaction (PCR) for herpesviridae routinely in all cases of aseptic CNSI.

**Results:** A total of 12 cases were detected, 5 of them in the first semester of 2011, corresponding to five meningitis, five encephalitis and two myelitis. Most cases took place in spring (58.3%) and summer (25%). No seasonal predominance of encephalitis and myelitis was seen but meningitis was predominant in spring (80%).

Mean age was 55.9, being females 58.3%, 83.3% had suffered from varicella in infancy and no patients had received vaccination against VZV. 58.3% presented skin lesions due to VZV, all of them but 1 with shingles. Table 1 shows the clinical presentation, CSF data and comparative study between meningitis and encephalitis. Proportions were compared with Fisher's exact test and continuous variables with Student's *t*-test. Patients with meningitis were younger, had had epidemiological contact with a patient with VZV infection more frequently, presented a lower rate of immune deficiency and did not present skin injury by VZV.

All cases presented CSF alterations, 91.7% pleocytosis, always with lymphocitary predominance. Sixty percent patients with meningitis presented hypoglycorrhachia.

All patients received acyclovir IV (10–21 days) and 25% finished the treatment with oral acyclovir or valacyclovir.

Glasgow outcome scale (GOS) at discharge was "V" in 83.3%. Only patients with myelitis presented neurological sequels corresponding to GOS IV (8.3%) and GOS III (8.3%). There was no mortality.

VARIABLES	MENINGITIS	ENCEPHALITIS	MYELITIS	P
n (%)	(n=5)	(n=5)	(n=2)	Me vs E
Age, median (SD)	40 (19.7)	72.6 (17.4)	54	0.02
Male	3 (60)	2 (40)	0	NS
Immune deficiency or immunosenescent	1 (20)	5 (100)	2 (100)	0.02
Previous chickenpox	4 (80)	5 (100)	1 (50)	NS
Vaccination VZV	0	0	0	NS
VZV contact	3 (60)	0	1 (50)	0.04
Fever	2 (40)	0	1 (50)	NS
Headache	5 (100)	1 (20)	0	0.01
Vomiting, nausea	4 (80)	0	0	0.01
VZV rash	0	5 (100)	2 (100)	0.001
Backneck stiffness	2 (40)	2 (40)	1 (50)	NS
Focal neurologic sign	0	1 (20)	2 (100)	NS
GOS = V	5 (100)	5 (100)	0	NS
CSF WBC (cell/mm3) median (SD)	333.8 (217.3)	44.5 (50.5)	111	0.03
CSF WBC >100	5 (100)	1 (20)	1 (50)	0.01
CSF glucose (mg/dl) median (SD)	48 (16.2)	120.25 (54.5)	65	0.02
CSF glucose < 45	3 (60)	0	0	0.04
CSF protein (g/L) Median (SD)	1.95 (1.6)	0.71 (0.6)	1.52	NS
CSF protein > 1	4 (80)	1 (20)	1 (50)	0.05

**Conclusions:** Patients with meningitis by VZV are younger, healthy, and do not feature shingles. In contrast, patients with encephalitis present immune deficiency and skin manifestations of VZV infection.

The seasonal predominance and the epidemiological contact with VZV in patients with meningitis could be related to a reinfection. In contrast, patients with encephalitis corresponded to the classical reactivation of VZV.

**P969** Evaluation of the new Adeno Respi K-Set in comparison to the Adeno Respi-Strip and cell cultures for the detection of adenoviruses

*L. Busson\*, M. de Foor, J. de Marchin, D. Martiny, S. Van Den Wijngaert, A. Dediste, O. Vandenberg (Brussels, BE)*

**Objective:** To evaluate the performances of the new ready to use immunochromatographic test (ICT), Adeno Respi K-Set (Coris BioConcept, Belgium), in comparison to the Adeno Respi-Strip (Coris BioConcept, Belgium) and cell cultures for the diagnosis of adenoviruses in clinical samples under routine conditions.

**Methods:** from April to June 2011, 492 clinical samples submitted for the rapid diagnosis of adenovirus infection were evaluated with Adeno Respi K-Set.

Results were compared with those of Adeno Respi-Strip and viral cell cultures performed on three cell lines (Vero, MRC5 and LLC-MK2). The samples included 416 nasopharyngeal aspirates, 56 nasopharyngeal swabs, 11 throat swabs, three tracheal aspirations, two bronchoalveolar washes, two sputums and two urines. They were issued from 261 male and 231 female patients aged from 1 month to 90 years (mean age: 10 months). Results were compared with those of cell culture considered as the reference method but home made Adenovirus PCR was used to elucidate discrepant results.

**Results:** of the 492 samples tested, 63 (12.8%) were positive for adenovirus in one or more cell cultures. Sensitivities of the ICT were 74.62% and 74.62% for the Adeno Respi K-Set and the Adeno Respi-Strip respectively. Specificities were 100% and 99.05% for the Adeno Respi K-Set and the Adeno Respi-Strip respectively. The positive and negative predictive values found were 100% and 96.15% and of 92.59% and 96.11% for Adeno Respi K-Set and Adeno Respi-Strip respectively. For Adeno Respi K-Set, no false positive result was observed among samples yielding a positive culture for viruses other than adenovirus (56 parainfluenza, 50 rhinovirus, 21 enterovirus, 5 metapneumovirus, 5 cytomegalovirus, 5 HSV, 4 respiratory syncytial virus, 1 influenza A). There was only one equivocal result with Adeno Respi-Strip in an HSV positive culture. Three of the false negative results with the Adeno Respi K-Set were observed in slimy samples. Those samples were positive with the Adeno Respi-Strip indicating probably slightly better performances in such samples.

**Conclusions:** The new Adeno Respi K-Set is a reliable and easy to use test for rapid diagnosis of adenovirus infection in comparison with methods used in our routine practice. This test could be used for patients for which early adenovirus diagnosis is needed or for epidemiological studies.

**P970** A phase 1, single ascending-dose study of AVI-6003, a combination of two PMOplus™ compounds with activity against marburgvirus

*A. Heald\*, T. Axtelle, A. Nelson, A. Vutikullird (Bothell, Cypress, US)*

**Objective:** Marburg hemorrhagic fever (MHF) is a rare human disease caused by marburgvirus, a filamentous single-stranded, negative-sense RNA virus of the family Filoviridae. No vaccine or established effective therapy is currently available for this catastrophic disease. AVI-6003 is an experimental combination of two phosphorodiamidate morpholino oligomers with positive charges (PMOplus™) that specifically target two viral messenger RNAs (mRNAs) encoding marburgvirus proteins. AVI-6003 has demonstrated evidence of protection against lethal infection in experimental mouse, guinea pig and non-human primate models of marburgvirus infection. The objective of this clinical study is to determine the safety, tolerability and pharmacokinetics of

intravenous administration of AVI-6003 in healthy human subjects over a dose range predicted to cover a therapeutic dose.

**Methods:** In this first-in-man study, 30 healthy male and female subjects between 18 and 50 years of age were enrolled in six dose escalation cohorts of five subjects each and received a single intravenous (IV) infusion of AVI-6003 (0.01, 0.1, 1.0, 3.0, 6.0 and 9.0 mg/kg) or matched placebo in a 4:1 ratio. Safety was monitored through adverse event collection, telemetry, oximetry and serial blood tests, urine tests and electrocardiograms. The study was overseen by an independent Data Safety Monitoring Board (DSMB).

**Results:** No significant safety concerns arose upon review of blinded study data from the first 5 cohorts by the independent DSMB. While 10 of the first 25 subjects dosed experienced a variety of adverse events such as headache (n = 3), almost all were mild or moderate in severity. The only exception was one episode of exacerbation of chronic schizophrenia, which was not considered related to study drug. No changes in kidney function related to study drug were observed.

**Conclusion:** Preliminary results of this first-in-man phase 1 study suggest that single IV administrations of AVI-6003 are well-tolerated up to a dose level of 6 mg/kg. Follow-up of subjects enrolled in the 6th cohort (9 mg/kg) is ongoing. Final, unblinded safety and pharmacokinetic results for all subjects will be presented.

ClinicalTrials.gov ID: NCT01353040. This work is being conducted under contract with the Department of Defense Joint Project Manager Transformational Medical Technologies.

**P971** A phase 1, single ascending-dose study of AVI-6002, a combination of two PMOplus™ compounds with activity against ebolavirus

*A. Heald\*, T. Axtelle, J. Thimmarayappa, W. Smith (Bothell, Knoxville, US)*

**Objective:** Ebola hemorrhagic fever (EHF) is a rare human disease caused by ebolavirus, a filamentous single-stranded, negative-sense RNA virus of the family Filoviridae. No vaccine or established effective therapy is currently available for this catastrophic disease. AVI-6002 is an experimental combination of two phosphorodiamidate morpholino oligomers with positive charges (PMOplus™) that specifically target two viral messenger RNAs (mRNAs) encoding ebolavirus proteins. AVI-6002 has demonstrated evidence of protection against lethal infection in experimental mouse, guinea pig and non-human primate models of ebolavirus infection. The objective of this clinical study is to determine the safety, tolerability and pharmacokinetics of intravenous administration of AVI-6002 in healthy human subjects over a dose range predicted to cover a therapeutic dose.

**Methods:** In this first-in-man study, 30 healthy male and female subjects between 18 and 50 years of age were enrolled in six dose escalation cohorts of five subjects each and received a single intravenous (IV) infusion of AVI-6002 (0.01, 0.1, 1.0, 3.0, 6.0 and 9.0 mg/kg) or matched placebo in a 4:1 ratio. Safety was monitored through adverse event collection, telemetry, oximetry and serial blood tests, urine tests and electrocardiograms. The study was overseen by an independent Data Safety Monitoring Board (DSMB).

**Results:** No significant safety concerns arose upon review of blinded study data from the first five cohorts by the independent DSMB. While 14 of the first 25 subjects dosed experienced a variety of adverse events such as headache (n = 4), nausea (n = 3) or fatigue (n = 2), almost all were mild or moderate in severity. The only exception was one episode of severe hypertension, which was not considered related to study drug. No changes in kidney function related to study drug were observed.

**Conclusion:** Preliminary results of this first-in-man phase 1 study suggest that single IV administrations of AVI-6002 are well-tolerated up to a dose level of 6 mg/kg. Follow-up of subjects enrolled in the 6th cohort (9 mg/kg) is ongoing. Final, unblinded safety and pharmacokinetic results for all subjects will be presented.

ClinicalTrials.gov ID: NCT01353027. This work is being conducted under contract with the Department of Defense Joint Project Manager Transformational Medical Technologies.

## Bacterial and viral respiratory infections in the paediatric population

### P972 Epidemiological changes of complicated pneumonia in Spanish children

A. Herrero, F. Gil, L. Moreno, E. Bernaola\*, A. Mosquera, M. Herranz, N. Viguria (Pamplona, Estella, ES)

**Introduction and objectives:** Pleural effusion is a frequent pneumonia complication in hospitalized pediatric patients. The main etiologic agent is pneumococcus. Since 2001, a Heptavalent pneumococcal conjugate vaccine was introduced in our region (Navarra, North of Spain). Our objectives are to describe the temporal evolution of these pathologies and to evaluate the possible effects that the introduction of the Pneumococcal vaccines has done in these diseases.

**Methods:** We retrospectively analyzed data from 1995 to 2010 of all the admissions in the pediatric ward due to complicated pneumonia with pleural effusion (PE) or empyema (E) in our hospital (the reference pediatric hospital, for approximately a 90 000 population under 15 years). The population figures were obtained from the Navarre Institute of Statistics.

Statistical analyses were performed using Student's t test and Pearson's r, and a binary logistic regression. We considered Pneumococcal pneumonia (NN) those with: positive culture either in blood or in pleural fluid, or positive Ag/PCR in pleural fluid.

**Results:** Two hundred and seventy cases were recorded, estimating a mean age of 52.6 months (DS:40.94). A significant increase of the this pathologies was found over the years ( $p < 0.001$ ): PE (Rp:0.906), E (81, Rp:0.860) and NN (110, Rp:0.834). Comparing the annual incidence of cases in the pre-vaccination years (1995–2001) with post-vaccination years (2002–2010), there was a significant increase ( $p < 0.05$ ) in PE (8.15 vs. 29.14/105 hab. <15 years old per year), E (1.32 vs. 9.46) and NN (2.26 vs. 12). There was a significant increase in the population risk level estimated for PE (OR: 3.70; CI95%:2.67–5.13) and E (OR:7.42; CI95%:3.42–16.11). This incidence increase was significant ( $p < 0.05$ ) in all age groups, but it was more pronounced in small children (2–5 years old) than in infants.

Comparing the initial post-vaccine period (2002–2005: vaccination rate: 20.99%) with the late post-vaccination period (2006–2010 vaccination rate: 53.18%) a increase was found of PE (OR:1.43; CI95%:1.08–1.88) and E (OR:1.94, CI95%:1.16–3.25), but it was only statistical significant in the older patients group (5–15 years) in age's subgroups analysis.

**Conclusions:** During the last 15 years in our country, an increase number of admissions for pneumonia with PE and E has been found. This increase is more pronounced in small children. Even though the vaccination rate has annually increased the admission for complicated pneumonia keeps growing, overall in older children.

### P973 Correlation of viral load of respiratory syncytial virus with disease severity in children hospitalized for bronchiolitis

C. Scagnolari\*, A. Pierangeli, F. Midulla, C. Selvaggi, K. Monteleone, L. Spano, A. Soldà, G. Cacciotti, P. Di Marco, C. Moretti, G. Antonelli (Rome, IT)

**Objectives:** It is well established that factors determining severity of respiratory syncytial virus (RSV) associated bronchiolitis are likely to be determined by a combination of host and viral factors. To this regard the relationship between viral load, disease severity and antiviral immune activation in infants suffering from RSV associated bronchiolitis has not been well identified. The main objective of this study was to determine the existence of any correlation between RSV load and disease severity and also between different clinical markers and mRNA-levels of the interferon stimulated gene (ISG) 56 in infants

hospitalized for bronchiolitis. We also evaluated whether viral load tended to be persistent over the course of the RSV infection.

**Methods:** The levels of RSV-RNA were quantified by using a TaqMan-based real-time PCR technique in nasopharyngeal washings (NPW), collected from 132 infants infected with RSV as a single (90.15%), or as a dual infection with other respiratory viruses (9.85%).

**Results:** There was a distribution of viral load values of several orders of magnitude in infants with bronchiolitis. When the RSV-positive infants were divided on the basis of RSV detection as a single infection or as a coinfection, the viral load was not significantly different between groups. In addition results showed that viral load was positively related to the clinical severity of bronchiolitis, the length of hospital stay, the levels of glycemia and number of ISG56-mRNA copies, whereas an inverse correlation was observed with levels of haemoglobin. We also found that the RSV load significantly decreased between the first and second NPW sample in most single and RSV coinfections.

**Conclusion:** These results suggest that infants with high RSV load on hospital admission are more likely to have both more severe bronchiolitis and a higher airway activation of antiviral immune response.

### P974 The role of viral infections in nasopharyngeal bacterial colonisation in children: a case-control study

C.L. Skevaki, A.I. Trochoutsou\*, P. Tsiailta, I. Logotheti, C.N. Makrinioti, E. Lebessi, I. Paraskaki, N.G. Papadopoulos, M.N. Tsolia (Athens, GR)

**Objectives:** There is accumulating epidemiological evidence indicating a close association between viral respiratory infections and bacterial superinfections. The present study aims at examining nasopharyngeal bacterial colonization among children with and without a viral respiratory tract infection.

**Methods:** Nasopharyngeal colonization with *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, and nasal colonization with *Staphylococcus aureus* was examined in children <5 years of age with symptoms of viral respiratory tract infection for <5 days, and in controls with no respiratory symptoms during the week prior to enrolment. Both patients and controls had not received any antibiotics for one week prior to inclusion. The presence of respiratory syncytial virus (RSV), influenza virus, parainfluenza virus, rhinovirus and adenovirus was examined with the use of PCR. A preformed questionnaire including demographic and clinical data was completed for each patient. Categorical data were compared with the use of chi squared or two-tailed Fisher's exact test and analysis was carried out with the GraphPad Prism v5 software.

**Results:** During the period February 2009–April 2011, 391 infants and children were recruited, while samples from 36 children were excluded from the study on the basis of inappropriate sampling technique. The average age of the remaining 355 children (217 males) included in the study was 26.4 months, among which, 128 were asymptomatic controls and 227 had respiratory symptoms and one of the following diagnoses: upper respiratory tract infection, bronchiolitis, bronchitis, bronchial asthma, pneumonia, croup, acute otitis media or sinusitis. A higher percentage of asymptomatic subjects was found negative for all bacteria examined in our study protocol ( $p < 0.01$ ). *S. pneumoniae* and *M. catarrhalis* were more frequently isolated ( $p < 0.01$ ) from children with symptoms of respiratory tract infection as compared to asymptomatic children. *S. pneumoniae* plus *H. influenzae* plus *M. catarrhalis* but also the presence of any four bacteria at the same time were more frequently observed among symptomatic children as compared to asymptomatic controls ( $p < 0.05$ ). Colonization of (any) virus positive children with any bacterium or *S. pneumoniae* was higher than in (any) virus negative children ( $p < 0.05$ ).

**Conclusion:** Viral infections influence nasopharyngeal bacterial colonization among children possibly leading to accentuation of disease severity or invasive disease.

### P975 Community respiratory virus infections among hospitalised children with acute respiratory diseases

S. Al-Hajjar\*, S. Al-Muhsen, S. Al-Thawadi, A. Al-Seraihi, I. Bin-Hussain, K. McIntosh (Riyadh, SA)

**Objective:** To describe the potential role of community respiratory viruses in the natural history of acute respiratory diseases in hospitalized children who have chronic medical conditions or are immunocompromised with the use of nucleic acid detection tests (NATs).

**Method:** From 2007 to 2009, children <14 years of age with chronic medical or immunocompromising conditions who were admitted to King Faisal Specialist Hospital and RC, Riyadh with acute respiratory diseases were included in this study. Clinical and epidemiological data were recorded and respiratory samples including nasopharyngeal aspirate/nasopharyngeal swabs and if available bronchoalveolar lavage were obtained. Respiratory samples were tested by NATs for respiratory syncytial virus (RSV), adenovirus, parainfluenza virus 1–4, influenza virus, rhinovirus, human metapneumovirus (hMPV) and coronavirus (OC43, 229E, & NL63).

**Results:** One or more respiratory viruses were detected in 156 hospitalized children with acute respiratory disease. Sixty-seven percent of patients had chronic medical conditions and 33% of patients had immunocompromising conditions. The median age was 4 years 3 months, 53% of patients were male. Forty-six percent of patient had severe community acquired pneumonia (CAP) with associated mortality of 14.1%. A single virus was identified in 83% of patient. Rhinovirus was the most frequently identified virus (37%) followed by RSV (22%), adenovirus (12%), parainfluenza (12%), influenza virus (8%), hMPV (5%), Coronavirus (4%), and mix viral infection (17%). Respiratory viruses were found to peak during the winter months, such as RSV type-B & parainfluenza 1 (November–January), Influenza A (October–Jan) Influenza B (January–February), and coronavirus (October and January) while there were also viruses detected during summer months such as Parainfluenza 3 (June–August), hMPV detected (March–May). RSV type-A, Adenovirus and Rhinovirus were isolated all throughout the year. Children with rhinovirus, adenovirus and RSV infections needed treatment in the intensive care unit more than often than others. hMPV infection was associated with idiopathic pneumonia and culture negative shock syndrome in immunocompromised children.

**Conclusion:** Respiratory viruses are frequent found in acute respiratory disease in hospitalized children who had chronic medical or immunocompromising conditions. Community acquired viral pneumonia is important cause of morbidity and mortality. Routine testing using NATs for respiratory viruses may be warranted in these high risk patients.

### P976 Varicella and children attending kindergartens in Lisbon

P. Palminha\*, P. Nogueira, M.T. Paixão, C. Dias (Lisbon, PT)

**Study design:** Based on pathognomonic features of varicella, a cross-sectional study was designed, using random sample of children attending kindergartens in Lisbon 2006. Children's parents were inquired through self-completion questionnaire. Sample size was estimated based on varicella prevalence in children <2 years old was 20% (varicella national seroprevalence was 40% in age group 2–3 years)

**Aims:** To estimate the proportion of children <2 years of age that had varicella, the mean duration of disease, the proportion of children medicated and those who had varicella complications. To analyse parent's knowledge/opinion about varicella vaccine and benefits of vaccination.

**Material and methods:** One thousand two hundred and seventy-five parents with children attending 50 kindergartens were inquired about

previous varicella history of child and siblings and the parent's knowledge/opinion about the varicella vaccine and its benefits.

Descriptive statistical analysis performed with 95% confidence interval. Analysis of variables was performed using Qui-square, Fisher, Exact test. Risk estimated by Odds Ratio. Averages compared using Student's t test. Logistic regression analysis was performed. Significance level was 5%.

**Results:** One thousand three hundred and thirty-three of non-vaccinated children included in the study. Varicella occurred in 559 (41.9%;CI95%:39.27–44.64) children with a 2 years median. Fever occurred in 407 (72.8%;CI 95%:68.92–76.46) cases; 515 (92.1%;CI95%:89.58–94.22) were assist by doctor; 519 (92.8%;CI95%:90.38–94.84) received medication. Duration of disease had a median of 10 days. Hospitalizations due to varicella complications occurred in 20 (3.6%;CI95%:2.06–5.13) children. Children <12 months showed a higher risk of complications (7.1%). Vaccine administration is considering a benefit by 87% of the parents and 90% vaccinated their children against varicella if available through the National Vaccination Programme (NVP).

**Conclusions:** in non vaccinated children attending kindergartens varicella occurs early. Varicella was associated with high morbidity, complication occurred in 3.6% with 55% of hospitalizations in children <3 years. More than 90% of the children had professional health care, 92% received medication. The parent's opinion on benefits of vaccination is high in Portugal; as in other EU countries, varicella has a high social cost due to work loss and medical expenses. Introduction of varicella vaccine in NVP could depend more on the economic impact of varicella than on the severity of the disease.

### P977 Occurrence of pathogenic bacteria in Danish child care centres

T. Ibfelt\*, L. Andersen (Copenhagen, DK)

**Background:** Pre-school children in day care are often sick, in average they have 6–8 disease episodes per year and most of these are caused by infections. Infections spread not only by direct contact, but also indirectly via toys, nursing pillows and other surfaces in day care centers. There is little knowledge about the type and prevalence of bacteria on these surfaces. Our objective was therefore to determine the prevalence of human pathogenic bacteria in Danish child care center environments.

**Methods:** Two hundred and twenty Environmental samples from six Danish child care centers in Copenhagen were analyzed during summer 2011. Forty predetermined spots in each center were sampled using 3 M Dip slide™ TV, TSA sampling plates and cotton swabs. After incubation, human pathogenic bacteria were isolated and identified using conventional identification and Maldi-Tof MS. The predetermined spots were situated in the toilet, play room and kitchen and were, among others, toys, tables, nursing pillows and kitchen tables.

**Results:** All samples were polymicrobial, but mostly low-pathogenic bacteria such as *Bacillus* sp., *Acinetobacter* sp. and CNS were grown. Pathogenic bacteria were found in 59 (27%) samples. Coliform bacteria were found in 22 (10%), airway bacteria in 33 (15%) and *S. aureus* in 4 (~2%) samples. The most prevalent coliform bacteria found were *Enterobacter* and *Pantoea* sp., whereas the dominant findings in airway bacteria were Non-hemolytic streptococci. These are all bacteria with low pathogenicity, but can be used as indicators of fecal and nasopharyngeal contamination. We did, however, also find more virulent bacteria such as *S. pneumonia* in five samples and *S. aureus* in four samples. The sites with the highest prevalence of coliform bacteria were the nursing pillows, kitchen tables and sinks. Most airway bacteria were found on toys, tables and pillows in the playroom.

**Conclusion:** Twenty-seven percent of all samples contained pathogenic bacteria, most of which were low-pathogenic coliform and airway bacteria. Coliform bacteria were most frequently found on nursing pillows and in the kitchens whereas the most common site for airway bacteria was on toys, tables and fabric surfaces in the playroom.

These sites appear to be the most important sites for indirect transmission of infectious microorganisms and therefore need special attention when cleaning and disinfecting in the day care centers.

**P978 Eradication of nasopharyngeal carriage of penicillin-non-susceptible *Streptococcus pneumoniae***

*I.M. Odenholt\*, M. Hellberg, S. Johansson, H. Norrgren, T. Holmdahl, H. Ringberg, P. WimarNilsson, J. Ahl (Malmö, SE)*

**Objectives:** The high presence of penicillin-non-susceptible pneumococci (PNSP) is a global problem and colonization is mainly seen in young children. The prevalence in Sweden has been low, but increased during the 1990s, especially in Skåne County. After a prolonged carriage of two to 3 months, eradication therapy with rifampicin in combination with amoxicillin, clindamycin or erythromycin was considered. The aim of the study was to evaluate the outcome of eradication therapy and to see if differences in outcome existed between the different antibiotic combinations.

**Methods:** Between the years of 1997 and 2011, 125 children, ages 0–10 years, were referred for eradication therapy due to a prolonged nasopharyngeal carriage of PNSP with a MIC of PcG  $\geq 0.5$  mg/L. All the children were part of the South Swedish Pneumococcal Intervention Project (SSPIP), which aims were to limit the spread of PNSP. When an individual with a clinical infection caused by PNSP was found, nasopharyngeal cultures were taken from the family members and, if the patient was attending day-care, from the other members of the day-care group, to identify asymptomatic carriers. All pre-school children identified as carriers of PNSP were denied attendance to their day-care centre until two consecutive nasopharyngeal cultures yielding no growth of PNSP could be obtained. Eradication was defined as two consecutive negative cultures, with the second one no shorter than 7 days after completed treatment.

**Results:** Of the 125 referred children (most of the excluded patients had resolved the carriage spontaneously), 71 received treatment with rifampicin in combination with amoxicillin (n 44), erythromycin (n 22) or clindamycin (n 5) for 7 days. The primary eradication rate was 91.5%. All of the children whose carriage was not eradicated had been treated with amoxicillin + rifampicin, giving this combination an eradication rate of 86%.

**Conclusion:** Our study indicates that the nasopharyngeal carriage of PNSP can successfully be eradicated by a combination of antibiotics.

**P979 Carriage rates of *Bordetella pertussis* and *Bordetella parapertussis* among school children in China as determined by pooled real-time PCR**

*Q. Zhang\*, Z. Yin, Z. Shao, Y. Li, Y. Gao, L. Xu, M. Li, M. Liu, Q. He, H. Luo (Beijing, CN; Turku, FI)*

**Objectives:** Many studies documented that symptomatic old children, adolescents and adults act as the source of pertussis for young infants who have not yet completed their primary immunizations. Objective of this study was to prove that *Bordetella pertussis* and *Bordetella parapertussis* colonized the nasopharynx of 7–15 years old asymptomatic population by designing a cross sectional study using method of pooled real-time PCR for IS481 and IS1001 gene.

**Methods:** Nasopharyngeal (NP) swab samples (n = 629) were collected from same number of 7–15 years old asymptomatic population in the period of 2 months in four counties (one county in each province) of China in 2011. All of NP swabs were inoculated Regan-Lowe agar (Oxiod<sup>®</sup>) supplemented cephalixin within 24 hour in provincial CDC laboratory. After inoculation, swabs were then eluted into 400 microlitre (µL) of PBS. 200 µL of individual elution samples were pooled into groups of 10 samples. The *B. pertussis* and *B. parapertussis* real-time PCR was based on the amplification of the 154 bp IS481 and 186 bp IS1001 gene respectively, and 155 bp human-2-microglobulin target acted as internal control. For pools and

specimens testing, under the strict quality control, any cycle threshold (Ct) value was considered to be a positive test result. Descriptive statistics was performed by using SPSS 13.0 software.

**Results:** There were three positive cultures: two for *B. pertussis* and one for *B. parapertussis*. Sixty-three pools were constructed. Only one supposed positive elution specimen was negative on human-2-microglobulin gene which indicated the loss of nucleic acid extraction as well as inhibition of the real-time PCR. Elution specimens of all three positive cultures also could be detected IS481 and IS1001 target in respective affiliated pools and relevant elution sample. The carriage rates of *B. pertussis* and *B. parapertussis* among studied population were 4.77% (30/628) and 2.07% (13/628). (Details in table).

Group (yr)	No. of Children	No. of positive RT-PCR and percentage		No. of positive Culture and percentage	
		<i>B. pertussis</i>	<i>B. parapertussis</i>	<i>B. pertussis</i>	<i>B. parapertussis</i>
7-9	215*	7(3.26)	2(0.93)	1(0.47)	
10-12	205	13(6.34)	9(4.39)	1(0.49)	1(0.49)
13-15	208	10(4.81)	2(0.96)		
Total	628	30(4.78)	13(2.07)	1(0.32)	1(0.16)

\*Indicate that one specimen was excluded from group due to the negative on human-2-microglobulin gene.

**Conclusion:** Our results indicated that it was feasible to apply a pooled real-time PCR for IS481 and IS1001 target in estimating the carriage rate of *B. pertussis* and *B. parapertussis* in elution specimens of NP swabs. Due to absence of booster pertussis vaccinations for old children and adolescents in China and protection effect of programmed pertussis vaccine of waning as age increasing, asymptomatic old children and adolescents had *Bordetella* organisms in their nasopharynx and could act as the reservoir of pertussis infection.

**P980 Pertussis epidemic in 2011, region of Vallès (Catalonia, Spain)**

*M.R. Sala Farré, C. Arias Varela, A. Recasens Recasens, J. Pérez Jové, E. Balias Fort, M. Simó Sanahuja\* (Terrassa, ES)*

**Objective:** The aim of this study is to describe the epidemic of pertussis based on whopping cough confirmed cases reported during 2011 at the Vallès Occidental and Vallès Oriental regions, with 1.283.000 inhabitants, at the Barcelona northern metropolitan area.

**Methods:** Pertussis is a statutorily reportable disease in Catalonia. Confirmed case was defined as a person with acute cough illness reported by a health professional with isolation of *Bordetella pertussis* or positive polymerase chain (PCR) reaction assay for *B. pertussis*. A confirmed case is also defined as an acute cough illness lasting at least 2 weeks with epidemiological linkage to a laboratory-confirmed case. A descriptive study was performed with demographic data, clinical and vaccine history and epidemiological information.

**Results:** As of November 2011, we have recorded 400 cases of pertussis during this year, a 12-fold increase from 2010. Incidence was higher during summer and on females (67%). The incidence of reported pertussis was 32 cases/100.000 persons. Cases aged between 5 and 9 years were the most frequent (28%), followed by those aged 1–4 years (20%) and under 1 year (17%) but the highest incidence was among <1 year old (405/100 000) followed by the 5–9 years (148/10 000). Around 8% of cases required hospitalization, 50% of those were infants under 2 months. The vaccination status was known for 93% of cases. The 78% of cases under 14 years old had been fully vaccinated with DTaP in accordance with Catalonia's guidelines for DTaP use: <1 year 56%, 1–4 years 78%, 5–9 years 86%, 10–14 years 95%.

**Conclusions:** The infants have the highest reported incidence of pertussis. Whopping cough can occur in children despite being well vaccinated, suggesting that the vaccine does not confer complete immunity against pertussis. Those findings should be taken into account

to develop a new vaccination policy with the aim of reducing the risk of transmitting *B. pertussis* to infants.

**P981** Prevalence of major middle-ear pathogens and adenoid in Iranian children with otitis media with effusion by culture and PCR

A. Sharifi\*, S. Khoramrooz, A. Mirsalehian, M. Emameini, F. Jabalameli, M. Aligholi for the Paediatric infection group

**Introduction:** Otitis media with effusion (OME) is one of the most common childhood diseases and it is the main cause of several otological problems. Although the etiology of OME is still unclear, bacterial and viral infections have an important role in its pathogenesis. The aim of the current study was to determine the common bacterial agents and their susceptibility pattern among both Iranian children with OME and without OME.

**Materials and methods:** PCR and bacterial culture methods were used for detection and isolation of *Alloicoccus otitidis*, *Streptococcus pneumoniae*, *Moraxella catarrhalis* and *Haemophilus influenzae* in 65 middle ear fluid samples and 50 adenoid tissues from 50 OME patients. Fifteen patients were bilaterally affected. Antimicrobial susceptibility of all bacterial isolates was determined by disk agar diffusion (DAD) method.

**Results:** Bacteria were isolated from 47% (n = 30) of the 65 middle ear fluid samples and 79% (n = 38) of the 65 adenoid tissue specimens in OME patients. *A. otitidis* was the most common bacterial isolated from the middle ear fluid 23.8% by culture and 39.7% by PCR method. *S. pneumoniae* was the most prevalent pathogen (35.5% and 31.2% by culture and PCR) in the adenoid tissues of OME patients. Antimicrobial susceptibility pattern showed that most isolates of bacteria were sensitive to amoxicillin, amoxicillin/clavulanate and fluoroquinolones.

**Conclusion:** The present study, being the first report on the isolation of *A. otitidis* by culture method in Iran and Asian countries, shows that *A. otitidis* is the most frequently isolated bacterium in Iranian children having otitis media with effusion. In this study *A. otitidis*, *S. pneumoniae*, *H. influenzae* and *M. catarrhalis* are the major bacterial pathogens in patients with OME and we found that amoxicillin, and amoxicillin/clavulanate have the excellent activity against bacterial agents.

**P983** Prevalence of *Chlamydomydia pneumoniae* in adenoid tissue of children with chronic adenoiditis

E. Podsiadly\*, A. Bielicka, B. Zielnik-Jurkiewicz, U. Demkow (Warsaw, PL)

The aim of the study was to determine the presence of *C. pneumoniae* in adenoid tissue and estimate risk factor of *C. pneumoniae* infection in children with chronic adenoiditis.

Two hundred consecutive children aged 2–16 years undergoing planned adenoidectomy between 02.2010 and 05.2011 were enrolled to the study. Eligibility criteria: upper airways obstruction, caused by adenoid hypertrophy and/or with chronic adenoiditis.

Adenoids were analysed for the presence of *C. pneumoniae* DNA by real-time PCR on a LightCycler® 2.0 with LightMix® Kit *Chlamydomydia pneumoniae* (Tib Molbiol GmbH, Germany). DNA from a tissue was isolated with High Pure PCR Kit (Roche Diagnostics, Germany). Smears from the adenoids were cultured on bacteriological media. Additionally, adenoid tissue samples from 22 patients were examined with immunohistochemical methods with application of monoclonal anti-*C. pneumoniae* antibodies (Thermo Scientific) for the presence of chlamydia.

*C. pneumoniae* DNA in the adenoid was present in 11 children (5.5%). *C. pneumoniae* DNA was detected most frequently (24.1%) in children 10–16 years old. Girls were infected more often than boys 63.6% vs 36.26%.

No statistically significant differences were observed between PCR (+) and PCR (-) children as a result of, a cough, recurrent respiratory

infections, otitis media, an asthma, atopic diseases and frequency of antibiotic courses. In PCR (+) children more frequently (54.5%) than in PCR negative children (14.2%) poor standard of living was observed (p < 0.01). *C. pneumoniae* PCR (+) children tend to have rhinitis prolonging ≥3 weeks (90.9% vs 68.7%). Interestingly, *C. pneumoniae* DNA was detected in one case in adenoid removed from siblings.

In nine out of 11 (81.82%) *C. pneumoniae* PCR (+) children other pathogenic bacteria were detected: *S. pneumoniae* (4), *S. aureus* (4), *S. pyogenes* (3) and *H. influenzae* (2). In two of the PCR (+) patients no co-pathogens were found.

Results of immunohistochemical staining showed presence of *C. pneumoniae* in lymphocytes and epithelium of analysed tonsils.

Existence of *C. pneumoniae* in an adenoid tissue suggest participation of the bacteria in adenoid hypertrophy. However, comparison of results of bacteriological culture from adenoid swabs with PCR results suggests co-participation of *C. pneumoniae* in pathogenesis rather than decisive part. This etiology specially concerns school children who are more prone to *C. pneumoniae* infections.

**P984** Aetiology of acute otitis media and pneumococcal serotypes in children from Saint Petersburg

V. Gostev, M. Volkova, S. Belanov, A. Ruleva, S. Kcharit, M. Syrochkina, S. Sidorenko\* (Saint-Petersburg, Ekaterinburg, RU)

**Objectives:** *Streptococcus pneumoniae* (Spn), *Haemophilus influenzae* (Hin), *Moraxella catarrhalis* (Mca) and *Streptococcus pyogenes* (Spy) are leading pathogens causing acute otitis media (AOM) in children. Possible role of *Alloicoccus otitidis* (Aot) in the development of AOM is under discussion. Microbiologic diagnosis of AOM requires a sample of middle ear fluid (MEF) and often complicated by antibiotics pretreatment. Molecular methods are more sensitive in the detection of pathogens and allow identification of pneumococcal serotypes from pure cultures and culture-negative specimens.

**Methods:** The study was approved by local ethical committee. Children (>18 years) admitted to the emergency department with AOM and requiring paracentesis were enrolled. Paracentesis was performed by an otolaryngologist. Immediately after incision MEF was collected by the swab applicator and put into transport medium. (ESwab, Copan, Italy). Specimens were refrigerated at 4–8°C and stored for not more than 48 hour before processing. Swab applicator was used for inoculation of agar plates for isolation and identification of Spn, Hin, Mca and Spy. Bacterial DNA was isolated from 100 µL of transport medium using Ribo-Prep kit (Interlabservice, Russia). DNA of Spn, Hin, Mca and Aot were detected in both culture-positive and negative samples by multiplex PCR using primers targeting 16S RNA genes. Identification of serotypes of Spn isolates and of DNA from culture-negative, Spn DNA-positive MEF samples was carried out by multiplex PCR.

Bacteria	n (%)
Total 268 samples	
<i>S. pneumoniae</i>	80 (29.8)
<i>H. influenzae</i>	18 (6.7)
<i>M. catarrhalis</i>	18 (6.7)
<i>S. pyogenes</i>	8 (3)
<i>A. otitidis</i>	12 (4.5)
<i>S. pneumoniae</i> + <i>H. influenzae</i>	15 (5.6)
<i>S. pneumoniae</i> + <i>M. catarrhalis</i>	20 (7.5)
<i>S. pneumoniae</i> + <i>A. otitidis</i>	19 (7)
<i>S. pneumoniae</i> + <i>S. pyogenes</i>	2 (0.7)
<i>S. pneumoniae</i> + <i>H. influenzae</i> + <i>M. catarrhalis</i>	10 (3.7)
<i>S. pneumoniae</i> + <i>H. influenzae</i> + <i>A. otitidis</i>	4 (1.5)
<i>S. pneumoniae</i> + <i>M. catarrhalis</i> + <i>A. otitidis</i>	10 (3.7)
<i>S. pneumoniae</i> + <i>H. influenzae</i> + <i>M. catarrhalis</i> + <i>A. otitidis</i>	3 (1.1)
Total	219 (81.7)
Negative samples (PCR + culture)	49 (18.3)

**Results:** A total of 268 children (180 of them >5 years) were included in the study between December 2010 and November 2011. Data on bacteria and their combinations isolated from MEF or detected by PCR are presented in Table. Among 57 Spn isolates cpsA gene was detected in 54. Among 106 Spn culture-negative, 16S rRNA-positive MEF samples cpsA was detected in 64. In a total of 99 Spn isolates and culture-negative MEF samples serotypes were detected. Serotype 19F was the most prevalent – 37 (37.4%), followed by serotype 3 – 22 (22.2%). Serotypes 9L/N and 23F were represented by 9 (9.1%) each, 6A/B/C – by 6 (6.1%), 9V/A – by 5 (5.1%), 19A – by 3 (3%), 8, 14, and 10A – by 2 (2%) each and 18A/B/C – by 1 (1%), 19 (16.1%) – were non-typable.

**Conclusion:** Spn is the major cause of AOM in children in St.-Petersburg responsible for 60.8% of cases, PCV-7 and PCV-10 are covering 51.8% of circulating serotypes, the broadest coverage – 73.7% is provided by PCV-13.

## Gastrointestinal tract infection in children

### **P985** A clinico-epidemiological comparison study of paediatric acute viral gastroenteritis in South Korea

T.H. Kim\*, M.K. Lee, H.R. Kim, B.S. Shim (Seoul, KR)

**Objectives:** Acute viral gastroenteritis, especially rotavirus, norovirus, enteric adenovirus, and astrovirus is a common disorder in young children. Our aim was to monitor the epidemiologic characteristics of the aforementioned viruses and to determine the laboratory and clinical characteristics of patients associated with these viruses.

**Methods:** From December 2009 to November 2010, 685 stool specimens from patients hospitalized in Chung-Ang University Hospital were tested for aforementioned viruses by using multiplex PCR, and their medical record review was conducted retrospectively.

**Results:** The overall rates of prevalence were 44.8%, and the prevalence for rotavirus, norovirus, enteric adenovirus, and astrovirus were 36.3%, 55%, 7%, and 1.7%, respectively. Mixed virus infections were detected in 37 (5.4%). The highest incidence was in March 2010 (18.9%), in the 13–24 months age group (38.1%) and among males (53.1%). In clinical aspect, chilling was most frequently observed with adenovirus (44.4%), and diarrhea was most frequently observed with rotavirus (93.7%). The incidence of diarrhea was higher in the rotavirus-infected group (93.7%) than in the norovirus-infected group, but leukocytosis (55%) and lymphocytosis (21%) were more common in the norovirus-infected group.

**Conclusions:** Our finding showed prevalence and clinical differences of each gastroenteritis-associated viruses. For a better understanding, further epidemiologic and clinical investigations are essential.

### **P986** Evaluation of infectious agents frequencies and epidemiological features in children with acute gastroenteritis

A. Celik, M. Emiroglu, A. Inci, F. Akin, M. Kurtoglu, R. Kesli\*, D. Odabas (Konya, TR)

**Objectives:** Acute gastroenteritis remains a common illness among infants and children throughout the world. The aim of this study was evaluation of infectious agents frequencies and epidemiological features in children with acute gastroenteritis in and around Konya.

**Methods:** A total of 62 stool specimens obtained from 27 female and 35 male children <14 years who were admitted to an education and research hospital with symptomatic acute gastroenteritis, during February–September 2011 were included to the study. Stools were examined using antibody-based ELISA for rotavirus, adenovirus, norovirus, astrovirus, *Campylobacter* spp, *Salmonella* spp, VTEC, *E. coli* H7, *Clostridium perfringens*, and Shigella.

**Results:** Diarrhea was the most common symptom in children with acute infectious gastroenteritis (95.2%), while the rates of vomiting and fever were 64.5% and 50%, respectively. The positivity rates of

*Campylobacter* spp, *Salmonella* spp, VTEC, *E. coli* H7, *C. perfringens*, and Shigella were 8%, 4.8%, 1.6%, 4.8%, 1.6%, and 1.6%, respectively. Viral antigen positivity was detected in 58.1% of the samples, and the positivity rates of rotavirus, adenovirus, norovirus and astrovirus were 32.3%, 16.1%, 16.1%, and 3.2%, respectively. Rotavirus was the most frequently detected agent in children with viral gastroenteritis (55.6%). Six of 36 patients (16.7%) yielded two at a time viral antigen positivity in their stool samples. Rotavirus + norovirus (33.3%), adenovirus + norovirus (33.3%), rotavirus + adenovirus (16.7%), and adenovirus + astrovirus (16.7%) associations were detected coinfections. The difference between the rates of rotavirus positivities in age groups was found statistically insignificant ( $p > 0.05$ ). Rotavirus infections were mainly detected in winter season (50%). Adenovirus positive cases were detected in winter (21.4%) and in spring (20.6%). Norovirus infections were mainly detected in spring (20.6%) and summer (16.7%). The duration of hospitalization was found as 35.5% in lesser than a day group, 29% in 1–7 days group, and 3.2% in more than 7 days group.

**Conclusions:** More than half of the childhood gastroenteritis cases (58.1%) were due to viral agents. Rotavirus is most common viral enteric agent. The antigens of the viral agents may guide the clinical approach to the patients with acute gastroenteritis among ≤5 years of age, especially in the winter and spring months.

### **P987** Temporal trends in rate of hospitalisation for rotavirus gastroenteritis in the paediatric population in Italy: cross-sectional study utilising national hospital discharge database

A. Mattei\*, A.M. Angelone, M. Sbarbati, F. di Orio (L'Aquila, Rieti, IT)

**Study design:** This was a retrospective observational study, conducted using hospitalization data from national Hospital Discharge Database (HDD) available on the website of the Italian Ministry of Health.

**Objective:** The primary objectives were to estimate the frequency of hospitalization for Rotavirus gastroenteritis (RVGE) for the period 2002–2005 in children aged 0–14 years in the different regions of Italy, and to analyze temporal trends of hospitalization rates (HR) for geographical location.

**Methods:** In Italy there are no specific surveillance systems for RV disease in place, so HDD are one mean by which diseases trends among hospitalizations may be observed. Cases of RVGE were identified using ICD9-CM code 00861. Three aged groups are studied: 0–1, 1–4, and 5–14 years. In order to estimate HR, we used population for each study year published by the National Institute of Statistic website. Data analysis was performed using STATA 12. The nptrend command was used to examine for significant trends in temporal HR ( $p < 0.05$ ), based on the Wilcoxon rank-sum method.

**Results:** In the study period, a total of 21 300 RVGE diagnosis were collected in children. The following HR for rotavirus were recorded: 71/100 000 residents in 2002, 49/100 000 in 2003, 51/100 000 in 2004 and 66/100 000 in 2005. RVGE accounted for the highest percentage of admission in children of 1–4 years of age. The respective HR were found to be: 2002:181/100 000; 2003:157/100 000; 2004:161/100 000; 2005: 204/100 000. The region with higher HR is Trentino Alto Adige while Calabria, while Valle D'Aosta and Sardegna present the lowest values. The analysis of temporal trends by geographical location shows that in the North, the average HR reached a peak in 2002, before declining in 2003 and 2004 and return to a high value in 2005. A similar trend, was observed for the Centre. In the South and Islands observed a different trend, indeed the HR varies from 39/100 000 in 2002 to 31/100 000 in 2003. In the following years, HR substantially increases, going to 48/100 000 residents. The analysis of temporal trend in the HR in the 4 years examined showed no statistically significant differences ( $p > 0.05$ ).

**Conclusions:** The highest HR observed in the Northern compared to the rest of Italy could reflect actual geographic variability in incidence

of rotavirus infection or disease, or could be due to differences in the sensitivity of the hospital discharge databases for detecting RVGE.

#### **P988** Rotavirus surveillance: genotyping and epidemiological evaluation in hospitalised children in Milan

*S.G. Rimoldi\*, M. Monini, C. Pagani, L.L. Chenal, L. Tocalli, F.M. Ruggeri, M.R. Gismondo (Milan, Rome, IT)*

**Objective:** Concerning the magnitude of the rotavirus infection worldwide this study was designed to assess the most prevalent circulating rotavirus genotypes and to devise strategies for intervention in pediatric children admitted with acute gastroenteritis to the L. Sacco University Hospital (Milan, Italy).

**Methods:** A 41 months study (2008–2011) involving 700 children aged between 1 and 204 months (40 mos, males 57%), was carried out. ImmunoCardSTAT Rotavirus test (Meridian, USA) was performed as screening; for G- and P-typing RT-PCR of VP7 and VP4 genes was used. A subset of rotavirus strains was characterized by nucleotide sequencing of PCR products and compared with the NCBI data bank, using DNASIS Max software (Hitachi Software Engineering Company, Alameda, CA, USA).

**Results:** Rotavirus was the cause of acute gastroenteritis in 97 children (14%); 84 out of 97 samples (86.6%) were available for genotyping, 13 (13.4%) proved negative to RT-PCR.

Sequence analysis of the VP4 and VP7 genes were carried out on 13 strains out of 84 that could not be G- and P- typed at first by PCR. After sequencing 9 out of 13 resulted G1, 3 were identified as G9 and in one case infection was due to G1 and G9 strains together.

The distribution of the different rotavirus Group A genotypes detected in our hospital showed a prevalence of the G1 genotype, 81% (68/84). Other major strains reported in this epidemiological evaluation were G9, 8.4% (seven cases), followed by G4, 3.6% (three cases), G2 and G3, one case each (1.2%). Also the rarer G12 and G10 were reported in one case each (1.2%) and two mixed infections with G1 and G9 types (2.4%) were detected. Among the P-types P[8] accounted for the total of the samples tested. Sequences analysis of VP4 and VP7 genes of typed samples has confirmed the presence of the human G and P types described, and revealed a close relationship between strains isolated in the rest of Europe reported in GenBank (97% to 99% sequence similarity).

**Conclusion:** In the present study rotavirus surveillance genotyping reveals new emerging rotavirus genotypes sporadically detected G9P, G10 and G12.

Given the unbalance in the representation of the genotypes any detailed comparison between genotypes occurrence or properties was not possible, and only a representative set of study cases was available for clinical parameters of G1.

#### **P989** Norovirus gastroenteritis in a paediatric population

*N. Palaiologou\*, G. Zarnaveli, N. Filntisi, E.E. Vetouli, D. Hatzaki, I. Paraskakis, E. Lebessi (Athens, GR)*

**Objectives:** Noroviruses (NoVs) are recognized as an important cause of epidemic and sporadic acute gastroenteritis in humans of all ages worldwide. In Greece, there is not surveillance system for viral gastroenteritis. The aim of the present study was to give our experience about gastroenteritis due to NoVs in children in the area of Athens, Greece.

**Methods:** A total of 846 stool specimens, obtained from an equal number of children (56% boys) under 14 years of age hospitalized or referred to outpatient clinic with gastroenteritis from November 2009 to October 2011, were tested by using an immunochromatographic test (RIDA QUICK Norovirus Test<sup>®</sup>, R- Biopharm, Germany) for determining genogroup I and II NoVs. Cases were studied by

reviewing the medical charts for clinical and epidemiologic characteristics. NoVs were not covered by routine analysis during summer months July and August (cost effective criteria), so these months were not included in the study.

**Results:** Children infected by NoVs comprised 27 out of 846 (3.2%) enrolled patients. Of these, two were suffering from chronic diarrhea, and the remaining 25 cases were presented with acute diarrheal syndrome. Other than diarrhea, vomiting and abdominal pain were the most common symptoms among the 25 norovirus-positive patients, reported for 15 patients (60%), following by fever (>37.5°C) reported for 10 patients (40%). Sixteen patients were boys (59%), with median age 12 months (range 27 days to 14 years). The majority of NoVs infections (n = 21, 78%) occurred in children up to 2 years of age. The highest incidence (82%) was recorded in winter and spring months from February through May. Outbreak was not identified, but person-to-person transmission in different hospital wards was detected in eight cases from March to May 2010 and one case in January 2011. Of note, eight cases (29.6%) with a dual infection were found; co-infection with rotavirus was found in four patients and viral – bacterial co-infection in a further four cases: *Escherichia coli* (2), *Salmonella enterica* (1), *Campylobacter jejuni* (1). During the study period, the incidence for rotavirus was 15% and for adenovirus 2.7%.

**Conclusion:** NoVs were the second most common agent responsible for viral gastroenteritis in Greek children, especially under 2 years. Co-infection viral-viral or viral-bacterial was common. Virus transmission in hospital wards occurred in a high rate. Strict hygiene measures must be taken when caring for patients with gastroenteritis.

#### **P990** Outbreak of *Salmonella* Poona among infants during 2011 in the Vallès region, Catalonia, Spain

*M.R. Sala Farré, C. Arias Varela, A. Recasens Recasens, L. Corominas Farres, M. Simó Sanahuja\*, M. Olsina Tebar, A. Martínez Planells, J. Pardos Bosch, C. Martí Sala (Terrassa, Girona, Sant Cugat del Vallès, Granollers, ES)*

**Objective:** In 2010 the National Centre of Epidemiology (Instituto de Salud Carlos III, Madrid) detected an increase of *Salmonella enterica* serotype Poona (SP), mostly on infants aged under 1 year suggesting a transmission from formula milk, but until February 2011 it was not informed state wide. *Salmonella* isolates are only reported for some laboratories and on a voluntary basis. The aim of this study is to describe the epidemiological investigation of the SP outbreak in the Vallès Occidental and Vallès Oriental region, with 1.283.000 inhabitants at the Barcelona northern metropolitan area.

**Methods:** A case was defined as an infant with symptoms compatible with a *Salmonella* infection and SP isolate from a clinical specimen. The health centres were alerted and encouraged for the ESUVV to inform about any presumptive case. Data about demographic, clinical and food consumption was collected. *Salmonella* strains from patients and formula milk recipients provided by their parents were analysed by pulse-field gel electrophoresis (PFGE) by the PHAC laboratory since February 2011.

**Results:** Until April 2011, 28 cases were reported to ESUVV: 2 in 2010 and 26 in 2011, 75% of the cases were under 5 months. All the cases had diarrhoea (67% bloody diarrhoea), 5 were hospitalised, one case needed intensive care. All cases had consumed the same batch of a milk brand. SP was cultured from two milk cans. All SP strains had the same PFGE. It was the first time during the outbreak that SP was isolated from a not manipulated recipient. These findings let the Spanish food safety authorities recall the batch of milk, source of the infection. The last case was in April 2011.

**Conclusions:** The investigation of this outbreak shows the usefulness of information management and active surveillance at regional level. Microbiological reporting should be mandatory, together with the establishment of a *Salmonella* data bank in order to identify and investigate clusters of cases.

**P991** The occurrence of *Helicobacter pylori* specific genotypes in symptomatic children and evaluation of immune response to infection

M.M. Biernat\*, B. Iwanczak, J. Grabinska, G. Gosciniak (Wroclaw, PL)

**Objectives:** *Helicobacter pylori* (*H. pylori*) infection is acquired in early childhood and its progress seems to be associated with bacterial virulence factors, environmental factors and host determinants, including immune response to pathogen. Analysis of the relationship between these factors can contribute to a better understanding of the course of *H. pylori* infection. The aim of the study was to establish the prevalence of *H. pylori* cagA, vacA, iceA, babA genotypes in a cohort of pediatric patients and to analyze the association between the presence of IgG antibodies against specific *H. pylori* antigens with strain genotype and clinical outcome.

**Methods:** The retrospective study was performed on one hundred and two (n = 102) *H. pylori* strains and 102 serum samples collected in years 2007–2010. The strains were isolated from gastric biopsies of children aged 4–18 years, diagnosed and treated for: chronic gastritis (CH) (n = 69), peptic or duodenal ulcer disease (UD) (n = 14), gastroduodenal reflux disease (GERD) (n = 19). Genotyping of virulence factors cagA, vacA, iceA, babA was performed by multiplex PCR. Serum antibodies reactivity against *H. pylori* specific proteins was tested by Western blot.

**Results:** The high frequency of IgG antibodies against 95 kDa (VacA) and 120 kDa (CagA) was detected in 73% and 80% of examined children. The highest prevalence of anti-CagA and anti-VacA antibodies was observed in youngest children (81%). In children with CH the percentage of anti-CagA and anti-VacA antibodies amounted 61.4% and 37.6% whereas in subjects with UD 92.3% and 82%, respectively. In patients with UD the most prevalent *H. pylori* genotypic profile was: vacA s1m2, cagA+(28.5%) whereas in patients with GERD: vacAs2m2, cagA-, iceA+ genotype (31.5%), respectively. In children with CH the most frequently detected *H. pylori* genotype was vacAs2m2, cagA-, iceA+ (17.3%).

**Conclusions:** The specific antibodies against CagA and VacA proteins are observed more frequently in children with peptic and duodenal ulcer than in patients with chronic gastritis. A high prevalence of the presence of anti-CagA and anti-VacA antibodies in youngest children might be associated with the high rate of infection caused by CagA+, VacA+ *H. pylori* strains. The high frequency of serological response to VacA and CagA antigens well correlates with high prevalence of vacA s1, cagA+ *H. pylori* genotype. Grant support: Ministry of Science and Higher Education, No3230/P01/2007/32, Poland.

**P992** Sero-epidemiology of *Helicobacter pylori* in children in Greece. Is there any difference between allergic and nonallergic individuals?

M. Matsas\*, M. Papadimitriou, A. Doudoulakakis, E. Vetouli, A. Doxara, I. Paraskakis (Athens, GR)

**Objectives:** The prevalence of *Helicobacter pylori* infection in asymptomatic children varies greatly between countries worldwide. It has been suggested that the lack of exposure to *H. pylori* is an important risk factor of asthma in childhood. Thus, *H. pylori* seropositivity has inversely related to allergic disorders in children. The aim of this study is to determine the antibody status against *H. pylori* in a paediatric population in Greece and the correlation of seropositivity with total IgE serum levels.

**Methods:** Serum samples from 270 outpatients or hospitalized children [159 boys (59%) and 111 (41%) girls] from January to August 2011, aged 2–15 years old, were analysed. This pediatric population did not present any peptic or other chronic disease. The children were distributed in three groups according to age, each age group represented a similar number of samples with normal and abnormal levels of IgE: group a; 2–5, group b; 6–10, group c; 11–15 years old.

All samples were tested for IgG and IgA *H. pylori* antibodies by ELISA (Dia.Pro Diagnostics Bioprobes). Total IgE levels were measured using a FEIA method (Immunocap 250-Pharmacia). Statistical analysis was performed using a chi-square test.

**Results:** Out of 270 samples, 45 (16.7%) were found positive for *H. pylori* IgG or/and IgA antibodies. Of these, 11 (24.5%) children with negative IgA results were found to have detectable anti-*H. pylori* IgG, while in 16 (35.5%) with negative IgG results determined exclusively IgA antibodies. There was no significant difference in positive samples between boys and girls (15.7% vs 18.0%). In these three study groups the seroprevalence was 10.8% (10/93), 13.3% (13/98), and 27.8% (22/79) in group a, b and c, respectively. As concerning as the correlation of seropositivity for *H. pylori* with the high IgE levels (>150 kU/L) suggesting allergic status, there was not found statistically significant correlation (p > 0.05) between healthy and allergic children [20.2% (26/129) vs 13.5% (19/141)]. However, in the latter group the proportion of positive for *H. pylori* results was inversely associated with IgE levels [151–500 kU/L; 15.20% (7/46), 501–1000 kU/L; 13.10% (8/61) and >1000 kU/L; 11.80% (4/34)].

**Conclusions:** Healthy children infected with *H. pylori* are prevalent in our country. The positive *H. pylori* results increase with age. Contrary to other studies, the inverse relation of seropositivity with allergic disorders in childhood has not been detected in our study.

## Serological diagnosis of infections

**P993** Evaluation of rapid immunofiltration assays for the diagnosis of Epstein–Barr virus infectious mononucleosis

I. Garcia-Bermejo\*, R. Alonso, A. González-Torralba, F. de Ory (Madrid, ES)

**Objectives:** The aim of this study was to compare two rapid immunofiltration assays (IMFAs) (BIO-RAD, France), requiring no specific instrumentation, one to detect Epstein–Barr virus (EBV)-VCA IgM (RDT EBV IgM) and the other for the simultaneous detection of EBV-VCA IgG and EBNA-1 IgG (RDT EBV IgG), with the methods used in our laboratories, for the diagnosis of EBV infectious mononucleosis (IM).

**Materials and methods:** A total of 107 serum samples, grouped in two panels, were studied. Panel A included 76 samples from IM patients (median age 13 years old) received for routine EBV-specific antibody testing, showing antibody profiles compatible with acute primary EBV infection (presence of VCA-IgM and -IgG in absence of EBNA-1-IgG antibodies [62] or single VCA-IgM positive result [14]). Panel B included 31 samples from EBV seronegative individuals. All samples were tested with chemiluminescent immunoassays (CLIAs) for VCA-IgM, VCA-IgG and EBNA-1-IgG (Liaison®, DiaSorin, Italy) and for heterophile antibodies (HA) (Monogen®, Biokit, Spain). All assays were performed according to the manufacturer's instructions. Samples showing discrepant results were retested and classified according to indirect immunofluorescence (IIF) for VCA-IgM and -IgG and anticomplement immunofluorescence (ACIF) for EBNA antibodies (Merifluor®, Meridian Bioscience, USA).

**Results:** Out of the 76 sera from Panel A, 70 were reactive for VCA-IgM by CLIA and IMFA. Six samples were only reactive by CLIA; 5 of them were IIF positive. No positive results were detected by IMFA in samples from Panel B. Thus the figures for sensitivity, specificity and agreement were 93.3%, 100% and 95.3%, respectively. Forty-four samples from Panel A were positive for HA, all of them showing positive result in IMFA for VCA-IgM. For VCA-IgG, 56 samples were positive and 43 negative by both assays. After testing discrepant samples by IIF, six samples were classified as false negative and 2 as false positive by VCA-IgG IMFA. The values for sensitivity, specificity and agreement, were 90.3%, 95.6% and 92.5%, respectively. Finally, eight samples showed false positive result in IIF for EBNA-1-IgG, as referred by ACIF (92.5% for both specificity and agreement).

**Conclusion:** RDT EBV assays were accurate for the diagnosis of acute EBV IM. The IgM assay was found as especially useful in patients with

no HA response. Both IMFA assays are easy to perform, include ready-to-use reagents and they are suitable for point-of-care use.

#### **P994** Evaluation of three immunoassays for the determination of Epstein–Barr virus IgG and IgM specific proteins

V. Polymerou\*, E. Mokou, I. Plianos, G. Kargiolakis, F. Chrysou, K. Konstantinakou, J. Kremastinou (Athens, GR)

**Objective:** Epstein Barr (EBV) is the etiologic agent of infectious mononucleosis (IM). Diagnosis of infectious mononucleosis is based upon clinical manifestations in conjunction with serological and haematological findings. Serologically, heterophile antibodies can be detected as well as antibodies against EBV IgG and IgM specific proteins. The aim of the present study was to evaluate the performances of three immunoassays: Immulite 2000 (Siemens), Liaison® (Diasorin) and Vidas (Biomérieux).

**Methods:** The first group of our study consists of sera from 41 patients (both sexes, aged 5–45 years old) with positive heterophile antibodies and clinical findings. The second group consists of 63 samples from healthy individuals. All samples were tested for EBV IgG and IgM antibodies using Immulite 2000 Siemens (CLIA), Liaison® Diasorin (CLIA) and Vidas Biomérieux (ELFA). Samples with discordant results were also tested for Epstein Barr nuclear antigen IgG (EBV NA IgG). Indirect immunofluorescence (IIF) was used as a reference method. The SPSS 17.0 was used for the interpretation of the results.

**Results:** The specificity of Immulite, Liaison® and Vidas for EBV IgM was 90.8%, 93.8% and 92.3% respectively. The sensitivity of EBV IgM were 95.1% for Immulite, 95.3%, for Liaison 97.6% and 95.3% for Vidas. In the IgG immunoassays the specificity of Immulite was 89.4%, for Liaison® was 94.4% and for Vidas was 94.4%. The sensitivities of EBV IgG were 98.9%, for all immunoassays. The agreement of EBV serology profile between Immulite and Liaison® was 94.3%, between Liaison® and Vidas 93.3% and between Immulite and Vidas 92.4%.

**Conclusion:** In conclusion, our results indicate that the three immunoassays have similar performances. Thus, any of the above immunoassays can be used for routine detection of EBV IgG and IgM specific proteins in serum samples. To distinguish EBV primary infection from seronegative or past infection EBV nuclear antigen can be very useful. In addition, the combination of EBV IgG and IgM specific proteins and EBV NA IgG can help us resolve false-positive testing.

#### **P995** Evaluation of serological assays on the Vidas (bioMérieux) platform for delineation of Epstein–Barr virus serostatus

M. Noel, A. Galloway, S. Black, M. Shearman, C. Graham, I. Johannessen\* (Edinburgh, UK)

**Background:** Epstein–Barr virus (EBV) persistently infects over 90% of adults. Whilst primary infection in childhood is generally asymptomatic, it may cause infectious mononucleosis (IM) in adulthood. Immunosuppression following solid organ transplantation (SOT) reduces T cell-mediated immune control of EBV which is an oncogenic virus that may drive formation of post-transplant lymphomas.

**Objective:** The aim was to compare performance of Vidas (bioMérieux, France) with Liaison (Diasorin, USA) enzyme immunoassays (EIAs) and immunofluorescence (IF; MBL-Bion, USA) in the IM and SOT setting.

**Methods:** For each study population, 100 stored serum samples were analysed by EBV VCA IgM, VCA (or VCA/EA) IgG and EBNA IgG EIAs and IF. For each assay platform, delineation of EBV serostatus was based on all three test results [“no evidence of infection”, “acute infection” (VCA IgM+ve), “recent infection” (VCA IgM+ve and VCA IgG+ve) or “past infection” (EBNA IgG+ve)].

**Results:** The study assessed three patient populations (n = 100 each): (i) patients suspected clinically of IM [37 males; age range 7–50 years (mean (SD) 24.6 (9.7) years)]; (ii) SOT (live kidney) donors [51 males; age range 20–86 years (mean (SD) 51.2 (12.2) years)]; (iii) SOT (cadaveric kidney) recipients [70 males; age range based on 99 patients 17–77 years (mean (SD) 51.0 (14.5) years)]. Overall, the proportional agreement between individual Vidas and Liaison EBV tests ranged from 88% to 100% (median 96%) demonstrating similar performance of these assays as reflected further in overlapping confidence intervals. Furthermore, EBV serostatus (based on all three tests) determined on the Vidas platform mirrored that shown by Liaison. Similar results were obtained when VCA IgG or EBNA IgG results on Vidas or Liaison were compared with IF. In contrast, the proportional agreement between individual Vidas or Liaison VCA IgM tests and IF ranged from 48% to 72% (median 52%) which resulted in discrepancies in EBV serostatus between Vidas or Liaison and the IF assay.

**Conclusion:** Overall, the Liaison and Vidas assays gave similar performance. The same applied to the IF assay – with the notable exception that the VCA IgM IF test often gave discrepant results between the Vidas and Liaison platforms. The main reason for this discrepancy was likely inherent operator subjectivity of IF assessments which can be avoided by using automated EIA platforms.

#### **P996** Comparison of three testing algorithms for staging of Epstein–Barr virus infection by the new ARCHITECT EBV prototype panel

E. Sickinger\*, H.B. Braun, J. Herzogenrath, S. Bernhardt, H. Christ, C. Buening, M. Berth (Wiesbaden, DE; Antwerp, BE)

**Objectives:** Staging of EBV infection and differentiation from other illnesses with similar symptoms are the major goals of serological EBV testing. The most routinely used serological test panels consist of three assays: EBV viral capsid antigen (VCA) IgM, EBV VCA IgG and Epstein–Barr virus (EBV) nuclear antigen (EBNA) IgG. In this study we compared three testing algorithms using the ARCHITECT EBV VCA IgM, VCA IgG and EBNA-1 IgG assays currently in development. Purpose was to validate the testing algorithms regarding their ability to stage of Epstein–Barr virus (EBV) infection.

**Methods:** Five hundred and forty-seven diagnostic specimens, including presumed acute (n = 49) and prospective (n = 498) specimen, were evaluated by three testing algorithms: (i) Initial testing by VCA IgM/IgG; follow up testing with EBNA-1 IgG (VCA M/G screening), (ii) Initial testing with EBNA-1 IgG; follow up testing with parallel VCA IgM/IgG testing (EBNA screening) and (iii) Parallel testing of all three assays. Acute phase specimens had been selected based on a positive heterophile antibody test, prospective specimens were collected from daily EBV routine serology. Specimens were staged as EBV negative, suspected acute, acute, transient phase, past infection or rated as unresolved (VCA IgG only or EBNA IgG only reactive). Follow-up testing is required if specimens were staged as suspected acute, transient phase or unresolved. Calculation was performed both with grayzone (GZ) results considered unresolved, or using an algorithm that evaluates GZ results for one marker based on the outcome of the other two markers (GZ resolved).

**Results:** The EBNA screening algorithm required follow up tests in 4% of patients, while VCA M/G screening as well as testing of all assays in parallel necessitated follow up tests in 7% of patients. The GZ resolved evaluation as well reduced the need for follow-up testing. Forty-two of 49 heterophile antibody positive specimens staged acute independent of testing algorithm. Six were either Epstein–Barr virus (EBV) serologically negative or identified as past infection. Six specimens staged acute in the prospective specimens independent of testing algorithm.

**Conclusions:** When using the new ARCHITECT EBV prototype panel with an EBNA screening and GZ resolved approach, only 4% of patient results required further follow-up testing to resolve the state of EBV infection, while presumed acute Epstein–Barr virus (EBV) infection was still detected with high sensitivity. With these features the

ARCHITECT EBV panel might improve workflow and time to result in the diagnostic laboratory.

**P997** A comparative analysis on five different fully automated anti-rubella IgG immunoassays reporting results in IU/mL

L. Grangeot-Keros, C. Vauloup-Fellous\* (Clamart, FR)

**Objectives:** Since the 1980s rubella IgG assays have been calibrated against the same World Health Organization (WHO) international standard and the test results reported in International Units per milliliter (IU/mL).

The aim of this study was to compare in term of sensitivity and specificity five fully automated anti-rubella IgG immunoassays that report results in IU/mL: ACCESS<sup>®</sup> Rubella IgG (Beckman), LIAISON<sup>®</sup> Rubella IgG (DiaSorin), ARCHITECT<sup>®</sup> Rubella IgG (Abbott), IMMULITE<sup>®</sup> 2500 Rubella IgG (Siemens Healthcare Diagnostics) and ELECSYS<sup>®</sup> Rubella IgG (Roche Diagnostics).

**Methods:** The study was performed in 482 selected samples from pregnant women with different level of IgG anti-rubella antibodies. Samples that showed discordant results between systems were further investigated by resolution with immunoblot (Mikrogen).

Analytical performances were calculated vs. expected results obtained using a combination of the consensus and immunoblot classification.

**Results:** At first evaluation 88 samples were negative by all methods, 175 positive and 219 discordant. After immunoblot analysis on discordant samples, 217 were classified as positive and 2 as negative. The classified 90 negative and 392 positive samples were used to determine the sensitivity and specificity of each assay. When equivocal results were interpreted as positive, the sensitivity of the immunoassays ranged from 71.4% to 99.5% and the specificity ranged from 97.8% to 98.9%.

When equivocal results were interpreted as negative, the sensitivity of the immunoassays ranged from 47.7% to 85.7% and the specificity ranged from 97.8% to 100%. (Table1).

Assay	Sensitivity (%) [95% confidence limits [%]] with equivocal results assigned as:		Specificity (%) [95% confidence limits [%]] with equivocal results assigned as:	
	Positive	Negative	Positive	Negative
ACCESS*	71.4(66.7-75.9)	47.7(42.9-53.0)	97.8(92.2-99.7)	100(96.0-100)
LIAISON*	73.2(68.5-77.5)	68.9(64.0-73.4)	98.9(94.0-100)	98.9(94.0-100)
ELECSYS*	85.7(81.9-89.0)	85.7(81.9-89.0)	97.8(92.2-99.7)	97.8(92.2-99.7)
ARCHITECT*	95.2(92.5-97.1)	68.9(64.0-73.4)	97.8(92.2-99.7)	98.9(94.0-100)
IMMULITE*	99.5(92.2-99.9)	84.9(81.0-88.3)	97.8(92.2-99.7)	97.8(92.2-99.7)

**Conclusions:** Even though all assays reported results in IU/mL this study showed only a moderate correlation, particularly in term of sensitivity. Further investigations have been performed to evaluate sensitivity and specificity of assays using a cut off with wider grey zone, which may be useful in population where vaccination is commonplace.

**P998** Usefulness of rubella IgM detection: evaluation of serological samples from patients with acute rubella infection following a rubella outbreak in southern Italy

F. Greco\*, C. Vauloup-Fellous, A.M. Giandomenico, O. Savino, R. Tenuta, C. Giralddi (Cosenza, IT; Clamart, FR)

**Objectives:** Rubella virus infection causes a generally benign exanthema disease but it is particularly disastrous if contracted during the first 4 months of gestation. If not immunologically protected, women infected during pregnancy run a high risk of embryo fetal damage. Congenital rubella causes a wide range of severe defects, many of which are permanent and adversely affect later development. Pathological consequences on the fetus or newborn depend on teratogenicity of the virus and on the time of pregnancy when the infection has been contracted.

The aim of this study was to assess the performance of four automatic systems for the serodiagnosis of primary acute infection.

**Methods:** The study was performed upon 68 samples of symptomatic patients who were infected by rubella virus during the course of an epidemic in Southern Italy (Cosenza 2008). All of the patients had fever and were affected by lymphadenopathy, a short lasting rash and joint pain. To evaluate the sensitivity of the tests paired sera were also assessed.

The sera were screened for the presence of anti-rubella IgM using LIAISON<sup>®</sup> Rubella IgM (DiaSorin), ARCHITECT<sup>®</sup> Rubella IgM (Abbott), IMMULITE<sup>®</sup> 2500 Rubella IgM (Siemens Healthcare Diagnostics) and ELECSYS<sup>®</sup> Rubella IgM (Roche Diagnostics) assays.

**Results:** On 68 symptomatic patients LIAISON<sup>®</sup> showed 55 IgM positive results, IMMULITE<sup>®</sup> 47, ARCHITECT<sup>®</sup> 42 and ELECSYS<sup>®</sup> 38.

At first evaluation of paired samples all patients were symptomatic with high level of IgM antibodies. After 3–5 days seroconversion of IgG was observed as confirmation of clinical signs.

**Conclusions:** Statistical analysis of the findings showed a good sensitivity for all the systems and confirmed the usefulness of serological Rubella IgM detection to diagnose an acute rubella infection.

**P999** The challenges of serological prediction of chronic Q fever

L.M. Kampschreur\*, J.J. Oosterheert, A.M.C. Koop, M.C.A. Wegdam-Blans, C.E. Delsing, C.P. Bleeker-Rovers, M.G.L. De Jager-Leclercq, C.A.R. Groot, T. Sprong, M.H. Nabuurs-Franssen, N.H.M. Renders, M.E. van Kasteren, Y. Soethoudt, S.N. Blank, M.J.H. Pronk, A.I.M. Hoepelman, P.C. Wever (Utrecht, Veldhoven, Nijmegen, Oss, Veghel, 's-Hertogenbosch, Tilburg, Helmond, Eindhoven, NL)

**Introduction:** After primary infection with *Coxiella burnetii*, 1–5% of patients develop chronic Q fever. PCR and culture have low sensitivity for detection of chronic Q fever. Hence diagnosis relies mainly on serologic tests, of which immunofluorescence assay (IFA) is the most commonly used. Cut-off titers for phase I IgG to detect chronic infection are matter of debate, but are estimated between 1:800 and 1:1600. To improve diagnostic work-up, we studied the serological profiles in patients with established chronic Q fever.

**Methods:** We selected all patients included until September 2011 in the Dutch National Database of Chronic Q Fever Patients. According to Dutch consensus, patients were categorized as proven, probable or possible chronic Q fever. This classification ranks the probability of having chronic Q fever based on PCR results, serology, clinical parameters, imaging studies and pathology. We examined phase I IgG antibody titers (IFA) at time of positive blood PCR, at diagnosis, and at peak levels and compared these between the three chronic Q fever subgroups.

**Results:** We evaluated 200 patients, of whom 56 (28.0%) had possible chronic Q fever, 51 (25.5%) probable chronic Q fever, and 93 (46.5%) proven chronic Q fever. Of the patients with proven chronic Q fever, 52 patients (55.0%) had a positive *C. burnetii* PCR in blood, 10 (10.8%) in tissue and 13 (13.9%) in both blood and tissue. High phase I IgG levels did not negatively influence positive blood PCR results. Median phase I IgG titers at time of diagnosis and peak titer in patients with proven chronic Q fever were significantly higher (both 1:8192,  $p < 0.05$ ), compared to patients with probable (1:2048 and 1:4096, respectively) and possible chronic Q fever (both 1:2048). Test characteristics of

Phase I IgG titer	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
1:1024	97.8%	nd	62.2	nd
1:2048	94.6%	21.4%	66.7	70.6
1:4096	80.6%	38.9%	76.3	64.7
1:8192	60.2%	83.9%	86.2	60.0
1:16384	47.3%	94.6%	93.6	52.0
>1:16384	25.8%	96.4%	94.4	47.8

PPV, positive predictive value; NPV, negative predictive value; nd, not determinable

different phase I IgG titers, comparing proven cases and possible cases are displayed in table 1.

**Conclusion:** Our study shows that high phase I IgG titers are strongly associated with proven chronic Q fever, especially when exceeding 1:4096 (PPV >86%). However, due to low sensitivity of these titers (<60%) and high morbidity and mortality of untreated chronic Q fever, increasing the current diagnostic phase I IgG cut-off is not recommended. Our study emphasizes that, in case of chronic Q fever, serology is not a diagnostic tool on its own. Therefore, serologic results should, in the absence of a positive PCR, be interpreted in combination with clinical parameters.

#### **P1000** Evaluation of three immunoassays for serodiagnosis of human *Mycoplasma pneumoniae* infection

P. Huynen\*, F. Toussaint, M.P. Hayette, C. Meex, P. Melin (Liege, BE)

**Objectives:** Serology is still the most widely used method to diagnose the infections. Several immunoassays are available for the detection of specific *Mycoplasma pneumoniae* IgG and IgM. The aim of this study was to evaluate a new commercial chemiluminescent assay based on recombinant capsid proteins derived from baculovirus for diagnosis of *M. pneumoniae* infection. This assay has been adapted by Savyon® to be fully automated on LIAISON® instrument (DiaSorin) using chemiluminescence detection system. We have compared this assay with enzyme immunoassays from Savyon® and Medac® performed on the Eti-max® 3000 (DiaSorin) analyser.

**Methods:** A total of 355 sera from different patients from routine daily practice (142 for both IgM and IgG, 100 for IgM and 113 for IgG) were tested with *M. pneumoniae* IgM and IgG kits from Savyon®, Medac® and DiaSorin®. Discordant results were solved by Virion® complement fixation (CF) testing. Furthermore clinical data and PCR results when available were also used.

Intra-assay and inter-assay imprecision based on samples tested in replicates have been performed for both IgM and IgG.

Agreement for at least two results or confirmation with CF assay established reliable diagnosis.

**Results:** Sensitivity was 97.9%, 92% and 93.3% and specificity was 77.2%, 95.9% and 95.2% for *M. pneumoniae* IgM from Savyon®, Medac® and DiaSorin® assays respectively; accuracy was 86.2%, 94.5% and 94.3% respectively.

The degree of agreement between DiaSorin® and Savyon® was 85.1% and 84.1% for IgM and IgG respectively, and between DiaSorin® and Medac® was 86.3% and 88.7% for IgM and IgG respectively.

All discordant results were close to the equivocal range values of each assay.

Intra-assay and inter-assay imprecisions were <10% coefficient of variation for both positive IgM and IgG samples.

**Conclusion:** According to our evaluation, DiaSorin® and Medac® *M. pneumoniae* IgM and IgG assays have similar analytical and clinical performances. Moreover, these assays discriminate sick from healthy patients well, show good specificity, and detect less residual IgM and IgG. *M. pneumoniae* DiaSorin® assays appear to be a valid alternative for the detection of *M. pneumoniae* antibodies. These assays performed on the LIAISON® instrument combine robust analytical and clinical performance with all the advantages of a fully automated, random access instrument system.

#### **P1001** Evaluation of a new chemiluminescent assay for detection of *Mycoplasma pneumoniae* infections

T.D. Ly\*, S. Gonzalo (Ivry-sur-Seine, Lyon, FR)

**Background:** *Mycoplasma pneumoniae* is an important etiologic agent of tracheobronchitis and primary atypical pneumonia in children and adults. The diagnosis of *Mycoplasma pneumoniae* infection is commonly confirmed through nucleic acid amplification or serologic testing since bacterial culture of this organism is slow and lacks sensitivity.

**Aim:** In this study, the performance of two new assays, LIAISON *Mycoplasma pneumoniae* IgG and IgM (DiaSorin, Saluggia, Italy), was compared to that of six ELISA assays: *Mycoplasma pneumoniae* IgG, IgM (Ani LabSystems, LabSystems, Helsinki, Finland), *Mycoplasma pneumoniae* IgG, IgM (MEDAC, Hamburg, Germany) and SeromP Recombinant IgG and IgM (Savyon Diagnostics, Ashdod, Israel).

**Methods:** Group I: 136 selected paired samples from 68 patients with primary infection of *M. pneumoniae* (46 children and 22 adults); group II: 122 selected samples from 27 children and 95 adults with respiratory infections, other than those caused by *Mycoplasma pneumoniae*.

**Results:** The results of the seroconversion panel (number of positive samples to total number of samples) is as follows: 71.3% (for Ani LabSystems IgG), 90.4% (for Ani LabSystems IgM), 62.5% (for LIAISON IgG), 72% (for LIAISON IgM), 62.5% (Savyon IgG), 69.9% (Savyon IgM), 65.4% (MEDAC IgG) and 71.3% (MEDAC IgM). On evaluation of samples from the group II panel Ani LabSystems gave higher IgG seroprevalence (87.7%) when compared with that LIAISON (23.8%), Medac (34.4%) and Savyon (18.9%). IgM seroprevalence was 5.7%, 6.6%, 12.3% and 39.3% for LIAISON, Medac, Savyon and Ani LabSystems respectively. An update version of the Ani LabSystems assays is available whereby the cut off of the IgG kit is increased (from 30 EIU to 45 EIU) and IgM kit cut off 1.1 as opposed to 0.5 (index). Calculation of the results based on these new cut offs would lead to Ani LabSystems score in group I of 64% for IgG and 79.4% for IgM. In group II, the IgG and IgM seroprevalence will be 84.4% and 12.3% respectively.

**Conclusion:** LIAISON *Mycoplasma pneumoniae* IgG and IgM, the first fully-automated assay, showed a good concordance with MEDAC and Savyon assays.

## STD and other infections in women

#### **P1002** Prevalence of *Streptococcus agalactiae* colonisation in pregnant women and antimicrobial resistance profiles

E. Prifti, A. Papanagioutou\*, Th. Kyriakopoulos, S. Vlachos, S. Lianos, E. Metzidakis, P. Tsetsa, D. Apostolou, K. Tzanetou (Athens, GR)

**Background:** Group B Streptococcus (GBS) is a cause of early neonatal morbidity and mortality. Maternal vaginal colonization with GBS is a risk factor for invasive disease in the first week of newborn life.

**Objectives:** To study the prevalence of vaginal colonization by GBS in pregnant women and to determine the antibiotic susceptibility pattern of the isolates.

**Material and methods:** During a 2 year period from October 2009 through October 2011, 2793 pregnant women attending the department of Obstetrics and Gynecology of "Alexandra" Hospital of Athens were examined for GBS colonization as a part of routine culture of vaginal swabs for common bacterial and fungal pathogens. A vaginal swab obtained in Stuart transport medium was cultured onto Columbia CNA blood agar with colistin and nalidixic acid for Streptococcus isolation. A rapid latex agglutination test was performed for identification of Lancefield A, B, C, D, F and G group antigens of streptococci. Antibiotic susceptibility testing was performed by disc diffusion technique on Mueller-Hinton agar with 5% sheep blood according to CLSI recommendations and MICs were determined by Etest (AB Biodisk, Solna, Sweden).

**Results:** During the study period 93 (3.33%) out of 2793 pregnant women were found positive for GBS. Susceptibility testing of 93 isolates to penicillin, ampicillin, erythromycin, clindamycin, tetracycline, levofloxacin, vancomycin and linezolid showed the following resistance rates: 0% (MICs of 0.094–0.12 µg/mL), 0% (MICs of 0.023–0.032 µg/mL), 26.88% (MICs >256 µg/mL), 19.36% (MICs >256 µg/mL), 92.48% (MICs of 8–12 µg/mL), 3.23% (MICs of 12–24 µg/mL), 0% (MICs of 0.75–1 µg/mL), and 0% (MICs of 0.75–1.5 µg/mL) respectively. The susceptible isolates to penicillin can be considered susceptible to all beta-lactams (cefazolin cephalothin, cefuroxime, ceftriaxone, cefotaxime, cefepime, imipenem) according to CLSI guidelines. Inducible clindamycin resistance was not detected by D-test.

**Conclusions:** (i) The prevalence of GBS in pregnant women of our study is low. (ii) Penicillin or ampicillin remain the drugs of choice for intrapartum antibiotic prophylaxis as isolates with increasing MICs to both agents were not detected. (iii) Clindamycin, the drug of choice for penicillin-allergic women at high risk for anaphylaxis, demonstrates a significant resistance rate. (d) GBS show an unusually very high resistance rate to tetracycline.

**P1003** Epidemiological survey of *Streptococcus agalactiae* isolates from university clinics, Budapest, Hungary

S. Kardos\*, K. Kristóf, E. Ostorházi, K. Nagy, O. Dobay (Budapest, HU)

**Objectives:** *Streptococcus agalactiae* (GBS) remains the leading cause of serious neonatal infections, but can also cause diseases in adults. The aim of the present study was to perform an epidemiological survey of GBS isolates in Hungary. The actuality of the topic is emphasized by the fact that obligatory screening of pregnant women was introduced this year in the country.

**Methods:** Two hundred and ninety-two GBS strains, isolated at the Central Diagnostic Laboratory and the Dermatology Department of Semmelweis University, between March 2009 and May 2011, were involved in the study. PCR was used to detect the *dlrR* gene for strain identity and to determine the prevalence of the ST-17 clone. To distinguish serotypes I, II and III, the Pastorex latex agglutination test was used. Antibiotic sensitivity was determined by disc diffusion.

**Results:** 57.2% of the strains derived from the Obstetric and Gynaecology Clinics, 20.2% from Dermatology, 8.2% from Urology, 5.8% from Surgery, 4.5% from Internal Medicine, and 4.1% from others (e.g. Orthopedics). The types of specimen were as follows: 49.3% female genitals (cervix, vagina), 16.1% newborn colonisation (ear, nose, anus), 12.0% urine, 9.9% male genitals, 9.3% skin, wound or abscess, 1.7% haemoculture and 1.7% respiratory tract. The serotype distribution was: type III (49.7%), type I (23.0%), type II (4.8%), and non-I-II-III (22.6%). Half of the type I strains derived from the Obstetric Clinics. One third (30.1%) of the isolates belonged to the hypervirulent ST-17 clone, and 2/3 of these derived also from the Obstetric Clinics, in many cases from newborn colonisation. Most of the strains were sensitive to both erythromycin and clindamycin, 33% resistant to both, and three strains showed only clindamycin resistance. In five cases we could link the specimens of the newborn and the mother. These isolates were genetically identical, macrolide resistant (ermB+), and three of the pairs were ST17+ (type III).

**Conclusions:** Although serotype III was most prevalent, especially in asymptomatic colonisation, but a higher variation of types among the different specimens was observed, compared to previous data from Hungary. The high prevalence of the ST17 clone in Hungary, which can lead to development of invasive neonatal infections, support the necessity of regular screening during pregnancy. Furthermore, a relative high proportion of adult infections was observed, indicating the increasing pathogenic significance of this bacterium.

**P1004** Susceptibility of vaginal group B *Streptococcus* isolates to penicillin and erythromycin

I. Hadji-Petrusheva Meloska\*, B. Curcic Trajkovska, B. Jaglikovski, A. Hadji-Petrusheva Jankijevic (Skopje, MK)

**Objectives:** Group B *Streptococcus* (GBS) is capable of causing invasive infections in neonates and pregnant women. Antibiotic intrapartum prophylaxis with penicillin G, or macrolides in allergic patients is mandatory. However, lately erythromycin resistance rates are increasing, leading to severe complications in newborns.

**Aim:** To study the vaginal GBS for susceptibility to antimicrobials including those recommended for prophylaxis.

**Methods:** A total of 50 vaginal GBS isolates from pregnant patients in Skopje were analyzed. Isolation and identification were performed with

conventional microbiology techniques. Mueller Hinton agar with 5% defibrinated sheep blood was used for antimicrobial susceptibility testing to erythromycin (E), azithromycin (AZM), clarithromycin (CLR), penicillin (P), clindamycin (CL), and co-trimoxazole (SXT). Broth dilution technique and M.I.C Evaluator (M.I.C.E.) Strips (Oxoid, UK) were used to determine erythromycin and penicillin MICs and MBCs.

**Results:** Disc diffusion technique revealed resistance of CL and SXT in 19.7% and 100.0% of the strains, respectively. Macrolides showed similar susceptibility, i.e. 16.7% and 13.3% strains were resistant to AZM and CLR, respectively. ERY resistant were 12 (24%) strains with MIC >8 mg/L and MBC ≥16 mg/L. The majority of the GBS strains, 37 (74%) had ERY MIC ≤1 mg/L out of which 27 had MBC 4–8 mg/L; the remaining 10 strains showed tolerance towards ERY (MIC = 1 mg/L and MBC = 16 mg/L). All 50 GBS isolates were susceptible to penicillin MIC ≤0.03 mg/L. There was no significant difference in results between the data obtained by conventional broth dilution and commercial MIC Evaluator.

**Conclusion:** Our study shows that erythromycin resistance is rather high in our environment and antibiotic prophylaxis must be guided by susceptibility testing of each GBS isolate, where commercial methods are both reliable and time efficient.

**P1005** Symptomatic and asymptomatic infections of the lower genital tract in pregnant and non-pregnant women of reproductive age

A. Papanagiotou\*, N. Terzi, S. Vlachos, E. Prifti, E. Metzidaki, A. Avlonitou, D. Chaidopoulos, D. Apostolou, K. Tzanetou (Athens, GR)

**Objectives:** To investigate the prevalence of bacterial and fungal pathogens in pregnant and non pregnant women of reproductive age over a 2-year period.

**Materials and methods:** Between October 2009 and October 2011, 8403 pregnant and non-pregnant women aged 16–42 years attending the department of Obstetrics and Gynecology of “Alexandra” Hospital of Athens were tested for bacterial and fungal pathogens of the lower genital tract. Combined cervical and vaginal or vaginal and urethral swabs were obtained from non-pregnant and pregnant women respectively. The specimens were cultured onto chocolate agar, chromogenic sabouraud dextrose agar, Columbia CNA blood agar with colistin and nalidixic acid and A7 Mycoplasma agar. *Chlamydia trachomatis* were detected in cervical or urethral specimens by immunofluorescence assay. Vaginal swabs were used for wet mount microscopy (detection of yeasts, *Trichomonas vaginalis*, polymorphonuclear leucocytes, clue cells) and preparation of Gram stain. Bacterial vaginosis (BV) was diagnosed based on at least three Amsel criteria and Nugent scoring system.

**Results:** Pathogens were identified in 2282 (40.68%) out of 5610 non-pregnant and 1039 (37.20%) out of 2793 pregnant women examined. The frequency of *Candida albicans*, non-*C. albicans*, BV, group B *Streptococcus* (GBS), group A *Streptococcus* (GAS), *Chlamydia*, *M. hominis*, *U. urealyticum*, *T. vaginalis*, and mixed infection (more than one pathogen) was 29.14%, 17.88%, 16.87%, 10.08%, 0.44%, 8.28%, 0.22%, 3.47%, 1.70%, 11.92% in non-pregnant and 41.48%, 24.54%, 7.80%, 8.95%, 0%, 1.64%, 0%, 3.95%, 1.73%, 9.91% in pregnant women respectively. *Neisseria gonorrhoeae* was not detected in any specimen. Leukocytes were detected in 33.17% of non-pregnant and in 31.18% of pregnant women found positive for pathogens. For a total number of non-pregnant (5610) and pregnant women (2793) studied, the prevalence of GBS was 4.09% and 3.33% respectively. Statistical analysis by chi squared test showed statistically significant: (i) higher frequency of BV and *Chlamydia* infection in non-pregnant and (ii) higher rate of *Candida* infection in pregnant women.

**Conclusions:** *Candida* spp is the most common pathogen in both groups with higher infection rate in pregnant women. The frequency of BV and *Chlamydia* infection is higher in non-pregnant than in pregnant women, whereas there is no statistically significant difference in GBS prevalence among the two groups.

**P1006** Increased quinolone-resistant *Ureaplasma urealyticum* and *Mycoplasma hominis* isolated in reproductive-age women with vulvovaginitis

S. Baka, I. Tsirmpa, I. Tsouma, E. Logothetis, E. Kouskouni\* (Athens, GR)

**Objectives:** *Ureaplasma urealyticum* (Uu) and *Mycoplasma hominis* (Mh) are members of a unique group of microorganisms commonly found in the genital system of reproductive age women. However, these mycoplasmas have been associated with a plethora of genital tract infections with different clinical manifestations. We aimed to study the prevalence and the susceptibility to antibiotics of Uu and Mh isolated from the vaginal secretions in a group of reproductive age women with vulvovaginitis.

**Methods:** Vaginal samples from 3702 symptomatic women of reproductive age, presenting with signs and symptoms of vulvovaginitis to the Outpatient Clinic of Aretaieion University Hospital from January 2007 to October 2011, were studied. For the isolation and susceptibility testing of both mycoplasmas the commercial kit Mycoplasma IST2 (BioMerieux, France) was used. After inoculation onto the respective nutrient medium, the samples were incubated at 36–37°C for 48 hour in aerobic conditions.

**Results:** Out of the 3702 samples Uu was isolated in 769 (20.8%) samples while Mh in 70 (1.9%), always in association with Uu. Only concentrations of  $>10^4$  CFU/mL at 48 hour were included as positive samples in the study. As for the susceptibility testing to antibiotics, we considered both resistance and intermediate susceptibility as resistance and the data is presented as such. In the isolates studied, doxycycline and tetracycline displayed the lowest percentages of resistance (1.0% and 3.0%, respectively). Among the macrolides, the same percentages for clarithromycin, azithromycin and erythromycin were 12.2%, 17.6% and 18.1%, respectively. In contrast, the genital mycoplasmas tested showed decreased susceptibility to quinolones. Specifically, 86.1% and 53.7% of the mycoplasmas were resistant to ciprofloxacin and ofloxacin.

**Conclusions:** The isolates studied were highly resistant to quinolones, due to the increased and irrational use in the last years. As a result, it is imperative to stop the empirical treatment of genital mycoplasmas and clinicians must adjust the therapeutic approach to the results of the in vitro susceptibility testing.

**P1007** Vaginal microflora in postpartum females after vaginal delivery

A. Savicheva\*, Z. Martikainen, Z. Kolesayeva, M. Tarasova, M. Bashmakova (St. Petersburg, RU)

**Objectives:** In postpartum period, the composition of vaginal microflora changes due to wash-out of microorganisms with amniotic fluid and blood, traumatizing the birth channel, contamination of the vagina with intestinal microflora. These changes are temporary, and gradually the vagina is populated with bacterial species characteristic for this ecological niche. Timely restoration of normal vaginal microbiota is necessary for successful postpartum period. The study aimed to assess the duration of the period after vaginal delivery during which vaginal microflora is restored.

**Methods:** Cultural investigations of lochia from 43 postpartum females who had vaginal delivery were performed on days 1, 3, 5, and 15 postpartum.

**Results:** On day 1, in 23.2% of the females no microorganisms were isolated. By day 5, different bacterial communities were detected in most subjects (93.0%), due to intense migration of microorganisms from the anogenital area to the vagina. On days 1–5, enterococci, bacteria of the family Enterobacteriaceae, epidermal staphylococci, and non-fragilis Bacteroides were present in 27.9–37.2%, 34.9–44.2%, 27.9–51.6%, and 44.2–60.5% of the females, respectively. The frequency of detection of corynebacteria from lochia in the puerperas during the period from day 1 to day 5 increased three-fold. Yeasts were

isolated rarely (in 4.6–7.0% of the females). Lactobacilli on days 1–5 were detected in 7.0–11.6% of the females. By day 15, lactobacilli were present in the majority of the subjects.

**Conclusion:** Vaginal microbiota on the first days after delivery is characterized by predominance of anaerobic microorganisms belonging to the genus Bacteroides (non-fragilis Bacteroides). Complete restoration of normal vaginal microflora (predominance of lactobacilli) occurs in two weeks after delivery.

**P1008** Microbiological features of vulvovaginitis in prepubertal age

A. Papanagiotou\*, S. Vlachos, A. Charalabopoulou, E. Prifti, A. Avlonitou, L. Michala, D. Apostolou, K. Tzanetou (Athens, GR)

**Background:** The aetiology of most cases of vulvovaginitis in prepubertal age is not specific. However in some girls the symptoms are caused by specific bacterial or fungal pathogens.

**Objectives:** To evaluate the prevalence of various pathogens involved in the pathology of vulvovaginitis in girls of prepubertal age over a 2-year period.

**Materials and methods:** Three hundred eighty (380) prepubertal girls of age from 1 to 10 years, presenting at the paediatric gynaecology clinic from October 2009 to October 2011 with symptoms and signs of vulvovaginitis (vaginal discharge, erythema or pruritus), were tested for bacterial and fungal pathogens. Swabs of vaginal secretions were obtained and placed in normal saline for wet preparation and in Stuart transport medium for culture. The wet preparation was examined for yeasts, Trichomonas and polymorphonuclear leucocytes. The swab in transport medium was cultured onto chocolate agar for *Haemophilus influenzae* growth, Columbia CNA blood agar with colistin and nalidixic acid for Streptococcus isolation, chromogenic sabouraud dextrose agar for *Candida* isolation and species identification and MacConkey agar for isolation and differentiation of Enterobacteriaceae, and non-Enterobacteriaceae. Urea-Arginine broth for specimen collection and A7 Mycoplasma agar for culture of *U. urealyticum* and *M. hominis* were not routinely used. A rapid latex agglutination test was performed for identification of Lancefield A, B, C, D, F and G group antigens of streptococci (SLIDEX® Strepto-Plus, bioMérieux SA Lyon, France).

**Results:** Causative agents were isolated from vaginal secretions in 48 (12.63%) out of the 380 study girls, whereas in 332 (87.37%) girls non-specific pathogens were identified. Of the 48 culture-positive cases, group A streptococcus (*S. pyogenes*), group B streptococcus (*S. agalactiae*), non-*Candida albicans*, *Candida albicans*, *Haemophilus influenzae*, *Escherichia coli*, *Ureaplasma urealyticum* and *S. pyogenes* with non-*C. albicans* (mixed infection) were isolated in 23 (6.05%), 13 (3.42%), 6 (1.58%), 2 (0.53%), 1 (0.26%), 1 (0.26%), 1 (0.26%), and 1 (0.26%), girls respectively.

**Conclusions:** (i) In most cases of vulvovaginitis in prepubertal girls non-specific bacterial or fungal pathogens are identified as causative agents. (ii) The most common infectious cause of vulvovaginitis in prepubertal age is *S. pyogenes* followed by *S. agalactiae* and *Candida* spp.

**P1009** Pathogens implicated in cases of vulvovaginitis in prepubertal and pubertal girls

S. Baka, I. Tsouma, E. Logothetis, E. Kouskouni\* (Athens, GR)

**Objectives:** Vulvovaginitis is recognized as the most common gynecological problem in prepubertal and pubertal girls. However, the clinical significance of the pathogens isolated from the vaginal cultures performed in children can be interpreted only after taking into consideration clinical information and possible risk factors, if any. This study aimed to evaluate the vaginal pathogens isolated in a group of prepubertal (PP) and pubertal (P) girls with vulvovaginitis.

**Methods:** A total of 441 girls aged 2–18 years, presenting at the outpatient clinic for pediatric and adolescent gynecology of our hospital

during January 2008 to June 2011 with signs and symptoms of vulvovaginitis (vaginal redness and discharge and/or itching) were included. Cases were divided into two groups: 198 PP (age 2–11 years) and 243 P (age 12–18 years). Vaginal samples were collected using a sterile newborn suction catheter carefully inserted into the vagina. Samples were inoculated onto blood agar, MacConkey, Mannitol Salt, Sabouraud Dextrose agar, Gardnerella agar and Wilkins-Chalgren agar as well as Thayer-Martin and chocolate agar followed by incubation in aerobic, anaerobic or CO<sub>2</sub> atmosphere at 37°C for 24 or 48 hours, as appropriate. Wet mount and Gram stain preparations were examined to assess the presence of leukocytes and the type of bacteria present. The identification of isolated strains and their susceptibility test to antibiotics were carried out with the API System and the automated system VITEK 2 (BioMérieux, Marcy l'Etoile, France).

**Results:** Bacterial pathogens were isolated from 105/198 (53.0%) of PP girls and 191/243 (78.6%) of P girls. Interestingly, leukocytes were observed only in samples where pathogens were retrieved. Isolated bacteria in the PP and P groups included 21/198 (10.6%) and 143/243 (58.8%) Gardnerella vaginalis and anaerobes, 45/198 (22.7%) and 15/243 (6.2%) Gram-positive cocci, 39/198 (19.7%) and 20/243 (8.2%) Gram-negative rods, respectively. *Candida* species were isolated in 13/243 (5.3%) only in the P group. Finally, in 93/198 (47.0%) in PP group and 52/243 (21.4%) in P group no pathogen was isolated.

**Conclusion:** The presence of leukocytes in vaginal samples increases the likelihood of finding pathogens which require specific treatment. In the PP girls predominantly Gram-positive cocci and Gram-negative rods were isolated while in the P girls, Gardnerella vaginalis and anaerobes. *Candida* species were found only in the P group.

#### **P1010** Asymptotic co-infection of candidiasis and vaginal trichomoniasis among pregnant women in southeastern Nigeria

M. Alo\*, M. Elom (Abakaliki, NG)

**Objective:** Morbidity and mortality rate among pregnant women in rural setting in third world countries are ever increasing. This condition is often caused by infections that may occur at sub-clinical level but may progress to acute clinical condition in the course of pregnancy.

**Methods:** A total of one thousand five hundred (1500) pregnant women of ages between 25 and 40 years, attending antenatal clinic at Federal Medical Centre Abakaliki between March and October 2010 were enlisted for this study. Personal biometric data and trimesters of the gestation were considered. Wet preparation, culture and germ tube test were used to examine high vaginal swab specimen.

**Result:** The result showed that a total of 326 (22%) women had asymptomatic co-infection of *Candida* and trichomonas while 412 (275%) and 355 (24%) women had asymptomatic candidiasis and trichomoniasis as single infection respectively.

**Conclusion:** This study therefore underscores the need to screen pregnant women regularly for candidiasis and trichomoniasis especially considering its public health importance in the transmission of HIV/AIDS and other undesirable pregnancy outcome such as low birth weight and preterm delivery.

#### **P1011** Is bacterial vaginosis associated with cervical (pre)neoplasia in asymptomatic reproductive-age women?

S. Baka, I. Tsouma, E. Politi, A. Kapoula, E. Elefteriou, E. Kouskouni\* (Athens, GR)

**Objectives:** Early detection of cervical cell abnormalities by Papanicolaou (Pap) smear has reduced the risk of cervical cancer development. It has been suggested that other factors besides human papillomavirus (HPV) infection, might be involved in the malignant progression. Cervical inflammation has been proposed as one of the cofactors in cervical carcinogenesis, because disturbance of the vaginal microflora is associated with an increased risk of acquisition of HPV

infection. Bacterial vaginosis, which sometimes can be asymptomatic, is a clinical entity quite common in women all over the world and is characterized by an increased production of N-nitrosamines by Gardnerella vaginalis, which are carcinogenic. We aimed to evaluate a possible association between the presence of *G. vaginalis* in asymptomatic reproductive age women with cervical (pre)neoplasia.

**Methods:** Asymptomatic women with inflammatory changes on routinely performed Pap smear and recalled for cultures in the last year were included in the study. Vaginal and cervical cultures were performed under standard conditions. A wet mount as well as a gram-stained smear were examined under microscope to obtain valuable information about the microorganisms present and to apply Nugent criteria for the diagnosis of bacterial vaginosis.

**Results:** For this preliminary study we included 77 women with bacterial vaginosis and 41 women with negative cultures (normal flora present), who served as controls. In the bacterial vaginosis group cervical cytology was normal in 64 (83.1%) and abnormal in 13 (16.9%) cases. Epithelial cell abnormalities included seven cases of atypical squamous cells of undetermined significance (ASCUS), five cases of low-grade squamous intraepithelial lesions (LGSIL) and one case of high-grade squamous intraepithelial lesions (HSIL). In the controls, normal cervical cytology was present in 38 (92.7%) and abnormal in 3 (7.3%), including two cases of ASCUS and one LGSIL. All patients with epithelial cell abnormalities were referred for colposcopy and managed according to standard practices, while women with bacterial vaginosis were treated with metronidazole

**Conclusions:** The higher prevalence of abnormal cytology in the group of women diagnosed with bacterial vaginosis stresses the need for cervical cytology screening in these patients. Further research on women with bacterial vaginosis is needed to study the causal relationship between *G. vaginalis* infection and cervical (pre)neoplasia.

#### **P1012** Prevalence and antibiotic susceptibility of *Ureaplasma urealyticum* in genital samples between 2007 and 2011

M. Pappné Ábrók\* (Szeged, HU)

**Objectives:** The genital mycoplasmas constitute a group of microorganisms commonly found in the genitourinary tract. The most frequently isolated species among them, *Ureaplasma urealyticum*, is an important opportunistic pathogen, which has been associated with various urogenital and intrauterine infections.

**Methods:** We assayed the positive cultures for *U. urealyticum* detected from vaginal, cervical, male urethral and ejaculatum samples at our Institute from 01. January 2007 to 30. June 2011. For screening, enumeration, identification and antimicrobial susceptibility testing, the Mycoplasma IST 2 kit (bioMérieux) was used. Only samples containing mycoplasmas above the pathological threshold were regarded as positive.

**Results:** During the examined period 1144 specimens were found to be positive for *U. urealyticum*. The vast majority of the strains (1044) were cultured from vaginal samples, while 17, 56 and 27 strains originated from cervical, male urethral and ejaculatum samples, respectively. Because of the routine screening of pregnant women, the number of vaginal specimens was much higher than those of the other types of samples. Altogether, 5677 vaginal specimens from pregnant women were tested for *U. urealyticum*, among which 450 proved to be positive (7.93%). In 19.77, 18.22% and 8.22% of these cases, *U. urealyticum* was detected in co-infection with *Candida* spp., *Streptococcus agalactiae* and *E. coli*, respectively. Antimicrobial susceptibility was tested against doxycycline, josamycin, ofloxacin, erythromycin, tetracycline, ciprofloxacin, azithromycin, clarythromycin, and pristinamycin. Nearly all of the strains cultured proved to be susceptible to doxycycline (99%), tetracycline (98%), josamycin (99%), pristinamycin (99%) and clarythromycin (91%). Eighty-four percent and 68% of the strains were susceptible to azithromycin and erythromycin, respectively. At the same time, only a few strains were susceptible to ofloxacin (26%) and ciprofloxacin (13%); moreover, 51% of the strains proved to be resistant to ciprofloxacin.

**Conclusion:** Our results indicate that only the detection of mycoplasmas in genital samples is not sufficient for successful therapy, and highlight the need for accurate susceptibility tests.

#### P1013 Sexually transmissible infections among young adolescents in Milan areas: a multicentre study

S.G. Rimoldi\*, C. Pagani, V. Giacomel, R. Besana, G. Montrasio, G.V. Zuccotti, M.R. Gismondo (Sacco, Desio, Saronno, IT)

**Objective:** Sexually transmitted infections (STIs) are a major health problem affecting mostly young people, the exact magnitude of STIs is frequently unknown due to lack of country surveillance systems.

Aim of this study was to determine the prevalence of STIs and relative risk factors among and adolescents in Milan areas, Italy.

**Methods:** From May to October 2011, 117 adolescents (63 female, 54%), median age 15 years, attending hospitals from the north-western areas of Milan, Italy, were enrolled. All subjects completed a questionnaire and provided a urine sample, which was tested for *Neisseria gonorrhoea*, *Chlamydia trachomatis*, *Mycoplasma hominis*, *Mycoplasma genitalium*, *Ureaplasma urealyticum/parvum*, *Trichomonas vaginalis*, *Treponema pallidum*, *Streptococcus agalatae*, Haemophilus ducrey, Citomegalovirus (CMV), Herpes Simplex Virus 1 (HSV1) and Lymphogranuloma venereum by a multiplex PCR assay: Seeplex® STI Master ACE Detection (Seegene, Seoul, Korea).

Forty three out of 117 adolescents (36%) were HIV-1 positive, 63% (74/117) were without any underlying infectious disease.

**Results:** Fifty seven (48.7%) out of 117 adolescent were sexually active (SA), 20 out of 57 (35%) had STIs as follow: 24.5% (14 cases) *U. urealyticum/parvum*, 7% (four cases) *C. trachomatis*, 1.7% (one case each) *M. genitalium* and *N. gonorrhoea*.

Thirty-two (56%) out of 57 SA adolescents were HIV-1 positive and infected with *U. urealyticum/parvum* (37.5%, 12 cases) and *C. trachomatis* (6.2% two cases). A single case (3.1%) of mixed infection due to *C. trachomatis*, *N. gonorrhoea* and *U. urealyticum/parvum* was observed.

Six out of 60 (10%) sexually inactive (SI) adolescents resulted positive for *U. urealyticum/parvum* (three cases), *C. trachomatis* (two cases) and *N. gonorrhoea* (one case). Eleven out of 60 were HIV-1 positive and among this group one case of *C. trachomatis* and *U. urealyticum/parvum* infection was reported. For *T. vaginalis*, *T. pallidum*, *S. agalatae*, H.ducrey, CMV, HSV1 and Lymphogranuloma venereum any infection was reported.

**Conclusion:** STIs as expected were higher in SA adolescent than in SI and in HIV-1 positive patients ( $p < 0.025$ ). Twenty-two percent of SA adolescents resulted positive for at least one STIs.

A prevalence of 14.5% (17/117) for *U. urealyticum/parvum*, was detected in the adolescents studied, even if its clinical significance has yet to be assessed. Findings suggest that surveillance and screening programs should be implemented to prevent sequels on this vulnerable population.

#### P1014 Prevalence and risk factors for *Chlamydia trachomatis* infection in adolescents and university women from north Portugal

J. Silva\*, J. Ribeiro, H. Sousa, F. Cerqueira, L. Teixeira, I. Baldaque, T. Osório, R. Medeiros (Porto, PT)

**Objectives:** Worldwide, Chlamydia is a common bacterial sexually transmitted disease (STD) in younger women. Our goal was to characterize *Chlamydia trachomatis* infection status in female students from university and pre-university schools resident in the northern region of Portugal.

**Methods:** Gynaecological samples were obtained from 435 young women (14–30 years) by self-collection using a commercial kit. Demographic, behavioural, and clinical factors were accessed through

an anonymous questionnaire. *C. trachomatis* were detected by Polymerase Chain Reaction (PCR) using CP24/CP27 primers.

**Results:** The results revealed that the median age of participants was 17.0 years; the frequency of sexually active women in the group was of 63.7% ( $n = 277$ ) with a median age of first sexual intercourse of 16.0 years; a median number of years after first sexual intercourse of 2.0 years and 33.9% ( $n = 94$ ) of the sexually active women had two to five sexual partners and 96.4% ( $n = 267$ ) had no STD history. *C. trachomatis* prevalence was 8.7%, among sexually active women. Statistical significant differences were observed when comparing *C. trachomatis* distribution to median age (OR = 4.87;  $p = 0.006$ ), median age of first sexual intercourse (OR = 3.74;  $p = 0.004$ ), education level (OR = 2.90;  $p = 0.011$ ) and Human Papillomavirus vaccination (OR = 0.24;  $p = 0.017$ ) (Table1).

	p	OR	IC95%
<b>Education level</b>			
University vs Pre-university	0.011	2.90	1.24 – 6.813
<b>HPV Vaccination</b>			
Vaccinated vs Non-Vaccinated	0.017	0.24	0.07 – 0.84
<b>Median age</b>			
≤17 vs >17	0.006	4.87	1.42 – 16.81
<b>Median age first menarche</b>			
≤12 vs >12	0.350	1.49	0.64 – 3.46
<b>Median age first sexual intercourse</b>			
≤16 vs >16	0.004	3.74	1.43 – 9.73
<b>Nº Sexual Partners</b>			
1 vs 2-5	0.670	1.21	0.50 – 2.91
<b>Nº years after first sexual intercourse</b>			
≤2 vs >2	0.989	1.01	0.41 – 2.45
<b>Contraception use</b>			
No vs yes	0.251	1.10	1.06 – 1.15
<b>Smoking status</b>			
Smoker vs Non-smoker	0.268	0.50	0.14 – 1.75

p, Significance level; OR, Odds Ratio; CI, Confidence interval.

**Conclusion:** In young Portuguese women, *C. trachomatis* infection is common in asymptomatic women, university students and who initiated sexual activity over the 16. Furthermore, these results revealed that *C. trachomatis* detection can be performed in self-collected samples. The knowledge of *C. trachomatis* profile in young women may be important to appraise better preventive measures within different populations.

#### P1015 Emergence of macrolide resistance for *Mycoplasma genitalium* in France

D. Christment, S. Pereyre, A. Charron, C. Cazanave, C. Bébéar\* (Bordeaux, FR)

**Objectives:** *Mycoplasma genitalium* is a sexually transmitted organism associated with non gonococcal urethritis (NGU) in men and several inflammatory reproductive tract syndromes in women such as cervicitis, pelvic inflammatory disease and infertility. A dose of 1 g of azithromycin is commonly used for NGU and cervicitis treatment but is responsible for 13–33% of treatment failures. Resistance to macrolides has been recently identified in *M. genitalium* in Scandinavia, Australia, New Zealand and Japan and is associated with point mutations in 23S rRNA. Our goal is to identify such a resistance and to determine its prevalence in France.

**Methods:** A retrospective study conducted in France over a period of 8 years (2003–2010) has selected 156 urogenital clinical samples positive for *M. genitalium* from 136 patients. Detection of mutations in the domain V of 23S rRNA of *M. genitalium* was performed by amplification and sequencing. The genotyping of the mutated strains was performed by studying the single nucleotide polymorphisms of the *mgpB* gene directly from specimens and clinical data and treatment of the patients were collected.

**Results:** A substitution in the 23S rRNA was found in 10.6% (13/123) of the patients infected with *M. genitalium*. No mutation was found

before 2006, they have been detected in samples from 2006 at a rate between 10% and 15% of patients per year. Ten mutations at position 2059, two A2058G mutations, mutations A2062T and C2038T were identified in *M. genitalium* (*Escherichia coli* numbering). These patients had treatment failure with azithromycin in 75% (6/8) of cases. For one patient, genotyping showed the selection of a mutation during treatment with azithromycin 1 g.

**Conclusion:** We describe for the first time the emergence of macrolide resistance in *M. genitalium* in France. This resistance seems to have appeared in 2006 and its epidemiological surveillance is needed to adapt the treatment of *M. genitalium* infections, given the high rate of treatment failure with azithromycin 1 g in case of resistance.

**P1016** Prevalence and risk factors associated with *Chlamydia trachomatis*, *Neisseria gonorrhoeae* and *Mycoplasma genitalium* infections in French pregnant women

O. Peuchant, C. Le Roy, C. Desvaux, A. Paris, J. Asselineau, C. Maldonado, G. Chêne, J. Horovitz, D. Dallay, B. de Barbeyrac\*, C. Bébéar (Bordeaux, FR)

**Objectives:** In France, screening for sexually transmitted infections (STIs) is recommended in at-risk populations to the exclusion of pregnant women, for whom screening is performed only if the patient is symptomatic. The objectives of this study were to estimate the prevalence and to identify risk factors of *Chlamydia trachomatis* (CT), *Neisseria gonorrhoeae* (NG) and *Mycoplasma genitalium* (MG) infections in pregnant women consulting at the Bordeaux University Hospital.

**Methods:** Were included in the study pregnant women aged more than 18 years old (yo) for which a vaginal swab was realized during pregnancy follow-up. Patients received a note written information and gave their oral consent. Patients treated within 3 weeks by macrolides or beta-lactams were excluded from the study. Clinical, sexual behavior and sociodemographic patient's characteristics were collected. Real-time PCRs were performed on vaginal swabs by using the Roche Cobas® 4800 CT/NG test for CT and NG detection and an in-house Taqman assay for MG detection.

**Results:** A total of 1070 patients were eligible. Among them, 42 patients refused to participate in the study, one patient did not understand the objectives of the study, 10 patients had antibiotics before and in 12 cases, the vaginal swab was not performed. Of 996 patients included, the prevalence of CT and MG infections were 2.5% (25/996) (95% CI: 1.6–3.7) and 0.8% (8/996) (95% CI: 0.6–1.6), respectively. Increased infection rates were found in patients aged 18–24 year, with 7.9% for CT and 2.4% for MG. No NG infection was found and no dual CT/MG infection was diagnosed. Most infected patients were asymptomatic (81.8%, 27/33), 9.1% were symptomatic of urogenital infection (3/33) and 9.1% were hospitalized for premature rupture of membranes or threatened premature delivery (3/33). CT infection was associated with the following independent risk factors: age  $\leq 24$  year ( $p = 0.001$ ), being single ( $p = 0.01$ ) and having more than five sexual partners in life ( $p = 0.0001$ ). A younger age ( $p = 0.001$ ), a history of abortion ( $p = 0.01$ ) and having first sexual intercourse after 20 years ( $p = 0.01$ ) were associated with MG infection.

**Conclusions:** Our study shows that pregnant women aged 18–24 year, mainly asymptomatic, represent a population at risk of CT infection. A systematic test screening for CT infection for pregnant women aged under 25 year could be recommended.

**P1017** Epidemiology and clinical characteristics of gonorrhoea in northern Denmark region, 2000–2010

L. Oestergaard\*, T. Hoebjerg, M. Dalager-Pedersen, H. Nielsen (Aalborg, DK)

**Introduction:** An increase in the incidence of gonorrhoea has been reported in several European countries, along with a concomitant rise in the level of fluoroquinolone resistance. To ascertain temporal trends in

*Neisseria gonorrhoeae* infections in the North Denmark Region (population 580 000 inhabitants in mixed urban and rural communities), we conducted a population based study from 2000 to 2010.

**Materials and methods:** We reviewed medical records for all incident episodes of microbiologically confirmed *N. gonorrhoeae* infections.

**Results:** A total of 296 incident episodes from 285 patients were included, with the majority of infections observed in men (71%). The majority of patients (275/285 = 96%) had only 1 diagnosed episode of gonorrhoea during the study period, whereas nine patients had two episodes and one patient had three episodes. The annual incidence increased five-fold during the study period, from 2–4 per 100 000 inhabitants in 2000–2007 to 17 per 100 000 inhabitants in 2009. Most infections were acquired in Denmark: 87% for males vs. 98% for females ( $p = 0.003$ ). Median age was 22 years for females and 26 years for males ( $p < 0.0001$ ).

In 10% of male episodes and 23% of female episodes ( $p = 0.004$ ) swabs were performed from anatomical sites according to recommendations from the National Board of Health (NBH), with highest accordance in the latter part of the study period ( $p = 0.02$ ). Swabs from non-genital sites were performed in 15% of males and 34% of females ( $p = 0.001$ ). Follow-up swabs were performed in 60% of male episodes and 78% of female episodes ( $p = 0.003$ ), and were performed according to recommendations from NBH in 51% of male episodes and 36% in female episodes. In 79% of episodes a concurrent chlamydial swab was performed, 18% of these were positive with no gender-difference.

The level of fluoroquinolone resistance fluctuated between 13% and 93%, with the highest level in 2009. No isolates were resistant to ceftriaxone. All episodes of fluoroquinolone resistance were treated with ceftriaxone i.m. or (in two cases of allergy) with gentamicin i.v. We observed no cases of treatment failure, although not all patients returned for follow-up examination.

**Conclusions:** We have described a recent increase in *N. gonorrhoeae* infections in North Denmark Region and an increasing level of fluoroquinolone resistance. Our study highlights the importance of microbiological confirmation, treatment, and follow up of gonorrhoea in accordance with national guidelines.

**P1018** Syphilis – the peak of the iceberg

A. Petrescu, M. Constantin, L. Benea, A. Hristea, I. Niculescu, A. Streinu-Cercel, R. Moroti-Constantinescu\* (Bucharest, RO)

**Background:** Recent epidemiological data show an increased trend of incidence and prevalence for syphilis (S) infection in the general population. *Treponema pallidum* invades the central nervous system early in the course of disease and causes persistent infection in a subset of infected persons. The manifestations of neurosyphilis (NS) can be asymptomatic or symptomatic (acute meningitis, meningovascular S, parietic NS and tabes dorsalis). The incidence of NS is increasing, some reports being of 0.4/100.000 in west European country.

**Objectives:** The aim of this study is to characterize from epidemiological point of view the patients diagnosed with S in the last 4 years in Matei Bals National Institute for Infectious Disease (INBI) – Bucharest, Romania and focused on NS.

**Methods:** This is a retrospective analysis based on reviewing data of patients diagnosed with S in INBI, comparing two consecutive periods: 2008–2009 (I) and 2010–2011 (till 01.10) (II). All patients were serology screened using the Venereal Disease Research Laboratory (VDRL) and confirmed with T pallidum hemagglutination test (TPHA). The staging of the disease was based on clinical presentation: Primary S – painless chancre with/without lymphadenopathy; Secondary S – systemic manifestations (malaise, fever, myalgias, arthralgias, lymphadenopathy) and rash or condylomata lata and patchy alopecia; Tertiary S – neurological or cardiac involvement; Latent S – asymptomatic; NS: asymptomatic or symptomatic with CSF abnormalities (pleocytosis, elevated protein, decreased glucose, and positive VDRL test).

**Results:** In the studied period (2008–2011) the total patients (pts) number was 165, medium age of 31.2 years, 103 males and 62 females. Congenital S – 15 cases (9%); 16 NS cases (9.7%): one meningitis, eight meningovascular S, four general paresis and four latent S. Out of 165, 47 pts (28.5%) were S-HIV-coinfected.

Regarding the two periods, (I) with 93 pts and (II) with 72 pts, there are 2 vs 3 cases for primary S (2 vs 3 cases), 16.2% vs 19.4% secondary S, 8.6% vs 11.1% tertiary S; for latent S 61.6% vs 56.9%; for NS 8.6% vs 11%.

**Conclusions:** In our study there was a high number of latent S reminding the need for S screening especially among HIV infected patients, pregnant women and neonates. There was also a trend of increasing in NS proportion, mostly meningovascular S, so any neuropsychiatric patient or vascular thrombotic neurologic accident and meningitis without a clear etiology should be evaluated for S.

#### P1019 Cost-effectiveness of azithromycin for the treatment of pelvic inflammatory disease in a multi-field hospital in Russia

Y. Belkova\*, S. Ratchina, R. Kozlov (Smolensk, RU)

**Objectives:** Pelvic inflammatory disease (PID) is a major source of gynaecological morbidity, infertility, ectopic pregnancy and abscess formation, which makes it a very important and expensive problem of healthcare system. Azithromycin (AZI) has potent in vitro activity against main PID pathogens. Two randomised controlled trials showed similar overall clinical success rates for AZI as monotherapy or combined with metronidazole (MET) as well as amoxicillin/clavulanic acid (AC) combined with doxycycline (DOX) (97.1% vs. 98.1% vs. 94.6%), whereas the duration of treatment courses was different (7 vs. 12 vs. 21 days) [Bevan C.D. et al. J Int Med Res. 2003]. We aimed to assess the cost-effectiveness of above mentioned treatment strategies in patients with PID hospitalised into a multifield hospital in Russia.

**Methods:** A cost-minimisation model was developed from the perspective of the Russian National Healthcare System as similar efficacy was assumed between comparators. Only direct medical costs were considered. Drug costs (for original ones where possible) were extracted from Pharmindex database (www.pharmindex.ru). The length of hospital stay was calculated to correspond treatment course duration and average one in Russia (14 days). Uncertainty was explored in two-way sensitivity analyses.

**Results:** The respective total healthcare costs per patient are listed in the table. The results were insensitive to drug cost and length of hospital stay changes.

Treatment regimen	Total costs per patient, €	
	Length of hospital stay corresponds treatment course duration	Length of hospital stay corresponds real practice (14 days for AZI+MET, 21 days for AC+DOX)
AZI IV day 1, AZI orally day 2-7	276.78	534.0
AZI IV day 1-2, AZI orally day 3-7	284.3	541.5
AZI IV day 1, AZI orally day 2-7, MET IV day 1, MET orally day 2-12	467.7	541.2
AZI IV day 1-2, AZI orally day 3-7, MET IV day 1-2, MET orally day 3-12	479.6	553.0
AC IV day 1-5, AC orally day 6-21, DOX orally day 1-21	865.8	865.8

Doses: AZI IV – 500 mg QD, AZI orally – 250 mg QD, MET IV – 500 mg TID, MET orally – 500 mg TID, AC IV – 1.2 g TID, AC orally – 625 mg TID, DOX orally – 100 mg BID

**Conclusion:** AZI as monotherapy or with MET is the most cost-effective regimen for the treatment of PID in a multifield hospital in Russia regardless of rout of administration and hospital stay length.

#### P1020 Nonpuerperal breast infection: epidemiology and predictors for recurrences

V. Sakka\*, L. Galani, G. Bakoyannis, A. Antoniadou, M. Souli, S. Athanassia, K. Kiale, C. Tsompalioti, H. Giamarellou (Athens, GR)

**Background:** Nonpuerperal breast infection (NPBI) is an infection arising within 1 cm of the areola in the nonlactating breast. Although a rare entity, due to its recurring nature, often leads to development of mammary duct fistulae, repeated surgical manipulations and disfigurement of the breast. The aim of the study was to evaluate prognostic factors leading to relapses.

**Methods:** All patients with NPBI referred to our Outpatient Clinic, treated and prospectively followed-up, were evaluated. Epidemiological and clinical features were recorded. Cure was defined as normal ultrasound study and clinical presentation, and improvement as only normal clinical presentation, before discontinuation of treatment. Statistical analysis was made by Kaplan–Meier estimator, Cox proportional hazards model and Prentice–Williams–Peterson model.

**Results:** The 149 patients evaluated, had the following characteristics: median age 39 years old (IQR 33, 46), female gender 96.6%, menopause 14.5%, smokers 74.6%, fibrocystic breast disease 10.1%, chronic infection 91.3%, previous surgery 62%, fistulae 54.1%, and median number of mastitis episodes before recruitment 3 (IQR 2, 5). Twenty-nine patients were excluded from further evaluation due to failure of first treatment or lost to follow up. Most common pathogens were coagulase-negative staphylococci (15.8%), *Proteus mirabilis* (12.5%), *S. aureus* (7.5%), and anaerobes (4.2%).

Amox/clav, moxifloxacin, clindamycin, cotrimoxazole, ciprofloxacin or metronidazole alone or in combination were mostly used for a median duration of 8 weeks. Cure was reported in 104 (86.7%) patients and improvement in 16 (13.3%). Median time until relapse was 1.43 (0.82–3.93) years. When only the first relapse was considered, cure as a result was protective (HR 0.406 95%CI: 0.203–0.811 p = 0.011), whereas the presence of fistula was associated with a significantly increased rate of relapse (HR 1.804 95%CI: 1.055–3.86 p = 0.031). When all relapses were considered cure as a result remained significantly protective (HR 0.44 95%CI: 0.240–0.810 p = 0.008) whereas the presence of fistula was no longer a significant factor (HR 1.48 95%CI: 0.999–2.192 p = 0.051). Surgical intervention didn't protect from recurrences (HR 1.116, p = 0.614).

**Conclusions:** The presence of fistula was associated with a higher relapse incidence. Sonographic evaluation is mandatory, since confirming cure was proved to be a major protective factor.

## Vaccines

#### P1021 Evaluation of immune responses against fused p24 and gp41 genes of human immunodeficiency virus type 1 by using two recombinant vectors as a vaccine candidate

F. Roodbari\*, F. Mahboudi, F. Sabahi, R. Edalat, O.R. Alaei (Babolsar, Tehran, Sari, IR)

**Objective:** To date, 60 millions persons have been infected with HIV-1 from which 22 millions have lost their lives due to AIDS. Therapeutic expenses for an AIDS infected patient are about \$20 000 per year. Antiretroviral medications can not completely destroy the virus, and in addition, they cause the appearance of mutant variants. An effective vaccine represents the best hope to curtail the HIV epidemic. It is now widely believed that an HIV vaccine strategy must both a strategy humoral and as well as cell-mediate immune response. DNA vaccine induce conformational – dependent humoral and cellular responses and mimic live vaccines without their pathogenic potential.

**Methods:** In this study, two recombinant plasmids, pcDNA3.1/Hygro (lacking the signal sequence) and pSecTag2/HygroA (with signal sequence), containing immunogenic sequences of p24-gp41 were produced and the expression of p24 and gp41 proteins was confirmed by immunofluorescence techniques. Induction of effective immune responses against the designed vectors as DNA vaccine candidate in Balb/C mice was evaluated. Levels of total antibodies, IgG isotypes (IgG2a and IgG1); IFN-gamma and IL4 were measured by ELISA. MTT assay was used to evaluate the lymphoproliferative activity of lymphocytes.

**Results:** Analysis of results of experiments showed that suitable immune responses can be induced against both vaccines. However, a

significant difference was observed in total antibody and IL4 production in the vector containing signal sequence.

**Conclusions:** The use of pSecTag2/HygroA vector seems to be more suitable in future research. More research needs to follow up to confirm this.

**P1022 Immune response after booster vaccination in HIV-infected patients who had previously received primary rabies immunisation**

S. Sibunruang\*, W. Jaijaroenup, P. Khawplod, A. Sawangvaree, K. Bootdee, U. Banjongkasaena Na Ayuthaya, T. Tantawichien (Bangkok, TH)

**Objective:** Current WHO recommended pre- and post exposure rabies immunizations have been reported not be able to induce adequate immune response in HIV-infected individuals with low CD4+ T lymphocytes, remained the controversial issue for rabies prophylaxis in these vulnerable people. So the principle of priming immunity which thereafter booster injection induced accelerated potential immune response was applied to our prospective study in order to evaluate the immunogenicity after rabies booster strategy in HIV-infected patients.

**Method:** HIV-infected adults who were identified either prior primary rabies immunized with cell-culture rabies vaccines or ever had rabies neutralizing antibody (RNab) titers >0.5 IU/mL received simulated intramuscular post-exposure rabies booster vaccination with purified Vero cell rabies vaccines on day 0 and 3. Serum samples were taken on day 0, 7, 14 and 28 for serological analysis of RNab by the rapid fluorescent focus inhibition test (RFFIT). CD4+ counts were determined before vaccination.

**Results:** Total 29 HIV-infected adults enrolled (median age 43 years, range 20–56 years). 96.5% were receiving highly active antiretroviral therapy (HAART) with median CD4+ count was 460 cell/mm<sup>3</sup> (range 94–913 cell/mm<sup>3</sup>). Average duration from primary rabies vaccination to this study was 3.6 years (range 2 months–17 years), 62.0% of participants had longevity persistence of acceptable RNab level. After booster injection, all except one recipient who had CD4+ count <100 cell/mm<sup>3</sup> elicited rapid satisfactory anamnestic response by day 7 with at least protective antibody threshold was reached. Patients whose CD4+ count >500 and 200–500 cell/mm<sup>3</sup> had statistically significant higher GMTs on day 7 than patients whose CD4+ count <200 cell/mm<sup>3</sup>. An AIDS patient who previously failed to seroconvert could evoke the immunologic memory response after quantitative CD4+ count recovery. No serious adverse reaction among all subjects.

	GMTs of RNab titers (IU/ml) on days (range)			
	Day 0	Day 7	Day 14	Day 28
CD4+ > 500 cell/mm <sup>3</sup> (n = 13)	1.99 (0.09-183.4)	11.75 (1.24-239.4)	23.34 (1.83-369.21)	36.57 (8.05-297.3)
CD4+ 200 - 500 cell/mm <sup>3</sup> (n = 13)	1.48 (0.17-29.54)	7.72 (1.31-41.77)	22.09 (3.83-219.53)	13.34 (0.71-1354.2)
CD4+ < 200 cell/mm <sup>3</sup> (n = 3)	0.35 (0.16-0.96)	0.75 (0.68-0.81)	9.55 (0.88-54.04)	5.21 (0.96-17.56)

**Conclusion:** Booster rabies vaccination in HIV-infected patients was immunogenic and safe thus its advantages of omitting Rabies Immunoglobulin demand and shortening the vaccination course after subsequent exposure could be beneficial in developing countries where rabies and HIV infection were coexistent. However, particular concern still was needed among severe immunodeficiency subjects (CD4+ counts <100 cell/mm<sup>3</sup>) by which HAART-induced immune reconstitution might be a resolving option. ClinicalTrials.gov identifier: NCT01286493

**P1023 Varicella vaccination in HIV-1-infected children after immune reconstitution**

K. Peter\* (Kampala, UG)

**Background:** HIV-1-infected children have an increased risk of severe chickenpox. However, vaccination is not recommended in severely immunocompromised children.

**Objective:** Can the live-attenuated varicella zoster virus (VZV) Oka strain be safely and effectively given to HIV-1-infected children despite previously low CD4 T-cell counts?

**Methods:** VZV vaccine was administered twice to 15 VZV-seronegative HIV-1-infected children when total lymphocyte counts were >700 lymphocytes/μl, and six HIV-negative VZV-seronegative siblings. Weekly clinical follow-up and sampling were performed.

**Results:** None of the children developed any clinical symptom or serious adverse reaction after immunization. Only nine (60%) of the HIV-1-infected children had VZV-specific antibodies after two immunizations, whereas 100% of the siblings seroconverted. Age at baseline was negatively correlated with the VZV IgG titre at 6 weeks after the second vaccination in HIV-1-infected children. VZV-specific antibody titres after two immunizations were at a similar level to those found after wild-type infection in non-vaccinated HIV-1-infected patients, but significantly lower than in HIV-negative siblings. Importantly, VZV-specific T-cell responses increased after vaccination and were comparable in both groups over time. Documented wild-type VZV contact in three vaccinated patients did not result in breakthrough infections.

**Conclusion:** VZV vaccination of previously immunocompromised HIV-1-infected children was safe. Vaccination induced specific immune responses in some of the vaccinated HIV-1-infected children, suggesting that previously immunocompromised individuals are protected against severe forms of varicella.

**P1024 A new chromatographically purified Vero cell rabies vaccine: results of a comparative trial with purified Vero cell rabies vaccine in intradermal post-exposure treatment**

T. Tantawichien\*, S. Sibunruang, T. Tantawichien, K. Limsuwan (Bangkok, TH)

The Thai Red Cross intradermal (TRC-ID) regimen with purified Vero cell vaccine (PVRV) for rabies post-exposure treatment (PET) has been proven to be immunogenic, effective and safe. It represents a significant saving in vaccine cost in several developing countries. The chromatographically purified Vero cell rabies vaccine (CPRV), produced by Sanofi Pasteur, was assessed in many post-exposure clinical trials for the immunogenicity and safety profile. However, this vaccine was never commercially sold in the market. The new CPRV is obtained by rabies virus infection of a continuous Vero-cell line propagated on microcar-

Rabies vaccination with TRC-ID	GMTs of rabies Nab titers (IU/ml) on days (range)				
	D0	D7	D14	D28	D90
Group A: new CPRV/without ERIG (n=30)	negative	<0.5	12.69 (2.18-49.35)	6.03 (1.35-33.42)	6.95* (2.00-22.63)
Group B: PVRV/without ERIG (n=31)	negative	<0.5	8.97 (1.09-28.10)	4.58 (1.61-13.45)	2.73 (0.50-8.72)
Group C: new CPRV/with ERIG (n=33)	negative	<0.5	9.98** (1.14-69.79)	6.95** (0.74-49.35)	2.84** (1.09-20.75)
Group D: PVRV/with ERIG (n=20)	negative	<0.5	4.36 (0.62-19.87)	2.67 (0.40-16.00)	1.18 (0.35-7.34)

\*p < .05, Gr. A VS gr. B

\*\*p < .05, Gr. C VS gr. D

riers in bioreactors. This vaccine doesn't contain adjuvant, and is purified by column chromatography. We therefore conduct a prospective study to compare the immunogenicity of new CPRV vs. PVRV in the TRC-ID regimen with or without rabies immunoglobulin (RIG).

**Methods:** In the first stage, 70 healthy veterinary students were randomized and received two 0.1-mL intradermal doses of either new CPRV (SPEEDA<sup>®</sup>, Liaoning Cheng Da Biotechnology, China; Lot no. 200904012-3; antigenicity 6.4 IU/vial: gr. A) or PVRV (VERORAB<sup>®</sup>, Sanofi Pasteur, Lyon, France; Lot no. D0998; antigenicity 10.6 IU/vial: gr. B) on days 0, 3, 7, and 28 in simulated PET. In the second stage, 70 patients with low-risk rabies exposure were enrolled and received two 0.1-mL intradermal doses of either new CPRV (gr. C) or PVRV (gr. D) on days 0, 3, 7, and 28 concurrently with equine RIG. Rabies neutralizing antibody (Nab) was determined by rapid fluorescent focus inhibition test on day 0, 7, 14, 28, and 90 after vaccination. Nab titers of at least 0.5 IU/mL were considered "acceptable" for protection.

**Results:** In both stages of study, post-immunization Nab titers in the new CPRV groups with or without ERIG reached 0.5 IU/mL or greater in all subjects by day 14 and remained above that level through day 90. Geometric mean titers of Nab in subjects receiving new CPRV without ERIG, had no significant difference compared with PVRV group on day 7, 14, and 28 ( $p > 0.05$ ). However, subjects receiving new CPRV with ERIG (gr. C) had significantly higher Nab titers than PVRV group (gr. D) on day 14, 28 and 90 (as Table 1;  $p < 0.05$ ). No serious adverse reactions were detected. However, 23% and 43% of subjects in the new CPRV gr. A and 19% and 55% in the PVRV gr. B experienced pain and itching respectively.

**Conclusion:** The new CPRV is safe and immunogenic when given in TRC-ID regimen for PET.

#### **P1025** Measles immunity and measles vaccine acceptance among healthcare workers in Paris, France

*R. Freund, A. Krivine, V. Prevost, D. Cantin, E. Aslangul, M.-F. Avril, Y. Claessens, F. Rozenberg, A. Casetta, M.-F. Baixench, V. Dumaine, O. Launay, P. Loulergue\* (Paris, FR)*

**Background:** A measles outbreak is ongoing since 2008 in Europe, including France. Unprotected healthcare workers (HCWs) may contract and spread the infection to patients. The objective of this study was to evaluate HCWs' measles immunity and vaccine acceptance in our setting.

**Methods/results:** In a survey-based study conducted in three university hospitals in Paris (France), 353 HCWs were included between April 27, and June 30, 2011. The following data were collected at inclusion: age, hospital unit, occupation, history of measles infection, measles vaccination (number of doses and dates), previous measles serology and acceptance of a measles vaccination in case of seronegativity. Sera were tested for the presence of specific anti-measles IgG and IgM antibodies using the "Captia<sup>®</sup> measles" ELISA assay (Trinity biotech, USA).

The mean age of the participating HCWs was 36 years old (range 18–67) and 280 (79.3%) were women. One hundred and five persons (29.8%) declared a history of measles, and 90 (25.5%) declared never having received a measles vaccination. Among the 353 HCWs included in the study, 324 (91.8%) were immunized against measles (IgG above 90 mIU/mL). The risk factors for being unprotected were age (18–24 years, OR 11.8, 95% CI [2.4–58.4] and 25–34 years, OR 8.4, 95% CI [1.8–38.4] compared >35 years), absence of history of measles and absence of vaccination. The global acceptance rate for a measles vaccination, before knowing their results was 80.8%.

**Conclusions:** In this cohort of HCWs, 8.2% were susceptible to measles, mostly among the youngest (<35 years). Vaccine acceptance against measles was high. Vaccination campaign in healthcare settings should target specifically healthcare students and junior HCWs.

#### **P1026** Antibody profiles in response to vaccination against influenza A virus (H1N1) 2009 measured by a protein microarray

*E. Huijskens\*, J. Reimerink, P. Mulder, J. van Beek, E. de Bruin, G. Rimmelzwaan, J. Rossen, M. Koopmans (Tilburg, Bilthoven, Breda, Rotterdam, NL)*

**Objectives:** The emergence of a new influenza A virus (H1N1) variant in 2009 led to a world-wide vaccination program. In this prospective, longitudinal study we tested if antibody responses induced by a 2009 Influenza A (H1N1) Monovalent MF59-Adjuvanted vaccine (Focetria<sup>®</sup>, Novartis) differ between healthy individuals with or without a history of seasonal influenza vaccination.

**Methods:** We collected three serum samples from 98 subjects; prior to the first vaccination against Influenza A virus (H1N1) 2009, before the second vaccination (three weeks later) and before the vaccination with trivalent seasonal influenza vaccine (5 weeks after the second vaccination). Forty subjects (40.8%) were yearly vaccinated against seasonal influenza virus and 58 subjects were never vaccinated. Antibody titres were determined by a protein microarray containing hemagglutinin 1 (HA1) proteins from a range of recent and historic seasonal H1, H2 and H3 influenza viruses, the A(H1N1) 2009 pandemic influenza virus, and three avian influenza viruses.

**Results:** The median age of the subjects was 49 years (range, 25–66), 64.3% of them were women. Subjects with a history of seasonal vaccination in general had a higher baseline geometric mean titre (GMT) against the various HA antigens than subjects without a seasonal vaccination history. Furthermore, the increase of the HA specific antibodies was less pronounced in the seasonally vaccinated group than in the never vaccinated group. For example, for the antigen H1N1 (2009), the GMT at baseline was 25.25 for the seasonally vaccinated and, 37.86 for the never vaccinated group ( $p 0.096$ ; 95% CI:  $-0.82$  to  $0.06$ ). After the first vaccination the GMT was 241.84 for the seasonally vaccinated and 92.57 for the never vaccinated group ( $p 0.001$ ; 95% CI:  $0.41$ – $1.55$ ). After the second vaccination, the GMT was 215.75 for the seasonally vaccinated and 138.29 for the never vaccinated group ( $p 0.056$ ; 95% CI:  $-0.01$  to  $0.98$ ).

**Conclusion:** A history of seasonal influenza vaccination diminished the antibody response against the various HA antigens elicited by vaccination against H1N1 (2009). More research is needed to better understand the immune responses after vaccination in subjects with a history of seasonal vaccination.

#### **P1027** Comparison of the side effects seen after rabies postexposure prophylaxis with two different verocell vaccines

*T. Sari, N. Tulek, F. Temocin, F.S. Erdinc, C. Bulut, G. Tuncer Ertem\*, B. Oral (Ankara, TR)*

**Objective:** In our country, rabies prophylaxis has been implemented according to the guideline of Turkish Ministry of Health (Either Zagreb regimen with 2-1-1 vaccination protocol alone or Essen regimen with five doses vaccination with rabies immunoglobulin (RIG). Although human rabies cases were apparently declined in recent years, more than a hundred thousand of people have been receiving postexposure prophylaxis per year because of rabies- risk-contact in our country. In this study, the side effects of rabies vaccines were investigated and compared according to the schedules and brand names.

**Methods:** Rabies vaccine applied patients for postexposure prophylaxis at our center in 2010 were included into the study. All patients were followed up to the end of schedule. The adverse events were compared according to the age, gender of the patients, the type of the vaccine and the schedule used.

**Results:** A total of 1685 patients (1089 male, 596 female) were vaccinated. The Essen regimen with equine RIG was applied to 265 patients (15.7%) and Zagreb regimen was applied to 1420 patients (84.3%). A verocell vaccine, Verorab (Sanofi Pasteur) was used in 761 (45.2%) patients and Abhayrab (Indian Immunologicals Ltd.) also a verocell vaccine was used in 924 patients (54.8%). All side effects were higher in female patients. The patients were divided in three groups, according to ages as; the first group 0–15 years, the second 15–60 years and above 60 years. Whereas fever (21.2%), vomiting (2.4%) and coughing (2.1%) were significantly higher in the first group, headache (8.8%) and joint pain (6.7%) were significantly higher in the second group compared to the other two groups ( $p < 0.05$ ). All side effects were more frequent with first doses of each type of vaccine and those were more frequent after the first doses of 2-1-1 regimen. All side effects were higher after Zagreb regimen than Essen ( $p < 0.05$ ). Fever (15.8% vs 10.6%), local pain (6.6% vs 2.6%), headache (7.5% vs 3%), fatigue (10.2% vs 4.5%) and arthralgia (4.9% vs 1.5%) were the most common complaints, respectively. Fever (23.8% vs 4.8%), fatigue (13.6% vs 4.6%), headache (9.7% vs 3.1%), local pain (8.9% vs 2.5%) and arthralgia (6.8% vs 3.1%) were significantly higher with Abhayrab than Verorab, respectively.

**Conclusion:** As a result, each of the vaccines seemed safe but although they are both verocell vaccines, side effects seen may vary according to the product and regimen.

#### **P1028** Mandatory measles vaccination – are healthcare workers really safe?

T. Mrvic\*, M. Petrovec, M. Breskvar, T. Lejko Zupanc, M. Logar (Ljubljana, SI)

**Objectives:** Mandatory vaccination against measles in Slovenia was introduced in 1968 and since 1978, all children should receive two doses of vaccine. Compliance rate is more than 95%. This resulted in eradication of the disease from our country for more than 10 years. In 2010 one case was introduced to Slovenia from Ireland and this year 22 cases were reported; four imported from abroad and 18 secondary transmissions; 5 of them were healthcare workers (HCW). All patients were treated in University medical centre Ljubljana (3 hospitalized, 19 ambulatory). Because measles pose a risk of epidemic, we tried to establish if our HCW are really protected against the disease.

**Methods:** From June to October 2011 we conducted a survey among HCW employed in University medical centre Ljubljana regarding protection against measles. HCW born before 1960 were excluded. We demanded from HCW written proof of vaccination or having the measles. If they did not provide that, we performed serologic testing.

**Results:** Data from 3424 HCW were collected. Only 1609 (47%) employees provided a written record about vaccination; 608 (38%) received two doses, and 68 (2%) had the disease. For 1747 (51%) no data were available. In this group serologic testing determining IgG measles antibodies was performed using ELISA. One thousand four hundred and seven (80%) had positive IgG and 340 (19%) had IgG under the positive reference value; 131 (7%) were completely negative. Also 49 HCW with written record of two-dose vaccination against measles in childhood were tested. Interestingly, only 31 (63%) had adequate IgG levels. Five (10%) were completely negative. Analysis of 172 serological negative HCW according to their birth year showed, that 10 (5%) were born before measles vaccination was introduced to Slovenia, 110 (64%) were born between 1968 and 1977 when some children received only one dose and 52 (30%) were born after 1978 when all children should have received two doses of measles vaccine.

**Conclusions:** Our serologic data represent one of the largest epidemiologic studies about protection of HCW against measles. It shows that in spite of mandatory vaccination in Slovenia for the last 40 years, HCW are not protected enough. There is clearly evidence that too many of them did not receive two mandatory doses of vaccine. Among fully vaccinated we found 10% with negative measles IgG antibodies and further 26% with IgG under the positive reference value.

It is questionable, whether they are really protected when in contact with measles.

#### **P1029** Serotype distribution among bacteraemic pneumococcal pneumonia in adults in Germany

M. van der Linden\*, M. Imöhl (Aachen, DE)

**Objectives:** *Streptococcus pneumoniae* remains a leading cause of pneumonia, sepsis and meningitis and disproportionately affects young children and the elderly. In July 2006, vaccination with pneumococcal conjugate vaccine was generally recommended by the German Health authorities for all children up to the age of 24 months. In this study, we present the serotype distribution among adults with bacteraemic pneumococcal pneumonia before and after the start of childhood vaccination.

**Methods:** The National Reference Center for Streptococci has monitored the epidemiology of invasive pneumococcal disease (IPD) in adults in Germany since 1992. Cases of IPD in adults are reported by a laboratory-based surveillance system, including 265 laboratories throughout Germany. The present analyses include only bacteraemic pneumococcal pneumonia cases documented between 2002 and 2011. Species confirmation was done by optochin testing and bile solubility testing. All isolates were serotyped using the Neufeld Quellung reaction.

**Results:** In the first pneumococcal season following recommendation, 2006–2007, the most prevalent serotypes among bacteraemic pneumococcal pneumonia in adults were serotypes 14 (19.1%), 3 (10.9%), 1 (8.6%), 7F (6.7%) and 9V (6.5%). In the most recent season, 2010–2011, serotypes 3 (14.9%), 7F (13.9%), 19A (13.1%), 1 (11.4%) and 22F (8.4%) were most prevalent. The serotypes 1, 3, 4, 5, 6A, 6B, 7F, 9V, 14, 18C, 19F, 19A and 23F, covered by PCV13, caused 66.3% of all bacteraemic pneumonia cases in 2010–2011.

**Conclusions:** The burden of pneumococcal pneumonia among German adults is considerably high. The most prevalent serotypes have changed following recommendation of childhood vaccination and are currently serotypes 3, 7F, 19A, 1 and 22F.

#### **P1030** Incidence of invasive pneumococcal disease in adults

A. Agulla\*, G. Bou, B. Regueiro, M. García-Campello, X. Torres, P. Alonso, G. Esteban, P. Alonso, I. Rodríguez, E. Prieto, P. Romero, A. Malvar (Ferrol, A Coruña, Santiago, Pontevedra, Vigo, Lugo, Ourense, Monforte, Burela, Barco de Valdeorras, ES)

**Objectives:** Vaccination with the 23-valent polysaccharide pneumococcal vaccine (PPV23) was implemented in Galicia (in the Northwest of Spain) in adults aged  $\geq 65$  years from year 2000 on, with vaccine coverage reaching around 60% the first year and approximately 20% of new targeted population (those reaching 65 years of age) and 5% of previously unvaccinated targeted population vaccinated per year in the following years. This study analyses evolution of invasive pneumococcal disease (IPD) pre- and post-PPV23 vaccination.

**Methods:** IPD incidence was calculated using data (1998–2009) on isolation of *S. pneumoniae* from blood and cerebrospinal fluid (CSF) at clinical laboratories of the Sistema Gallego de Saúde and population data from the annual census of inhabitants. Incidence was aggregated by triennial periods and expressed as cases/100000 inhabitants per year. The relative risk for the last period (RR) was estimated from changes in incidence between the first and last triennia. Isolates from last triennia were serotyped by Quellung and/or dot blot assay at the Spanish

	IPDs (blood & CSF)				Meningitis (CSF only)			
	1998/00	2001/03	2004/06	2007/09	1998/00	2001/03	2004/06	2007/09
45-64 yrs.	6.1	7.3	10.4	11.7	1.3	0.9	0.7	1.1
$\geq 65$ yrs.	19.4	16.1	20.8	26.6	2.3	1.1	1.1	1.7

reference laboratory for pneumococci. Prevalences of serotypes included in PPV23 were determined and 95% confidence intervals were calculated.

**Results:** The table shows per triennia evolution of IPD incidence by age group (45–64 years and ≥65 years) separating cases of meningitis from other IPDs. For IPDs, in the ≥65 years population, after an initial decrease there was an increase (RR = 1.4) while in the 45–64 years population there was a continuous increase (RR = 1.9). For meningitis, in both age groups there were initial decreases, more marked in the ≥65 years group, followed by increases, with final values not reaching those of the first triennia (RR = 0.7 for ≥65 years and RR = 0.8 for the 45–64 years group). In the last triennia 77% (95% CI: 70–84%) of serotypes isolated from the group of ≥65 years, and 87% (95% CI: 80–94%) from the group of 45–64 years were included in the 23v-PPV.

**Conclusion:** The evolution of IPD incidences over the study period and prevalences of serotypes included in PPV23 in the last triennia in both age groups suggests the absence of significant and maintained impact of PPV23 vaccination.

#### **P1031** Serotype distribution of *Streptococcus pneumoniae* isolates from invasive disease in adults aged ≥50 years in Galicia, Spain

S. Mendez\*, A. Agulla, N. Somaza, P. Alvarez, F. Garcia, C. Zuñiga, E. Prieto, P. Romero, I. Paz, F. Pardo, M. Alvarez, F. Vasallo, I. Losada, I. Rodriguez, P. Alonso on behalf of the Study Group for Pneumococcal Disease in Galicia Spain

**Objectives:** To determine serotype distribution and susceptibility of *S. pneumoniae* isolates causing invasive pneumococcal disease (IPD) in adults aged ≥50 years in Galicia, Spain.

**Methods:** A total of 140 isolates (one per IPD) collected in the period January to October 2011 were studied. Isolates were serotyped by latex agglutination and Quellung reaction, and susceptibility to penicillin, erythromycin and levofloxacin was determined by broth microdilution following CLSI recommendations.

**Results:** Of the 140 isolates, 88 (62.9%) came from IPDs in males. Origin of samples was: blood in 126 (90%) cases, cerebrospinal fluid in 6 (4.3%), pleural fluid in 4 (2.9%), and other samples in 4 (2.9%) cases. A total of 30 different serotypes were found, with 71.5% of isolates belonging to seven serotypes: 3 (24.3%), 7F (13.6%), 19A (12.9%), 14 (6.4%), 11A (5.7%), 4 (4.3%) and 6C (4.3%). These seven serotypes represented 69.0% isolates in patients ≥65 years. The table shows by age group distribution of serotypes included in 23v-PPV (23-valent polysaccharide pneumococcal vaccine), in PCV13 (13-valent pneumococcal conjugate vaccine) and of serotypes with ≥4 isolates not included in one or both vaccines.

Penicillin MIC for all isolates was ≤2 µg/mL, only one isolate (serotype 8) was resistant to levofloxacin (MIC ≥8 µg/mL) and 25% isolates were resistant to erythromycin (MIC ≥1 µg/mL), being 40% of them serotype 19A.

	50-64 yrs.	65-74 yrs.	≥75 yrs.	Total
n	24	32	84	140
23v-PPV	20 (83.3)	25 (78.1%)	67 (79.8)	112 (80.0)
PCV13	19 (79.2)	23 (71.9)	52 (61.9)	94 (67.1)
11A <sup>a</sup>	1 (4.2)	1 (3.1)	6 (7.1)	8 (5.7)
6C	1 (4.2)	1 (3.1)	4 (4.8)	6 (4.3)
15A	1 (4.2)	1 (3.1)	2 (2.4)	4 (2.9)

<sup>a</sup>Included in 23v-PPV

**Conclusions:** A total of 82.8% IPDs in adults ≥50 years occurred in patients ≥65 years, with 79.3% cases caused by serotypes included in 23v-PPV, the vaccine currently used in elderly vaccination campaigns. Since 64.7% (75 out of 116) IPDs in adults ≥65 years were caused by serotypes included in PCV13, this new conjugate vaccine, recently approved by European Commission for use in adults, could offer advantages in preventing IPDs in the elderly.

#### **P1032** Effects of childhood vaccination on serotype distribution and coverage of PCV13 among adults in Germany

M. van der Linden\*, M. Imöhl (Aachen, DE)

**Objectives:** *Streptococcus pneumoniae* remains a leading cause of pneumonia, sepsis and meningitis and disproportionately affects young children and the elderly. The serotype distribution for invasive pneumococcal disease (IPD) among adults has always been different from that among children. In July 2006, vaccination with a pneumococcal conjugate vaccine was generally recommended by the German Health authorities for all children up to the age of 24 months. In this study, we report on the effects of childhood vaccination on the serotype distribution among adults with IPD (herd protection effect) and the implications on the current coverage of adult pneumococcal vaccines.

**Methods:** The National Reference Center for Streptococci has monitored the epidemiology of IPD in adults in Germany since 1992. Cases of IPD in adults are reported by a laboratory-based surveillance system, including 265 laboratories throughout Germany. The present analyses include IPD documented between 1992 and 2011. Species confirmation was done by optochin testing and bile solubility testing. All isolates were serotyped using the Neufeld Quellung reaction.

**Results:** Prior to the introduction of childhood vaccination (1992–2006), the most prevalent serotypes among adults with IPD were 14, 3, 7F, 4, 23F, 1 and 9V. In contrast, serotypes 3, 7F, 19A, 1 and 22F were most prevalent in the most recent season 2010–2011. While in the first period 40–45% of IPD among adults were caused by PCV7 serotypes, these serotypes were less detectable in the following years. In 2010–2011, only 11.8% were PCV7 serotypes indicating a herd protection effect among adults. The serotypes 1, 3, 4, 5, 6A, 6B, 7F, 9V, 14, 18C, 19F, 19A and 23F, covered by PCV13, caused 58.8% of all IPD cases 2010/2011 in Germany.

**Conclusions:** Following the general recommendation for pneumococcal conjugate vaccination, a clear reduction in IPD was observed among children. The reduction of PCV7 serotypes among IPD in adults indicates a herd protection effect.

#### **P1033** Invasive *Streptococcus pneumoniae* isolates between 2008 and 2011 in Hungary: antimicrobial susceptibilities and serotype distribution

T. Tirczka, B. Berta\*, K. Horváth, J. Pászti, Á. Csohán (Budapest, HU)

**Objectives:** At 1st September 2008, a new IPD survey has started in Hungary. In this project, every laboratories were permitted of sending *S. pneumoniae* isolates to the National Center for Epidemiology for serotyping and to determine the antimicrobial susceptibility.

**Methods:** The identity of the isolates was confirmed by optochin sensibility test, bile solubility test and *lytA* PCR. Serotyping was performed by Neufeld's Quellung reaction using antisera according to manufacturers' instructions. Minimal inhibitory concentrations (MICs) of penicillin, ceftriaxon, erythromycin, clindamycin and meropenem were determined by gradient MIC test. The results were interpreted according to the Clinical and Laboratory Standards Institute (CLSI) guidelines.

**Results:** A total number of 649 isolates were evaluated until 1st of October 2011. Only 11 strains of them proved not to be *S. pneumoniae*. Fifty nine percent of the pneumococcal strains isolated from blood, CSF or other normally sterile site and the other 41% derived mainly from middle ear, sputum and nose. Of the 350 non-duplicated invasive pneumococcal isolates 48 were originated from children under age 5 years (Risk group 1, RG1) and 206 from adults older than 50 years (Risk group 2, RG2). Except two nontypeable strains, in the RG1 and in the RG2, 17 different serotypes and 33 different serotypes were recognized, respectively. The most prevalent serotypes in RG1 were 3 (19%), 19A (19%) and 7F (12.5%) and in RG2 were 3 (33%), 14 (6%), 19A (6%) and 19F (6%). Strains showing intermediate susceptibility (MIC 0.12–1 mg/L) to penicillin (PEN) were found in 17%, and high-level resistance (MIC ≥2 mg/L) in 2% of IPD strains. Twenty three percent of the isolates revealed resistance (MICs ≥1 mg/L) to

erythromycin and more than a half of these isolates showed non susceptible phenotype to PEN (MICs  $\geq 0.12$  mg/L).

**Conclusion:** In Hungary the 7-valent pneumococcal conjugate vaccine (PCV7) was released in December 2005. Compared to our earlier findings our results show changes in the distribution of prevalent serotypes over the time before PCV7 introduced. PCV13 was licensed in the summer of 2010 therefore further distribution shift is expected. Continuous monitoring is needed to predict the effect of vaccines and will be essential to the management of pneumococcal disease.

**P1034** Differences in nasal pneumococcal carriage of vaccinated and non-vaccinated children, during the first 2 years of wide-spread PCV uptake in Hungary

A. Tóthpál\*, S. Kardos, K. Nagy, M. van der Linden, O. Dobay (Budapest, HU; Aachen, DE)

**Objectives:** Infections caused by *Streptococcus pneumoniae* often originate from children who carry this bacterium in the nasopharynx. Conjugate vaccines (PCVs) are available for children to prevent not just infections, but also carriage. In Hungary, Prevenar (first PCV7, later PCV13) was inserted into the national vaccination calendar as an optional but recommended and free vaccine in April 2009. The aim of the present study was to observe the effect of PCV vaccination on pneumococcal carriage of children attending DCCs in Hungary.

**Methods:** Nasal specimens were collected from 751 children (aged 3–6 years) from 18 DCCs in different parts of Hungary, from February 2009 to December 2010. Serotyping of the isolated pneumococci was done using antisera and a PCR-based method, antibiotic sensitivity was determined by agar dilution, and the genetic relatedness of the strains was examined by PFGE.

**Results:** Out of 751 children, 281 were carriers (=37.4%), no difference in genders. 18.1% of all children (=136) were vaccinated with PCV7, and 55 of them were carriers. We could determine the serotypes of 232 strains. The most prevalent types among the vaccinated children were: 11A (n = 18), 6B (n = 7) and 19F (n = 6); while among the non-vaccinated ones: 19F (n = 22), 6B (n = 21), 15B (n = 20), 23F (n = 16), 14 (n = 16). The strains (especially the new types, e.g. 11A, 15B, 3) were generally very sensitive to antibiotics, except for macrolides (R = 18%). The close genetic relatedness of the isolates from a given DCC group was obvious by the PFGE results, indicating the intense exchange of bacteria between children.

**Conclusions:** During the examined period the PCV vaccination rate increased, but there were differences between nurseries. The carriage rate was nearly the same in the vaccinated and non-vaccinated population, but there was a clear difference in the serotype distribution. For example, while serotypes 14 and 23F were found almost entirely in the non-vaccinated group, rare types such as 11A or 15B emerged rapidly in the entire population. It seems so that even if only a certain percentage of children within a group is vaccinated, it helps in the elimination of the PCV types. Interestingly 19F and 6B remained frequent. The coverage of PCV13 over the non-vaccinated carriers would be 52.5%, while that of the vaccinated ones only 34.5%. This could be explained with the emergence of the new types, but it indicates the need for newer vaccine composition in Hungary.

**P1035** Serotypes causing invasive pneumococcal disease in young adults prior to the use of new conjugate vaccines

A.N. Horácio\*, J. Diamantino-Miranda, S.I. Aguiar, M. Ramirez, J. Melo-Cristino and the Portuguese Group for the Study of *Streptococcal Infections*

**Objectives:** The 13-valent pneumococcal conjugate vaccine (PCV13) currently used in children was also recently approved by EMA for use in adults aged  $\geq 50$  years old. In this study we evaluated the effect of a high uptake (75%) of PCV7 in children and estimated the potential effect of the most recently licensed conjugate vaccine PCV13 in young adults (18–64 years old).

**Methods:** A total of 425 isolates were recovered from invasive disease in 2008 and 2009: 249 (58.6%) from adults aged 18–49 years and 176 (41.4%) from adults aged 50–64 years. All strains were serotyped and characterized for their antimicrobial susceptibility profiling.

**Results:** Among the 425 isolates, 43 different serotypes were detected. The most frequent, accounting for 51% of all infections, were serotypes 1, 3, 7F, 14 and 19A. While in adults aged 18–49 years, serotype 1 was the most common (21%), in adults aged 50–64 years, serotypes 1 and 3 were equally frequent (14.2%).

PCV7 serotypes accounted for 18.1% of young adults' IPD, which represents a marked decline from the pre-vaccine period (30.9%,  $p < 0.05$ ). PCV13 serotypes were responsible for 65.6% of all infections. In adults aged 50–64 years, where PCV13 vaccination is approved, 68.2% of all infections could have been prevented with this vaccine.

Although PCV7 serotypes were detected in only a small proportion of isolates, 60.6% of penicillin non-susceptibility (PNS) and 43.5% of erythromycin resistance (ER) were caused by these serotypes. Since PCV13 includes serotype 19A, 80.3% of PNS and 77.4% of ER were covered by this vaccine. Among the 30 serotypes not included in any conjugate vaccine, 16 presented isolates resistant to some of the antimicrobials tested.

**Conclusion:** Children's high PCV7 uptake resulted in a herd effect in young adults. PCV13 will have the possibility to significantly affect pneumococci responsible for IPD in young adults and may also reduce infections caused by resistant serotypes. PCV13 use in adults may further and more rapidly reduce the infections caused by the serotypes included in this vaccine.

**P1036** Invasive pneumococcal disease in elderly: serotype distribution and antimicrobial resistance before 13-valent conjugate vaccine introduction in Portugal

J. Diamantino-Miranda\*, A.N. Horácio, S.I. Aguiar, M. Ramirez, J. Melo-Cristino and the Portuguese Group for the Study of *Streptococcal Infections*

**Objectives:** Elderly have an increased risk of pneumococcal infections and the 23-valent pneumococcal polysaccharide vaccine (PPV23) is recommended for this age group. We have previously shown that the serotypes covered by the 7-valent pneumococcal conjugate vaccine (PCV7) decreased not only in children but also in adults after the introduction of this vaccine in 2001 in Portugal. However, there was no reduction in penicillin and erythromycin resistance in adults. PCV13 replaced PCV7 in paediatric vaccination in December 2009 and the European Medicines Agency has recently authorized the use of this vaccine also in adults with  $\geq 50$  years of age.

To evaluate the effect in the elderly of the continued use of PCV7 in children and to anticipate the potential benefits of PCV13, we characterized the pneumococcal population right before PCV13 introduction in Portugal.

**Methods:** A total of 399 pneumococcal invasive isolates were recovered from elderly patients ( $\geq 65$  years of age) in 2008–2009 in Portugal. Serotyping and antimicrobial resistance testing were performed. A comparison was done with data from 1999–2003, which we previously considered the pre-vaccination period since no effect of PCV7 was seen in adults.

**Results:** The most frequent serotypes were 3 (15%), 7F (13%), 19A (12%), 14 (10%) and 1 (6%), together accounting for more than half of the infections. It was not seen any effect of PPV23, probably due to low uptake of this vaccine. However, there was a decrease in the PCV7-serotypes (30–20%), confirming that the herd effect continued to occur. It was also seen an increase of the non-PCV7 serotypes 7F and 19A. Serotype 1 was the most prevalent in invasive infections of children  $\geq 2$  years and adults 18–64 years of age in 2006–2007, but in the elderly it was not so frequently found. Penicillin and erythromycin resistance was 20% and 21%, respectively. Serotype 19A accounted for a significant fraction of resistant isolates. The potential coverage of PCV13 was 68% of all infections and 79% of infections caused by

multi-resistant strains. An association between multidrug resistance and two non-PCV13 serotypes – 6C and 15A – was noted.

**Conclusion:** PCV7 use in children continued to benefit the elderly and the same is expected from the ongoing vaccination with PCV13. Direct vaccination of the elderly with PCV13 may have an increased beneficial impact due to its high coverage. An increase of non-PCV13 serotypes can be expected and they may be associated with resistance.

**P1037** Recent changes in the proportion of piliated pneumococci: consequences of vaccine use and future prospects

S.I. Aguiar\*, J. Melo-Cristino, M. Ramirez (Lisbon, PT)

**Objective:** Evaluate the recent changes of the prevalence of the two pilus islets (PI-1 and PI-2) among *Streptococcus pneumoniae* recovered from invasive infections after 7-valent vaccine (PCV7) use.

**Methods:** Pilus-like structures have been recently recognized in pneumococci, implicated in virulence and suggested as potential vaccine targets. However, these structures are not universally distributed among pneumococcal strains. We had previously demonstrated that carrying PI-1 was a clonal property of *S. pneumoniae* and that only 27% of the invasive strains carried the rlrA islet. Furthermore, 83% of these piliated strains expressed vaccine serotypes. Similar findings were reported by others for the PI-2 islet which was shown to be present in 16% of a convenience sample and associated with serotypes 1, 2, 7F, 19A, and 19F.

To evaluate the distribution of pili in invasive pneumococci we determined the presence of the two pilus islets in a collection of invasive isolates recovered from children and adolescents (<18 years) in Portugal between 2003 and 2009 (n = 623) and analyzed their association with capsular serotypes, antimicrobial resistance and clusters defined by PFGE and MLST. We also evaluated the impact of PCV7 in pili distribution by comparing with the datasets of the pre-vaccine period (1999–2002).

**Results:** Overall, 49% of the strains presented one of the pilus islet. A high correspondence between serotype, PFGE and presence and type of pili was observed (Wallace coefficient,  $W > 0.8$ ). The rlrA islet was identified in 15.6% of the strains, most of them expressing serotype 6B, 9V, 14, 19A and 19F, as seen previously. In contrast, the PI-2 islet, was found in 37.6% of the pneumococcal strains and was found mainly among serotypes 1 and 7F, two serotypes not included in the current PCV7 formulation but covered by the currently used PCV13.

**Conclusion:** A decrease in the presence of the PI-1 islet among invasive pneumococcal strains was observed in the post-PCV7 period. However, an increase of the proportion of strains carrying the PI-2 islet was observed which suggests that expression of pilus-like structures may be important for the ability of pneumococci to cause IPD. Yet, since most of the strains carrying pili presented serotypes that are included in current conjugate vaccine formulations, their potential use in a vaccine would offer limited additional benefits.

**P1038** Cloning, expression and purification of autolysin from methicillin-resistant *Staphylococcus aureus* as vaccine candidate

S. Haghghat, S.D. Siadat, S.M. Rezayat Sorkhabadi, M. Mahdavi, A. Akhavan Sepahi, M. Aghasadeghi, S.M. Sadat, M.H. Pouriavali, B. Rajaei, I. Dejbani Golpasha (Tehran, IR)

**Objective:** *Staphylococcus aureus*, a major human pathogens is of increasing importance due to the spread of antibiotic resistance. Novel potential targets for therapeutic antibodies are products of Staphylococcal genes expressing during human infection.

The atl is an autolysin gene in *S. aureus*. The gene product, ATL, is a unique, bifunctional protein that has an amidase and a glucosaminidase domain. It undergoes proteolytic processing to generate two extracellular peptidoglycan hydrolases, a 51-kDa endo-b-N-acetylglucosaminidase and a 62-kDa N-acetylmuramyl-L-alanine amidase, involved in the separation of daughter cells after cell division. The objective of this

study was to Clone, express and purification of atl with the prospect of constructing Staphylococcal vaccine candidate.

**Methods:** The 1120 bp fragment of the atl gene was amplified via PCR which was extracted from *S. aureus* COL strain (methicillin-resistant *S. aureus*) and then cloned into prokaryotic expression vector pET-24a. For expression of recombinant protein, pET24a-atl plasmid was transformed into competent *E. coli* BL21 (DE3). Recombinant protein was overexpressed with isopropylthio-beta-D-galactoside (IPTG) and was exposed to affinity purification by Ni-NTA agarose. SDS-PAGE and western blotting were performed for protein determination and verification.

**Results:** The atl clone was confirmed by colony-PCR and enzymatic digestion as well as sequencing. SDS-PAGE analysis showed that the constructed prokaryotic expression system pET24a-atl Origami efficiently produced recombinant protein target with molecular weight of 43 kDa. The recombinant atl was overexpressed as inclusion bodies by the use of 1.0 mmol/L IPTG.

**Conclusion:** This prokaryotic expression system provides a simple method for producing recombinant atl and may also be useful for the production of other bacterial surface proteins for vaccine studies. This protein purified in high concentration and good conformational structure to be used as Staphylococcal vaccine candidate after further studies.

**P1039** Pertussis: characteristics of hospitalised and outpatient cases

I. Crespo\*, G. Carmona, M.R. Sala, P. Godoy, A. Domínguez on behalf of the Pertussis Surveillance Group of Catalonia

**Objectives:** Pertussis is a respiratory disease caused by *B. pertussis*. In Catalonia (a region in the Northeast of Spain with >7 million inhabitants), pertussis generates high public health costs due to disease-related hospitalizations. The objective of the study was to evaluate differences between hospitalized and outpatient cases of pertussis, the determinants of hospitalization and strategies to avoid admissions.

**Methods:** The study included cases reported to the Department of Health of Catalonia during 2004–2008. Only confirmed cases were included (laboratory-confirmed or epidemiologically-linked). Cases were classified in 2 groups: hospitalized and outpatients.

**Results:** A total of 555 confirmed cases were reported, of which 222 (40%) were hospitalized 333 (60%) outpatients. Distribution by sex was the same in hospitalized and outpatient cases: 54% female and 46% male. The age distribution was 211 (95.0%) <1 year; 10 (4.5%) 1–14 years and 1 ≥15 years in hospitalized cases, and 103 (30.9%) <1 year; 134 (40.2%) 1–14 years and 96 (28.8%) ≥15 years in outpatients.

Only 3 (1.4%) hospitalized cases were diagnosed by epidemiological link compared with 88 (26.4%) outpatient cases ( $p < 0.001$ ).

Clinically, 136 (61.3%) hospitalized patients and 277 (83.2%) outpatients had cough for more than two weeks at the time of diagnosis ( $p < 0.001$ ). Eighty (36.0%) hospitalized patients and 38 (11.4%) outpatients had apnoea at the time of diagnosis ( $p < 0.001$ ).

Only 24.8% of hospitalized cases were fully vaccinated according to age, compared with 48.6% of outpatients ( $p < 0.001$ ). Table 1 shows the proportions of hospitalized and outpatient cases fully vaccinated according to age.

A total of 157 (70.7%) hospitalized cases had received no dose of vaccine compared with 85 (25.5%) outpatients ( $p < 0.001$ ).

Fully vaccinated according to age	Hospitalized cases (n=222)	Outpatient cases (n=333)
<1 year	50 (23.7%)	63 (62.2%)
1-14 years	5 (50.0%)	88 (65.7%)
≥15 years	0 (0%)	10 (10.4%)

**Conclusions:** The percentage of hospitalized cases fully vaccinated according to age, although lower than that of outpatients cases, shows that vaccination coverage should be improved in children. New strategies such as cocooning pertussis vaccine to prevent cases in infants should be considered.

**P1040** Surveillance of invasive meningococcal disease and vaccination strategy in the Czech Republic

P. Krizova\*, Z. Vackova, M. Musilek, J. Kozakova (Prague, CZ)

**Objectives:** The aim of this study is to assess the actual epidemiological situation of invasive meningococcal disease (IMD) in the Czech Republic with the purpose of updating the vaccination strategy accordingly.

**Methods:** Nation-wide enhanced surveillance of IMD was implemented in 1993. The case definition is consistent with the European case definition. Culture and PCR are used for confirmation of cases. Notification is compulsory and *Neisseria meningitidis* isolates from IMD cases are referred to the National Reference Laboratory for Meningococcal Infections to be characterized by serogrouping, PorA and FetA sequencing (<http://neisseria.org/nm/typing/>), and multilocus sequence typing (<http://pubmlst.org/neisseria/>).

**Results:** The IMD incidence has been stable since 2005 (ranging 0.6–0.9/100 000 annually), with an average case fatality rate of 8.4%. The disease has been caused mainly by serogroup B meningococci (ranging 56.7–71.3% annually), followed by serogroups C (decreasing trend, ranging 28.9–5.8% annually) and Y (increasing trend, ranging 1.1–6.0% annually). The following clonal complexes have been most frequently associated with IMD: cc11, cc18, cc41/44, and cc32. The highest age-specific morbidity rates have been observed in the lowest age groups, i.e. 0–11 months and 1–4 years and have been associated with high prevalence of serogroup B. The involvement of serogroup Y in IMD cases has recently increased, causing the highest serogroup-specific case fatality rate. New vaccination guidelines for IMD were issued by the Czech National Immunisation Committee in 2010: vaccination of children aged 2–6 years with conjugate meningococcal vaccine C; revaccination of adolescents aged 11–14 years with tetravalent conjugate meningococcal vaccine A, C, Y, W235. Vaccine effective against *N. meningitidis* B is needed for infants.

**Conclusions:** Detailed surveillance of invasive meningococcal disease including molecular epidemiology is essential for updating the vaccination strategy. New vaccination guidelines for IMD were issued by the Czech National Immunisation Committee in 2010.

**Acknowledgement:** This work was supported by research grant NT11424-4 of the Internal Grant Agency of the Ministry of Health of the Czech Republic and made use of the Multi Locus Sequence Typing website (<http://pubmlst.org/neisseria/>) sited at the University of Oxford and funded by the Wellcome Trust and European Union.

**P1041** Recombinant outer membrane secretin PilQ406-770 as a vaccine candidate for serogroup B *Neisseria meningitidis*

F Haghi\*, S. Najar peerayeh, H. Zeighami, S. Siadat (Zanjan, Tehran, IR)

*Neisseria meningitidis* is a major causative agent of bacterial meningitis in human. Prevention of serogroup B meningococcal disease represents a particularly difficult challenge in vaccine development. PilQ is an antigenically conserved outer membrane protein which is present on most meningococci. This protein naturally expressed at high levels and is essential for meningococcal pilus expression at the cell surface. A 1095 bp fragment of C-terminal of secretin pilQ was amplified by PCR from serogroup B *N. meningitidis* and cloned into prokaryotic expression vector pET-28a. Recombinant protein was overexpressed with IPTG and affinity-purified by Ni-NTA agarose. BALB/c mice were immunized subcutaneously with purified rPilQ406-770 formulated with either an outer membrane vesicle of serogroup B *N. meningitidis* or Freund's adjuvant. Serum antibody responses to serogroup A and B *N. meningitidis* whole cells or purified rPilQ406-770 and functional activity of antibodies were determined by ELISA and SBA, respectively. SDS-PAGE analysis showed that our constructed prokaryotic expression system pET28a-rPilQ406-770-BL21 efficiently produces target recombinant protein with molecular weight of 43 kDa. The output of rPilQ406-770 was approximately

50% of the total bacterial proteins. Serum IgG responses were significantly increased in immunized groups with PilQ406-770 in comparison with control groups. Antisera produced against rPilQ406-770 demonstrated strong surface reactivity to serogroup A and B *N. meningitidis* tested by whole-cell ELISA. Surface reactivity to serogroup B *N. meningitidis* was higher than serogroup A. The sera from PilQ406-770 immunized animals were strongly bactericidal against serogroup A and B. The strongest bactericidal activity was detected in sera from immunized group with PilQ406-770 formulated with OMV. These results suggest that rPilQ406-770 formulated with an outer membrane vesicle is a potential vaccine candidate for serogroup B *N. meningitidis*.

**P1042** Recombinant system for expression of cholera toxin B subunit in *Escherichia coli*

M. Bustanshenas\*, B. Bakhshi, M. Ghorbani, M. Atyabi, D. Norouziyan (Tehran, IR)

**Background and objectives:** Cholera toxin (CT) is the key virulence factor of *Vibrio cholerae*, which is encoded by the ctxAB operon, which resides in the genome of a filamentous bacteriophage (CTX) that specifically infects *V. cholerae*. The symptoms of cholera are mainly caused by cholera toxin (CT), B subunit of which binds to the GM1 ganglioside and promote the endocytosis of CT. The aim of this study was to clone and express ctxB and to purify the recombinant protein using pAE as an efficient expression vector.

**Materials and methods:** The recombinant pAE-CTB was transformed to the competent *E. coli* BL21 to express CTB protein. The system was induced by IPTG after which cells were harvested from LB medium by centrifugation and analyzed by 15% SDS-PAGE. Western blotting performed using cholera toxin-specific antibody. Recombinant CTB was expressed in this system with 6XHis tag at N-terminus and was purified through Ni<sup>2+</sup>-charged column chromatography. Concentration of protein measured with Bradford assay. The functionality of the CTB pentamers was assessed by GM1-ELISA assay.

**Results:** SDS-PAGE analysis showed the expression of rCTB in the system and western blot analysis confirmed the presence of recombinant CTB in blotting membranes. Recombinant CTB was able to bind GM1 in a dose-dependent manner. Some part of rCTB may be expressed in the inclusion bodies so we also lubricated the inclusion bodies.

**Conclusion:** Our results confirmed that although expressed in the inclusion bodies, 6XHis-tagged rCTB was properly refolded, easily purified, and as expected was free of possible CTA contaminants. This will enable us to study CTB immunological properties, oral tolerance, its use as mucosal adjuvant or in vaccine development.

**P1044** Efficacy of *Candida albicans* di- and tri-saccharide vaccine conjugates in an animal model and observation of complement binding to reduce bio burden

R. Rennie\*, L. Turnbull, D. Bundle, T. Lipinski (Edmonton, CA)

**Objective:** This study was undertaken to determine if candidate *Candida* vaccine compounds would elicit an antibody response in a rabbit model of invasive candidiasis and to determine if opsonised yeasts would bind complement to support clearance of invasive infection in the model.

**Methods:** Neutropenia was induced in New Zealand White rabbits with cyclophosphamide and triamcinolone. *Candida* beta-mannan antigens, conjugated with tetanus toxoid were administered twice (tri-saccharide) or four times (di-saccharide) prior to infection. *C. albicans* ATCC3153A (10<sup>4</sup> CFU/mL) was inoculated intravenously. A control group immunized with tetanus toxoid was included. The animals were followed for 7–10 days and then were euthanized. Necropsy tissues were collected for colony counts from liver, spleen, kidney and lung. Complement fixation was performed by incubating diluted tri-

saccharide rabbit serum from immunized animals with the appropriate yeast culture. Complement (1:100 dilution) was added; then polyclonal goat anti-complement C3 was added. Fixation was detected with rhodamine-labeled anti-goat antibody. Appropriate controls were included.

**Results:** Control animals showed an increase in colony counts for all sites cultured from  $10^6$  to  $10^9$  CFU/g of tissue. The highest counts were in kidney. For the tri-saccharide vaccine, colony counts were reduced from control animals by approx. one-half log in lung and kidney, but were increased in liver and spleen. For the di-saccharide vaccine, colony counts were reduced by approximately 2 logs in liver and spleen, and by one-half to one log in kidney and lung compared to controls. No infection in brain was noted. Further, antibody opsonized *C. albicans* cells also induced the deposition of complement C3 component. This is consistent with the findings of others for protective monoclonal antibody C3.1

**Conclusions:** The efficacy of these synthetic *Candida* conjugate vaccines was observed to reduce the bioburden of invasive *Candida* in the neutropenic animal model. The model suggests that there are a few differences in efficacy between these di- and tri-saccharide vaccines. In these experiments, di-saccharide No. 2 reduced the expansion of organism loads by 2 logs in liver and spleen. *Candida* is often found in these two organs in serious infections in susceptible hosts. The observation of complement fixation by opsonised *Candida albicans* cells provides further evidence to support the protective effect of these vaccine candidates.

#### **P1045** Study of the APC gene function in the mouse APC+/APC1638N model

Z. Adamcikova\*, K. Hainova, L. Wachsmannova, V. Stevurkova, V. Holec, Z. Cierna, P. Janega, P. Babal, V. Zajac (Bratislava, SK)

Familial adenomatous polyposis (FAP) is an autosomal dominant disease characterized by the presence of many of polyps in the colon is induced by germline mutation in the APC gene. If not removed prophylactically they represent a risk of developing colon cancer with an almost 100% penetrance.

One of the possibilities of cancer prevention could be an alternative gene therapy using recombinant bacteria as vectors for delivery of therapeutic APC protein. The first step of this work was cloning of a complete APC gene into the vector for expression in bacterial cells. For this purpose the vector pET24a+ was used and expression was performed in *E. coli* BL21 (DE3) pLysS. After transformation, accuracy of the complete APC gene was tested by sequencing. Expressed APC protein was identified by Western blotting using monoclonal and polyclonal antibodies. Recombinant bacteria were orally applied into transgene mice APC+/APC1638N carrying a mutated APC gene resulting in the production of nonfunctional protein and consequently formation of intestinal tumors. Potential reduction of intestinal tumor formation after application were analyzed.

The whole gastrointestinal tract was investigated macroscopically, microscopically and immunohistochemically with the use of polyclonal rabbit antibody against APC protein. Also we analysed cytokines (IL-1b; IL-2; IL-4; IL-5; IL-10; IFN-gamma; TNF-alpha) in mouse serum using Bio-Plex ProTM Assay.

All four transgenic mice without therapy developed adenomatous polyps in the gastrointestinal tract. Six transgenic mice treated by oral administration of bacteria expressing the APC gene, developed polyps in 33.3% of two cases. The remaining four mice 66.7% were without polyps development and immunohistochemistry confirmed in all parts of the gastrointestinal tract positive APC protein more or less strong intensity.

We observed positive effect of this therapy at mouse model. The expression of APC protein by non-pathogenic bacteria may be suitable for clinical use as a potential drug.

This work was supported by the grant VEGA 2/0096/11, the grant APVV-0404-07 and SF ITMS project code: 26240220058, Bratislava, Slovakia.

#### **P1046** Using recombinant *E. coli* as a novel vaccine against foot and mouth disease virus

G. Ahmadian, M. Shamsara, M. Karbalayi Ali, S. Hadji khodadad\* (Tehran, IR)

**Background:** Foot-and-mouth disease (FMD) is a highly contagious disease of livestock that causes severe economic loss in susceptible animals and it may lead to a new outbreak of FMD because of either incomplete inactivation of Foot and Mouth Disease Virus (FMDV) or the escape of live virus from vaccine production workshop. Thus, it is urgent to develop a novel FMDV vaccine that is safer, more effective and more economical. We have designed a peptide-based vaccine for FMD effective in livestock. Display of heterologous proteins on the surface of microorganisms, enabled by means of recombinant DNA technology, has become an increasingly used strategy in various applications in microbiology, biotechnology and vaccinology.

**Methods:** Several different FMDV peptides containing the immunogenic regions of vp1 were fused to the OMPA of Salmonella and transferred into *E. coli*. After induction the expression was shown by SDS PAGE and to confirm the presence of this fused protein on the surface of *E. coli*, fractionation method performed. By ELISA method the activity of the epitopes approved and the lyophilized bacteria was inoculated to the mice feed and the immunogenicity was evaluated.

**Results:** The immunogenicity of these recombinant bacteria was tested by immunizing the mice. Ten days after the last inoculation, the animals were bled and the sera analyzed to evaluate the presence of Antibody against FMDV by ELISA and Western blot. The results show extra stimulation in the immune system of the mice which the recombinant bacteria were inoculated in their daily feed.

**Conclusion:** These result suggested that designing a recombinant peptide vaccine would be a good and possible way to gain high levels of immunity in veterinary medicine but there is still a strong need for additional studies.

#### **P1047** The live attenuated *B. pertussis* vaccine strain BPZE1 subverts the immune functions of RSV-infected human dendritic cells

I. Schiavoni, G. Fedele, A. Quattrini\*, M. Bianco, C. Schnoeller, C. Locht, P. Openshaw, C. Ausiello (Rome, IT; London, UK; Lille, FR)

**Objectives:** The respiratory syncytial virus (RSV) is a leading cause of lower respiratory tract infection in infants. The immune response to RSV is still not fully understood and many data suggest an activation of innate immunity mainly focussed on the induction of a cytokine storm and a consequent tissue damage. Despite several efforts to develop effective vaccines, none have been successful to date. Recently, BPZE1, a live attenuated *Bordetella pertussis* vaccine strain, has been developed and entered a phase I safety trial ([www.ChildINNOVAC.org](http://www.ChildINNOVAC.org)). Immunization with BPZE1 protects mice challenged with influenza virus, suggesting potent adjuvant properties. To support the potential application of BPZE1 as adjuvant in a future RSV vaccine, we evaluated the immunomodulatory properties of BPZE1 in a model of human dendritic cells (DC) infected with RSV.

**Methods:** GM-CSF and IL-4 monocytes-derived DC (mDC) were exposed to RSV and/or to BPZE1. Functions of infected mDC were assessed, including cytokine production and polarization of T helper cells in co-culture experiments with allogeneic T cells. The phosphorylation of mitogen-activated protein kinases (MAPKs) p38, ERK1-2 and IkbAlfa was evaluated by Western Blot. RT-PCR was used to measure IFNbeta, IRF-8, RANTES and IL-12p35 and IL-12p40 gene expression.

**Results:** BPZE1 was able to induce the production of IL-10, IL-23, and low level of IL-12p70 while RSV infection did not induce any of these cytokines. BPZE1 and RSV induced two different signal pathways: BPZE1 triggered the activation of p38 and ERK 1/2 MAPKs phosphorylation and expression of IL-6, IL12p40 and low level of IL-12p35 subunits; RSV triggered the activation of STAT1

phosphorylation and the expression of IFN $\beta$  and several IFN-regulated genes, including IRF-8, RANTES and high levels of IL-12p35 subunit. Remarkably, in BPZE1/RSV co-infection the intracellular pathways complement each other as demonstrated by the enhanced production of IL-12p70. In vitro polarization experiments showed that RSV-primed mDC drive the expansion of a mixed Th1/Th2. Strikingly, the co-infection greatly decreased Th2 and increased Th17 expansion.

**Conclusion:** BPZE1 is able to re-direct the RSV immune response by modification of the cytokine profile that has a profound effect on polarization of T helper cells. These results support a potential application of BPZE1 as adjuvant in a future RSV vaccine. Supported by EC grant agreement 201502 (ChildINNOVAC).

#### **P1048 Immunogenicity and safety of tick-borne encephalitis vaccination in healthy elderly individuals**

K. Wanke, A. von Braun, L. Häberli, A. Mekker, P. Steffen, K. Stiasny, F. Heinz, B. Unger, U. Karrer\* (Zurich, CH; Vienna, AT; Winterthur, CH)

**Introduction:** Tick born encephalitis (TBE) is a major viral cause for central nervous system disease in Europe. Serious disease with debilitating neurological sequelae is more frequently observed in older TBE patients compared to younger adults and children. Causal antiviral treatment is not available but prevention by active immunization is highly efficacious and widely recommended in Europe. However, evidence for TBE vaccine immunogenicity and protective efficacy in the elderly population is scarce. Since the risk for serious TBE is increased and immunogenicity of vaccines is generally reduced in the elderly, additional data on immunogenicity of TBE vaccine in a naïve elderly population is highly warranted.

**Objectives:** Detailed investigation of immunogenicity and safety of a licensed inactivated whole-virus TBE vaccine (FSME Immun CC<sup>®</sup>) after primary immunization of 137 healthy elderly subjects in a controlled clinical trial (NCT00461695).

**Patients and methods:** Of 183 screened patients 137 were included and immunised with a standard three dose regimen of TBE vaccine at week 0, 4 and 24. Major inclusion criteria were: age >70 years, healthy ( $\leq$ one co-morbidity;  $\leq$ one medication), negative TBE-serology. Immunogenicity was assessed longitudinally by neutralization and ELISA test, safety was evaluated clinically and by standardized questionnaires. Results were compared with previous studies in younger adults that had used the same assays.

**Results:** Four weeks after the 2nd and 3rd vaccination 98.5% and 99.3% of subjects were seropositive ( $\geq$ 10) in the neutralization test. Using a threshold of 126 VIEU/mL in the ELISA the seropositivity rates were 93.4% and 97.8%. Geometric mean titer (GMT) measured by neutralization test were 29.2 and 70.6 after the 2nd and 3rd vaccination, respectively. GMT were 799.4 VIEU/mL and 1933.8 VIEU/mL in the ELISA. In summary, the seropositivity rates for elderly subjects obtained in this study were similar to earlier studies in young adults and children using the same test assays. However, antibody titer were generally lower. Adverse events were mild, transient and comparable to earlier studies in adults.

**Conclusions:** These results suggest that primary TBE vaccination of healthy elderly leads to satisfactory immune responses well above levels considered protective. However, duration of protective immunity may be shorter than in younger individuals.

#### **P1049 Designing and studying of defensin peptides analogues as a mucosal adjuvant/microbicide: a study towards the development of peptide-based vaccine against AIDS**

T. Mohan\*, D. N. Rao (New Delhi, IN)

**Background:** The mechanisms of resistance to HIV infection in the human oral cavity are incompletely understood while salivary components have been implicated in protection.

**Methodology:** We have synthesized HIV and Defensin peptides and their corresponding analogues by making some modifications in the natural sequence. We have done Anti HIV, Anti-microbial and other characteristic study of defensins to prove them active. Then, immunized these formulations in Outbred and Two different Inbred mice (H2b, H2d) through IN route using Microsphere as delivery vehicle. We have studied Humoral Response of HIV peptides with and without Defensins by estimating antibody levels (IgG/IgA) in the serum as well as in lung, intestinal, vaginal and rectal washes till day 120. For cell mediated immune response, peptide specific T cell proliferation and cytokine/chemokine levels were studied in the cells isolated from the three different mucosal sites i.e. spleen, lamina propria and peyer's patches of the primed mice. We have also done Cytolytic activity analysis, by estimating IFN-gamma/Perforin secretion by CD4+/CD8+ also through FACS, which was checked by IFN-gamma/Perforin secretion.

**Result and discussion:** All the HIV peptide with defensins in different formulations has increased titre significantly both in sera (1 02 400–4 09 600) and washes (800–12 800) ( $p < 0.05$ ) as well as the proliferation response was also significantly higher (upto two fold ranging from 10 to 50 stimulation index) ( $p < 0.001$ ) as compared to HIV peptide alone. The cytokine measurement profile showed mixed Th1 and Th2 type of immune response. The FACS analysis data revealed that CD8+/CD4+ T cells showed significantly higher Cytolytic activity in the HIV with Defensin peptide formulations. Surprisingly, CD4+ T-cells were also showing Cytolytic property.

**Conclusion:** Thus, the results reported here demonstrate the effectiveness of synthetic defensin peptide analogues to induce strong and long lasting humoral and cellular immune response through intranasal route using PLG- microsphere as a delivery vehicle. Our findings may have implications in the development of new antiviral agent for AIDS therapy.

#### **P1050 Deficient long-term response to pandemic vaccine results in an insufficient antibody response to seasonal influenza vaccination in solid organ transplant recipients**

E. Cordero\*, T. Aydllo, A. Pérez-Ordoñez, J. Torre-Cisneros, R. Lara, C. Segura, M.A. Gentil, M.A. Gómez-Bravo, E. Lage, J. Pachón, P. Perez Romero on behalf of REIPI-GESITRA

**Introduction and objectives:** Long-term antibody response to the 2009-H1N1 vaccine in solid organ transplant recipients (SOTR) and its clinical repercussion on the efficacy of the following 2010–2011 influenza vaccine has been poorly studied. The aim of this study was to evaluate the long-term seroprotection of the 2009-H1N1 vaccine and its impact on the effectiveness of the following seasonal vaccine.

**Methods:** Multicenter prospective study in SOTR receiving one-dose of the non-adjuvanted 2010–2011 seasonal influenza vaccine. The immunological response at baseline and five weeks after vaccination by a microneutralization assay. Follow up: 90 days after vaccination, or 10 months if adverse effects were detected.

**Results:** One hundred SOTR were included (kidney 42.7%, liver 41.7%, heart 15.6%). Median time after the transplantation was 39.7 months (range from 2.3–277.8). Among the 73 patients that received the 2009-H1N1 vaccine, only 22 (30.1%) maintained antibody titers (GMT<sub>pre</sub> 11.1, 8.3–14.9) 1 year after vaccination. The overall rates of seroprotection and seroconversion were 79.2% and 77.1%, respectively for the 2009-H1N1 strain, 67.7% and 66.7% for the H3N2 strain and 72.9% and 67.7% for the B strain, with a median GMT<sub>post</sub> of 106.0 (73.8–152.4) for 2009-H1N1 strain, 98.6 (63.3–153.6) for the H3N2 strain and 119.0 (76.5–185.1) for the B strain, after vaccine. Patients with baseline titers had significantly higher seroprotection for all three influenza strains: 2009-H1N1 (100% vs. 73%, RR 1.37 CI95% 1.19–1.57,  $p = 0.006$ ), H3N2 (100% vs. 62.2%, RR 1.61 CI95% 1.36–1.90,  $p = 0.005$ ) and B (100% vs. 69%,  $p = 0.02$ ). GMT<sub>post</sub> was also higher if basal antibody titers were present: 2009-H1N1 (529.8 vs. 65.7,  $p < 0.001$ ), H3N2 (353.3 vs. 79.3,  $p < 0.001$ ) and B (239.7 vs. 107.7,  $p = 0.08$ ). Three patients (3.1%) were diagnosed with 2009-

H1N1 infection having mild disease and no one required hospital admission.

**Conclusions:** SOTR long-term response to the 2009-H1N1 influenza vaccine is insufficient. The response to 2010–2011 seasonal influenza vaccine is related to baseline titers, however, most of the patients did not exhibit detectable antibodies at the time of next-season vaccination. New strategies are necessary to improve seasonal vaccination efficacy in SOTR.

## Antibiotic use and antibiotic stewardship

**P1051** **The Antibiotic Resistance and Prescribing in European Children (ARPEC) project: the European neonatal and paediatric antimicrobial web-based point prevalence survey in 56 hospitals within Europe and globally in 2011**

A. Versporten\*, M. Sharland, J. Bielicki, N. Drapier, V. Vankerckhoven, H. Goossens (Antwerp, BE; London, UK)

**Objectives:** The European neonatal and paediatric antimicrobial Point Prevalence Survey (PPS) is part of the ARPEC project (<http://www.arpecproject.eu/>). The aim of the study is to develop a standardized method for surveillance of antimicrobial use in hospitals within Europe and globally. The variation in antibacterial drug use will be used to identify targets for quality improvement and hospital Antimicrobial Stewardship Programmes.

**Methods:** Data collection was completed during 2 weeks between September 19th and 30th 2011. The pilot survey included all admitted children receiving an antimicrobial treatment on the day of survey. Mandatory data were age, gender, (birth) weight, underlying diagnosis, antimicrobial agent, dose and indication for treatment. Data were entered online using a web-based system for data-entry and reporting based on the WebPPS program developed by the University of Antwerp for the ESAC (European Surveillance of Antimicrobial Consumption) project.

**Results:** There were 5122 inpatients reported for the 56 participating hospitals originating from Europe, USA, the Middle East and Africa (22 countries). Overall, 37% of paediatric patients (N = 1436) and 35% of neonates (NICU, N = 299) were receiving at least one antibiotic. Mainly cephalosporins (30%), penicillins (22%), aminoglycoside antibacterials (17%) and other antibacterials (13%) were used. Third-generation cephalosporin use was highest in the Islamic Republic of Iran and Georgia (total proportional use >36%) followed by Latvia (32%) and Romania (30%) and the lowest use was reported for hospitals in Lithuania, Spain, Belgium and UK (<7%). The most common sites of infection for which antibacterials were prescribed were lower respiratory tract infections (15%), prophylaxis for medical problems (13%) and prophylaxis for surgical disease (12%) for paediatric patients, and sepsis (32%) and prophylaxis for newborn risk factors (12%) for neonates. Two quality indicators were identified: surgical prophylaxis for >24 hours (80%) and therapy with third-generation cephalosporins for community acquired lower respiratory tract infections (pneumonia) (28.3%).

**Conclusion:** The ARPEC-WebPPS method was successfully piloted in 56 hospitals worldwide. It offers a standardized tool to identify targets for quality improvement. The first global web-based ARPEC-PPS with quantifiable outcome measures will be organized in 2012. Interest in the project is high!

**P1052** **ASPEN© – Antimicrobial Stewardship PracticEs in the NHS (North London)**

N. Cooley\*, P. Panesar, M. Gilchrist, K. Hatton, T. Lyons, H. Wickens, W. Lawson (London, UK)

**Objectives:** Antimicrobial pharmacists in the UK have been embedded in clinical practice for over a decade. The role of the pharmacist has evolved and expanded over this time. We discuss the impact of such

posts across three acute London teaching Trusts (covering eight hospitals, incorporating ~3000 in-patient beds).

**Methods:** Antimicrobial stewardship activities were reviewed on medical wards at each of the Trusts over the last 4 years. Local data collection tools were used by antimicrobial pharmacists to ascertain practices. Where comparable methodology was applied across the sites, regional benchmarking was undertaken.

**Results:** Over the last 4 years, improvements have been observed in documentation of indication for antibiotic therapy (average 75% in 2008 to 95% in 2011) and recording of a stop/review dates (20% in 2008 to 80% in 2011) on drug charts. This has been achieved through the introduction of initiatives such as automatic stop dates, electronic prescribing systems, medication charts with specific areas for antibiotic prescriptions and education and training – both at induction and through continual feedback and via key performance indicators. The introduction of electronic stop dates, at one centre, has significantly reduced oral antibiotic usage by 9% (p = 0.07). Data has also shown an increase in the number of antimicrobial guidelines available to clinicians for treatment and prophylaxis (61% in 2008 to 85% in 2011), whilst improved electronic technology has provided a platform to broaden the access to guidelines e.g. pocket guide versions, local intranet and Smartphone applications. Documentation of allergy status on drug charts ranged from (88–98%), and compliance with guidelines has been maintained at a high rate (75–98%) despite the regular turnover of clinical staff. The establishment of joint antimicrobial pharmacist/microbiology ward rounds for the Acute Admissions ward and for patients diagnosed with *Clostridium difficile* infection has seen an increase in the numbers of patients reviewed, resulting in greater numbers of prescriptions being optimised.

**Conclusion:** Antimicrobial pharmacists have implemented novel approaches to support antimicrobial stewardship. This has resulted in clear improvements in antimicrobial use as well as changing healthcare professionals' attitudes towards antimicrobial prescribing.

**P1053** **Antimicrobial stewardship practices in North London hospitals**

N. Cooley\*, P. Panesar, M. Gilchrist on behalf of North London Antimicrobial Pharmacist Network

**Objectives:** The Antimicrobial Self-assessment tool (ASAT)1 was developed to aid identification of areas of strength and weakness within Trust stewardship practices. This tool was applied in 16 North London hospitals to benchmark regional practice and to identify differences and commonality between Trusts.

**Method:** Self assessment of practice was undertaken against seven aspects of stewardship. The mean scores for the assessed elements were: risk assessment (90.1%), operational delivery of strategy (86.7%), structure and lines of responsibilities (82.7%), antibiotic pharmacist post (82.3%), clinical governance (63.7%), education and training (50.2%), and information for public, patients and carers (43.7%).

**Results:** For the operational delivery of strategy element, teaching hospitals scored significantly higher than district general hospitals, 92.5% vs. 81% (p = 0.0003).

Greatest variability within the scores was identified for education and training and information for public and patients. These elements required quantifiable data to be able to score on the tool. Whilst these aspects are recognised as important and often performed, Trusts found it difficult to quantifiably demonstrate this practice.

**Conclusion:** The ASAT is a useful aid for organisations to identify current gaps in local antimicrobial stewardship activities. However, Trusts need robust mechanisms for demonstrating the quantifiable aspects. The tool may require refining to address this.

**Reference:** 1. Cooke J, Alexander K, Charani E et al. Antimicrobial stewardship: an evidence-based, antimicrobial self-assessment toolkit (ASAT) for acute hospitals. *J Antimicrob Chemother* 2010; 65(12): 2669–2673.

**P1054 Adherence to recommendations of an antimicrobial stewardship programme**

L. Martin, J. Murillas\*, A. Campins, M. Peñaranda, L. Periañez, A. Oliver, O. Delgado, M. Riera (Palma de Mallorca, ES)

**Background:** Several barriers have been identified to the development of an Antimicrobial Stewardship Program (ASP). Adherence to recommendations varies depending on who makes the intervention, the kind of suggestion and on the patient status. The objective of the present study is to identify the characteristics of the interventions with the lowest adherence.

**Methods:** Prospective study from June 2006 to December 2010 in a 850 beds community based Hospital in Balearic Islands in Spain. In the context of a program to improve antibiotic (AB) prescription in the Hospital, that also included educational activities and development and dissemination of guidelines, an AB prospective audit was performed. Interventions were made after chart review by a team of infectious diseases physicians by leaving a note with the justified suggestion. Recommendations could be to stop, to change or to maintain the antibiotic treatment. Forty-eight hours later the adherence to the recommendation was evaluated.

**Results:** During the study period 11 082 interventions were made with an adherence of 60%. A suggestion was given in 50% of the prescription reviewed, 13.2% to stop and 27.8% to modify. Adherence was analyzed by departments in the Hospital and by the reason to make the suggestion. The departments of Urology, General Surgery and Gastroenterology had the poorest adherence, around 40%, and the best adherence rates were obtained in Orthopedics, neurosurgery and Neurology, reaching 85% in orthopedics. The reasons to make interventions more associated to low adherence were to fit the prescription to the local guidelines and to stop due to lack of indication, 40%. However, interventions aimed to deescalate (60.8%) or to stop due to completed therapy (55.7%) or to set the ending date (90%) were more often followed.

Interestingly, adherence improved during the 3 years follow up, reaching 69% in the last year.

**Conclusion:** The map of adherence in the Hospital could be useful to identify those departments less engaged in antimicrobial stewardship programs and potential barriers to successfully implement the program as inadequate diffusion of the aim of the program, absence of consensus in the elaboration of protocols. Furthermore, some interventions as those devoted to improve adherence to local guidelines must be redesigned considering the low adherence obtained. New tools like the use of biomarkers could help to improve the adherence to those recommendations made to stop unnecessary antibiotic prescription.

**P1055 Trends in antibiotic use and antimicrobial resistance in French hospitals, 2008–2010. Data from the nationwide network “ATB-RAISIN”**

C. Dumartin\*, A.-M. Rogues, F. L'Heriteau, M. Pefau, X. Bertrand, P. Jarno, S. Boussat, A. Savey, P. Angora, L. Lacave, O. Ali-Brandmeyer, A. Machut, S. Alfandari, B. Schlemmer, S. Touratier, S. Vaux, A. Raisin (Bordeaux, Paris, Besançon, Rennes, Nancy, Lyon, Tourcoing, Saint-Maurice, FR)

**Objectives:** French programmes to control antimicrobial resistance (AMR) and antibiotic (AB) use put an emphasis on surveillance in hospitals. We performed three nationwide surveys since 2008 to monitor trends in AB use and AMR in hospitals and to provide a tool for benchmarking and to identify areas for improvement at national and at hospital level.

**Methods:** AB for systemic use (class J01 of WHO Anatomical Therapeutic Chemical classification, ATC-DDD system, rifampicin and oral imidazole derivatives) and AMR were surveyed according to the national surveillance network ATB-RAISIN. Data retrospectively collected each year, for the whole previous year, by voluntary hospitals were: hospital status; AB consumption for inpatients,

expressed in number of defined daily doses (DDD) per 1000 patients-days (PD); number of susceptible strains for specified AB/bacteria couples, number of PD.

**Results:** Eight hundred and sixty-one hospitals in 2008, 997 in 2009 and 1115 in 2010 participated in the survey, accounting for 52% of PD in France in 2010. In 662 hospitals participating each year, AB use (pooled mean) slightly increased by 3% each year: 366, 378 and 389 DDD/1000 PD from 2008 to 2010. Trends varied according to hospitals status: AB use increased by 28%, 17%, 9% and 7% in long-term care centres, rehabilitation centres, public hospitals and cancer centres. Major increase occurred in the use of piperacillin/tazobactam (+33%), carbapenems (+31%), ceftriaxone (+28%) and imidazole derivatives (+18%). Fluoroquinolone use remained stable over the study period; levofloxacin use increased by 12% in 2009 and remained stable in 2010. AMR increased in Enterobacteriaceae while meticillin-resistant *Staphylococcus aureus* incidence remained stable.

**Conclusion:** This national network, gathering standardized data from a large sample of hospitals, allows surveillance of trends in AB use and AMR. It also allows benchmarking between hospitals and providing help to outliers to analyse results and implement improvements. Despite the national action plan, AB use did not decrease in recent years in French hospitals when expressed in DDD/1000 PD. Moreover, increase in AMR of Enterobacteriaceae is worrisome. Considering these data, emphasis will be reinforced on rational use of carbapenems and ceftriaxone. Increase in carbapenem use was also reported in Sweden (+9%), in the Netherlands (+37% between 2007 and 2009) and in Denmark (+49%), illustrating the urgent need to better control the use of these last-line agents.

**P1056 Antibiotic stewardship programmes in French hospitals: time to change the national structure and process indicator, ICATB**

V. Marie, C. Dumartin, B. Amadeo, M. Pefau, P. Parneix, A.-M. Rogues\* (Bordeaux, FR)

**Objectives:** Since 2007, it is mandatory for French hospitals to report to health authorities a structure and process indicator on their antibiotic stewardship programme (ABS), ICATB, measuring implementation of recommended activities, for public disclosure. We conducted a study in 2009 to assess metrological performance of the indicator ICATB and to identify needs for its improvement.

**Methods:** A retrospective survey was performed in 440 Southwestern France hospitals. ICATB was retrieved from the national database provided by health authorities. Content validity, internal consistency and reproducibility of ICATB were assessed by multiple correspondence analysis, Cronbach's alpha and Kappa coefficients calculations. Information on ABS measures in 2009 was collected by auto-questionnaire sent to pharmacists, antibiotic (AB) advisors and/or infection control teams. Implementation of organisation measures, resources (human and information technology (IT) support), educational and restrictive activities was studied and compared with ICATB.

**Results:** Two hundred and forty-six hospitals participated (56%). ICATB showed low content validity and internal consistency but good reproducibility (assessed against replies to the auto-questionnaire). Most hospitals had implemented measures included in ICATB: ICATB median score was 16/20. However, some activities and resources, as detailed in the auto-questionnaire, were among the least frequent: training (32%) and IT support (in <50%). Practice audits had been carried out in 66% of hospitals but 33% had provided feedback to prescribers. Only 42% of AB advisor had passed one of the two recommended diplomas; the median weekly time spent was 4 hours. An antibiotic management team was in place in 41%.

**Conclusion:** Overall, the level of compliance with recommended ABS measures included in ICATB was high in 2009, thus limiting ICATB usefulness to trigger new improvements. In addition, its metrological characteristics could be improved. Replacement of some components, already widespread, by less frequent measures and addition of questions

on practical modalities of implementation could improve both its ability to foster progress and its consistency. We suggest to include measures that have proven their efficacy to improve AB use and able to discriminate between hospitals, such as AB advisor activity, feedback to prescribers, multidisciplinary teams. Items could be weighted so that known synergistic measures (bundle) could be given more value.

#### **P1057** Institutional programme for improvement of antimicrobial treatment (PRIOAM)

*J.M. Cisneros\*, F. Jiménez-Parrilla, O. Neth, J. Cano, E. Cordero, M.J. Rodríguez-Hernandez, J.A. Márquez-Vácaro, R. Amaya-Villar, M. Porras, J. Palomino, M.E. Jiménez-Mejías, M. Herreros, J. Molina (Seville, ES)*

**Objectives:** PRIOAM is an antimicrobial stewardship program with four basic objectives in 3 years: (i) To improve the antimicrobial prescription, (ii) To reduce the hospital mortality in severe infection, (iii) To reduce the morbidity of patients with severe infection (iv) To reduce the antimicrobial resistance and (v) To reduce the economic cost. We exposed the results of first 10 month of the first objective.

**Methods:** During the first 10 months has been reached to achieve the following tasks within the program. (i) The program was approved by the hospital's manager and publicized for all wards, (ii) We performed 17 local guidelines of infectious diseases in collaboration with the rest of units of the Hospital (iii) Clinical consultancies of antimicrobial prescription were performed by 13 clinician expert in infectious disease. The objective of the clinical consultancy does not the change of antimicrobial prescription if no the training of the doctor advice. Each clinical consultancy the expert checks specific items of the antimicrobial prescription with the doctor advice of a real patient. Each clinical consultancy was scored 0–10 and a prescription was considered inappropriate if at least one item in the check was wrong. To assess the different ratio of inappropriate prescription for months we performed a Chi square test and evaluated the change in the score with Kruskal–Wallis test. At the end of the clinical consultancy the doctor advised may completed a satisfaction survey.

**Results:** Since January to October was performed 975 clinical consultancies in 24 different clinical units. Of them 511 (52.4%) were empirical treatment, 240 (24.6%) were antimicrobial treatment with microbiological confirmation and 224 (23.0%) were surgical prophylaxis. In the January months the inappropriate treatment was 56.8% (79/139) and in October was 31.3% (36/152)  $p < 0.001$ . Surgical prophylaxis 63.2% (12/19) vs. 17.1% (7/41)  $p < 0.001$ ; empirical treatment 59% (49/83) vs. 28% (23/82)  $p < 0.001$  and 48.6% (18/37) vs. 20.7% (6/29)  $p = 0.019$  in treatment prescribed with microbiological confirmation. The satisfaction survey was completed by 321 (32.9%) of doctors advised and 97.8% (314/321) find it useful.

**Conclusions:** In this interim analysis we find that PRIOAM is useful for improve the antimicrobial prescriptions.

#### **P1058** The barriers and facilitators to optimal antimicrobial prescribing: a qualitative study

*E. Charani\*, N. Shah, R. Edwards, L. Drumright, A. Holmes (London, UK)*

**Objectives:** Successful interventions to optimise antimicrobial prescribing (AP) need to be underpinned by research investigating the barriers and facilitators to optimal APB. Published studies on interventions to optimise APB often omit or fail to report on the application of theory and primary research to inform intervention development and design. We report here on a qualitative study to identify (i) attitudes and perspectives of healthcare professionals (HP), including doctors, pharmacists and nurses on AP; (ii) key barriers and facilitators to APB; and (iii) key determinants of APB.

**Methods:** A random sample of 39 HP (19 nurses, 10 doctors and 10 pharmacists) working in three hospital sites of a large University Hospital Trust in the UK were interviewed. Data was extracted and

coded using a framework approach using inductive and deductive approaches. In depth analysis of the coded transcripts was conducted to identify emerging themes based on the initial objectives of the research.

**Results:** The analysis identified four key determinants of APB: (i) influence of peers and seniors; (ii) delineation of responsibility in AP; (iii) influence of local and organisational culture on APB; and (iv) experience and expertise as barriers and facilitators to optimal APB. APB was influenced by prescriber attitudes towards policy, evidence base, and more importantly by consultants and senior doctors. Junior staff expressed difficulty in questioning “out-of-policy” practices of their senior colleagues due to perceived social hierarchy or their own self-efficacy in being able to question APB. The barriers and facilitators to optimal APB identified by HPs differed by profession, specialty and their perceived position in organisational hierarchy. This study demonstrates a need to clarify HP involvement in antimicrobial stewardship e.g. empowering nurses, pharmacists and doctors to champion antimicrobial stewardship.

**Conclusion:** The influence of senior physicians as role models and the experience and expertise of individual HP's need to be acknowledged as key determinants of APB. Based on this research we recommend that APB interventions will benefit from targeting the prevailing cultural attitudes and behaviours, however we caution that social dynamics may differ by culture and specialty. Interventions targeting APB must be multimodal and include audience segmentation, and role definition for HCPs in antimicrobial stewardship.

#### **P1059** Development of a worldwide antimicrobial stewardship survey

*P. Howard\*, C. Pulcini, D. Nathwani on behalf of the ESCMID Study Group for Antimicrobial Policies*

**Objectives:** Antimicrobial stewardship (AMS) has been surveyed at national and continental level, but never at a global level. At the 2011 ECCMID meeting, the ESCMID Study Group for Antimicrobial Policies supported a worldwide survey of antimicrobial stewardship.

**Methods:** A small multidisciplinary project group was established (England, France and Scotland). Volunteers were identified from each continent to be the development advisory group. A literature search was undertaken to identify published surveys and standards for antimicrobial stewardship. A draft survey was developed from these results using the good practice methodology for conduct and reporting survey research [1, 2] and CHERRIES criteria for improving internet surveys [3]. These suggested piloting the survey to ensure that questions could not be misinterpreted especially where English is not the predominant language, then pre-testing in a larger group. Pre-testing was planned in 11 countries in six continents (Asia: Hong Kong, China and India; Europe: UK, France, Switzerland, Austria or and Slovenia; Africa: South Africa; Oceania: Australia; South America: Argentina, and USA in North America. SurveyMonkey© software was used to develop the survey. This allowed question order to be randomised for each respondent.

**Results:** A survey has been developed to collect data on antimicrobial stewardship at a global level that collects data on AMS governance arrangements, staffing levels, strategies, audit and feedback and education within hospitals and community. The results will be presented at a future meeting.

**Conclusion:** It is possible to develop and test an internet based survey of antimicrobial stewardship that is applicable across all continents, but a thoroughly planned development phase is needed.

**P1060** Lack of correlation between antibiotic use and mortality in Swedish intensive care units – report from Swedish registry of intensive care

M. Edström, G. Fransson\*, S. Walther, H. Hanberger on behalf of the Swedish ICU Registry and ICU-Strama/Swedish Institute for Communicable Disease Control

**Objective:** The high antibiotic use in intensive care is a driving force of antibiotic resistance. The aim of this study was to report and analyse antibiotic consumption and correlation with mortality among patients admitted to Swedish ICUs.

**Methods:** *Setting:* Starting 10 years ago an increasing number of ICU:s in Sweden reports each episode of care (EOC) after discharge systematically to the Swedish Intensive care Registry (SIR). Mortality is followed weekly for all patients in the registry. Data on antibiotic consumption was collected from the web based statistical system Concise (Apotekens Service AB), containing information on all sales of antibiotic drugs in Sweden.

*Participants:* 49 and 52 Swedish ICUs participated 2009 and 2010 respectively.

*Variables:* Antibiotic consumption expressed as defined daily doses (DDD) per 1000 occupied bed days (DDD1000), using the annually updated DDD calculated by the WHO Collaborating Centre for Drug Statistics Methodology (<http://www.whocc.no>). Standardized mortality rate (SMR) calculated as observed mortality within 30 days after admission/predicted mortality based on the Simplified Acute Physiology Score 3 (SAPS 3) model. Spearman rank correlation was used and statistical significance was assumed if  $p < 0.05$ .

**Results:** The median antibiotic consumption was 1354 and 1484 DDD1000 2009 and 2010 respectively. Antibiotic consumption varied widely (four fold) between units ranging from 680 to 2698 and 658 to 2515 DDD1000 2009 and 2010 respectively. Isoxazolylpenicillins (16%) were most frequently used, followed by cephalosporins (14%), carbapenems (14%), triazoles (9%) piperacillin-tazobactam (9%), fluoroquinolones (6%) and beta-lactamase sensitive penicillins (5%). Mean SMR (SD) was 0.63 (0.17),  $n = 75$ . No significant correlation between antibiotic consumption and standardised mortality rate was found 2009 and 2010.

**Conclusions:** The lack of correlation between antibiotic consumption and mortality suggest that it is possible to lower antibiotic consumption in high consumption units. The Swedish ICU Registry provides a quality control system which ensures that such reduction of antibiotic consumption does not compromise patient outcome.

**P1061** Improved antimicrobial susceptibility of uropathogenic *Escherichia coli* due to decline in ambulatory antibiotic consumption

T. Marijan\*, J. Vranes, A. Mlinaric-Dzjepina, B. Bedenic, V. Ticic, M. Anusic (Zagreb, HR)

**Objectives:** The aim of this study was to assess the impact of ambulatory antibiotic consumption on resistance patterns of *Escherichia coli* strains isolated from patients with community-acquired urinary tract infections (CA-UTIs) in Zagreb region.

**Methods:** All urinary specimens with significant bacteriuria processed during two study periods (January–October 2005 and January–December 2010) were included in the survey. Urinary specimens were collected in the course of routine diagnostics procedures of Zagreb outpatient population. Resistance patterns of 3052 *E. coli* strains collected during the first study period were compared with those of 4817 *E. coli* strains from the second study period. Antimicrobial susceptibility of isolates to commonly prescribed antibiotics was tested by disk diffusion method according to CLSI criteria. Information on ambulatory consumption of antibiotics, expressed in defined daily doses per 1000 inhabitants per day (DID), was obtained from annually published report by The Croatian Academy of Medical Sciences.

**Results:** In the period from 2001 to 2009, ambulatory consumption of broad spectrum penicillins, first generation of cephalosporins and co-trimoxazole declined from 4.09 DID, 1.65 DID and 1.70 DID in 2001 to 3.60 DID, 1.21 DID and 0.98 DID in 2009, respectively. While consumption of fluoroquinolones (FQs) remained more or less unchanged, usage of nitrofurantoin showed since 2007 constant increase. Considering the resistance of *E. coli* between 2005 and 2010, significant decrease in resistance was observed for amoxicillin (from 46.1% to 42.9%;  $p = 0.006$ ), cephalixin (from 21.3% to 10.2%;  $p < 0.0001$ ) and co-trimoxazole (from 28.9% to 23.3%;  $p < 0.0001$ ). While resistance to nitrofurantoin remained very low in both study periods (2.4% in 2005, 2.1% in 2010), resistance to FQs significantly increased (8.6% in 2005, 12.0% in 2010;  $p < 0.0001$ ).

**Conclusion:** Due to the updates in Croatian guidelines on empirical treatment of CA-UTIs, changes in ambulatory use of antibiotics occurred. Withdrawal of amoxicillin, cephalixin and co-trimoxazole from the list of first line agents for empirical treatment of uncomplicated cystitis, elicited significant improvement in susceptibility of uropathogenic *E. coli* to these antibiotics. Since no obvious rise in FQ use occurred, the increasing trend in FQ resistance which might be caused by the spread of highly epidemic FQ-resistant uropathogenic *E. coli* clonal groups requires further investigation.

**P1062** An innovative study of intra-abdominal infections to test the appropriateness of the revised trust antibiotic prophylaxis in adult surgery guidance. Results from intra-abdominal infections study for monitoring antimicrobial resistance trend

A. Gan\*, R Sharma, S. Ravi, M. Wong, A. Peel, M. Przybylo, A. Guleri (Blackpool, UK)

**Background:** Blackpool Teaching Hospitals (BTH) operate a successful healthcare associated infection (HAI) and antibiotic stewardship programme. Revised antibiotic prophylaxis in adult surgery (APAS) guidance including new antibiotic choices to reduce *C. difficile* infections (CDI) was implemented. BTH was one of the UK sites for the study monitoring antimicrobial resistance trend (SMART) in intra-abdominal infections (IAI). We present findings of an innovative project aimed to assess the appropriateness of the revised APAS antibiotic choices in abdominal surgery by comparing it to SMART IAI isolates/susceptibility results.

**Methods:** A review of database of 61 intra-abdominal infections (IAI) isolates (from pus/intra-abdominal swabs) submitted to SMART (2008–10). Comparing this to the revised APAS guidance for abdominal surgery **Results:** Revised APAS guidance for abdominal surgery is an aminoglycoside plus metronidazole at induction replacing previous guidance of cefuroxime plus metronidazole.

Results from SMART: *Escherichia coli* 60% (18/30), followed by *Klebsiella pneumoniae* 13% (4/30), *Enterobacter cloacae* 7% (2/30). Five percent *E. coli* isolated were ESBL positive but fully sensitive to gentamicin. MICs to following antibiotics were tested in the study: ertapenem (ETP), imipenem (IMP), cefepime (CPE), cefotaxime (CFT), cefoxitin (CFX), ceftazidime (CAZ), ceftriaxone (CAX), ampicillin/sulbactam (A/S), piperacillin/tazobactam (P/T), amikacin (AK), ciprofloxacin (CP), levofloxacin (LVX). Key susceptibility results included: *E. coli*: 100% to ETP, IMP and AK; >90% to cephalosporins; >80% to A/S, CP and LVX. *Klebsiella pneumoniae*: 100% susceptible to all antibiotics tested. ESBL+ *E. coli* organisms: 100% susceptible to ETP, IMP, A/S, P/T and AK.

From 2008 to 2010, a downward trend of reduced susceptibility was noticed – *E. coli* to cephalosporins, fluoroquinolones and piperacillin/tazobactam. *K. pneumoniae* remained 100% susceptible to all agents in this study over the years.

**Discussion:** The trust has successfully and significantly reduced rates of CDI, MRSA and ESBL +ve Gram negatives over the last 3 years. There is high emphasis on antibiotic stewardship, education/training, regular microbiology ward rounds and consultations, regular antibiotic compliance audits and feedback. This innovative project examined the

appropriateness of the revised APAS guidance. All isolates were susceptible to aminoglycosides while reduced susceptibility to cefuroxime was evident from this study. Details to be presented.

**P1063 Point prevalence study for local antibiotic prescription and usage trends used in a large non-academic teaching hospital in the Netherlands**

T. Sprong\*, H. Huntjens-Fleuren, I. Gyssens, A. Horrevorts, J. Schouten, A. Voss, J. Meis, T. Dofferhoff, M. Nabuurs-Franssen (Nijmegen, NL)

**Introduction:** In order to optimize in-hospital antibiotic usage, it is essential to gain insight which antibiotics are used and how these choices are made in the local situation. Recently, the European Surveillance of Antibiotic Consumption (ESAC) has developed a Point Prevalence Study for antibiotic surveillance. This is a limited time consuming method to gain insight in local prescribing policies. We adapted this method to see whether, how and when infection specialists (microbiologists and ID physicians) are involved in the decision to start a certain antibiotic.

**Methods:** The Canisius–Wilhelmina Hospital is a large 653-bed non-academic teaching hospital in the Netherlands with all the major hospital specialties present. Via the electronic prescription system of the hospital pharmacy, all patients that used one or more antibiotics at 1 day in the fall of 2007 and spring of 2011 were identified. Patients with surgical prophylaxis were excluded. With a standardised questionnaire, the treating physicians were interviewed to gain insight how the choice for a certain antibiotic prescription was made.

**Results:** Of all admitted patients, 27% (2007) and 22% (2011) were using antibiotics. Types of antibiotics prescribed and indications were similar between 2007 and 2011. An infection specialist was involved in 39% (2007) and 28% (2011) of prescriptions. Reasons for consultation were a positive culture result in 23%, a direct question about empirical therapy in 23% and a multidisciplinary meeting in 44% of cases. If an infection specialist was consulted, antibiotic therapy was often aimed at a certain pathogen, in contrast to patients that received prolonged (>72 hours) empirical therapy, for which in a minority of patients consultation was sought (50% vs. 8.8% of patients respectively  $p < 0.001$ ).

**Conclusions:** A point prevalence study is a fast way to gain insight into local antibiotic prescription and usage trends in a hospital. The PPS can be used to detect reasons for infection consultation. In our hospital we found that multidisciplinary meetings are very important for advice on antibiotic decision making. However, we had poor control on patients that are using prolonged empirical therapy, which is an important group for streamlining antibiotics.

**P1064 Adherence to recommendations by infectious disease consultants and its influence on outcomes of intravenous antibiotic-treated hospitalised patients**

G. Saravia\*, J. Calvo, C. Fariñas-Alvarez, M. Gutierrez-Cuadra, B. Abascal-Bolado, M. Fernández-García, R. Rodríguez-Galindo, J. Sanabria-Cabrera, M. Gomez-Fleitas, M.C. Fariñas (Santander, ES)

**Background:** There is a well-established role of infectious diseases (ID) specialists in antimicrobial stewardship. A prospective, randomized, 1-year study was performed to analyse the effects of ID recommendations and adherence by treating physicians on clinical outcome in hospitalized antibiotic-treated patients in a tertiary university hospital in Spain.

**Methods:** Patients receiving intravenous antimicrobial therapy prescribed by the primary service for 3 days were identified and randomised to intervention or non-intervention. Interventions consisted of treatment recommendations by IDs. Appropriateness of empirical treatments (prescribed by treating physicians) was classified as adequate, inadequate or unnecessary. In the intervention group, the

degree of adherence to intervention was classified as complete, partial or non-adherence.

**Results:** A total of 1173 antibiotic-treated patients were included in the study, 602 patients in the non-intervention and 571 patients in the intervention group (199 [34.9%] showing complete adherence, 141 [24.7%] partial adherence and 231 [40.5%] non-adherence to recommendations). In the multivariate analysis for adherence (R2 Cox = 0.065,  $p = 0.009$ ), non-adherence was associated with prolonged antibiotic prophylaxis ( $p = 0.004$ ; OR = 0.37, 95%CI = 0.19–0.72). In the multivariate analysis for clinical outcome (R2 Cox = 0.126,  $p < 0.001$ ), Charlson index ( $p < 0.001$ ; OR = 1.19, 95%CI = 1.10–1.28), malnutrition ( $p = 0.006$ ; OR = 2.00, 95%CI = 1.22–3.26), nosocomial infection ( $p < 0.001$ ; OR = 4.12, 95%CI = 2.27–7.48) and length of hospitalization ( $p < 0.001$ ; OR = 1.01, 95%CI = 1.01–1.02) were associated with clinical failure, while complete adherence ( $p = 0.001$ ; OR = 0.35, 95%CI = 0.19–0.64) and adequate initial treatment ( $p = 0.010$ ; OR = 0.39, 95%CI = 0.19–0.80) were associated with clinical success.

**Conclusions:** Intervention and adherence to recommendations were associated with favorable clinical outcome, which in turn was associated with shortened length of hospitalization. This may have important health–economic benefits and stimulates further investigation.

**P1065 Comparison of antimicrobial consumption measured by defined daily dose and days of therapy in VINCat hospitals**

S. Grau\*, E. Fondevilla, S. Mojal, M. Palomar, J. Vallés, T. Arranz, M. Barrera, N. Bosacoma, M. Espona, P. Marcos, C. Mestres, E. Òdena, F. Gudiol (Barcelona, ES)

**Background:** Several units of measurement have been performed to estimate antimicrobial consumption. Studies focused on relationship between defined daily dose (DDD) and days of therapy (DOT) are scarce.

**Objectives:** The aim of this study is to assess the relationship between DDD and DOT measures in antimicrobial consumptions in several VINCat hospitals in Catalonia (Spain).

**Methods:** The average of antimicrobial consumption of a representative sample of 7 VINCat hospitals in 2010 was calculated in DDD/100 occupied bed-days (OBD) and DOT/100 OBD.

Global, medical and surgical antimicrobial consumption was analyzed. Antibacterial (J01) and antimycotic (J02) consumption were calculated separately.

Data of antimicrobial consumption are presented with means and standard deviation. Relationship and differences between two measures was assessed using simple linear regression and paired Student's *T* test. Agreement was also calculated with intraclass correlation coefficient (ICC). *p* Values <0.05 were considered statistically significant.

**Results:** The mean of antibacterial consumption in global area was 90.4 DDD/100 OBD ( $\pm 44.1$  of standard deviation) and 68.8 DOT/100 OBD ( $\pm 31.6$ ), with differences statistically significant ( $p = 0.016$ ). The ICC was 0.787 (95%CI: –0.029; 0.964). In surgical wards, the antibacterial consumption was 72.1  $\pm$  16.2 (DDD/100 OBD) and 59.5  $\pm$  16.7 (DOT/100 OBD);  $p = 0.006$ , ICC = 0.743 (95%CI:

-0.063; 0.971). In medical wards, the differences were not significant ( $p = 0.092$ ).

The antimycotic consumption in global area was  $1.72 \pm 1.97$  (measured in DDD/100 OBD) and  $1.43 \pm 1.46$  (in DOT/100 OBD). The differences between the two measurements were not significant ( $p = 0.283$ ) and the ICC was 0.938 (95%CI: 0.677; 0.991).

Graphic 1 shows the relationship between DDD/100 OBD and DOT/100 OBD, including estimated formula from simple linear regression.

**Conclusions:** Differences between DDD and DOT were observed in antibacterial (J01) group, mainly in surgical wards. In general, antimicrobial consumption measured with DOT seems to be lower than in DDD. Simple linear regression shows greater differences when consumption is higher.

Wide confidence intervals in estimations have been observed. Further studies based on bigger samples should be performed to confirm our results.

#### **P1066** Analysis of antibiotic usage in Ukraine

H. Demchuk\*, Y. Mostovoy (Vinnitsa, UA)

**Objectives:** To estimate dynamics of antibiotic consumption in Ukraine expressed in DDD per 1000 inhabitants per day (DDD/1000/day).

**Methods:** Data about antibiotic selling in Ukraine during 2007–2010 years from data base SMD company was analyzed. Information about DDD was taken from site of WHO. Dynamics of total antibiotic consumption and different groups was evaluated.

**Results:** In Ukraine antibiotic consumption had tendency to decreasing: in 2007 it was 9.30 DDD/1000/day, in 2008 – 9.20, in 2009 – 9.16 and in 2010 it was decreased till 8.64 (-8.5%). Penicillines was the most frequently prescribed antibiotics. Level of their use was almost in two times higher than antibiotics of the other groups and varied in range 2.82–2.95 DDD/1000/day. Top in this group was amoxicillin but with little diminishing use in dynamics. Consumption of amoxicillin/clavulanate during 4 years was increased on 76.9%. Ampicillin use was decreased on 40%, ampicillin/oxacillin – on 46.2%. Second place of antibiotic use occupied fluoroquinolones with tendency to diminishing from 1.77 DDD/1000/day in 2007 till 1.5 in 2010. More than 86% of prescriptions were ofloxacin, norfloxacin, ciprofloxacin. But part of their use was gradually decreasing on 76.5% in 2010 in comparing with 2007. During this period use of levofloxacin increased in five times. Macrolides consumption had tendency to diminishing from 1.65 DDD/1000/day in 2007 till 1.30 DDD/1000/day in 2010 (-12.9%). Leading position among macrolides took up azithromycin with growth +113.3% and clarithromycin. Use of midecamycin was decreased in 2.5 times. Consumption of cephalosporines raised on 19.4%. The most frequently used drug from this group was ceftriaxone with growth from 0.45 DDD/1000/day in 2007 till 0.59 in 2009 and little decrease to 0.54 in 2010. Consumption of cefuroxime rose in 2.5 times and cefazolin use was diminished more than 50.0%. Use of tetracyclines decreased on 28.0% co-trimoxazole on 42.9% and chloramphenicol on 22.8%. It reflected positive changes in antibiotic prescriptions.

**Conclusion:** Level of antibiotic consumption in Ukraine is low. We found positive tendency at the penicillines, macrolides, cephalosporines use that may restrain developing antibiotic resistance in our country. Level of fluoroquinolones use requires conducting actions for diminishing consequence of non-rational antibiotic therapy.

#### **P1067** Experience of a large Belgian centre in multidrug-resistant *Pseudomonas aeruginosa* bloodstream infections

M. Hanappe, M. Hites\*, S. Roisin, R. Surin, O. Denis, D. De Backer, J.L. Vincent, F. Jacobs (Brussels, BE)

**Objectives:** Emergence of MDR, including strains producing metallo- $\beta$ -lactamase, has been increasingly reported in *P. aeruginosa*. As these

strains are frequently resistant to all antibiotics except colistin, treatment of infections by these strains remains an unevaluated therapeutic challenge. We aimed to review our clinical experience in treating patients (pts) who developed bacteraemia due to MDR *P. aeruginosa*.

**Methods:** Retrospective, observational study on all pts who developed bacteraemia due to MDR *P. aeruginosa* from 2004 to 2011, in our institution. An MDR *P. aeruginosa* was defined as a strain resistant to carbapenems, 3rd and 4th generation cephalosporins and aminoglycosides or quinolones. The presence of MBL was confirmed by PCR for blaIMP and blaVIM genes detection.

**Results:** Thirty pts (19M, 11F), median age 55 years (range 24–87) were included. All had received broad spectrum antibiotics during the preceding month, and 29/30 had at least one co-morbidity factor. Infection developed a median of 17 days after admission (0–139). VIM producing *P. aeruginosa* was identified in 18 episodes. Previous colonization by MDR-*P. aeruginosa* was detected in five pts. Primary sources of infection were: pulmonary ( $n = 13$ ), intra-abdominal ( $n = 8$ ), upper urinary tract ( $n = 2$ ), catheter ( $n = 2$ ), others ( $n = 2$ ) and unknown ( $n = 3$ ). Twenty-seven pts needed intensive care unit management. Susceptibility testing showed that all strains were susceptible to colistin, and that aztreonam, gentamicin and piperacillin-tazobactam were the next most effective drugs, but all with high MIC's. Empirical antimicrobial treatment consisted in a combination of a median of two antimicrobial drugs (range 1–4). Appropriate treatment (at least some in-vitro activity) was administered in a combination of 4 ( $n = 2$  pts), 3 ( $n = 11$  pts), 2 ( $n = 7$  pts) or 1 ( $n = 1$  pt) drugs. The most frequently used combination was aztreonam, colistin and either piperacillin-tazobactam, ciprofloxacin or gentamicin/amikacin (10 pts), given at very high dosages. Source control was performed in six pts. Eighteen pts died (60%) after a median delay of 4 days (0–16). Death was infection-related in 15/18 pts.

**Conclusion:** The mortality rate of our patients was very high, probably because patients had many co-morbidities, and because of the delay in administering appropriate antimicrobial treatment, due to the paucity of active drugs.

#### **P1068** Latvian point prevalence study for healthcare associated infections and antimicrobial use in acute care hospital by using ECDC PPS protocol

E. Dimina\*, M. Kula, A. Baholdina, U. Dumpis on behalf of the National Nosocomial Infections Study Team

**Objective:** Point prevalence studies on antibiotic use were performed in Latvian hospitals as a quality improvement tool since 2002. Lack of standardised methods and strict definitions of infections was the most important shortcoming of these studies. Our goal was to examine the prevalence of antibiotic use and healthcare-associated infections (HAI) in acute care hospitals with the new ECDC protocol designed for all EU countries.

**Methods:** Study was done in accordance with ECDC Point prevalence survey of HAI and antimicrobial use in European acute care hospitals (ECDC PPS) protocol version 4.2. All acute care hospitals were invited to participate in the first ECDC PPS organised in Latvia. Eighteen hospitals and hospital unions were invited and 14 voluntary agreed to participate. Two of them were specialized hospitals. Hospitals that didn't participate in the study were small size local hospitals. Investigators were trained in the special course before the start of the study. Training included detailed explanation of all variables collected during the study and practical exercise with case studies. Data were entered in HelicsWin database and analysed with EpiData 3.1.software.

**Results:** There were 3367 patients eligible for study and in average 37.8% of patients received antibiotics on the study date. The three most prevalent antibiotics were ceftriaxone, ciprofloxacin, and amoxicillin with enzyme inhibitor. There was substantial variability in antibiotic use across hospitals from the highest 59.3% to the lowest 26.2%. 9.8% of all antibiotics were prescribed for surgical prophylaxis. Antibiotics were predominantly used intravenously. The most common indications

for antibiotic treatment were community acquired pneumonia (CAP) and urinary tract infection (UTI). In 3.6% of patients investigators reported HAI, but not in all cases it corresponded to study HAI definitions due to lack of detailed investigations and laboratory data. The most common HAI recorded were pneumonia and surgical site infection.

**Conclusions:** We think that ECDC PPS protocol was successfully implemented in Latvia. High proportion of participating hospitals provided a good overview on situation in our country and the protocol could be used to assess interventions. At the same time it should be noted that strict HAI definitions constituted a problem for investigators since different diagnostic algorithms and financial possibilities exist in our hospitals.

#### **P1069** Antibiotic sales in rural and urban pharmacies in Northern Viet Nam: an observational study

*T.N. Do Thi\*, T.K.C. Nguyen, P.H. Nguyen, Q.H. Nguyen, T.T. Nguyen, T.L. Hoang, K.T. Tran, D.P. Ho, V.Y. Nguyen, V.K. Nguyen, P. Horby, H.F.L. Wertheim (Hanoi, VN)*

**Background:** In Vietnam, antibiotics can only be sold with a prescription. But previous studies have shown that there is a high inappropriate use of antibiotics in the community in Vietnam. The majority of antibiotics are sold without a prescription, often for acute upper respiratory infections that do not need antibiotic treatment. The problem of irrational use of antibiotics should be minimized as it drives resistance development. Better understanding of practices and economic incentives of antibiotic dispensing is needed to design effective interventions to reduce inappropriate antibiotic use.

**Objectives:** This study aims to assess the current practices and economic profitability of antibiotic sales for rural and urban pharmacies in northern Vietnam.

**Method:** This cross-sectional study used both quantitative and qualitative techniques. All drug sales were observed and recorded for 3 days at thirty private pharmacies (15 urban, 15 rural). Pharmacy staffs were interviewed by a semi-structured questionnaire and this was followed by in-depth interviews of drugstore owners and drug sellers.

**Results:** In total 2953 drug sale transactions (2083 urban and 870 rural) were observed. Twenty-four percent (499/2083) of the urban transactions contained antibiotics and 29.5% (257/870) of the rural transactions. Antibiotics contributed 13.4% in urban and 18.7% in rural to the total sales of pharmacies. Most antibiotics were sold without a prescription: 88% in urban and 91% in rural pharmacies. The most frequent reported reason for buying antibiotics in urban area was cough (31.6%) and fever in the rural area (21.7%). The three most common sold antibiotics were ampicillin/amoxicillin (29.1%), cephalexin (12.2%) and azithromycin (7.3%). Consumer often demanded antibiotics without a prescription: 49.7% in urban and 28.2% in rural, respectively. The qualitative data revealed that the knowledge of antibiotics and antibiotic resistance of drug sellers and customer's awareness are low, especially in rural area.

**Conclusion:** Suggested areas of improvement are enforcement of regulations and increase knowledge of drug sellers as well as customer's awareness to reduce pressure for drug sellers to dispense antibiotics inappropriately.

#### **P1070** Antimicrobial pharmacists in the UK – a role model for Europe

*K. Hand, W. Lawson\* (Southampton, London, UK)*

**Objectives:** To describe the evolving role of UK hospital pharmacists in antimicrobial stewardship, to allow pharmacists and hospital managers from other European countries to benchmark their pharmacy services.

**Methods:** Review of the UK published literature and informal discussion with practising hospital antimicrobial pharmacists.

**Results:** UK hospital pharmacists have established specialist roles and become integrated into multi-disciplinary clinical teams. The majority of UK hospitals now have specialist antimicrobial pharmacists (APs). Networks and training: Over 450 hospital pharmacists with an interest in infection subscribe to an infection management network e-mail discussion forum hosted by the UK Clinical Pharmacy Association and there are over 250 APs. Regional networks of APs exist throughout the UK, providing opportunities for shared learning and experience. Formal links have also been forged with several UK medical infection societies. A 2-year post-graduate Infection Management MSc course for antimicrobial pharmacists and short course are offered at Imperial College, London. Guidelines and education: A primary role of APs is facilitating the development, dissemination and implementation of treatment guidelines. APs lead projects to deliver innovative solutions to implementation including: intranet websites; pocket-sized booklets; and Smartphone applications.

APs lead on auditing adherence to antimicrobial prescribing policy with regular feedback to prescribers. APs from over 100 hospitals contributed to the first national point prevalence study on antimicrobial use as part of the 2011 European survey of Healthcare Associated Infections. APs provide expert advice to pharmacy colleagues and hospital doctors on the clinical pharmacology of antimicrobials. Many APs refer patients to and attend regular antimicrobial stewardship ward rounds with their microbiology or Infectious Diseases medical colleagues. Surveillance: and governance Antimicrobial consumption data are derived from hospital pharmacy dispensing computer systems in the UK. APs convert dispensing data to the standard currency of WHO defined daily doses for benchmarking and quality assurance reports for hospitals management boards. Such data are collated nationally for hospitals in Scotland, Wales and Northern Ireland.

**Conclusions:** UK hospital pharmacists have successfully established a specialist role in antimicrobial stewardship, bringing unique skills and adding value to the multi-disciplinary team.

#### **P1071** Off-label use of anti-infective drugs in an Italian paediatric cohort

*S. Aguzzi\*, F. Mignone, C. Bertaina, D. Montin, M. Pinon, S. Virano, D. Le Serre, S. Garazzino, C. Scolfaro, P.A. Tovo (Turin, IT)*

**Objectives:** The European Medicines Agency (EMA) estimated that 50–90% of drugs used for treating children were studied exclusively in adults. There are few clinical trials about safety of drug prescriptions in children. The aim of this study was to evaluate off-label (OL) anti-infective drugs prescriptions in hospitalized children.

**Methods:** We retrospectively reviewed 712 anti-infective systemic prescriptions in children hospitalized at Regina Margherita Children's Hospital (Turin, Italy), who underwent an infectious disease (ID) consult, from December 2010 to February 2011. Anti-infective drugs were assessed according to the following variables of prescription: indication, age, dose, method of administration and duration. We divided patients in two groups in relation to their acute or chronic disease. Data were assessed in each group according to drug-prescribing physician, pediatrician or ID consultant. The use of these anti-infective drugs was compared to the Italian Medicines Agency (AIFA) recommendations and to current available guidelines (see Table 1).

**Results:** One hundred and fifty patients received anti-infective drugs (mean age 5.7 years, 54% males). The most frequent conditions in

Variable of prescription	Prescription OL for AIFA	Prescription OL for AIFA and not conformed to current guidelines*
indication	11.5%	10%
age	12.9%	6%
dose	39.2%	36%
method of administration	24.3%	35%
duration	12.1%	13%

\* Sanford Guide to Antimicrobial Therapy (2010); Sanford Guide to HIV/AIDS Therapy (2011); National Institute for Health and Clinical Excellence's British Guidelines for urinary tract infections (2007), tuberculosis (2011) and meningitis (2010); Recommendations of the Italian Association of Pediatric Hematology and Oncology for anti-infective therapy and prophylaxis in oncohematological patients (2010)

acute group were respiratory (32%) and infectious diseases (28%), whereas in chronic group were oncological (31%) and cardiological (24%) ones. Ninety percent of children received at least an OL drug, without significant difference between acute and chronic group (91% vs. 90%). 53.8% of total prescriptions were OL: antibiotics, antivirals and antifungals were OL in 62%, 50% and 20% of cases, respectively. Including drugs with more than one OL variables, the total OL prescriptions were 502 (see Table 1). Seventy-two percent of OL drugs were prescribed by ID consultant (71% in acute and 73% in chronic patients). Twenty-three percent of OL prescriptions for AIFA agreed with current guidelines, whereas 41% of anti-infective prescriptions were OL for AIFA and not agreed with these guidelines (see Table 1). Sixty-seven percent of ID consultant's prescriptions agreed with analyzed guidelines.

**Conclusions:** Our study confirmed that there is a discrepancy between official licenses and use of drugs in paediatric clinical practice. The EMEA, with the institution of the European Regulation, the Task Force in Europe for Drug Development for the Young and the Paediatric Investigation Plans, is working to improve safety and propriety of children treatment. Innovative study design for paediatric clinical trials are emerging. A greater number of guidelines is needed.

#### **P1072** Creation of the European Surveillance of Veterinary Antimicrobial Consumption (ESVAC) project

J. Torren-Edo\*, A. Muller, D. Mackay, K. Grave (London, UK)

**Objectives:** The ESVAC project was launched in 2009 following a request from the European Commission to the European Medicines Agency (EMA) to establish a surveillance program for the collection of data on the sales of veterinary antimicrobial agents in the EU. The purpose is to obtain valid and standardised data for risk profiling, setting risk management priorities and to assess the impact of recommendations on responsible use of antimicrobials for animals.

**Methods:** In 2009, a pilot project was set up, including an advisory group consisting of representatives from already existing national surveillance programs. Representatives from ECDC, EFSA and ESAC (European Surveillance of Antimicrobial Consumption in man) were also involved in order to harmonise surveillance of consumption and antimicrobial resistance across the human and veterinary sectors. The pilot project defined the ESVAC protocol and form for data collection and submission, following recommendations from international organizations such as WHO and OIE.

To document the situation of antimicrobial consumption in animals, including agents critically important for humans, the project collected aggregated, retrospective data from nine countries.

In 2011, the project sent its first call for data collection to the EU countries.

**Results:** The ESVAC protocol and data collection form have been developed (<http://www.ema.europa.eu>). The annual sales data will be collected as the number of packages for each antimicrobial product, including the product's details and linked to the ATCvet classification. A technical unit for estimating the animal population potential exposed to treatment with antimicrobials has been created: The Population Correction Unit (PCU) taking into account weight at treatment and import/export of animals. Eighteen European Countries have already delivered data for 2010 using the ESVAC protocol. In parallel, ESVAC analysed 5 years of aggregated data from nine countries.

**Conclusions:** ESVAC developed a standardised protocol for collecting sales data for veterinary antimicrobial agents and an indicator for measuring the animal population potentially exposed to antimicrobial treatment. In 2011, nine of 18 countries delivering data started collecting such data for the first time. During 2011 two workstreams on collection of harmonised data per animal species in order to obtain use per species and on the development of standardised units of measurement have been initiated.

#### **P1073** Using milk from cows on antimicrobial therapy as feed for calves – a potential risk for dissemination of resistant bacteria?

A. Duse\*, U. Emanuelson, H. Ericsson Unnerstad, Y. Persson, K. Persson Waller, B. Bengtsson (Uppsala, SE)

**Objectives:** The aim of this ongoing cross-sectional study is to describe how and to what extent milk from cows on antimicrobial therapy is fed to calves in Swedish dairy herds and whether this approach can be linked to the high prevalence of resistance among fecal *Escherichia coli* from calves.

**Methods:** In a web-based survey, a representative sample of 457 farmers responded to questions covering the use of colostrum and milk from cows subjected to antimicrobial therapy. In 300 of these herds, fecal swabs from three calves in the age of 1–4 weeks will be collected for antimicrobial susceptibility testing. For each sample, the minimum inhibitory concentration for 14 antimicrobial substances and the within-sample prevalence of *E. coli* resistant to cefotaxime, streptomycin and quinolones will be determined. Additional data regarding use of antimicrobials in the herd will be collected from databases as well as from the farmers.

**Results:** Eleven percent of the farmers always discarded colostrum from cows treated during the dry period, while 45% of the farmers always fed such colostrum to calves. In the rest of the herds such colostrum was used only under special conditions, e.g. if colostrum from untreated cows was unavailable. When antimicrobial therapy was used during lactation, 56% of the farmers always, or with some restrictions, gave milk from these cows to calves during treatment as well as withdrawal period. Twenty-four percent of the farmers gave such milk during the withdrawal period only and the remaining 20% of the herds never fed such milk to calves. These results together with antimicrobial susceptibility results and data on antimicrobial usage will be analyzed to find significant associations or trends. Preliminary results from these analyses will be presented.

**Conclusions:** This study indicates that the use of milk from cows treated with antimicrobials is widespread on Swedish dairy farms, but at this point in time no conclusion can be drawn whether this has any effect on the prevalence of antimicrobial resistance among fecal bacteria from calves.

#### **P1074** ESBL-producing enterobacteria in retail chicken meat, Berlin, Germany

A. Kola\*, A. Eisele, C. Waigwa, Y. Pfeiffer, W. Witte, P. Gastmeier (Berlin, Wernigerode, DE)

**Objective:** To examine the role of retail chicken meat as a reservoir of ESBL-producing Gram-negative bacteria.

**Methods:** Between 16 and 26 August, 2011, 199 fresh raw chicken meat samples purchased from Berlin stores of six supermarket chains, two whole food shops and a butcher were cultured for ESBL-producing Gram-negative bacteria on selective chromogenic plates after broth enrichment. ESBL-positive isolates were affirmed by DDST using 3rd generation cephalosporins with/without clavulanic acid. Species identification and antimicrobial susceptibility testing was performed as well as PCR for ESBL genes, plasmid-mediated AmpC genes and PMQR genes. Strain typing by PFGE will be performed.

**Results:** Of the 199 retail chicken meat samples tested, 76 (38%) turned out to be positive for ESBL-producing Gram-negative bacteria (*Escherichia coli* n = 71, *Serratia fonticola* n = 3, *Escherichia fergusonii* n = 1 and *Enterobacter cloacae* n = 1). Using PCR and sequencing, ESBL-types CTX-M-1 (n = 36), SHV-12 (n = 32), TEM-52 (n = 6), CTX-M-14 (n = 1) and CTX-M-15 (n = 1) were identified. *E. coli* isolates from 43 samples additionally contained TEM-1 beta-lactamase and in two *E. coli* isolates the SHV-1 enzyme was identified. Two further *E. coli* strains isolated from two meat samples exhibited no effect in DDST with clavulanic acid. Molecular analyses revealed AmpC-production (CMY-2) in both strains. Antimicrobial

susceptibility testing showed increased MICs for ciprofloxacin (MIC 0.25–16 mg/L) in *E. coli* from 37 samples (19%) and resistance to SXT in *E. coli* from 30 samples (15%). PMQR genes were not detected indicating mutations in chromosomal-encoded genes (parC, gyrA) might be the cause for increased ciprofloxacin MICs.

There were no significant differences with respect to origin and point of purchase. All chicken meat samples were exclusively produced in Germany.

**Conclusion:** A substantial proportion of retail chicken meat samples purchased from Berlin groceries yielded ESBL-producing Gram-negative bacteria. Therefore, retail chicken meat may act as reservoir for the transmission of ESBL-positive bacterial strains or genes to humans via the food chain. Further molecular analysis has to be done to prove this hypothesis.

#### **P1075** Increased raw poultry meat colonisation by extended-spectrum beta-lactamase-producing *Escherichia coli* in southern Spain

P. Egea\*, L. López-Cerero, E. Torres, M.C. Gómez-Sánchez, L. Serrano, M.D. Navarro, J. Rodríguez-Baño, A. Pascual (Seville, ES)

**Objectives:** The present study was conducted in order to assess trends in the prevalence and diversity of extended spectrum beta lactamase producing *E. coli* (ESBLEC) colonizing retail poultry meat samples in our area. Results were compared to those obtained in a previous study in 2007 where a high percentage of retail meat (39.8%) colonized by ESBLEC was found. Spread of the O25b:H4-ST131 clonal group was also investigated.

**Methods:** In 2010, 15 of either chicken and turkey breasts samples were purchased in local supermarkets in Seville (Southern Spain) along a period of 12 weeks. Samples were processed by stomaching, incubated overnight in pre-enrichment broth and plated in MacConkey agar with cefotaxime and ceftazidime. Suspected *E. coli* colonies were selected from each sample based on morphological criteria and further identification was performed by standard biochemical tests. ESBL screening was performed by double disk synergy test according to CLSI. Characterization of ESBL and phylogenetic grouping of isolates were carried out by PCR and sequencing. Antibiotic susceptibility was determined by agar diffusion. Genetic relatedness was assessed by PFGE for phylogroup A1 isolates. Results were compared with those obtained in a previous study performed in 2007. For categorical variables comparison, chi-squared or Fisher's tests were performed.

**Results:** ESBLEC was detected in 14 (93.3%) of 15 chicken samples and in 14 (93.3%) of turkey meat samples. The prevalence of poultry meat ESBLEC colonization increased from 62.5% (2007) to 93.3% (2010) in our area ( $p = 0.005$ ). Sixty ESBLEC isolates were recovered from meat samples. Phylogroups B1 and A1 encompassed more than 60% of the isolates. Sequence type ST131 or B2 phylogroup isolates were not detected. Clonal relationship was found between 2 CTX-M-1-producing isolates included in A1 phylogenetic group. SHV-12 was the most frequently detected ESBL harboured by *E. coli* (65%), although its prevalence has significantly decreased since 2007 at expenses of CTX-M ESBLS. Resistance to quinolones continues to be significantly high, with 85.35% and 32.79% of isolates showing resistance to nalidixic acid and ciprofloxacin, respectively.

**Conclusion:** An increasing trend of ESBLEC colonization in raw poultry meat, particularly by CTX-M-producing isolates, has been observed in our area in a short period of time.

#### **P1076** Comparison of ESBL contamination in organic and conventional retail chicken meat

J.W.T. Cohen Stuart\*, T. Van den Munckhof, G. Voets, J. Scharringa, A. Fluit, M. Leverstein-Van Hall (Utrecht, NL)

**Objectives:** Contamination of retail chicken meat by Extended Spectrum Beta-Lactamase (ESBL) producing bacteria likely contributes to the increasing incidence of infections with these bacteria in humans. This study aimed to compare the prevalence and load of ESBL positive isolates between organic and conventional retail chicken meat samples, and to compare the distribution of ESBL genes, strain genotypes and co-resistance.

**Methods:** In 2010, 98 raw chicken breasts ( $n = 60$  conventional;  $n = 38$  organic) were collected from 12 local stores in the Netherlands. ESBL producing micro-organisms on the meat samples were detected by homogenizing 25 grams per meat sample with peptone water. The homogenate was directly inoculated on an ESBL selective agar for quantitative cultures, and after a pre-enrichment step for qualitative cultures. Species determination was performed usingaldi-tof. Phenotypic ESBL production was confirmed using ESBL Etests. ESBL genes were detected by PCR and sequencing. Minimum inhibitory concentrations (MICs) of antibiotics were determined by broth micro-dilution. Strain typing was performed using multi locus sequence typing.

**Results:** Prevalence of ESBL producing micro-organisms was 100% on conventional and 84% on organic samples ( $p < 0.001$ ). Median loads of ESBL producing micro-organisms were 80 CFU (range <20–1360) in conventional, and <20 (range 0–260) CFU/25 gram in organic samples ( $p = 0.001$ ). The distribution of ESBL genes in conventional samples and organic samples was 42% vs. 56%, respectively (N.S.), for CTX-M-1, 20% vs. 42% (N.S.) for TEM-52, and 23% vs. 3% ( $p < 0.001$ ) for SHV-12. CTX-M-2 (7%), SHV-2 (5%) and TEM-20 (3%) were exclusively found in conventional samples. Co-resistance rates of ESBL positive isolates were not different between conventional and organic samples (co-trimoxazole 56%, ciprofloxacin 14%, and tobramycin 2%), except for tetracycline, 73% and 46%, respectively,  $p < 0.001$ . Six of 14 conventional meat samples harbored four MLST types also reported in humans and five of 10 organic samples harbored three MLST types also reported in humans (2 ST10, 2 ST23, ST354).

**Conclusion:** The majority of organic chicken meat samples were also contaminated with ESBL producing *E. coli*, and the ESBL genes and strain types were largely the same as in conventional meat samples.

#### **P1077** Contamination of retail samples of roasted pork (Sui Mei) in Hong Kong

C. Young, M. Boost\*, M. O'Donoghue (Kowloon, HK)

**Objectives:** *Staphylococcus aureus* is a major cause of food poisoning and in Hong Kong the majority of such outbreaks have been ascribed to intake of roasted pork although there appear to have been no studies to determine rates of contamination of this popular local food. This study aimed to determine rates of *S. aureus* contamination. The presence of enterotoxin and leukocidin genes and resistance to methicillin was determined.

**Methods:** Samples were purchased from 50 retail outlets preparing roasted pork on the premises. Five millilitres of a 25 g homogenate were enriched in 6% NaCl Tryptone Soy Broth (TSB) for 24 hours and then streaked onto ChromeID SA agar. Five millilitres of the TSB were further enriched in TSB with 5 mg/L ceftiozime and 75 mg/L aztreonam for 24 hours before plating onto ChromeID MRSA agar. *S. aureus* isolates were confirmed by latex agglutination and susceptibility to cefoxitin determined by disc diffusion. Isolates appearing resistant were confirmed as methicillin-resistant *S. aureus* (MRSA) by presence of *mecA* and SCCmec type was determined. All isolates were characterized for presence of enterotoxins SEA-SEE and Panton-Valentin Leukocidin (PVL).

**Results:** Twenty-four (48%) samples yielded *S. aureus*, two samples having two strains. Of these three were resistant to cefoxitin, but only two (4%) were *mecA* positive (one SCCmec IVb, one V). The remaining strain was shown to be a beta-lactamase hyper producer (MIC penicillin 10 g/L). Enterotoxin genes were present in five methicillin-sensitive isolates and PVL in one.

**Conclusions:** Almost half of the samples were positive for *S. aureus* and 10% of samples yielded enterotoxin-positive strains, confirming that this food could be an important vehicle for staphylococcal food poisoning since it is usually kept at room temperature before sale and not reheated before consumption. The presence of community associated MRSA in two samples may be of concern as it demonstrates its ability to be transferred by contaminated foodstuffs. High rates of MRSA have been reported in pork carcasses in Hong Kong and further study of the source of contamination on roasted meat are needed.

**P1078** Did SARS have a long-lasting effect on levels of nasal colonisation and hand contamination of food handlers in Hong Kong?

J. Ho, M. Boost, M. O'Donoghue\* (Kowloon, HK)

**Objectives:** Hand and nasal carriage of *Staphylococcus aureus* in food handlers is recognized as a major source of food poisoning. During the SARS epidemic in 2003, strict enforcement of hand hygiene, use of face masks and gloves was implemented in efforts to reduce viral transmission. Immediately before SARS onset, we commenced a longitudinal study of *S. aureus* colonization of food handlers. A marked drop in both hand and nasal colonization was observed in the follow-up performed 2 months post-SARS, which we attributed to compliance with improved hygiene measures. Long term effects of the interventions have not been investigated. This study investigated colonization in food handlers 8 years on.

**Methods:** One hundred and fifty workers at four catering establishments provided nose and hand samples. Nasal swabs were enriched in Brain Heart Infusion broth supplemented with 5% NaCl at 37°C overnight and then subcultured onto ChromID *S. aureus*. Hand contamination was estimated by fingerprint impressions of the dominant hand on Mannitol Salt agar. All isolates were confirmed by Staphaurex and tested for susceptibility to a range of antibiotics.

**Results:** Pre-SARS nasal carriage was 35% and hand contamination 41%, reducing in the immediate post-SARS period to 22.3% and 11.5% respectively ( $p = 0.001$ ). In the current follow-up the nasal carriage rate remained stable (22.8%) and hand contamination dropped to 6.5%. Resistance to fusidic acid rose significantly over the period from 25% to 59%. Reductions in tetracycline and erythromycin resistance rates were noted though not reaching significance. Resistance to other antibiotics appeared unchanged (Table 1). Methicillin resistance rates remain low. Strains isolated were SCCmec type V.

**Conclusions:** The remarkable decrease in colonization rates following SARS may be attributed to reduced opportunities for spread to transient carriers due to use of protective measures accompanied by improved hand hygiene. Since SARS, food handlers' routine use of gloves and masks if having respiratory symptoms has resulted in sustained low

colonization rates. A significant increase in fusidic acid resistance may reflect increased use due to concern about community-associated MRSA infection. Decreases in erythromycin and tetracycline resistance may reflect reduced local use of these agents. Resistance to other agents had not increased and may be related to sustained efforts to reduce antibiotic prescribing in the community.

## Bacterial fitness and antibiotic resistance of Gram-negative bacteria

**P1079** In silico search for QnrVC-like family members

M.J. Pons\*, C. Gomes, J. Ruiz (Barcelona, ES)

**Objectives:** The present work was designed to analyse the phylogenetic relationships of QnrVC-like sequences with respect to the established plasmid-encoded Qnr-families (QnrA, QnrB, QnrC, QnrD and QnrS), as well as to search GenBank for possible QnrVC-related sequences.

**Methods:** Representative sequences of the established plasmid encoded Qnr-families such as those present in <http://www.lahey.org/qnrStudies> were included in the phylogenetic analysis. Additionally, a similarity search in GenBank was performed using the DNA and protein sequences of QnrVC1 (protein GenBank access No: ACC54440; DNA GenBank access No: EU436855) as a template. Following established criteria sequences were considered as possibly related if their similarity was higher than 70%.

**Results:** The results show the presence of 10 different Qnr sequences, either plasmid or chromosomal-encoded with amino acid similarities higher than 70% with respect to QnrVC1. Thus, two chromosomal-encoded sequences of *Vibrio cholerae*, two of *Photobacterium profundum* and one of *Vibrio orientalis* and *Allivibrio salmonicida* respectively, as well as three plasmid-encoded sequences, one recovered from *Aeromonas caviae* (protein GenBank access: ADI55014), other from *Vibrio fluvialis* (protein GenBank access: AEM62764) were detected, and, surprisingly, QnrC was also included. Finally, a non-indicate full closely related ORF was found in a class 1 integron environment (DNA GenBank accession number: GU944730) from *Acinetobacter baumannii*, but no information related to its chromosomal or plasmid location was found.

**Conclusion:** Eleven sequences that following the current established normative may be considered as family-related has been found in GenBank. From these, at least two sequences has been found as plasmid encoded, then QnrVC is need to be considered as a new transferable Qnr family. The close similarity (higher than 70%) between the QnrC and QnrVC families may suggest the need for nomenclature unification following the current established normative.

**P1080** Comparison of the virulence genetic pool of *Pseudomonas aeruginosa* clinical and environmental isolates with public health relevance

S.G. Pereira\*, A.C. Rosa, R. Leitão, O. Cardoso (Coimbra, PT)

**Objectives:** Virulence factors (VF) are intrinsic characteristics of bacteria related to their infection ability. Several VF have been described in *Pseudomonas aeruginosa* (PA). Although thoroughly known in clinical setting, PA is also an aquatic bacterium. Thermae is a health care unit where physicians treat several health conditions using natural mineral water (NMW) that cannot be disinfected prior to use. If PA is present in thermae NMW, users contact with contaminated water and a health problem may occur. The aim of this study was to understand the prevalence of VF in NMW PA and clinical isolates, in order to better understand the health risk associated to PA contamination of thermae NMW.

**Methods:** Seventy-seven PA clinical isolates (PACI) and 77 PA thermae isolates (PATI) were screened for 20 VF encoding genes, by Polymerase Chain Reaction (PCR): motility (flag, orfF, pilA, pilB),

Table. Antibiotic resistance rates of *S. aureus* isolates over an eight year period

Antibiotics	Sampling period		p-value (chi-square test)
	2002/03 (%)	2011 (%)	
Fusidic acid	25	59	<0.001
Ciprofloxacin	2	6	0.25
Co-trimoxazole	1	0	0.56
Gentamicin	3	3	0.98
Clindamycin	29	32	0.71
Erythromycin	25	18	0.51
Tetracycline	21	12	0.33
Methicillin	1	1	NA

phenazines (phzI, phzII, phzH, phzM, phzS), proteases (apr, lasA, lasB), type III effector system (exoS, exoY) and genomic islands PAG11 (orf3, orf12), PAG12 (C22, C105) and PAG13 (SG8, SG100). PCR products sequencing and Blast analysis was performed. Statistical analysis was executed on IBM® SPSS® version 19.0, to compare the distribution of VF genes individually (Fisher's exact test) and by classes (Mann-Whitney test).

**Results:** One thousand five hundred and forty PCR screens were performed in each population. Six hundred and twenty-seven and 653 positive results were obtained in PACI and PATI, respectively. Statistically significant differences between populations were observed in the distribution of flag, phzH, phzM, phzII, apr, lasA, lasB, exoY, orf3, orf18, C105, SG8 and SG100 ( $p < 0.05$ ). Fisher's exact test showed that phzM, apr and lasA were more prevalent in PACI and other genes were more prevalent in PATI. Mann-Whitney test showed that PAG12 genes were more prevalent in PACI; phenazine and type III effector system genes were more prevalent in PATI and no significant differences in the distribution of motility, protease, PAG11 and PAG13 gene classes were observed ( $p > 0.05$ ).

**Conclusion:** PACI and PATI presented similar amounts of VF genes, but significant differences in their distribution. This shows that PA isolates, regardless of source, have basic pathogenic mechanisms necessary for infection. The different VF genetic pool observed may suggest that the type of VF present in populations are relevant for their infection ability, since PA infections associated to thermae practice are not known and clinical isolates are effectively causing illness.

#### P1081 Impact of antibiotic resistance and beta-lactamase carriage on virulence of *Klebsiella* spp.

C. Caneiras\*, F. Calisto, G. da Silva, L. Lito, J. Melo-Cristino, A. Duarte (Lisbon, Coimbra, PT)

**Objectives:** In severe infections, Extended Spectrum beta-lactamases (ESBLs) and expression of various virulence factors may work in harmony, resulting in the treatment failure of Multidrug Resistant (MDR) *Klebsiella* spp. It remains somewhat unclear how beta-lactamase carriage affects virulence. We assessed the effects of  $\beta$ -lactamases and ESBL carriage on the virulence of *Klebsiella* spp. clinical isolates.

**Methods:** This study included 93 representative clinical isolates of *Klebsiella pneumoniae* ( $n = 86$ ) and *Klebsiella oxytoca* ( $n = 7$ ) that were collected between 1980 and 2011. The isolates were characterized in groups according to the  $\beta$ -lactamases produced, namely TEM, SHV, CTX-M and KPC. The virulence of each isolate was assessed by PCR amplification for six virulence genes: k2A (K2 serotype), fimH (fimbrial adhesins type 1), mrkD2 and mrkD3 (fimbrial adhesins type 3), khe (haemolysin) and iucC (aerobactin). A  $p$  value of  $\leq 0.05$  was used to indicate statistical significance. Average number of virulence factor genes per isolate was calculated.

**Results:** The isolates TEM-type  $\beta$ -lactamase producers (1980) showed an average number of virulence genes per isolate of 2.0 although the CTX-M-15 ESBL producers (2004–2009) showed 3.0. These results were higher when the *Klebsiella* spp. isolates are associated with carbapenemase KPC-3 genes (2009–2011), especially KPC-3 coupled with TEM-type, SHV-type and CTX-M-15 that showed an average number of 4.8. Among the KPC-3 producers no significant differences in virulence factor production were found. In the TEM-type isolates ( $n = 5$ ) was identified only khe (4/5, 80%), mrkD2 (3/5, 60%) and mrkD3 (3/5, 60%); The CTX-M-15 isolates ( $n = 40$ ) showed fimH (36/40, 90%), khe (22/40, 55%), mrkD2 (36/40, 90%), mrkD3 (24/40, 60%) and iucC (1/40, 2.5%). Finally the KPC-3/TEM/SHV/CTX-M-15 isolates ( $n = 5$ ) with K2 (3/5, 60%), fimH (5/5, 100%), khe (4/5, 80%), mrkD2 and mrkD3 (both with 5/5, 100%) and iucC (2/5, 40%). The presence of K2 serotype and iucC aerobactin in KPC-3 producers *Klebsiella pneumoniae* isolates was more significant ( $p \leq 0.05$ ) than in the other isolates.

**Conclusions:** The presence of ESBL enzymes suggested an association to virulence among the producing isolates. Carriage of

KPC-3 carbapenemase enzymes significantly impacts on the virulence of *K. pneumoniae* isolates producing these enzymes.

#### P1082 Colistin susceptible *Acinetobacter baumannii* that turns resistant after colistin treatment: effect on virulence and bacterial fitness

R. López-Rojas\*, M. McConnell, F. Fernández-Cuenca, M.E. Jiménez-Mejías, J.A. Lepe, J. Pachón (Sevilla, ES)

**Objectives:** Recently, we have observed the development of stable colistin (COL) resistance in *Acinetobacter baumannii* after COL treatment of a nosocomial infection by a COL susceptible *A. baumannii* strain (*J Infect Dis* 2011; 204: 1147–1148). The aim of this study was to evaluate the effect of COL resistance acquisition on the virulence and fitness of *A. baumannii* clinical strains, and the mechanism of resistance.

**Methods:** *Strains:* *A. baumannii* CS01 (MIC  $\leq 0.03$  mg/L) and its COL resistant mutant (CR17, MIC  $\geq 16$  mg/L) isolated after colistin treatment were used. For in vitro growth, bacterial duplication time, and competition index (CI) experiments, growth curves in Mueller-Hinton broth were performed for both strains separately and in combination, and bacterial concentrations at 2, 4, 8, 24, 48, and 72 hours were determined. Virulence was assessed in a murine peritoneal sepsis model by inoculating groups of five C57BL/6 mice with 0.5 mL of an 8 log CFU/mL inoculum, and diminishing the inoculum by a factor of 10 until 0% mortality was reached (mortality and time to death were measured). For in vivo growth and CI experiments, groups of 19 mice were infected with both strains separately, and with a 50% mixture of both. In each group, three animals were sacrificed at 2, 4, and 8 hours, and 10 animals at 24 hours (were the CI was calculated), and the bacterial concentration in the spleen was determined. In order to characterize pmrA and pmrB mutations, genomic DNA from both strains was extracted, amplified with specific primers, and sequenced.

**Results:** Duplication time was 43 min for CS01 and 40.7 min for CR17. There were no in vitro growth significant differences between strains when grown separately, but CR17 growth was lower than CS01 when grown in competition (24 hours CI 0.097, 72 hours CI 0.008). CS01 was more virulent than CR17 in terms of mortality (see Table 1) and time to death. During in vivo growth, CS01 reached a maximal concentration in the spleen of 10 log CFU/g, whereas CR19 reached a maximal concentration of 9.17 log CFU/g. Growing in competition, CS01 decreased to 9.31 log CFU/g (0.69 log decrease), while CR17 decreased to 6.97 log CFU/g (2.2 log decrease). The in vivo CI was 0.016. In pmrA a mutation was identified: met12lys; no mutations were found in pmrB.

Mortality	8 log CFU/mL	7 log CFU/mL	6 log CFU/mL	5 log CFU/mL	4 log CFU/mL	3 log CFU/mL	2 log CFU/mL
CS01	100 %	100 %	100 %	100 %	100 %	20 %	0 %
CR17	100 %	100 %	100 %	100 %	10 %	0 %	0 %

**Conclusion:** The acquisition of COL resistance in *A. baumannii* clinical isolates after COL treatment, related to a PmrA mutation (met12lys), leads to an in vivo fitness loss and a decreased virulence.

#### P1083 Contribution of a different pattern of stimulation of the innate immune system in virulence of *Klebsiella pneumoniae*-producing carbapenemase

I. Pantelidou\*, D. Carrer, M. Georgitsi, E. Giamarellos-Bourboulis (Athens, GR)

**Objectives:** It is postulated that mortality of nosocomial infections by multidrug-resistant (MDR) *Klebsiella pneumoniae* is related to the lack of active antimicrobials. It was investigated if part of the effect of MDR may be related with the stimulation pattern of host immune responses.

**Methods:** Twenty blood isolates were studied: five isolates susceptible to antimicrobials, five ESBL-producing, five VIM-producing and five

KPC. Genetic diversity was defined by PFGE. Peripheral blood mononuclear cells of healthy volunteers were in vitro stimulated at a density of  $5 \times 10^6$  CFU/mL by live and heat-killed (HK) isolates for the production of pro-inflammatory cytokines in the presence of monosodium urate (MSU) that is a NLRP3-inflammasome agonist. Cytokines were measured by an enzyme immunoassay. Survival of 30 C57B6 male mice was recorded after intraperitoneal challenge with three susceptible and three KPC-producing isolates in five mice each.

**Results:** Respective mean release of TNF $\alpha$  after 1.5 hours stimulation with  $5 \times 10^3$  CFU/mL of live susceptible, ESBL-producing, VIM-producing and KPC isolates was 1492.1, 1144.3, 1459.5 and 1381.0 pg/mL; it became 4104.8, 4619.3, 4157.0 and 4791.8 pg/mL after 2.5 hours. Respective mean release of IL-1 $\beta$  after 1.5 hours stimulation with  $5 \times 10^3$  CFU/mL of live susceptible, ESBL-producing, VIM-producing and KPC isolates was 38.9, 35.3, 53.4 and 63.5 pg/mL; it became 499.9, 572.7, 517.8 and, 684.2 pg/mL after 2.5 hours ( $p = 0.017$  KPC vs. susceptible). Surprisingly, mean release of IL-1 $\beta$  after stimulation of PBMCs with HK-susceptible and HK-KPC isolates was 383.2 and 311.9 pg/mL respectively; it was changed to 1902.8 and 2150.2 pg/mL after addition of MSU denoting significant synergy at the NLRP3-stimulation level. Median survival of mice challenged by the susceptible isolates was 166 hours as opposed to 122 hours after challenge by KPC isolates (log-rank: 4.908,  $p = 0.027$ ).

**Conclusions:** Considerable differences are encountered in the stimulation of human PBMCs by susceptible *K. pneumoniae* and KPC probably related with the potential for NLRP3 stimulation. These differences may have an impact on therapeutics.

#### **PI084** Inverse relationship between pathogenicity and NDM-1 carriage in *Escherichia coli*

J. Tyrrell\*, P. Warn, L. Payne, R. Howe, M. Woodward, T.R. Walsh (Cardiff, Manchester, Surrey, UK)

**Objectives:** Microbial virulence potential and antibiotic resistance are major contributors promoting survival and colonisation of an infected host. It has been hypothesised that the evolution of these two factors may be intrinsically linked. Herein we investigate the virulence potential of Multi-drug-resistant (MDR) NDM-1-carrying *E. coli* (EC), and whether this may be directly or indirectly related to the expression and transfer of blaNDM-1 plasmids.

**Methods:** Isolates in this study were EC of four categories: (i) parental NDM-1 positive isolates ( $n = 13$ ), (ii) 12 year old ESBL-positive EC from India ( $n = 12$ ), (iii) Cardiff susceptible EC from UTI specimens ( $n = 20$ ), (iv) Transconjugants of 1) were obtained by transferring blaNDM-1 plasmids into EC J53, with confirmation by NDM-1 PCR (PrimerF-GAA GCT GAG CAC CGC ATT, PrimerR-TGC GGG CCG TAT GAG TGA TT). Virulence was assessed in *Galleria mellonella* larvae using inocula of  $1 \times 10^7$ ,  $10^6$ ,  $10^5$ ,  $10^4$  and  $10^3$  CFU/larva for each test isolate administered in  $10 \mu\text{L}$  aliquots through the rear-left proleg of the larvae hemocoel. Larvae were incubated at  $37^\circ\text{C}$  and survival rates were scored at 24 hour intervals until 72 hours, death accepted once there is no longer a response to touch.

**Results:** Statistical analysis of mean survival rates showed all test categories were significantly different, apart from NDM-1 and ESBL EC. The NDM-1 EC were least virulent, with larvae survival rates comparatively high and LD90s seen for only five isolates, at  $10^7$  and  $10^6$  CFU/larva. In comparison, 80% of susceptible EC had LD90s as low as  $10^4$  CFU/larva, with ESBL isolates slightly less virulent with LD90s of  $10^5$  CFU/larva. Of 13 blaNDM-1 positive EC, 12 gave positive transconjugants. Of four NDM-1 with reasonable virulence, the corresponding transconjugants gave similar virulence with LD90s much lower than the mainly avirulent J53 recipient. All other transconjugants had low virulence reflecting that of J53.

**Conclusions:** We have highlighted the increased virulence of J53 by introduction of NDM-1 plasmids, suggesting the recruitment of mobile virulence-determinants onto these MDR-gene constructs. Contradictory

however, overall our results show a definite trend where virulence is inversely proportional to resistance phenotype, highlighted by the survival rate hierarchy seen; Susceptible EC > ESBL EC > NDM-1 EC. This suggests divergent evolution, favouring either a strongly resistant, or highly-pathogenic existence, but not both.

## Emergence of bacterial resistance in humans, animals and the environment

### **PI085** First report of an OXA-23 carbapenemase-producing *Acinetobacter baumannii* strain in Spain

P. Espinal\*, M. Maciá, E. Gato, I. Roca, F. Fernández-cuenca, L. Martínez-Martínez, J. Pachón, J. Rodríguez-Baño, A. Pascual, G. Bou, M. Tomás, J. Vila (Barcelona, Mallorca, A Coruña, Seville, Santander, ES)

**Background:** Resistance of *A. baumannii* isolates to carbapenems is on the rise, and it is mainly associated with a variety of combined mechanisms, among which, the production of carbapenem-hydrolyzing class D beta-lactamases (CHDLs) particularly OXA-23, OXA-24, and OXA-58 have been identified worldwide.

**Objective:** The aim of this study was to analyze the genetics of the blaOXA23 gene in an *A. baumannii* clinical isolate recovered in Spain.

**Methods:** We studied an *A. baumannii* clinical isolate recovered from the sputum of a 70-year-old male with chronic obstructive pulmonary disease, at the San Dureta hospital in Mallorca-Spain. The isolate was identified by MicroScan and confirmed by MALDI-TOF-MS. Antibiotic susceptibility was performed by MicroScan and interpreted according to CLSI guidelines. Multiplex PCR was performed to identify clonal lineages according to Turton et al. (CMI, 2007, 13: 807). Genes encoding CHDLs (OXA-23, OXA24, OXA-51 and OXA-58) and ISAb elements were detected by PCR and sequencing. Southern blot was performed by digestion with the S1 nuclease and hybridization with the blaOXA-23 probe. Genetic surrounding of the blaOXA-23 gene was obtained by inverse PCR mapping.

**Results:** The strain belonging to pan-European clone II showed resistance to amikacin (>256 mg/mL), ceftazidime (>128 g/mL), tetracycline, ciprofloxacin, gentamicin and netilmicin (>64 mg/mL), piperacillin (>512 mg/mL), imipenem and meropenem (16 mg/mL) and susceptibility to tigecycline and colistin (0.5 mg/mL). Multiplex PCR for CHDLs was only positive for blaOXA-51 and blaOXA-23. Southern blot clearly revealed that blaOXA-23 was located in the chromosome. Genetic surroundings showed two copies of ISAb1 in opposite directions of the blaOXA-23 gene, suggesting a composite transposon structure. An additional ATPase gene identical to that identified in Tn2006 was located downstream from the gene.

**Conclusion:** The presence of two ISAb1 sequences flanking the blaOXA-23 gene and constituting a Tn2006-like compound transposon might suggest their involvement in both blaOXA-23 expression and mobilization. While OXA-24 producing *A. baumannii* isolates are commonly found in Spain and Portugal, this is the first time that an OXA-23 carbapenemase producing *A. baumannii* isolate has been reported in Spain.

### **PI086** A case of New Delhi metallo-beta-lactamase 1 in the Netherlands with secondary transmission

T. Halaby\*, E.A. Reuland, N. Al Naiemi, A. Potron, P.H.M. Savelkoul, C.M.J.E. Vandenbroucke-Grauls, P. Nordmann (Enschede, Amsterdam, NL; Le Kremlin Bicêtre, FR)

**Objectives:** Acquired carbapenemases such as New Delhi metallo-beta-lactamase 1 (NDM-1) are emerging resistance determinants in Gram-negative bacteria, leaving few or no therapeutic options. Here we describe a NDM-1 case in the Netherlands, imported from the Balkan area, and a secondary case in the same hospital.

**Materials and methods:** The study was performed as part of a retrospective analysis on a collection of 485 Enterobacteriaceae isolates, from patients in the east of the Netherlands. Antimicrobial susceptibility testing and species identification were performed by the VITEC 2. Carbapenems MIC values were determined by the E-test. Phenotypic ESBL confirmation was performed by a combination disc diffusion. For phenotypic confirmation of carbapenemase production, the modified Hodge test (MHT) and two inhibitor-based tests: ertapenem-boronic acid and imipenem-EDTA, were used. A microarray was used for genotypic characterisation of ESBL's and carbapenemases. Characterisation of NDM-gene and plasmid analysis, were done using PCR, sequencing and cloning. Genetic relatedness is tested by Amplified Fragment Length Polymorphism (AFLP). For genotyping the Multilocus sequence typing (MLST) was used.

**Results:** Two ESBL producing *K. pneumoniae* strains from two patients were selected for further analysis by their elevated MIC's to meropenem. One patient was transferred from a hospital in Belgrado, Bosnia, to hospital in the east of the Netherlands on the 27th of August 2008 and directly placed in a separate room in isolation because of MRSA carriage. The second patient, with no travel history outside the Netherlands, was admitted to the same hospital between the 10th of October and the 7th of November 2008. The results of antimicrobial susceptibility testing and phenotypic confirmations are shown in Table 1. Molecular gene analysis revealed NDM-1, CTX-M-15, SHV-12, TEM-1, and OXA-1. Molecular plasmid analysis revealed the presence of a 70 kb, Inc II plasmid containing the bla NDM-1, and a 140 kb plasmid in both isolates. AFLP showed that both strains were identical. MLST analysis showed that both isolates belong to ST15.

patient	strain	MIC (µg/ml)										phenotypic confirmation				
		amikacin	aztreonam	cefepime	ceftriaxone	colistin	ertapenem	imipenem	meropenem	netilmicin	teicoplanin	vancomycin	MHT	ERT/EDTA	CD	ERT/EDTA
index case	<i>K. pneumoniae</i> strain	≥ 64	≥ 32	≥ 16	≥ 16	≥ 4	0	0	0	0.25	1.5	yes	yes	yes	yes	yes
secondary case	<i>K. pneumoniae</i> strain	≥ 64	≥ 32	≥ 16	≥ 16	≥ 4	0	0	0	0.19	1.5	yes	yes	yes	yes	yes

MHT: modified Hodge test; CD: combined disc

**Conclusions:** This first encountered NDM-1 producing *K. pneumoniae* in the Netherlands underlines further that Balkan states constitute a secondary reservoir for NDM-1 producers. While cross transmission in Europe of NDM-1 producers has sporadically been reported, the index case was associated with a secondary case despite proactive measures aimed to control spread of resistant bacteria.

#### P1087 Retrospective summary report of integron study in a local hospital in southern China

Z. Xu\*, L. Li, G. Yu, L. Shi, B. Li, J. Su, M. Shirtliff (Guangzhou, CN; Baltimore, US)

**Objectives:** To retrospectively summarize the occurrence and prevalence of resistance integron elements within clinical bacteria from the First Affiliated Hospital of Jinan University (FAHJU) in Guangzhou, China.

**Methodology:** During 1998 to 2006, integron screening had been conducted on a total of 583 clinical isolates, and data of this summary study were partially obtained from some of our PhD dissertations and local reports.

**Results:** Class 1 integrons were found in 73.6% (243/330) of the gram-negative strains, ranging from 85% to 90% for *Escherichia coli* (89.3%, 109/122), *Klebsiella pneumoniae* (87.5%, 28/32), *Acinetobacter* spp. (91.3%, 21/23), *Enterobacter cloacae* (86.7%, 13/15) and other organisms (90%, 18/20), except *Pseudomonas aeruginosa* (45.8%, 54/118). In gram-positive bacteria, the detection rate was 49.0% (124/253), with 42.5% (76/179) in *Staphylococcus aureus*, 56.6% (30/53) for coagulase-negative staphylococci, 84.6% (11/13) for *Enterococcus faecalis*, 100% (2/2) for *Enterococcus faecium* and 83.3% (5/6) for *Streptococcus* spp., summing up the total class 1 integron prevalence as 63.0% (367/583). The most frequently detected resistance genes were

*aadA* (88.3%, 324/367) and *dfrA* (74.9%, 275/367) family, with the identification rate of cassette arrays found to be 54.5% (200/367) for *dfrA12-orfF-aadA2*, 18.8% (69/367) for *dfrA17-aadA5* and 16.1% (59/367) for *aadA2*, respectively. Class 2 integron had been occasionally observed, taking up 5.7% (33/583) of all isolates, including 23 *P. aeruginosa*, 6 *E. coli*, 2 *E. faecalis*, 1 *Proteus vulgaris* and 1 *Proteus mirabilis* strains, and cassettes arrays were detected to be *dfrA1-sat1-aadA1*. None of the tested strains was positive for class 3 integron. Nevertheless, one *S. aureus* strain isolated from sputum in 2003 was found to be positive for *intI3*, while the variable region and both flanks remained unknown.

**Conclusions:** The commonly carriage of integron elements may confer multi-resistance for clinical organisms and further contribute to the unleashing waves of "Super Bugs".

#### P1088 Macrolide and tetracycline resistance in *Moraxella catarrhalis* isolates from 2009 to 2011 is higher in the Asia Pacific Region than in other regions of the world

R. Flamm\*, H. Sader, D. Farrell, R. Jones (North Liberty, US)

**Objective:** To evaluate the activity of macrolides and other agents against *Moraxella catarrhalis* by geographic region for isolates from 2009 to 2011. *M. catarrhalis* are generally susceptible to most agents except penicillins due to the production of beta-lactamases. Resistance (R) to tetracycline (TET), cephalosporins, and macrolides is generally <1% in most regions of the world.

**Methods:** Susceptibility (S) testing for *M. catarrhalis* was performed by Clinical and Laboratory Standards Institute (CLSI) broth microdilution methodology on isolates from 2009 to 2011 from medical centers in the SENTRY Antimicrobial Surveillance Program platform in the European Union (EU), United States (USA), Latin America (LA), and Asia-Pacific region (APAC). S interpretations were performed using CLSI guidelines (Clarithromycin [CLR], S ≤ 2 mg/L; TET, S ≤ 2 mg/L; trimethoprim/sulfamethoxazole [TMP/SXT], S ≤ 0.5 mg/L).

**Results:** In the EU, there were more than 400 isolates and none were R to CLR or TET. In the USA there was 1 (0.1%) isolate R to CLR and 1 (0.1%) R to TET. In LA, no isolate was CLR- or TET- (0/70) R. However in the APAC region 13 of 172 (7.6%) isolates were CLR-R and eight of 251 (3.2%) were TET-R. Twelve of 13 of the CLR-R and seven of eight of the TET-R isolates were from China. 5.8% of the isolates in APAC had telithromycin MIC values ≥ 2 mg/L (isolates were from China and Korea). TMP/SXT-R ranged from 5.1% in the US and EU to 7.0% and 7.1% in APAC and LA, respectively. Beta-lactamase production ranged from 97.1% (EU) to 100.0% (LA). 10.4% (APAC) to 15.7% (LA) of the isolates had cefepime MIC values at 2 mg/L. In APAC 2.8% of MIC values for ciprofloxacin were ≥ 0.5 mg/L.

**Conclusions:** Macrolide and tetracycline R in *M. catarrhalis* for isolates from the period 2009–2011 was ≤ 0.2% in NA and EU. In the APAC region CLR-R and TET-R were significantly elevated (3.2–7.6% R). The higher rate in the APAC region was primarily due to isolates from multiple sites in China. TMP/SXT-R occurred in all regions ranging from 5.1% to 7.1%.

#### P1089 Report of linezolid resistance from the Zyvox® Annual Appraisal of Potency and Spectrum programme (Europe, Latin America, Asia Pacific)

J. Ross, R. Jones\*, R. Flamm, L. Deshpande (North Liberty, US)

**Objectives:** To monitor the in vitro activity and to detect resistance (R) to linezolid (LZD) in various geographic areas of the world, excluding the United States (USA), the Zyvox® Annual Appraisal of Potency and Spectrum Program (ZAAPS) surveillance program was established in 2002. LZD, the first oxazolidinone agent clinically applied, is an important therapeutic option for infections caused by antimicrobial-R Gram-positive (GP) pathogens. Although rare, LZD-R has been observed among coagulase-negative staphylococci (CoNS) in more

frequency than enterococci (ENT). R rates remain extremely low for indicated *S. aureus* (SA) and streptococci.

**Methods:** Five thousand seven hundred and sixty-nine isolates were collected from 57 sites in 34 countries in 2011. Isolates were received from the following organism groups (n): SA (2831), CoNS (656), ENT (747), *Streptococcus pneumoniae* (SPN; 878), viridians group streptococci (VGS; 244) and beta-haemolytic streptococci (BHS; 413). At least 200 isolates from each country (except China [n = 800]; the United Kingdom and Japan [n = 400]) were requested to be sent to a reference laboratory. CLSI broth microdilution susceptibility (S) testing was performed using TREK Diagnostic (Cleveland, OH, USA) panels. LZD-R isolates were confirmed with frozen broth microdilution, Etest (BioMerieux, Marcy l'Etoile, France) and disk diffusion methods. PCR and sequencing were performed to detect mutations in 23S rRNA, L3, L4, and L22 proteins, and acquired genes (cfr).

**Results:** Overall LZD-S in the ZAAPS study was >99.8% with only nine isolates identified as non-susceptible (NS). LZD-S by organism group: SA 100.0%; CoNS 98.9%; ENT 99.7%; all streptococci had LZD MIC values of  $\leq 2$  mg/L (S). The cfr gene was identified in three CoNS strains with LZD MIC values of 4 mg/L (Mexico and France), also in a *S. epidermidis* from Spain with a LZD MIC of 8 mg/L and a *S. epidermidis* from France had both a G2576T mutation and cfr gene with a LZD MIC of >128 mg/L (three isolates with cfr in 2010 ZAAPS study). MRSA rate was 33.4% overall (27.7% Europe [EU]; 42.4% Latin America [LA]; 42.2% Asia Pacific [AP]). VRE rates were 9.2% in EU, 8.9% in LA and 1.1% in AP. SPN had overall penicillin and erythromycin R rates of 24.7% (MIC  $\geq 2$  mg/L) and 45.0%, respectively.

Table: Linezolid-R isolates found in the 2011 ZAAPS Program.

Species	City/Country	LZD MIC (mg/L)	R-mechanism
<i>E. faecium</i>	Leipzig/Germany	8	G2576T
<i>E. faecium</i>	Dublin/Ireland	8	G2576T
<i>S. capitis</i>	Athens/Greece	16	G2576T
<i>S. epidermidis</i>	Sao Paulo/Brazil	8	G2576T
<i>S. epidermidis</i>	Sao Paulo/Brazil	8	G2576T
<i>S. epidermidis</i>	Sao Paulo/Brazil	16	G2576T
<i>S. epidermidis</i>	Madrid/Spain	8	cfr
<i>S. epidermidis</i>	Genova/Italy	16	G2576T
<i>S. epidermidis</i>	Lille Cedex/France	>128	G2576T and cfr

a. 3 CoNS had a cfr associated with LZD MIC at 4mg/L.

**Conclusions:** LZD-R remains low at <1% among contemporary pathogens from surveyed organism groups. Continued worldwide monitoring of in vitro LZD activity appears warranted as the species containing the cfr gene continue to evolve.

#### P1090 Fifty per cent reduction of MRSA incidence in Belgian acute care hospitals: yes we can!

B. Jans\*, B. Catry, M. Costers, K. Mertens, A. Simon, O. Denis (Brussels, BE)

**Background:** Already in 1945, Sir Alexander Fleming warned scientists about the risk for antimicrobial resistance. Methicillin resistant *Staphylococcus aureus* (MRSA), first reported half a century ago, terrorises acute care hospitals in most European countries and abroad. In the early nineties, a Belgian policy for MRSA management in acute care hospitals was worked out including guidelines, microbiological and epidemiological surveillance, and improvement of identification techniques in the lab.

**Methodology:** Since 1994, the Scientific Institute of Public Health and the National MRSA Reference laboratory set up an epidemiological surveillance in acute care hospitals, collecting semi-annual MRSA data, aggregated at hospital level. Hospitals participated on voluntary basis until 2006, when participation became mandatory. Semestrial resistance rates (MRSA/*S. aureus*) and incidence of nosocomial MRSA (>48 hours after admission) were calculated on data excluding duplicates (patients counted only once). Semi-annual national and local feedback reports were sent to all hospitals. Surveillance data collected during 32 observation periods (1994–2010) are discussed here.

**Results:** Between 1994 and 1998, the resistance rate decreased from 24.4% to 14.4% and the incidence of nosocomial MRSA from 4.1 to 1.1 cases/1000 admissions. Afterwards, the resistance proportion and nosocomial incidence increased dramatically and doubled in a 5-year time span, reaching respectively 31.1% and 4.3 cases/1000 admissions. The year 2003 seemed to be a turning point. The resistance rate remained stable until 2005 and then slowly decreased (–8.7%) attaining 22.5% in 2010. In the same time span the incidence of nosocomial MRSA dropped from 4.3 to 1.8 cases/1000 admissions. Since 2006 all acute care hospitals perform MRSA screening of patients at risk or transferred from other healthcare facilities.

**Discussion:** Belgian hospitals successfully incurred the dramatic evolution. Since 2003, nationwide actions for the control of MRSA in Belgian healthcare facilities focus on five action lines: revision of guidelines for MRSA management in acute care hospitals, establishment of an antibiotic policy committee in each hospital, investigation of MRSA carriage in nursing homes (NH) resulting in specific NH MRSA guidelines, promotion of screening at admission and during hospital stay and the implementation of a successful Belgian hand hygiene program with four consecutive campaigns in healthcare settings.

#### P1091 In vitro doxycycline selection of *Bacillus thuringiensis*, *Bacillus cereus* and *Bacillus anthracis* Sterne with a one-step method

F. Janvier\*, F. Biot, E. Valade, F. Thibault, D.R. Vidal, J.D. Cavallo, A. Mérens (Saint Mandé, La tronche, FR)

*Bacillus anthracis* is a potential bio-threat agent. According to the recommendations of European Medicine Agency, doxycycline is an alternative therapy after ciprofloxacin. The ability of this pathogenic agent to develop quinolones and doxycycline resistance is a major concern.

**Objectives:** The first aim of this study was to determine the ability of *Bacillus cereus* related species, *B. thuringiensis*, *B. cereus* and *B. anthracis* to express resistance mechanisms to cyclines with a one step method using antibiotic selection pressure. The second aim was to test tige cycline in doxycycline resistant derivative strains.

**Methods:** *B. cereus* ATCC 7704, *B. thuringiensis* ATCC 36404, *B. anthracis* Sterne, and two clinical isolates of *B. cereus* and *B. thuringiensis* were used in this study. *B. anthracis* Sterne was handled in biosafety level 3 laboratory. Current cyclines resistance genes, tetL, tetK, tetM, tetO and tetS with specific PCR were screened before selection. Inoculation process was performed in triplicate with Mueller-Hinton agar containing increased doxycycline concentrations, using Whatman paper strips with different doxycycline concentrations (0.125–256 mg/L). After inoculation with a strong inoculum ( $10^8$ – $10^{10}$  CFU/mL), mutants were screened and mutational rate was estimated. MICs with and without efflux pump inhibitors were determined with agar dilution method.

**Results:** Screening of tet genes was negative for all wild-type strains. In vitro selection of *B. anthracis* Sterne was not possible with the

method used. We obtained doxycycline resistant mutants of *B. cereus* and *B. thuringiensis*. The two respective obtained mutants were resistant to doxycycline, tetracycline and minocycline but only *B. cereus* derivative resistant strain exhibited resistance to tigecycline. Efflux inhibitors were only effective in *B. thuringiensis*.

**Conclusions:** Opposite to *B. thuringiensis* and *B. cereus*, the selection of stable *B. anthracis* Sterne mutants resistant to doxycycline after in vitro antibiotic selection was not possible with our technique, confirming previous data with Szybalski method. These data have a clinical significance, since a course of doxycycline during 60 days is one of the recommended therapy/prophylaxis for inhalation anthrax related to intentional release. Mechanisms involved in the differences in mutational rate among *Bacillus cereus* related species need to be further investigated.

**P1092** Antimicrobial susceptibility and species identification of *Corynebacterium* spp. strains collected in Europe and USA medical centres, 2006–2010

H. Sader\*, P. Rhomberg, R. Jones, J. Ahman, E. Matuschek, G. Kahlmeter (North Liberty, US; Vaxjo, SE)

**Objectives:** To evaluate the antimicrobial susceptibility of *Corynebacterium* spp. clinical strains collected from European and USA medical centers. The accuracy of species identifications performed at local labs was also assessed.

**Methods:** One hundred and twenty-one *Corynebacterium* strains were collected from serious infections between 2006 and 2010 as part of the SENTRY Antimicrobial Surveillance Program from 15 and 18 medical centers in nine European countries and USA, respectively. The strains were susceptibility (S) tested by the CLSI broth microdilution method in cation-adjusted Mueller–Hinton broth against numerous antimicrobial agents. MIC results were interpreted according to CLSI M45 breakpoint criteria. There are yet no criteria from EUCAST. Species identifications were performed by MALDI-TOF methodology using the Bruker Biotyper system.

**Results:** Isolates were from bacteremia (53.6%), skin and skin structure (17.3%), pneumonia (12.7%), among other infection sites. Vancomycin (100.0% S) and daptomycin (99.1% S) showed potent activity against *Corynebacterium* with MIC<sub>50/90</sub> of 0.25/0.5 and ≤0.06/0.25 mg/L, respectively. *C. jeikeium* and *C. urealyticum* species groups demonstrated lower S rates, 0.0% for penicillin and 36.8–40.0% for gentamicin, compared to other *Corynebacterium* species groups (see Table 1). Sixty-one of 121 strains (50.4%) were identified to species level by the clinical laboratories and species identification was confirmed by the MALDI-TOF analysis on 47 (77.0%) of those strains. The remaining 14 strains had incorrect species (12) or genus (two strains, *Brevibacterium* and *Microbacterium*). Among the 60 strains submitted as unspiculated *Corynebacterium*, 51 (85.0%) strains were confirmed as *Corynebacterium* and identified to species level, while the remaining nine strains were identified to a different genus (*Brevibacterium* [3], *Microbacterium* [2], *Dermabacter* [1], *Rhodococcus* [1], *Staphylococcus* [1], *Truicella* [1]) by the MALDI-TOF analysis.

Organism/species (no. tested)	MIC <sub>50</sub> (mg/L) / % susceptible				
	DAP	ERY	GENT	PEN	VANC
All <i>Corynebacterium</i> spp. (110)	≤0.06/99.1	>2/24.6	≤2/80.9	1/51.8	0.25/100.0
<i>C. amycolatum</i> (33)	≤0.06/100.0	>2/27.3	≤2/84.9	1/63.3	0.5/100.0
<i>C. jeikeium</i> (19)	0.12/100.0	2/10.5	>8/36.8	>4/0.0	0.5/100.0
<i>C. striatum</i> (37)	≤0.06/99.3	>2/24.3	≤2/97.3	1/56.8	0.25/100.0
<i>C. urealyticum</i> (5)	≤0.06/100.0	>2/40.0	>8/40.0	>4/0.0	0.5/100.0
Other <i>Corynebacterium</i> spp. (16)	≤0.06/100.0	2/31.3	≤2/100.0	0.25/93.8	0.25/100.0

DAP = daptomycin, ERY = erythromycin, GENT = gentamicin, PEN = penicillin, VAN = vancomycin

**Conclusions:** Antimicrobial resistance differences among *Corynebacterium* species were noted with higher rates among the *C. jeikeium* and *C. urealyticum* species groups. Identification to the species level in clinical laboratories for *Corynebacterium* remains a challenge; however, the MALDI-TOF method appears to generate more complete and accurate identifications to be compared to antimicrobial-S profiles.

**P1093** Surveillance of non-O157 STEC isolates in the Netherlands, 2007–2011

W.K. Van der Zwaluw, D.W. Notermans\*, S. Kuiling, H.M.E. Maas, I.H.M. Friesema, M.E.O.C. Heck, W. van Pelt (Bilthoven, NL)

**Introduction:** In the Netherlands, an intensified surveillance of STEC O157 has existed since 1999. In 2007, the scope of this surveillance was widened to include non-O157 STEC isolates.

**Methods:** From 2007, laboratories were encouraged to use a real time PCR targeting shigatoxin (stx) genes 1 and 2 and submit up to five cultured isolates (sorbitol positive or negative) from a PCR positive faecal sample in an effort to obtain the isolate responsible for the positive signal. These isolates were tested for the presence of shigatoxin and other virulence genes and when found positive, were serotyped. Over the years, more laboratories included a PCR in their routine diagnostic workup. To limit the workload and to increase the recovery rate, in 2011 laboratories were asked only to submit isolates from faeces samples with a high DNA load (Ct ≤ 35).

**Results:** During 4 years (2007–2010) of STEC surveillance, this strategy resulted in submission of 3536 isolates from 703 different patients. Only for 193 patients (27.5%), an isolate could be found harbouring either the stx-1 or stx-2 gene. The preliminary results from 2011 indicate a significantly higher success rate (47.5%) for finding a shigatoxin gene positive isolate. In only 12 of these patients (6.2%), the isolate found was O157, but O157 is also submitted based on sorbitol negativity on SMAC, so this does not reflect the prevalence of O157 in the general population. Most frequently isolated serotypes are O63 (11.4%), O26 (10.9%) and O91 (7.3%). Remarkably, shigatoxin subtype 2f, which was added as a target for PCR in 2008, was found in 21.2% of all positive isolates.

**Discussion:** The increased success rate of isolating an STEC isolate in 2011 is most likely caused by a change in the submission criteria. Even though the number of O157 isolates found using this strategy does not represent prevalence in the general population, it is clear that diagnostic methods should also include non-O157 STEC. However, the clinical and public health relevance is not well-established for many of the non-O157 STEC serogroups. A new insight that this surveillance strategy has provided is the high occurrence of serotype O63, which carry subtype stx2f, and other STEC harbouring stx2f in the Netherlands. This shigatoxin subtype has also been described to be emerging in Germany but only occasionally in other countries.

**P1094** Occurrence of extended-spectrum beta-lactamases in *Shigella sonnei* and *S. flexneri* isolated after 2007 in Korea

N. Kim, S. Song, J. Kim, S. Hong, M. Park, S. Kim\* (Cheongwon-goon, KR)

**Objectives:** A nationwide survey was carried out in the Republic of Korea to know the prevalent type of extended-spectrum beta-lactamases (ESBLs) those produced by *S. sonnei* and *S. flexneri*

**Methods:** From 2007 to 2010, 507 clinical strains were isolated and screened for resistance to extended-spectrum cephalosporins based on the synergistic effect between clavulanate and selected beta-lactams (ceftazidime and cefotaxime) by the Clinical and Laboratory Standards Institute (CLSI) criteria. Classification of beta-lactamases was performed using multiplex PCR. Sequence analysis of the beta-lactamases including ESBL encoding genes was carried out.

**Results:** Twenty-six *S. sonnei* and two *S. flexneri* isolates were found to be ESBL positive by their phenotype. Twenty-four strains including two *S. flexneri* isolates, found to possess CTX-M ESBLs. Among these, 12 *S. sonnei* strains also contained TEM beta-lactamases. All 26 isolates found to possess CMY beta-lactamases by multiplex PCR. Nucleotide sequence analysis revealed that they harbored blaCTX-M-15 (13 *S. sonnei* and 2 *S. flexneri* strains), blaCTX-M-14 (10 *S. sonnei* strains), blaCTX-M-27 (10 *S. sonnei* strains), and blaTEM-1 (12 *S. sonnei* strains). In one strain, SS084469, we found two new TEM beta-

lactamses, did not reported so far. One contained a substitution (Phe55Leu), and the other had two substitution (Ser253Pro and His255Arg) in the blaTEM.

**Conclusion:** From these results, We found that, after 2007, the common type of ESBL in *S. sonnei* in Korea, changed from TEM type to CTX-M type. The predominance of CTX-M types in *S. sonnei* appears to be similar to that seen in other Enterobacteriaceae. This is the first report of the finding of two new TEM type beta-lactamases.

**P1095 Systemic and extraintestinal salmonellosis in Bulgaria: review of clinical cases, resistance to antimicrobial agents and PFGE typing of human non-typhoid *Salmonella* isolates**

G. Asseva\*, P. Petrov, K. Ivanova, T. Kantardjiev (Sofia, BG)

The self-limiting gastroenteritis is the most common form of human salmonellosis, but sometimes systemic generalization occurs and diverse extraintestinal foci appear as a consequence of the infection's spread. Multidrug-resistant isolates enhance the risk of a fatal outcome, because of the restricted choices for antimicrobial treatment.

**Objectives:** To review the clinical cases of systemic or extraintestinal salmonellosis diagnosed between 2005 and 2010 in Bulgaria, to screen for antimicrobial resistance and to analyze PFGE profiles of non-typhoid salmonellae.

**Methods:** Conventional methods for identification and serotyping of salmonellae. Resistance to 12 antimicrobial agents was studied with disc diffusion method. Screening for ESBLs was performed using the double-disc synergy method. PFGE typing was applied for comparative investigation of *S. corvallis* isolates.

**Results:** Between 2005 and 2010 2227 human non-typhoid *Salmonella* isolates have been investigated at the Reference Laboratory of Enteric Pathogens, NCIPD. Thirty-three strains (1.48%) from nine national regions were isolated from patients with systemic and extraintestinal forms of salmonellosis. The serotype distribution was: Enteritidis (n = 21), Choleraesuis (diphasic n = 3, monophasic n = 3), Typhimurium (n = 2), Corvallis (n = 2), Montevideo (n = 1) and Javiana (n = 1). Eight patients have developed severe forms of systemic infections: sepsis (n = 2), septic shock (n = 1 with fatal outcome), meningitis (n = 3), acute renal failure (n = 2). Diverse complications caused by non-typhoid salmonellae were diagnosed in surgical and haematological wards due to underlying diseases or to compromised immunological status. Twenty-two percent of isolates were resistant to ampicillin and gentamicin, 17, 64% – to tetracycline, 14, 28% – to nalidixic acid and 10% – to chloramphenicol. All but one *S. montevideo* were susceptible to ciprofloxacin. One *S. corvallis* recovered from a patient with chronic chemolytic anaemia produced an ESBL of CTX-M type and its PFGE profile demonstrated <96% similarity to fecal and wound *S. corvallis* isolates with susceptible phenotypes.

**Conclusions:** *S. enteritidis* was the most common cause of systemic and extraintestinal forms of human salmonellosis in Bulgaria. Resistance to ampicillin and gentamicin were the predominant profiles, one *S. corvallis* produced an ESBL and one *S. montevideo* was resistant to ciprofloxacin. The ESBL-producing *S. corvallis* clustered separately from the susceptible *S. corvallis* isolates.

**P1096 Comparative analysis of shiga toxin-producing *Escherichia coli* isolates from humans and animals in Peru**

F. Rivera, A. Medina, E. Sotelo, I. Morales, F. Menacho, M. Riveros, J. Ruiz\*, T. Ochoa (Lima, PE; Barcelona, ES)

**Objectives:** The objectives of this study were to compare the distribution of virulence genes, phylogeny, antimicrobial susceptibility and the mechanisms of antimicrobial resistance in Shiga toxin-producing *Escherichia coli* (STEC) strains isolated from animals (cattle) and humans in Peru.

**Methods:** We analysed 29 STEC strains isolated from stool samples of children (<36 months of age) with and without diarrhoea from four previous cohort studies, and 12 STEC strains isolated from farm animals (cattle) all recovered in Lima, Peru. STEC was identified by a multiplex real-time PCR for stx1 and/or stx2 genes. The strains were analysed to identify the presence of intimin (eae), alpha-hemolysin (hlyA) and enteroaggregative *E. coli* enterotoxin 1 (EAST1) genes. The phylogenetic group was determined by Clermont's method. The susceptibility to twelve antimicrobial agents was tested by disk diffusion, and mechanisms of resistance to ampicillin, to trimethoprim-sulfamethoxazole (Sxt) and to tetracycline were searched by PCR.

**Results:** Among all STEC isolates, stx1 was the most common toxin-gene (37/41, 90%), followed by stx2 (3/41, 7%) and stx1/stx2 (1/41, 2%). Also, eae gen (31/41, 76%) was frequently identified. Meanwhile hlyA was identified more frequently in animal than human strains (100% vs. 66%, p < 0.05); also EAST1 tended to be more frequent (42% vs. 21%). Strains mainly belong to B1-group (66% vs. 75%) and A-group (17 vs. 17%). Animal isolates tended to be more multiresistant than human isolates (33% vs. 27%). STEC isolates from animals were more resistant than those of humans isolates to Amp (58% vs. 17%, p < 0.05), to Sxt (34% vs. 17%, p < 0.01) and to amoxicillin-clavulanic acid (9% vs. 0%, p < 0.05). Animal isolates also tended to be more resistant than human isolates to Tet (42% vs. 17%), nalidixic acid (33% vs. 13%), nitrofurantoin (25% vs. 0%), and gentamicin (17% vs. 13%). Among all isolates, antibiotic resistance was mainly related to the presence of tem-like beta-lactamases (9/11, 82%) for Amp, while dfrA1, dfrA5 and dfrA7 genes account for the 50% of the Sxt resistance. Finally tetA (3/5, 60%) and tetB genes (2/4, 50%) were related to the Tet resistance in animal and human strains respectively.

**Conclusion:** Similarity of virulence profiles between STEC strains from human and animals and the higher resistance levels in animal strains suggest both a role of food chain in transmission to humans and the high use of antimicrobials in veterinary practice in the area.

**P1097 Prevalence and characterisation of extended-spectrum beta-lactamases in human and bovine isolates of *Escherichia coli* from Oyo state, Nigeria**

C. Inwezerua\*, N. Mendonça, V. Calhau, O.E. Adeleke, G.J. Da Silva (Ibadan, NG; Coimbra, PT)

**Objectives:** The advent of extended spectrum beta-lactamases' (ESBL) producers has posed a great threat to the beta-lactam antibiotics. The aim of this study was to determine the prevalence of ESBL producing human and bovine *Escherichia coli* isolates collected in Oyo state, Nigeria, characterize their resistance determinants, and assess their transfer.

**Methods:** Human isolates (n = 57) from two tertiary and secondary hospitals and bovine isolates (n = 57) were collected during August 2010–2011. Antimicrobial susceptibility was done by the Kirby-Bauer method. ESBLs were screened by the double disc synergy test. Positive ESBL strains were identified by PCR, and analyzed by sequencing. Plasmids were identified by PCR based replicon typing. The genetic relatedness of the isolates was determined by a rep-PCR genomic fingerprinting method (BOX-PCR). Conjugation was used to assess the transfer of the ESBL phenotype (cefotaxime resistance), using *E. coli* J503 (azide resistant) as a recipient cell.

**Results:** Eight (14%) human isolates were found to produce ESBLs. They were all resistant to cefotaxime, while only two showed reduced susceptibility to ceftazidime. No ESBL producer was identified among bovine strains. A high prevalence of resistance to amoxicillin (88%), trimethoprim (83%) and nalidixic acid (47%) among the human strains was remarkable compared with the bovine strains. All ESBL positive strains had AmpC, blaTEM, blaCTX-M genes. CTX-M-1 group enzymes were identified. ESBL positive strains were also resistant to gentamycin (87.5%), nalidixic acid (62.5%) and ciprofloxacin (50%). BOX-PCR identified five patterns among the ESBL positive isolates. All ESBL positive isolates had multiple plasmids belonging to Inc

FrepB, FIA, FIB, H12 and K plasmid groups. ESBL resistance was demonstrated to be conjugative in two strains.

**Conclusion:** Our findings showed a moderate prevalence of ESBL in clinical human strains, and not a major prevalent clone. However, ESBL were associated with conjugative plasmids. In contrast with other reported Nigerian studies, the healthy animals did not show considerable resistance, which may be associated with the geographic location. Nevertheless, this study highlights the need to adopt measures to monitor the dissemination of ESBLs in Nigeria. The detailed and reliable knowledge on the resistance of human and bovine pathogens will be required for a controlled and safe use of antibiotics in human and veterinary medicine.

**P1098** Analysis of trends in *P. aeruginosa* antibiotic resistance of animal and human isolates: a retrospective observational study in central Italy

A.-R. Attili\*, S. Preziuso, V. Ngu Ngwa, M. Moriconi, V. Cuteri (Materica, IT)

**Objectives:** *Pseudomonas aeruginosa* (PA) is a clinically significant pathogen responsible of nosocomial and community infections both in human and veterinary medicine. The high level of acquired resistance as well as the horizontal and clonal spread of resistant PA strains has become a serious problem, representing a limit for adequate antibiotic therapy and resulting in a serious threat to Public Health. A retrospective observational study was carried out to assess the antibiotic resistance trends in PA strains of animal and human origin from 2006 to 2011.

**Methods:** A total of 384 isolates of PA were obtained from different clinical specimens from animals (n = 298) and humans (n = 86) living in central Italy. The isolates were identified by PCR and were tested against 12 different antibiotics usually active against PA by disk diffusion method (Table 1). The significance of differences in resistance was evaluated using chi squared test (STATA software version 9.1), and p value <0.05 was considered statistically significant.

**Results:** The microorganisms were cultured from ear (43%), tonsillar swabs and bronchial alveolar washes (19%), naso-pharyngeal swabs (17%), wound swabs (13%), high vaginal swabs and urine samples (8%).

During 6-year period, the development of PA resistance to antibiotics is given in Table 1. There was evidence of increased resistance to gentamicin (p = 0.0431), fluoroquinolones (p = 0.0167), cephalosporins, and carbapenems in human isolates. At the same time, the resistance of PA to amikacin decreased from 6.4% in 2006 to 3.2% in 2011. Similar trends were observed for PA of animal origin: a significant increased resistance was observed for tetracyclines (p = 0.0483), and penicillins (p = 0.0325). Different trends were obtained for amikacin, cefquinome and carbapenems for which PA animal strains demonstrated a decreased, but not significant, resistance (p > 0.05).

Table 1. Resistance (%) of *Pseudomonas aeruginosa* to antipseudomonal antibiotics in veterinary and human isolates.

Antibiotics	Disk potency (µg)	2006		2007		2008		2009		2010		2011

\* Significant differences P<0.05

**Conclusion:** This study confirms that resistance profile of PA is changing in central Italy, acquiring gradually less antibiotic susceptibility to molecules used both in veterinary and human

medicine. Considering the potential role of PA as zoonotic microorganism, due care must be taken in the antibiotic treatment to prevent the increase of the spread of multidrug resistant zoonotic PA. This study confirms that the widespread antibiotic misuse could be the main risk factor for the occurrence of multiresistant PA strains.

**P1099** Antimicrobial susceptibility monitoring of non-typhoidal *Salmonella* from healthy pigs and poultry in Belgium, 2008–2011

A de Jong\*, C. Ludwig, B. Stephan, H. Imberechts, E. De Graef, M. Vanrobayeys (Leverkusen, DE; Brussels, Torhout, BE)

**Objectives:** For severe salmonellosis in man, fluoroquinolones (FQs) and 3rd generation cephalosporins (CPs) are the drugs of choice. From 2008 to 2011, a susceptibility survey with focus on FQs and CPs was conducted among Belgian *Salmonella* (Sal) strains from healthy pigs and chickens, the major sources of human food-borne Sal infections. Both epidemiological cut-off values (ECVs) and clinical breakpoints (CBPs) were applied to categorize antimicrobial susceptibility.

**Methods:** Non-repetitive faecal sampling was conducted at various farms and abattoirs across Flanders. Susceptibility to ciprofloxacin (CIP), cefotaxime (CTX), and seven older molecules was assessed by agar dilution (CLSI; M31-A3). Clinical resistance (CR) was based on CLSI breakpoints (M100-S21); decreased susceptibility (DS; % isolates with MICs > ECV and <CBPs) was determined for four antibiotics based on ECVs as defined by EUCAST and EFSA (2007).

**Results:** In all, 348 and 419 strains from pigs and chickens comprising various distinct serovars were recovered. Following serovars were mainly identified: Typhimurium (124), Typhimurium var. Copenhagen (88) and Derby (35) from pigs and Enteritidis (79), Paratyphi (60) and Typhimurium (32) from chickens. CR to CIP was absent in isolates from both host species, but mean DS of the pig and poultry isolates was 3.2% and 22.0%. *S. Hadar*, *S. Paratyphi* B, *S. Blockley* and *S. Virchow* were the most frequent serovars with DS to CIP. CTX resistance was 1.4% and 12.2%, DS to CTX was 0.9% and 1.9% in pig and poultry isolates. In pigs, CR or DS to CTX was mainly observed in *S. Typhimurium*; in chickens in nine different serovars, most frequently in *S. Paratyphi* and *S. Virchow*. Virtually all CTX-resistant strains were phenotypically determined as ESBL producers (47). For the older drugs CR percentages for respective pig and chicken isolates were: ampicillin (A) 63, 34; chloramphenicol 19, 3; nalidixic acid 2, 22; streptomycin 53, 24; tetracycline 58, 15; and trimethoprim/sulfadiazine 39, 27. Gentamicin (G) CR was low (0–1%) in isolates from either animal species. DS for A and G was negligible (0–1%).

**Conclusions:** Clinical resistance among Sal from pigs and chickens was absent for CIP and low for CTX, two essential drugs for treating salmonellosis in humans. Decreased susceptibility to CIP and CTX varied from 1% to 22%. For most older drugs, notably higher rates of CR were detected, with marked differences between the two animal species.

**P1100** Antimicrobial susceptibility of zoonotic *Salmonella enterica* from cattle, pigs and poultry isolated in eight countries over a 4-year period (2002–2006) (EASSA programme)

H. Moyaert\*, A. de Jong, P. Butty, U Klein, H. Marion, S Simjee, V Thomas, M. Vallé (Brussels, BE)

**Background:** The European Antimicrobial Susceptibility Surveillance in Animals (EASSA) is the first ongoing program monitoring antimicrobial susceptibility relevant for human medicine of zoonotic and commensal bacteria from healthy food-producing animals at slaughter across Europe. Susceptibility results of *S. enterica* (Se) isolated from 2002 to 2006 are presented here.

**Methods:** Colon or caecal content from healthy beef cattle, fattening pigs and broiler chickens was randomly sampled in eight EU countries (five countries/host; four slaughterhouses/country; one sample per herd/

flock). *Salmonella* isolation, identification and serotyping were performed by standard methods. MICs of 11 antimicrobials were determined by agar dilution (CLSI, M31-A3) in a central laboratory. Results were interpreted using clinical breakpoints (CLSI M100-S20, except colistin: EUCAST) and Epidemiological Cut-off Values (ECVs) as defined by EFSA (2007). Decreased Susceptibility (DS), i.e. MIC values exceeding the wild-type MIC distribution (>ECV) but not the clinical breakpoint, was determined for four antimicrobials.

**Results:** In total, 659 *Se* strains (48 different serotypes) were identified: 57 from cattle, 420 from pigs and 182 from chickens. Following serotypes were predominantly recovered: Typhimurium (18), Dublin (12), Enteritidis (9) and Montevideo (7) from cattle; Typhimurium (136), Derby (111) and Rissen (51) from pigs and Enteritidis (61), Indiana (43) and Typhimurium (17) from chickens. Overall, mean resistance percentage for each respective animal host was: ampicillin 19.3, 33.1, 12.6; chloramphenicol 17.5, 25.2, 4.4; colistin 10.5, 3.1, 27.5; gentamicin 0.0, 3.6, 1.6; nalidixic acid 3.5, 3.6, 36.3; sulfisoxazole 21.8, 53.0, 12.2; tetracycline 22.8, 73.8, 13.2 and trimethoprim/sulfamethoxazole 5.3, 23.6, 4.9. Clinical resistance against cefepime, cefotaxime and ciprofloxacin was absent. DS was particularly apparent for ciprofloxacin: 3.5% for cattle, 2.9% for pigs and 35.2% for chickens, whereas the corresponding figures for cefotaxime were 1.8, 1.9 and 1.1%. For ampicillin and gentamicin, DS was negligible (0.5% or less).

**Conclusion:** This pan-European survey demonstrates high variability in antimicrobial susceptibility among zoonotic *Salmonella enterica* isolates from healthy food producing animals at slaughter. For older molecules, prevalence of clinical resistance was notably high, but most isolates displayed high susceptibility to newer compounds, critically important in human medicine.

#### P1101 Serogroup screening and antimicrobial resistance in *Salmonella* isolated from broiler chickens

J. Akbarmehr\* (Sarab, IR)

The development of antimicrobial resistance has been a public health issue worldwide. The aim of this study was therefore to determine the antibiotic resistance pattern of *Salmonella* species isolated from broiler chickens in Iran. Thirty-seven isolates of *Salmonella* recovered from broiler chicken carcasses were analyzed for resistance to 14 antimicrobial agents. *Salmonella* isolates were serogrouped by standard agglutination test using O and H antisera before antibiotic susceptibility testing. Serogroup screening showed four different serogroups (D1, B, C1, C2) among 37 *Salmonella* isolates. *Salmonella* serogroup D1 with frequency 48.64% was the most prevalent serogroup. Antimicrobial susceptibility testing was performed by the standard disc diffusion method according national committee for clinical laboratory standards. Antibiotic sensitivity tests showed that Amikacin, Cephalotin, Tylosin, and Chloramphenicol, were the most effective antibiotics (100% sensitivity). Antibiotics for which *Salmonella* isolates exhibited resistance were: Neomycin (10.81%), Amoxicillin (18.91%), Streptomycin (29.72%), Chlortetracyclin (32.43%), Trimethoprim (13.51%), Nalidixic acid (18.91%), Tetracyclin (29.72%), Kanamycin (16.21%), Ampicillin (13.51%). Also 51% of resistant isolates were belonged to serogroup D1 and serogroups B, C1, and C2 included 37%, 9%, and 3% of resistant isolates respectively. In all 28% of *Salmonella* isolates were resistant to more than four antibiotics (MDR). Findings of present study indicated that the development of antimicrobial resistance in *Salmonella* is an increasing problem in Iran and resistant strains are widespread.

#### P1102 Antimicrobial susceptibility monitoring of respiratory tract pathogens isolated from diseased cattle and pigs across Europe

A. de Jong\*, S. Simjee, V. Thomas, K. Maher, I. Morrissey, P. Butty, U. Klein, H. Marion, H. Moyaert, D. Rigaut, B. Schiessl, M. Vallé (Brussels, BE; Fordham, UK)

**Objectives:** VetPath is an ongoing pan-European resistance monitoring program for veterinary pathogens isolated from diseased antimicrobial-naïve cattle, pigs and poultry. Here, antimicrobial susceptibilities of isolates from cattle and pig respiratory tract infections are presented.

**Methods:** Lung samples or deep nasopharyngeal swabs from cattle or nasal swabs from pigs were collected from animals with acute clinical signs, not recently treated with antibiotics, in 11 EU countries, predominantly in 2002–2006. *Pasteurella multocida* (Pm) and *Mannheimia haemolytica* (Mh) from cattle samples and Pm, *Actinobacillus pleuropneumoniae* (Ap) and *Streptococcus suis* (Ss) from pigs samples were isolated by standard methods (one isolate per farm per outbreak). Ss was also isolated from meningitis cases. MICs of 17 antibiotics were determined in a central laboratory by broth microdilution as per CLSI recommendations. Results were interpreted using CLSI resistance breakpoints (M31-A3, 2008) where available.

**Results:** In all, 1388 isolates were recovered. In cattle, 343 Pm and 230 Mh were isolated, the majority of these were susceptible to antibiotics for which resistance breakpoints are available (Table 1). For amoxicillin, 4 Pm and 8 Mh isolates showed MIC  $\geq$  64 mg/L while the highest MIC observed for cephalixin was 8 and 0.12 mg/L for cefquinome. MIC distributions of marbofloxacin and enrofloxacin were similar. With a susceptibility breakpoint of  $\leq$ 0.25 mg/L, 94.8% Mh and 96.5% Pm were susceptible to danofloxacin. Tylosin and lincomycin showed similar MIC patterns with MIC90 of  $\geq$ 32 mg/L for Mh and 32–64 mg/L for Pm. A total of 326 Pm, 262 Ap and 227 Ss were recovered from pig samples. For antibiotics having CLSI breakpoints, % resistance is shown (Table 1); for the others, similar MIC ranges as those obtained for cattle isolates were observed. For Pm and Ap, MIC90 amounted to 0.03 mg/L for cefquinome and 2 mg/L for cephalixin; amoxicillin MIC90 was 0.25 mg/L. In contrast, for Ss MIC90s were 0.03 mg/L for amoxicillin and cefquinome; cephalixin MIC90 was 0.25 mg/L. For Pm and Ap, tylosin and lincomycin showed similar MIC patterns with MIC90s of 32 mg/L and  $\geq$ 32 mg/L, respectively.

Antimicrobial (breakpoint)	Cattle		Pigs	
	Pm (n=343)	Mh (n=230)	Ap (n=262)	Ss (n=227)
Amoxicillin (R <sub>20</sub> mg/L)	0	0	0	0
Cefixur (R <sub>8</sub> mg/L)	0	0	0.3	0
Enrofloxacin (R <sub>2</sub> mg/L, R <sub>4</sub> mg/L, S <sub>8</sub> )	0.6	0.4	0	0.4
Florfenicol (R <sub>2</sub> mg/L)	0.3	0	0	0.4
Spectinomycin (R <sub>12</sub> mg/L)	3.2	0	nc	nc
Tetracycline (R <sub>8</sub> mg/L, cattle, R <sub>2</sub> mg/L, pigs)	2.9	16.1	19.8	11.1
Tiamulin (R <sub>2</sub> mg/L)	nc	nc	nc	0
Trimoxin (R <sub>2</sub> mg/L)	nc	1.7	0.8	0
TS (co-trimoxazole) (R <sub>4</sub> mg/L)	2.3	6.1	2.5	3.8

nc: not calculated; CTC was used 2003-2004

**Conclusion:** The results show an absence or low antimicrobial resistance, except to tetracycline, among the major respiratory tract pathogens isolated from diseased but non-treated cattle and pigs across the EU.

#### P1103 Antimicrobial susceptibility of mastitis pathogens isolated from diseased dairy cows across Europe: VetPath monitoring results

V. Thomas, A. de Jong\*, S. Simjee, K. Maher, I. Morrissey, P. Butty, U. Klein, H. Marion, H. Moyaert, D. Rigaut, M. Vallé (Brussels, BE; Fordham, UK)

**Objectives:** VetPath is an ongoing pan-European resistance monitoring program for veterinary pathogens isolated from diseased antimicrobial-naïve cattle, pigs and poultry. Antimicrobial susceptibilities of mastitis pathogens isolated from lactating cattle are presented here.

**Methods:** Milk was sampled from dairy cows with acute mastitis, not recently exposed to antimicrobial treatment, in eight EU countries, mainly during 2002–2006. *Escherichia coli* (Ec), *Staphylococcus aureus* (Sa) and *Streptococcus uberis* (Su), were isolated and biochemically identified (one isolate per farm). MIC values of 9 (Ec) and 12 (Sa, Su) antibiotics were determined in a central laboratory by

broth microdilution as per CLSI guidelines. Susceptibility was expressed as MIC<sub>50</sub> and MIC<sub>90</sub>, and % resistance was determined for antibiotics with defined CLSI breakpoints (M31-A3, 2008).

**Results:** In total, 1066 isolates were recovered, 363 Ec, 356 Sa and 347 Su. For Ec, resistance to beta-lactam antibiotics was virtually absent; tetracycline resistance amounted to 16%. For the cephalosporins tested without CLSI breakpoints, MIC<sub>90</sub> amounted to 0.06 mg/L for cefquinome and 8 and 64 mg/L for cephalexin and cephapirin. MIC distributions of marbofloxacin and enrofloxacin were similar, with MIC<sub>50</sub> and MIC<sub>90</sub> of 0.03 and 0.03–0.06 mg/L. For neomycin, five Ec isolates showed MICs > 128 mg/L, while MIC<sub>50</sub> was 1 mg/L. For Sa, resistance to amoxicillin/clavulanic acid was absent, whilst penicillin resistance was 38%, but MIC<sub>90</sub> for cloxacillin was as low as 0.5 mg/L. MIC<sub>90</sub> of cefquinome and cephapirin were 0.25 and 0.5; for cephalexin 4 mg/L. Erythromycin and tetracycline resistance were low (1.4% and 7.3%, respectively). MIC<sub>50/90s</sub> of enrofloxacin and marbofloxacin varied from 0.12 to 0.5 mg/L. Neomycin MICs ranged from 0.25 to 2 mg/L, except for two isolates. In contrast, for Su beta-lactam resistance was absent, whereas erythromycin and tetracycline resistance were 19% and 25%. For the beta-lactam antibiotics without CLSI breakpoints, MIC<sub>90</sub> of cefquinome, cephalexin and cephapirin were 0.25–0.5 mg/L; cloxacillin MIC<sub>90</sub> was 4 mg/L. Fluoroquinolone MIC<sub>50/90s</sub> were 0.5–2 mg/L, whereas neomycin MIC<sub>50</sub> and MIC<sub>90</sub> were 64 and ≥128 mg/L.

**Conclusions:** Overall, the prevalence of antibiotic resistance is low among the three major mastitis pathogens isolated from diseased but non-treated dairy cows across the EU, however penicillin resistance of Sa is fairly high. Generally, the tested antibiotics exhibited high efficacy.

#### **P1104** *Campylobacter* spp. in raw materials of animal origin and their resistance to antibiotics in the Czech Republic

J. Bardon\*, M. Kolár, V. Husicková, V. Hanulík (Olomouc, CZ)

**Objectives:** *Campylobacter jejuni* and *Campylobacter coli* are the most common bacterial pathogens causing alimentary tract infections in Europe. An important source of infection is poultry; a potential source is also raw cow's milk. The presentation is concerned with the prevalence of thermotolerant *Campylobacter* spp. in broilers and raw cow's milk in the Czech Republic. Resistance of isolates to selected antibiotics is studied.

**Methods:** In 2006–2007, cloacal swabs were collected from broilers in slaughterhouses to determine the presence of *Campylobacter* spp. In 2008, caeca and skin of broilers at slaughterhouses were examined. In 2009, fresh and frozen poultry skin was tested in screened supermarkets. In 2010, poultry caecum tests were continued at slaughterhouses and milk filters at dairy farms were examined. In 2011, more tests of poultry caeca were carried out. In all isolates, resistance to antibiotics was quantitatively determined by the microdilution method.

**Results:** The prevalence of *Campylobacter* spp. in cloacal swabs (years 2006 and 2007) was about 50%. The rates were higher in broiler caeca – 61%, 72% and 65% in 2008, 2010 and 2011 (as of 30 September), respectively. Skin tests revealed rates of 70% in broilers at slaughterhouses, 75% in fresh and 37% in frozen poultry in supermarkets. In dairy farm milk filters, the prevalence of *Campylobacter* spp. was 3%. *C. jejuni* was detected significantly more frequently than *C. coli*. Poultry isolates were highly resistant to quinolones, as opposed to *Campylobacter* spp. isolated from milk.

**Conclusion:** The prevalence of thermotolerant *Campylobacter* spp. in poultry is high in the Czech Republic. Broiler skin contamination is higher than the primary prevalence in the intestine, suggesting secondary contamination. Poultry isolates are characterized by higher resistance to quinolone antibiotics. The resistance is relatively low in milk isolates.

**Acknowledgements:** This study was supported by the European Commission, State Veterinary Administration of the Czech Republic and grants MSM 6198959223 and NAZV QH 91231.

#### **P1105** A comparison of primary and secondary clarithromycin and levofloxacin resistance of *Helicobacter pylori* in southern Poland between 2006–2008 and 2009–2011

E. Karczewska\*, K. Klesiewicz, I. Skiba, I. Wojtas-Bonior, E. Sito, M. Zwolinska-Weislo, A. Budak (Krakow, Cracow, PL)

**Objectives:** An increasing resistance of *Helicobacter pylori* (*H. pylori*) strains to the currently used antimicrobial agents is the serious therapeutic problem. Therefore, the aim of this study was to compare the primary and secondary resistance to clarithromycin and levofloxacin of *H. pylori* strains isolated between years 2006–2008 and 2009–2011.

**Methods:** One hundred and sixty dyspeptic patients before or after failed therapy who underwent gastroscopy in the Center of Medical Care Falck in Krakow were enrolled to the study. During the gastroscopy two biopsy specimens were taken from each patient. Minimal Inhibitory Concentration (MIC) values of clarithromycin and levofloxacin were determined by E-test method. The breakpoints used to classify strains as resistant according to the MIC value was 1 mg/L for clarithromycin and levofloxacin. The statistical analysis was conducted with the use of chi-squared test at the 0.05 significance level ( $p \leq 0.05$ ).

**Results:** One hundred and fifteen *H. pylori* strains (90 primary, 25 secondary) were isolated between 2006 and 2008, and 45 strains (37 primary, eight secondary) between 2009 and 2011.

2006–2008: In total, 34% of *H. pylori* strains were resistance to clarithromycin and the percentage of the secondary strains was significantly greater than the primary strains (80% vs. 21%,  $p < 0.001$ ). Five percent of strains were resistant to levofloxacin, and the difference between primary and secondary was statistically significant (2% vs. 16%,  $p = 0.006$ ).

2009–2011: In total, 24% of strains were resistant to clarithromycin and the percentage of the secondary strains was also significantly greater than the primary strains (38% vs. 22%,  $p = 0.01$ ). Sixteen percent of strains were resistant to levofloxacin, and the difference between primary and secondary was statistically significant (11% vs. 38%,  $p = 0.04$ ).

The noteworthy result is the decrease of *H. pylori* resistance to clarithromycin in 2009–2011 compared to the years 2006–2008 which is not significant (24% vs. 34%,  $p = 0.06$ ), whereas an increase of resistance to levofloxacin is significant (16% vs. 5%,  $p = 0.007$ ).

**Conclusion:** Higher rate of *H. pylori* resistant strains to levofloxacin may be justified by an increasing usage of levofloxacin instead of clarithromycin in the treatment of *H. pylori* infection. The resistance to fluoroquinolones is rapidly acquired, therefore levofloxacin, which is recommended for a rescue therapy, should not be used routinely. Scientific work partially funded by Polish Government as a research grant in the years 2011–2013 (NN404547640).

#### **P1106** *Helicobacter pylori* primary and secondary resistances to antimicrobials in a Portuguese adult population

J.M. Romãozinho, N. Almeida, M.M. Donato, C. Luxo, O. Cardoso\*, M.A. Cipriano, C. Marinho, R. Figueiredo, C. Sofia (Coimbra, PT)

**Objectives:** *Helicobacter pylori* (Hp) resistance to antimicrobials is increasing and information about susceptibility patterns in each country could be very relevant. The prevalence of primary and secondary resistance of Hp to antimicrobials was determined in order to improve the outcome of these patients and for studying the evolution of resistance patterns.

**Methods:** Evaluation of the prevalence of primary and secondary resistance in Hp isolates to antimicrobials on a population ( $n = 88$ ) of dyspeptic adult patients with positive 13<sup>C</sup> urea breath test (UBT) from May 2009 to May 2011. Patients were divided in two groups: A ( $n = 51$ ) – no previous Hp treatment (primary resistance); B ( $n = 37$ ) – previous failed Hp treatment (secondary resistance). All patients were submitted to upper digestive endoscopy with biopsies for histological and microbiologic characterization. Susceptibility to metronidazole

(MET), clarithromycin (CLA), levofloxacin (LEV), amoxicillin (AMX) and tetracycline (TET) was determined by E-test. Patients were treated with: group A-pantoprazole + AMX + CLA during 14 days; group B-pantoprazole + AMX + LEV for 10 days. Hp eradication rate was assessed with UBT after 8–12 weeks. Statistical analysis was performed with SPSS v17.0.

**Results:** Eradication was successful in 64.8% (A-74.5%; B-51.4%; p = 0.041). All Hp isolates were susceptible to AMX and TET. 46.6% of isolates were resistant to CLA and 40.9% to MET, however there was a statistically significant difference between group A and B (CLA: A-15.7%; B-89.2%; p < 0.0001; MET: A-27.5%; B-59.5%; p = 0.004). Relatively to LEV, 30.7% of the isolates were resistant, and difference between the two groups was observed but there was no statistical significance (A-25.5%; B-37.8%; p = 0.247).

**Conclusions:** Rates of Hp eradication associated with first and second line empirical treatments were lower than the usually accepted. The results also showed a high prevalence of Hp primary and secondary resistance to CLA, MET and LEV regimes. Hp secondary resistance rates to CLA and MET exceed 50%, dissuading the use of these antimicrobials agents in second line empirical anti-Hp protocols. This study suggest the development, in our country, of strategies of antibiotic therapy based on susceptibility tests, in order to improve Hp eradication rates.

**P1107** Prevalence of third-generation cephalosporin-resistant *Escherichia coli* and their resistance mechanisms in dogs in Finland

J. Jalava, N. Vuorela\*, S. Miettinen, S. Pelkonen, M. Rantala (Turku, Helsinki, Kuopio, FI)

**Objectives:** Third generation cephalosporin resistance among *Escherichia coli* is usually due to production of extended-spectrum betalactamases mediated by ESBL or AmpC genes. In humans, ESBL-producing *E. coli* strains are increasing rapidly. In veterinary medicine such isolates have been rare so far in Finland. The purpose of this work was to study the prevalence of third generation cephalosporin resistance among *E. coli* and to characterize their resistance genes in Finnish dogs.

**Methods:** Fecal specimens were taken from 471 dogs. Screened dogs were the patients of the Small Animal Veterinary Teaching Hospital (30%) which were presented for other reason than diarrhea, or were other healthy dogs (70%). The fecal specimens were cultured on selective plates (Brilliance, Oxoid). Identification of the isolates was done with standard techniques and susceptibility testing with the disk diffusion method. Isolates with decreased susceptibility to 3rd generation cephalosporins were further tested with the double disk method and AmpC detection disks (MAST, UK). The major ESBL genes (CTX-M, TEM, SHV) and AmpC genes (CIT, FOX, DHA, ACC) were detected by multiplex PCR.

**Results:** Fecal specimens were obtained from 471 dogs. The mean age of the dogs was 4.5 (SD ± 3.5 years) and 53% of them were females. Twenty-five dogs (5%; 95% CI 3–7%) carried a 3rd generation cephalosporin resistant Enterobacteriaceae isolate, of which 23 were *E. coli* and 2 *E. cloacae*. Of *E. coli* – isolates, eight carried CTX + TEM genes and four had CTX gene, eight had CIT + TEM and one had CIT gene alone.

**Conclusion:** Rather high proportion (5%) of the companion dogs carried either ESBL- or AmpC-producing *E. coli*. Further studies are needed to find a possible source, dog feed being one example. The next step is to type animal *E. coli* isolates by MLST in order to compare these with *E. coli* isolates of human origin. Due to this rather high prevalence of ESBL- and AmpC-producing strains, it is recommended that 3rd generation cephalosporin resistance is routinely screened in clinical specimens by veterinary laboratories.

**P1108** Comparison of veterinary medicines and natural feed constituents on curing efficacy and conjugation frequency of CTX-M plasmids in *Escherichia coli*

M. Bagnall\*, F. Lemma, M. Toszeghy, L. Randall, N. Coldham, L. Piddock, M. Woodward (New Haw, Birmingham, UK)

**Objectives:** In recent years, *Escherichia coli* containing large promiscuous plasmids carrying the blaCTX-M gene, that confers resistance to Extended-Spectrum Beta Lactam (ESBL) antibiotics, have become increasingly common in humans and farm animals. These CTX-M *E. coli* can cause human infections and there is a concern that in some cases people can become infected via animal products. The aim of this study was to determine if passage of *E. coli* in the presence of veterinary medicines and natural feed constituents could promote plasmid loss and therefore reduce the prevalence and potential dissemination of CTX-M genes.

**Methods:** The plasmid curing activity of veterinary medicines and natural feed constituents was determined in two field isolates (C159/11, LR8 3A) and a mutant (DH5alpha::pCTaph) by up to 21 passages at 1/2 and 1/4 MIC of these agents in Luria-Bertani broth. Ethidium bromide and LB broth were used as positive and negative controls respectively. Potentially cured strains were selected by replica plating to selective agar plates. Those colonies which grew in the absence of selective agent were selected for further plasmid analysis by PCR of specific genes and size profiling. The ability of test compounds to inhibit plasmid conjugation from test strains to a *Salmonella Typhimurium* (26R) recipient was evaluated in conjugation studies by prior growth with sub-lethal concentrations of test agents.

**Results:** The mutant strain lost its plasmid more readily than the two field strains tested but all three strains did show evidence of plasmid loss in the presence of test compounds (Table 1). PCR analysis showed loss of genes from around the plasmid as well as the loss of the blaCTX-M or Kanamycin gene. Further analysis by plasmid profiling, however, showed significant genomic rearrangement in a number of ‘‘cured’’ strains but in the majority of cases; no plasmid loss. Plasmid conjugation was not detectable following exposure to sub-lethal concentrations of enrofloxacin, whilst the pre-biotic Bimuno and streptomycin also significantly (p < 0.05) reduced conjugation rates for both isolates.

Strain	Conc. used (MIC)	Named curing rates (% cured) after 7, 10, 17 or 21 passages with drug and antibiotic																			
		Ethidium bromide			Acetic acid usage			Fluorocytin			Enrofloxacin			Streptomycin			Colistin				
Summary		7	10	17	21	7	10	17	21	7	10	17	21	7	10	17	21	7	10	17	21

a. Bacteria contain forward controls and is included as a replacement to feed to animals & the ‘‘probiotic’’ consists of equal media replacement of a *Lactobacillus plantarum* strain & 30000 yeast extract and yeast cells were not added (they at concentrations listed, or % and %MIC refers to how much concentration for these substances only)

**Conclusions:** The results suggest that some veterinary antibiotics and or natural feed or dietary constituents may promote loss of plasmids from bacteria and/or reduce the transfer of plasmids. These findings warrant further investigations in the battle against plasmid-mediated antibiotic resistance.

**P1109** Comparison of a rapid multiple combination bactericidal testing method vs. conventional time-kill studies for patients infected with extreme drug-resistant *Acinetobacter baumannii* with decreasing susceptibilities to polymyxin B

Y.Y. Cai\*, T.P. Lim, S. Sasikala, N. Rafida, T.Y. Tan, W. Lee, L.Y. Hsu, J. Teo, T.T. Tan, A.L. Kwa (Singapore, SG)

**Objective:** Extreme-drug resistant (XDR) bacterial infections are increasingly prevalent worldwide as a public health problem.

Combination (combi) therapy may be the only viable option until new antibiotics (abx) are available. Conventional time-kill studies (TKS) are the gold standard for evaluating abx combi. But, they are time-consuming and labourious, suffering from long turnaround time to obtain the results and evaluating very few abx combi. We aim to develop a high-throughput method using multiple combination bactericidal testing (MCBT) to identify optimal abx combi against XDR *Acinetobacter baumannii* (AB) and compare them with previously published results by TKS.

**Methods:** Thirty-five non-clonal XDR AB harbouring blaOXA-23/51 were collected from five Singapore hospitals over a 2006–2007. All XDR AB isolates were resistant to all abx except polymyxin B (P) (MIC 0.5–64 mg/L). MCBT was performed in 96-well microtiter trays using maximum achievable clinical, unbound concentrations (mg/L) of rifampicin (R) (2), tigecycline (T) (2) and P (2) alone and in combi against the test isolates. A final inoculum of  $5 \times 10^5$  CFU/mL was used and the trays were incubated at 37°C for 24 hours. Quantitative counts were obtained at 24 hours in duplicate. Three abx combi (P + R, P + T and T + R) were evaluated. A MCBT was scored as positive if it predicted bactericidal activity ( $\geq 3$  log CFU/mL decrease from baseline and compared to its most active abx alone), synergism ( $\geq 2$  log decrease from baseline and compared to its most active abx alone) or indifferent activity ( $\leq 2$  log decrease from baseline) that were similar to TKS results. An agreement for an isolate is determined from complete agreement amongst the three abx combi evaluated. Evaluation of agreement within abx combi regardless of isolates was also performed.

**Results:** In TKS, P + R, P + T and T + R were bactericidal against 15/35, 8/35 and 8/35 isolates respectively; synergistic against 1/35, 2/35 and 0/35 isolates respectively and indifferent against 19/35, 25/35 and 27/35 isolates respectively. 32/35 isolates were scored positive and in complete agreement for all three abx combi evaluated using synergy definitions when compared to TKS. Overall, a 91.4% agreement was achieved. There was 94.3% (33/35) agreement for P + R, P + T and T + R within abx combi regardless of isolates.

**Conclusion:** Our MCBT can be used to objectively assess the killing activity of two abx in combination against XDR AB. It may guide clinicians in selecting the optimal abx combi and warrants further investigations.

**P1110** **In vitro activity of the novel ceragenin compound, CSA-131 alone vs. a diverse collection of Gram-negative pathogens and in combination with vancomycin vs. multidrug-resistant *Acinetobacter baumannii***

M. Hornsey\*, P.B. Savage, D.W. Wareham (London, UK; Provo, US)

**Objectives:** Ceragenins are cholic acid derivatives that exhibit broad range antimicrobial activity. They act as antimicrobial peptide (AMP) mimics, permeabilizing the outer membrane of Gram-negative bacteria. These agents have a number of advantages over AMPs; most importantly they are resistant to cleavage by proteolytic enzymes. It is hoped that ceragenins will find clinical utility in the treatment of infections caused by MDR bacterial pathogens. We investigated the in vitro activity of the novel ceragenin compound, CSA-131 against both clinical isolates with defined resistance mechanisms and type strains of important Gram-negative species. In addition, the potential of a CSA-131/vancomycin combination vs. MDR *A. baumannii* (MDRAB) was studied using representative isolates of successful UK clones.

**Methods:** Isolates were identified by MALDI-TOF mass spectrometry and *A. baumannii* clinical isolates were assigned to specific clones by PFGE. MICs were determined by broth microdilution in IsoSensitest broth. Synergy of the CSA-131/vancomycin combination was assessed in standard checkerboard assays performed in microtitre plates. Endpoints were visualised with the aid of the redox dye-containing reagent, alamarBlue. Fractional inhibitory concentrations indices (FICI) were calculated.

**Results:** MICs of CSA-131 for all *A. baumannii* (including colistin-resistant), *Pseudomonas aeruginosa*, *Stenotrophomonas maltophilia* and *Escherichia coli* (including ST131) isolates tested were in the range

of 8–16 mg/L and for all *Enterobacter* sp. and *Klebsiella pneumoniae* isolates the MICs were in the range 16–32 mg/L. The compound was active against ESBL and carbapenemase-producing strains. CSA-131 was less active vs. *Proteus mirabilis* and *Serratia marcescens* (MICs > 64 mg/L). Though marked synergy (FICI  $\leq$  0.05) with vancomycin was not observed, in the presence of 2 mg/L CSA-131 the MICs of the former agent were reduced for all *A. baumannii* isolates (at least 32-fold).

**Conclusions:** CSA-131 displayed useful in vitro activity vs. type strains and problematic clinical isolates of several frequently encountered Gram-negative species. The majority of the isolates studied were MDR; many displaying resistance mechanisms of increasing importance including production of the New Delhi metallo-beta-lactamase (NDM). We also demonstrated the potential of a ceragenin/glycopeptide combination for the treatment of infections caused by MDRAB including colistin-resistant isolates.

**P1111** **Monitoring the activity of antimicrobials against multidrug-resistant *Clostridium* spp.**

S. Hawser\*, C. Zampaloni, F. Monti, S. Bouchillon, M. Hackel, M. Dowzicky (Schaumburg, US; Epalinges, CH; Collegeville, US)

**Background:** The incidence of multi-drug resistant (MDR) *Clostridium* spp. is unclear. Surveillance studies aimed at determining their incidence and susceptibility to antibiotics are necessary in order to better understand the incidence of such etiologic agents. This study evaluated the activity of tigecycline and comparators against MDR *Clostridium* spp. isolated from infections during 2009–October 2011.

**Methods:** A total of 1450 isolates were collected from Europe, of which 462 were multi-drug resistant (MDR; resistant to two antibiotic classes). Isolates were tested for susceptibility following the CLSI guidelines for anaerobes and interpreted using EUCAST guidelines or FDA guidelines for tigecycline.

**Results:** The susceptibility of all and MDR isolates are shown in the Table below:

%S, %I, %R, percent isolates susceptible, intermediate or resistant; \*, susceptibility determined using FDA breakpoints due to absence of EUCAST breakpoints.

Antibiotic	All (n = 1,450)				MDR (n = 462)				
	MIC <sub>90</sub>	%S	%I	%R	Antibiotic	MIC <sub>90</sub>	%S	%I	%R
Clindamycin	>8	65	-	35	Clindamycin	>8	9	-	91
Meropenem	2	92	4	4	Meropenem	>8	80	8	12
Metronidazole	2	99.6	-	0.4	Metronidazole	2	99.6	-	0.4
Penicillin	4	38	10	52	Penicillin	>32	0	0	100
Pip-Tazo	16	89	9	2	Pip-Tazo	16	71	22	7
Tigecycline*	0.5	99.9	0.1	0	Tigecycline*	0.12	100	0	0

**Conclusions:** Of the 1450 isolates collected, 462 (32%) were resistant to two antibiotic classes. The most active antibiotic was tigecycline with MIC<sub>90</sub> of 0.12–0.5 mg/L, followed by metronidazole (MIC<sub>90</sub> 2 mg/L). Susceptibilities were highest for metronidazole and tigecycline (>99% susceptible). Against MDR isolates, only these two agents exhibited susceptibilities >90%.

**P1112** **Chlorhexidine-resistance in clinical isolates of coagulase-negative staphylococci, a descriptive study**

B. Söderquist\*, G. Prag, K. Falk-Brynhildsen, S. Jacobsson, M. Unemo (Örebro, SE)

**Objectives:** Coagulase-negative staphylococci (CoNS) comprise the major part of the normal flora of the human skin. Despite regarded as nosocomial pathogens, especially in infections associated with implanted foreign body materials. Pre-operative antiseptic preparation

is an important strategy for reducing the risk of complications such as surgical site infection (SSI). The most widely used compounds today are alcohols and quaternary ammonium compounds (QACs), predominantly chlorhexidine.

The aim was to investigate, by using both phenotypic and genotypic methods, if decreased susceptibility to chlorhexidine among CoNS isolates was present in our setting.

**Methods:** Coagulase-negative staphylococci (n = 150) obtained from four different studies were investigated; *S. epidermidis* isolates (n = 61) obtained from prosthetic joint infections (PJI), commensal *S. epidermidis* (n = 24), *S. epidermidis* from two trials investigating post-operative infections after cardiothoracic surgery (n = 31), and finally CoNS isolated from the skin of the thorax after routine disinfection prior cardiothoracic surgery (n = 34). Determination of MIC against chlorhexidine was performed on Müller Hinton agar plates supplemented with serial dilutions of chlorhexidine. PCR was used for the detection of five different QAC resistance genes, qacA/B, SMR, qacH, qacJ, and qacG.

**Results:** Decreased susceptibility to chlorhexidine was found among 54% of the PJI isolates, 64% of the cardiothoracic isolates, in 17% of the commensals, and 12% of the isolates obtained from the skin of cardiothoracic patients, respectively.

The qacA/B gene was present in 64 of 150 isolates (43%), SMR in 8/150 (5%) and qacH was found in one isolate (0.7%). The qacA/B gene was found among 52% of the PJI isolates, 61% of the cardiothoracic isolates, in 25% of the commensals, and 21% of the isolates obtained from the skin of cardiothoracic patients, respectively.

**Conclusion:** Decreased susceptibility to chlorhexidine as well as QAC resistance genes is present among *S. epidermidis* causing deep SSIs.

#### **P1113** High antibiotic resistance patterns of *Escherichia coli* in hospital wastewater in Nicaragua

*E. Amaya, D. Reyes, M. Paniagua, S. Calderón, M. Rashid, P. Colque, I. Kühn, R. Möllby, C.E. Nord, A. Weintraub\* (Huddinge, Stockholm, SE; León, NI)*

**Objectives:** The emergence of antibiotic resistant bacteria presents a major threat to public health because it reduces the effectiveness of antibiotic treatment, leading to increased morbidity, mortality and health care expenditure. Resistant bacteria found in the aquatic environment may disseminate among the population and the genes conferring resistance may be introduced in the natural bacterial ecosystems. The aim of this study was to determine the antibiotic resistance patterns of *Escherichia coli* isolates from different aquatic environmental sources in León, Nicaragua.

**Methods:** Antibiotic resistance patterns were studied among 493 *E. coli* isolates from different aquatic sources collected through October 2008 to May 2009 in León, Nicaragua. The following antibiotics were tested: ampicillin, amoxicillin-clavulanic acid, cefotaxime, ceftazidime, ceftriaxone, ciprofloxacin, chloramphenicol, gentamicin, nalidixic acid and trimethoprim-sulfamethoxazole by the agar dilution method. Phenotypic detection of extended-spectrum beta-lactamase (ESBL) was analysed using the Etest® system. All ESBL positive *E. coli* strains were screened for the resistance genes by PCR. To identify the beta-lactamase genes, sequencing was performed.

**Results:** High levels of antibiotic resistance were found in *E. coli* isolates in all hospital sewage water samples and in eight of 87 well water samples. Among the resistant isolates from the hospital sewage, ampicillin, chloramphenicol, ciprofloxacin, nalidixic acid, trimethoprim-sulfamethoxazole showed the most common multi-resistance profile. *E. coli* producing ESBL and harbouring the genes for CTX-M enzymes were detected in one of the hospital sewage samples and in 26% of the resistant isolates from the well water samples. CTX-M-9 group was more prevalent in *E. coli* isolates from the hospital sewage samples and CTX-M-1 group in the well water samples.

**Conclusion:** The presence of antibiotic resistant *E. coli* strains was frequent in the environmental water samples. Isolates carrying the

CTX-M group of enzymes have become one of the main public health concerns due to their ability to be involved in nosocomial and community acquired infections. In the present study, it was found that CTX-M-15 and CTX-M-9 were the specific beta-lactamases present in the *E. coli* isolates. Our results suggest that multi-resistant ESBL-producing *E. coli* are widely spread in hospital sewage water and in some well water samples in Nicaragua.

#### **P1114** Recovery of extended spectrum beta-lactamase (ESBL) producing bacteria from the hospital environment

*C. Judge, L. Burke, S. Galvin, H. Humphreys, D. Fitzgerald Hughes\* (Dublin, IE)*

**Objectives:** Inanimate surfaces adjacent to hospitalized patients are a potential reservoir for the transmission of bacteria. The contribution of the hospital environment to the transmission of antimicrobial-resistant Gram-positive bacteria in hospitals is widely documented. Due to their relatively short-term survival on surfaces, spread of antimicrobial resistant Gram-negative bacteria such as extended spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae by this route is less common and therefore is often overlooked. We investigated inanimate surfaces adjacent to ESBL-positive patients for the presence of ESBL-producers.

**Methods:** Recovery of ESBL-producing Enterobacteriaceae from six surfaces adjacent to three patients with confirmed ESBL infections was investigated using both pre-moistened environmental swabs and chromogenic selective contact plates. Recovered isolates were characterised using phenotypic combination disc tests, multiplex PCR for the detection of blaTEM, blaSHV and blaCTX-M genes and pulsed field gel electrophoresis (PFGE).

**Results:** ESBL-producing *Klebsiella pneumoniae* which harboured bla-SHV, blaTEM and blaCTX-M-1 genes were recovered from multiple surfaces adjacent to one of three patients. Isolates recovered from the patient's environment were closely-related (90–100%) by PFGE analysis to the clinical isolate that caused the urinary tract infection in the patient.

**Conclusion:** Using the recovery methods optimized in this study, we have shown that viable ESBL-producing Enterobacteriaceae may be present on inanimate surfaces close to patients and that environmental isolates are genetically closely related to the infecting isolates. Therefore, in relation to ESBL-producing Gram-negative bacteria, the hospital environment is a potential reservoir for further cross-contamination and infection.

## Environmental control and healthcare-associated infections

#### **P1115** In-use evaluation of an automated ultraviolet lamp (Germ Genie®) for bio-decontamination of hospital computer keyboards

*I.K. Hosen\*, T. Aseez, A. Livermore, R. Smith, G. Barrett, G. Bengel, J. Silles, R. Jackson (London, Reading, Hertfordshire, UK)*

**Objectives:** As high-touch surfaces in hospitals, computer keyboards can be a source for nosocomial infection. The electrical nature and irregularity of keyboards makes them difficult to clean by traditional methods. This study evaluated an automated ultraviolet lamp (Germ Genie®) for bio-decontamination of such keyboards. A second objective was to get feedback from hospital staff on its usability in a busy working environment.

**Methods:** Prior to the hospital field trial, computer keyboards across a number of settings including the hospital were sampled using sterile, cotton-tipped swabs. Additionally, a laboratory evaluation of efficacy using deliberately inoculated keyboards was also undertaken. For the hospital setting evaluation the Germ Genie® ultraviolet lamp was placed at two keyboards on each of four wards and there were a further two control keyboards on each ward for simultaneous sampling.

Samples were taken at least six times per keyboard over a 2-week period. The bacteria on sample keyboards were enumerated using direct plating and dilution methods. Bacterial identification was done by standard clinical microbiological methods including use of API strips. Semi-structured interviews about the device were conducted with 15 members of staff.

**Results:** Baseline sampling of keyboards both within and outside the hospital environment indicated significant contamination with fifty-eight skin-type and environmental morphotypes including *Acinetobacter* sp., *P. aeruginosa* and *S. aureus*. Results in the laboratory setting with inoculated keyboards showed that ten 1-minute cycles of the lamp were sufficient to kill 99–100% of artificially inoculated *E. coli*, *B. subtilis* and *S. aureus*. In the hospital, in all cases where Germ Genie® was correctly positioned (40 samples), no bacteria were recovered by any of the enumeration methods. Where the Germ Genie® was not installed (67 samples), significant levels of bacteria were found. Staff interviews indicated the view that the Germ Genie® was a valuable addition to efforts to combat hospital infection.

**Conclusions:** Our results show that hospital keyboards are colonised by a range of bacteria, including potential pathogens, and that installation of the tested automated UV lamp significantly reduces bacterial numbers to near-zero by the sampling methods employed. The UV lamp did not adversely affect workflow and there were favourable views from healthcare workers about its potential use for prevention of nosocomial infection.

**P1116** Effect of a decontamination device producing hydroxyl radicals on the survival of airborne opportunistic pathogens

L. Rayner\*, C.B. Beggs, K.G. Kerr, S.J. Shepherd, A.M. Snelling (Bradford, Harrogate, UK)

**Objectives:** There is increasing evidence that decontamination of the clinical environment can help reduce nosocomial infections. Systems that can disinfect air and surfaces whilst patients and staff are still occupying a room are being sought. The Inov8 Air Disinfection (AD) device releases hydroxyl radicals into room air continuously. These highly reactive oxygen species are thought to have multiple effects on microbes, reducing their viability in air and on surfaces. Few investigations of the AD device have been published so far, and results from hospital rooms have been conflicting. We thus evaluated the device against two nosocomial pathogens under defined conditions, in an aerobiological chamber set to mimic airflow rates typical of those encountered in wards.

**Methods:** *Staph aureus* NCTC 10399 and *Acinetobacter baumannii* NCTC 12156 were nebulised into the centre of a 72 m<sup>3</sup> chamber (6 m L × 4 m W × 3 m H). Air was sampled at regular intervals with a 6-stage Andersen sampler, and surviving bacteria calculated as CFU/m<sup>3</sup> of air. Steady-state experiments were carried out with the ventilation set at ~3 air changes/hour, ambient temp (20°C) and RH (~50%). Within each run, levels of bacteria in the air during a control period (AD off) were compared to levels when the device was on. Runs were done in triplicate.

**Results:** When placed in Position A (centre of room next to point of aerosol dispersal), the AD device achieved a mean percentage reduction of 37.3% (SD 22.5%) in *S. aureus* viable counts, with the AD ‘‘on’’ and ‘‘off’’ counts being significantly different ( $p < 0.001$ ) in two of the three runs. With *A. baumannii*, the mean reduction was 36.3% (SD 29.2%) with only one of the three runs displaying a statistically significant ( $p < 0.001$ ) difference when the device was on.

When in Position B (back of room, 2.7 m from point of dispersal), viable counts of airborne bacteria generally increased. A mean % increase of +10.8% (SD 8.9%) was observed with *S. aureus*, and +3.9% (SD 8.2%) for *A. baumannii*. With the device at Position B, none of the results for the AD ‘‘on’’ vs. ‘‘off’’ periods were significantly different ( $p > 0.05$ ).

**Conclusion:** Some modest reductions in airborne counts of the two pathogens were obtained when the AD device was close to the source of

bacterial dispersal. When the device was further away (2.7 m), there was no significant effect on viability. The AD device appears to have a limited range, which might explain the variations in results reported by others.

**P1117** Sporicides: the importance of in-use volume for effective surface disinfection

S. Ali\*, G. Moore, A. Wilson (London, UK)

**Objective:** We previously demonstrated the spread and persistence of *Clostridium difficile* spores during and after cleaning with sporicidal disinfectants. The aim of this study was to determine whether the in-use volume of two commercially available sporicides is sufficient for adequate disinfection of surfaces contaminated with *C. difficile*.

**Methods:** Microfibre cloth swatches (15 × 15 cm) immersed in either chlorine dioxide (140 ppm) or hypochlorite (1000 ppm) solution retained ~15 mL of sporicide. Subsequent wiping of a polypropylene surface deposited 20 µL of sporicide onto each consecutively wiped test area (25 cm<sup>2</sup>).

Sporicidal activity in suspension: microtitre wells containing 20 µL of test sporicide were inoculated with 10 µL of *C. difficile* spore suspension (10<sup>4</sup> CFU). Sporicidal activity was stopped after 0, 1, 3, 5, 10, 15, 30, 45, and 60 min by adding 20 µL of neutralising solution to each well (n = 5). Well contents were plated onto Brazier’s agar.

In-use activity: test areas (25 cm<sup>2</sup>) were inoculated with 10 µL of *C. difficile* spore suspension (10<sup>4</sup> CFU). Twenty micro litres of test sporicide was added and spread over the surface. After the appropriate contact time, test areas (n = 10) were sampled using cotton-tipped swabs. Each swab was transferred to 10 mL neutralizing solution prior to plating.

**Results:** When incorporated within the microtitre assay, 20 µL of chlorine dioxide or hypochlorite solution reduced the number of *C. difficile* spores to below the detection limit (20 CFU) within 5 min achieving a 3.69 and 4.72 log reduction respectively. In contrast, when 20 µL of sporicide was applied to a surface, a 5 min contact time resulted in spore numbers being reduced by between 0.42 (hypochlorite) and 1.15 (chlorine dioxide) log values. Increasing the contact time to 60 min achieved a further 1.00 (chlorine dioxide) and 1.20 (hypochlorite) log reduction. However, neither sporicide achieved a 3 log reduction and surfaces remained contaminated 60 min after cleaning.

**Conclusions:** When using microfibre cloths, the volume of sporicide (20 µL) transferred to a surface during cleaning, although effective when tested in suspension, was insufficient to decontaminate a surface. These findings confirm that suspension tests do not accurately reflect in-use activity and imply that sporicides, even when applied to a surface at the correct in-use concentration, may fail to reduce the number of *C. difficile* spores to a level that minimises patients’ risk of acquiring an infection.

**P1118** A pilot before and after intervention study on the effect of a liquid oxygen releaser sporicidal surface disinfectant compared with the usual disinfection procedure on the risk of nosocomial CDI in a university hospital, Austria, 2007–2011

M. Hell\*, C. Bernhofer, M. Voith, F. Berr, J.M. Kern, G. Chmelizek, M. Maass, S. Huhulescu, A. Indra, F. Allerberger, D. Schmid (Salzburg, Vienna, AT)

**Background:** *Clostridium difficile*, an important nosocomial pathogen is the leading cause of hospital-acquired diarrhea associated with high risk of fatal outcome.

A conventional, sporicidal surface disinfection applied in response to the occurrence of CDI was compared with daily application of a new sporicidal agent at two wards of a University hospital with respect to the risk reduction of CDI.

**Methods:** The routine CDI-surveillance data indicated a high endemic incidence of community-acquired (CA)-CDI and health-care associated (HA)-CDI (n = 118) at two wards (A, B) of an internal medicine department. CDI patients were classified into CA-CDI and HA-CDI according to ECDC definitions. Two intervention studies with a before-after design were performed at the wards A and B: ward A including four to six-bed-rooms and ward B single or two-bed-rooms. At ward A the "pre-intervention phase", in which the hospital policy based usual disinfection procedure (sporocidal surface disinfection in response to occurrence of nosocomial CDI only) was applied, took place from November 2007 until April 2009; the intervention phase, in which a new liquid oxygen releaser disinfectant with high sporocidal activity was daily used regardless of CDI occurrence, took place from May 2009 until July 2010. At ward B the pre-intervention phase lasted from August 2009 until June 2010 and the intervention phase from July 2010 until May 2011.

**Results:** A total of 67 cases of CDI (including 26 CA- and 41 HA-CDI cases) occurred at ward A and 51 cases (including 34 CA- and 17 HA-CDI cases) at ward B.

At ward A, the incidence rate difference of nosocomial CDI cases (0.4/1000 hospital days) observed was insignificant. At ward B, the incidence rate of nosocomial CDI at the end of the pre-intervention phase was 1.84/1000 hospital days compared with an incidence rate of 0.77/1000 at the end of the intervention phase, resulting in a rate difference of 1.07/1000 hospital days at borderline significance (p = 0.10) (see Table 1).

		Nosocomial CDI cases		*Per 1000 Person Time Units			**Two-Tailed	
		Beddays	Rate*	Rate Ratio	Rate Difference	P value		
Ward B	Intervention	5	0.42	0.42 (0.15-1.19)	-1.07 (-2.31, 0.17)	0.10		
	N	12	1.84					
Ward A	Intervention	16	1.45	0.78 (0.41-1.46)	0.40 (-1.42, 0.61)	0.45		
	N	25	1.85					

**Conclusion:** We concluded that the daily use of a liquid oxygen releaser disinfectant with high sporocidal activity at a ward with single or two bed-rooms was superior in preventing occurrence of nosocomial CDI to the sporocidal surface disinfection, applied as needed.

#### P1119 Equal efficacy of glucoprotamin vs. an aldehyde product for environmental disinfection in haematologic transplant unit: a prospective cross-over trial

R. Meinke\*, B. Meyer, R. Frei, J. Passweg, A. Widmer (Basel, CH; Düsseldorf, DE)

**Objectives:** Traditionally, aldehydes as broad spectrum microbicides have been used for surface disinfection in many settings. Glucoprotamin, an aldehyde-free disinfectant had been introduced as an active ingredient of disinfectants. In-practice data for surface disinfection with glucoprotamin are lacking and we therefore initiated a cross-over study to evaluate the effectiveness of glucoprotamin in comparison to the current standard of an aldehyde containing compound in a high risk hospital environment.

**Methods:** The study was a prospective, cross-over study with random allocation of the sequence of the disinfectant from October 2010 to December 2010. It was run at the hematological transplant unit of the University Hospital Basel, Switzerland. Access to this unit is limited, and protective care is applied for every patient. The study unit was split into two equal parts, the first part of the study lasted 4 weeks, after this time a cross over of the used disinfectants followed after a neutral cleaning of the ward. The used disinfectants were Deconex® 50 FF (Bode, Germany) and Incidin® Plus (Ecolab, Germany). Swabs of defined size were taken from five dedicated places in each room and cultured on blood agar and selective media for *Clostridium*, Gram-positives and *Staphylococcus aureus*.

**Results:** A total of 1528 samples (negative and positive) were available for analysis from surfaces disinfected with Deconex® 50 FF and 1540 (negative and positive) samples from surfaces disinfected with Incidin®

Plus. Ten percent of the samples with Deconex® 50 FF showed positive results (detection of pathogens) and 12% of the samples with Incidin® Plus. High counts of Enterococci were detected even shortly after disinfection with both disinfectants.

Tab: Species of pathogens detected in swabs

CFU/10C cm <sup>2</sup>	Deconex® 50 FF	Incidin® Plus	p-value
Overall bacterial counts	160	205	0.686
Mean (range)	0-8840	0-30028	
Enterococci	0	0	1.0
Mean (range)	0-2000	0-8000	
Other pathogens	0	0	1.0
Mean (range)	0-100	0-2000	

**Conclusions:** No significant difference was observed after applying the aldehyde, and aldehyde-free compound. *C. difficile* was not detected despite lack of activity against spores in the aldehyde-free compound. Enterococci – despite being highly susceptible to both compounds – did rapidly recolonize surfaces after successful disinfection. In conclusion, the aldehyde-free and the aldehyde-containing compound appear to be equally effective for disinfection of the hospital environment.

#### P1120 Microbial air contamination in operating theatres during hip and knee arthroplasties: first results from the ISChIA project

A. Agodi, F. Auxilia, M. Barchitta, D. D'Alessandro, I. Mura, M. Nobile, C Pasquarella\* on behalf of the GISIO-SItI Italian Study Group of Hospital Hygiene – Italian Society of Hygiene, Preventive Medicine and Public Health

**Objectives:** The ISChIA (Infezioni del Sito Chirurgico in Interventi di Artroprotesi) project has been funded by the Italian CCM (Centro Controllo Malattie, Ministry of Health) with the main aim of evaluating the role of microbial air contamination in the risk of surgical site infection (SSI) in hip and knee arthroplasties. This report describes the first results for microbial air contamination in the operating theatres (OTs) included in the survey, focusing on the role of the HVAC (Heating Ventilation and Air Conditioning) system, number of persons and number of door openings during interventions.

**Methods:** Microbial contamination was evaluated in the patient area, when empty and during operations. Passive sampling was used to determine the Index of microbial air contamination (IMA) (Pasquarella et al., 2000) and active sampling (SAS, International PBI) was used to determine CFU/m<sup>3</sup>. Tryptic Soy Agar with incubation at 37°C for 48 hours was used. SSI surveillance, which is still ongoing, is conducted according to the HELICS protocol (2004).

**Results:** From March 2010 to September 2011 a total of 1396 surgical procedures (60.4% hip and 39.6% knee arthroplasties) were included: among those 395 were performed in unidirectional airflow OTs, 256 in turbulent air ventilation OTs, 356 in turbulent air ventilation OTs with surgical team wearing Steri-Shield Turbo Helmet (Stryker). Microbial contamination values in empty OTs were: 0.0 IMA and 4 ± 3.6 CFU/m<sup>3</sup> (range 0–7) for in unidirectional flow OTs; 0.5 ± 1.1 IMA (range 0–2) and 11.7 ± 16.6 CFU/m<sup>3</sup> (range 0–23.5) for turbulent air ventilation OTs. During operations both IMA and CFU/m<sup>3</sup> increased: 7.3 ± 7.0 IMA and 50.3 ± 42.0 CFU/m<sup>3</sup> in unidirectional airflow OTs; 9.6 ± 13.5 IMA and 58.3 ± 41.2 CFU/m<sup>3</sup> in turbulent air ventilation OTs. In turbulent air ventilation OTs with surgical team wearing Steri-Shield Turbo Helmet 4.6 ± 4.1 IMA was obtained. In occupied OTs, a significant positive correlation between mean number of persons/number of door openings and microbial air contamination values was shown. A significant correlation between IMA and CFU/m<sup>3</sup> was also found.

**Conclusion:** Few data are available on air quality in OTs. Our preliminary results show a high variability in microbial air contamination values. Notably, the values obtained in unidirectional air flow OTs were higher than the recommended values (HTM03-012007; ISPEL, 2009; H+ Schweiz, 2007). The number of persons and of OT door openings are shown to affect the air bioburden.

**P1121** Emergent infection risk associated with hot water disinfection practices

A. Buzzigoli\*, B. Casini, A. Vecchione, E. Ramirez Quiroz, R. Banducci, P. Valentini, A. Baggiani, G.P. Privitera (Pisa, IT; Mexico City, MX)

**Background:** Control measures that are effective in minimizing legionella will be effective against many, but not all other pathogens. The aim of the study was to analyze the effect of chlorine dioxide and monochloramine on the fitness of relevant waterborne pathogens.

**Methods:** During 8 years surveillance of our hospital water network, 101 *Legionella pneumophila* serogroup 1 environmental strains, isolated prior to and following the start of chlorine dioxide disinfection were genotyped according to Sequence-Based Typing (SBT) and pulsed-field gel electrophoresis (PFGE). Chlorine susceptibility was assessed in accordance with BS EN 1040:1997 and after chlorine exposure, the virulence expression profile of locus lvh, region rtx and mip gene, related to host invasion was analyzed. The intracellular growth kinetics in *Acanthamoeba polyphaga* was also evaluated.

Starting from November 2010 the monochloramine-based disinfection started in a new building; hot water samples were analyzed also for nontuberculous Mycobacteria (NTM) by using culture method and QPCR for 16S rRNA gene; presumptive culture positive for NTM were confirmed by sequencing of hsp65 gene and restriction fragment length polymorphism (RFLP) analysis.

**Results:** Our observations indicated the emergence of a prevalent clone of *Legionella pneumophila* serogroup 1 (SBT 269, pulsetype 2, 70% of isolates) isolated following the start of chlorine dioxide water disinfection. The persisting clone appeared to be more chlorine-tolerant, showing the ability to express more promptly and markedly the virulence genes and to infect more efficiently *Acanthamoeba polyphaga*.

Before the application of monochloramine, all samples resulted positive for legionella with a mean load of  $7.2 \times 10^3$  CFU/L, while NTM mean load was  $4.0 \times 10^1$  CFU/L. After disinfection, legionella was never isolated, while NTM loads increased up to  $1.1 \times 10^4$  CFU/L; *Mycobacterium gordonae* was the predominant specie.

**Conclusion:** The occurrence of emergent infection risk could be related to disinfection practices: long-term disinfection with chlorine dioxide seemed to induce an adaptative response of legionella, selecting more virulent clones; on the other hand, monochloramine reduced the risk of legionella infection, but selected opportunistic mycobacteria. The choice of an appropriate disinfection method represents a determining factor for reducing water-associated infections.

## Clinical epidemiology of nosocomial infections – general

**P1122** Are cardiac surgeons the only common denominator between surgical site infections and poor compliance to antibiotic prophylaxis in cardiothoracic surgery?

M. Hassan\*, T. Al-Badawi, L. Moorhouse, S. Staff, A. Guleri (Blackpool, UK)

**Background:** Surgical site infections (SSI) are associated with complications, increased mortality, length of stay and associated costs. Literature/guidelines suggest optimal prophylactic antibiotics reduce risk of postoperative infections. Lancashire cardiac centre (LCC), a tertiary unit within Blackpool Teaching Hospitals, serves a population of 1.5 millions population in the northwest England and undertakes 1800 cardiothoracic (CT) surgeries annually. Blackpool Teaching Hospitals operates a successful HAI programme with high emphasis on antibiotic stewardship. Regular audits; HAI surveillance (incl.SSI surveillance) and action plan help fine tune local policies. We present findings from audit of a new antibiotic prophylaxis guidance in CTsurgery, introduced as a consequence findings of SSI (incl postdischarge) surveillance in CT surgery.

**Methods:** Audit of compliance (all Cardiac/thoracic surgeries conducted over 1-week in Sept 2011) to a new antibiotic prophylaxis policy. New policy suggests use of Flucloxacillin or Teicoplanin, plus gentamicin at induction and cover 1st 24-hours post surgery as opposed to previous practice of variable duration use of cefuroxime +/- Teicoplanin subject to surgeon variation. Comprehensive SSI surveillance (sternal/leg wounds) in post CT surgery including post discharge, over January–March 2011, using health protection agency (HPA) criteria.

**Results:** Key findings from prophylaxis audit: 8-CT surgeons/9 anaesthetists involved in 29 CT surgeries (including 20 elective cardiac; two emergency open heart procedures, six thoracic and one epicardial pacing insertion via thoracotomy); patients – 23 males/six females; mean age 60.9 years; Mean hospital stay 6 days and no SSI during hospital stay; non compliance with policy in 48.2% (14/29) including no gentamicin use in 24% (7/29); extended prophylaxis in 27.5% (8/29); doxycycline use in 17% (5/29); tazocin use 3% (1/29). SSI surveillance January–March 2011 revealed a SSI rate of 9% (23/255) for sternal and leg wounds.

**Conclusions:** LCC is committed to reduce rates of SSI as a part of NHS quality initiatives to improve quality/patient care. The comprehensive SSI surveillance earlier this year reported a rate of 9% (sternal/leg wounds) including post discharge. Current audit has revealed issues including limited compliance to the new prophylaxis policy, poor documentation and gaps in the policy. This has been used to inform the HAI programme within CT surgery and action planned.

**P1123** Advancing quality in patient care initiative at a tertiary care cardiac unit: an innovative project drawing on surgical site infections (including post discharge) surveillance in cardiothoracic surgery to drive quality

T. Al-Badawi, A. Guleri\*, L. Moorhouse, S. Staff, R. Sharma, M. Purohit, M. Hassan, V. Srivastava, K. Matiam (Blackpool, UK)

**Background:** Surgical site infections (SSI) are associated with complications, increased mortality, length of stay (LoS) and associated costs. Literature suggests SSI comprise up to 20% of all healthcare associated infections (HAI); 5% of all surgeries; doubles the cost of care and extends LoS upto 6.5 days. Lancashire cardiac centre (LCC), a tertiary unit within Blackpool Teaching Hospitals, serves a population of 1.5 million in the northwest England and undertakes 1800 cardiothoracic (CT) surgeries annually. We present findings from an innovative project on advancing quality. This includes gathering high quality data, a comprehensive SSI surveillance (including post discharge and both sternal/leg wounds) over 3-months to establish baseline SSI rate, assess any epidemiological links, impact of patient or healthcare factors and baseline to evaluate impact of interventions.

**Methods:** Analysis of database on 255 CT surgeries over 3-months (January–March 2011). SSI surveillance included both sternal and leg wounds. Surveillance period included up to 30 days post surgery and post discharge data. Data was collected from patient questionnaire

(posted after 30 days and postage paid), readmissions, followup clinics, GP consultations and contacting patients if no response. HPA standard criteria for definition of SSI was used.

**Results:** *Key findings:* Total of 255 CT surgeries during 3-months, 8-CT surgeons undertook between 22 and 38 surgeries/consultant; 7.8% (20/255) patients had a SSI including deep (3/20) and superficial (17/20) infections. Fifty percent (10/20) had leg wound infections; 50% (10/20) had SSI within 1st 10 days; predominant SSI noted in Males (3:1); Age range 71–80 years; BMI range 25–30; ASA scores of 3+.

**Conclusions:** LCC is committed to reduce rates of SSI as a part of commissioning for quality and innovation (CQUIN) schemes to improve quality/patient care. An innovative project was initiated with collaboration between cardiac surgery – microbiology – infection control. The aim was to gather high quality baseline data to drive a variety of interventions and measure the impact against baseline SSI rates. These interventions are in various stages and include new antibiotic prophylaxis in cardiothoracic surgery guidance, change of skinprep from povidone iodine-IPA to chlorhexidine-IPA; dedicated link nurse conducted hand-hygiene compliance audit to secret shopper style audits; enhanced Microbiology ward rounds; antibiotic compliance audits. Details to be presented.

**P1124 Debridement and implant retention in periprosthetic joint infections: could long-term antibiotic therapy improve the outcome?**

C. Pensotti, F. Nacinovich\*, L. Guzzi, P. Titanti, J. Thierer, A. Ferraris, C. Di Stefano, D. Stamboulian (Buenos Aires, AR)

**Introduction:** Several medical and surgical treatment strategies are currently available for the treatment of periprosthetic joint infections (PJI). Retention of the implant is gaining greater acceptance when the joint function is adequate. Debridement and implant retention (DIR) is an attractive strategy but the outcome may be not better or even could be worse than in other treatment options.

**Objective:** To evaluate the outcome of prolonged antibiotic treatment of PJI with DIR.

**Materials and methods:** A retrospective cohort analysis (from a prospective register of patients with PJI treated with DIR) was carried out from 10/91 to 9/10. Patient management was not previously standardized but on individual case evaluation and according to the criteria of the treating team physicians. STATA 10 was used for statistical analysis.

**Results:** One hundred sixty one episodes (ep) of PJI treated with DIR in 136 patients were evaluated; it accounts for 37.9% (161/424) of all PJI seen in the period considered. Mean age: 67.3 year-old (SD + 12.1), 55.9% were female. Co-morbidities (rheumatoid arthritis, diabetes, cancer) 34.7% of the ep. Prosthesis location: hip 52.2%, knee 44.1%, shoulder 3.1% and elbow 0.6%. Early PJI (<30 days after surgery) 65 ep (40.4%). Clinical findings: soft tissue swelling 65.8%; pain 64.0%, purulence discharge 44.7%, sinus tract 34.8%, fever 29.8%. Microbiology: grampositive cocci 67.1% (*S. aureus* 45.3%), gramnegative bacilli 16.7%, polymicrobial 16.8%. Antibiotic therapy: 27 weeks (median; IQR 25–75% = 16–48); route of administration: parenteral/oral 53.4%, only oral 39.1%, only parenteral 6.2%. Follow-up: 26 months (median; RIQ 25–75%; range = 17–52.5). DIR was performed by surgery in 159 ep; 2 ep. underwent arthroscopy. Successful outcome (cure/improvement) 56.5%, relapse 36.0%, failure 7.5%.

In the univariate analysis the age, gender, co-morbidities, sinus tract, prosthesis location, time of PJI since surgery and type of microorganism were not related to a better/worse outcome. Prolonged antibiotic therapy more than 24 weeks in early PJI showed to be related with a more successful outcome ( $p = 0.001$ ).

**Conclusion:** In PJI treated with DIR, a prolonged antibiotic therapy should be recommended to improve to outcome.

**P1125 Differential risk of post-surgical wound infection according to patient ethnicity**

T. Lamagni\*, S. Elgohari, C. Wloch, E. Sheridan (London, UK)

**Objectives:** A number of studies have identified differences in risk of infection according to patient ethnicity. Such studies have been largely focused on community-acquired infections with less work undertaken to examine risks for infections acquired in healthcare settings. As a means to investigate whether there is any evidence of excess risk, we investigated risk of wound infection surgical patients according to ethnic group.

**Methods:** Surveillance data for 2009/2010 submitted by NHS hospitals participating in the HPA surgical site infection surveillance for the following categories were extracted for analysis: coronary artery bypass graft; large bowel surgery; vascular surgery; reduction of long bone fracture. Patient preoperative health was recorded using the American Society of Anesthesiologists score. In parallel, data from the NHS Information Centre Hospital Episode Statistics for the same period and surgical categories were extracted to provide additional data fields, including patient ethnicity. Stepwise logistic regression analyses were undertaken to assess the relationship between risk of infection (detected during the inpatient stay or through readmission) and patient ethnicity with adjustment for other patient and surgical risk factors.

**Results:** Surveillance records for a total of 14 277 patients undergoing one of the four selected categories of surgery were submitted in 2009/2010, of which 73% ( $n = 10\,383$ ) were successfully matched to a corresponding HES record. Patient ethnicity was recorded for 9738 of the matched records, of which 93% were coded as being white, 4% Asian, 1% black, 1% Chinese and 0.4% of mixed ethnicity. With exclusion of the small number of patients of mixed ethnicity ( $n = 42$ ), rates of post-surgical infection across all surgical categories combined varied significantly ( $\chi^2$  (3 df) = 8.05,  $p = 0.045$ ) according to patient ethnicity, being highest in black patients (9%) followed by Asian (6%), white (5%) and patient of Chinese or other ethnic group (2%). Adjustment for additional patient factors (BMI, social deprivation, age, sex) and operational factors (category of surgery, duration of operation, wound class, ASA score) removed any significant association between ethnicity and risk of infection although odd ratios remained elevated for black (OR = 1.73, 95% CI: 0.84–3.56) and Asian patients (OR = 1.31, 95% CI: 0.82–2.07) compared to white patients.

**Conclusion:** Unadjusted risk of post-surgical wound infection was higher in non-white vs. white patients. Adjustment for additional factors diminished the association although odds ratios remained elevated suggesting a possible residual increased risk. Further analyses examining other categories of surgery should be undertaken to better characterise the association between ethnicity and risk of surgical site infection and the necessity of targeted prevention measures.

**P1126 Does preoperative statin therapy reduce postoperative infectious complications in patients undergoing cardiac surgery? A systematic review and meta-analysis**

I. Tleyjeh\*, F. Alasmari, M. Riaz, A. Bin Abdulhak, L. Baddour (Riyadh, SA; Rochester, US)

**Objective:** Post cardiac surgery infectious complications are a major problem with significant morbidity and mortality. Statins have been shown to have a modulation impact on both innate and adaptive immune system and anti-inflammatory effects, as well as direct inhibitory effects on pathogenic microorganisms. Having this pleiotropic effect, statins might help in the prevention of post-surgical infections. We sought to systematically examine the association between statins use and the risk of post-operative infectious complications in patients who undergo cardiac surgeries.

**Methods:** We searched OVID MEDLINE from 1950 to 2010; EMBASE from 1988 to 2010; Scientific Web of Science (inception through February 2011), and Elsevier Scopus (inception through February 2011); for any comparative studies examining the association

between statins use and risk of post-operative infections in patients who undergo cardiac surgeries. Two reviewers independently extracted data. We contacted study's authors for missing information. We conducted a random-effects meta-analysis of individual studies' odds ratios (adjusted for potential confounders). I-squared was used to examine for heterogeneity.

**Results:** We identified six cohort studies. All studies were published between 2005 and 2010. Three studies were conducted in Canada and three in USA. Three studies were single-center studies, two were population-based, and one was unclear. Statin exposure ascertainment was based on a review of admission medication list, or prescription databases. Infectious outcomes were heterogeneous and included surgical site infections within 30 days, serious infections (sepsis and deep sternal wound infection) or any postoperative infection. Use of statins in preoperative period was associated with a trend for reduced incidence of post-operative infections in patients who underwent cardiac surgeries (OR 0.81; 95% CI [0.64–1.01]),  $I^2 = 75%$  (Figure 1).

**Conclusion:** Our meta-analysis suggests that statins use may be associated with a lower risk of post-operative infectious complications after cardiac surgeries. Given the safety of statins and the major sequelae of post-operative infections, our results merit further validation in randomized controlled trials.

#### P1127 Incidence and microbiological characterisation of infections related to implantation of joint prostheses in São Paulo, Brazil, over a 5-year period

A.L. Lima\*, P.R. Oliveira, C.S. Felix, A.P. Paula, J.F. Tavares, F. Rossi, G.L. Camanho (Sao Paulo, BR)

**Objectives:** Describe the incidence and profile of agents involved in surgical site infections secondary to implantation of joint prostheses at an orthopaedic reference centre in São Paulo, Brazil, over a 5-year period.

**Methods:** This survey included all procedures for implantation of joint prostheses of the hip, knee and shoulder between January 2006 and December 2010. All patients received antimicrobial prophylaxis consisting of cefuroxime for 24 hours. The definition of surgical site infections followed the criteria of the Centers for Disease Control and Prevention, United States (USA). For microbiological characterization, only the agents obtained from cultures of samples of bone, soft tissue, synovial fluid, joint capsule or exudate that had been collected after antisepsis and debridement were taken into consideration. The cumulative antibiograms followed the standards recommended by the Clinical and Laboratory Standards Institute, USA.

**Results:** Over the study period, 2085 procedures to implant joint prostheses were carried out. Superficial or deep surgical site infections were diagnosed in 133 cases, with an incidence of 6.4%. It was possible to isolate the causative agent in 49% of the cases, and the rates of

positive cultures were 37%, 39% and 66% for cases relating to the shoulder, knee and hip, respectively. For these cases, the mean number of isolates was 1.35 microorganisms per patient. Among the 89 isolates, 50% were Gram-positive cocci (GPC), 48% Gram-negative bacilli (GNB), 1% fungi and 1% mycobacteria. The most frequent agents were: *Staphylococcus aureus*, with 27 isolates (30%); Coagulase-negative Staphylococci, 13 isolates (15%); *Acinetobacter baumannii*, 12 isolates (14%); *Klebsiella pneumoniae*, 11 isolates (13%) and *Pseudomonas aeruginosa*, eight isolates (9%). Other species of GPC were seen in four isolates (5%) and other species of GNB, in 12 isolates (14%). Table 1 shows the susceptibility profiles for the most frequent agents.

Table 1 – Susceptibility profiles for the most frequent isolates

Pathogen/antimicrobial tested	Antimicrobial susceptibility (%)
<i>S. aureus</i> (n = 27)	
CEFOXITIN	100
CLINDAMYCIN	63
CIPROFLOXACIN	63
LINEZOLID	100
METICILLIN	75
TRIMETHOPRIM/SULFAMETOXAZOLE	77
TEICoplanin	100
VANCOMYCIN	100
CEFOXITIN	100
<i>Coagulase-negative Staphylococci</i> (n = 13)	
CLINDAMYCIN	30
CIPROFLOXACIN	37
LINEZOLID	100
METICILLIN	9
TRIMETHOPRIM/SULFAMETOXAZOLE	57
TEICoplanin	80
VANCOMYCIN	100
<i>A. baumannii</i> (n = 12)	
AMIKACIN	25
AMPICILLIN/SULBACTAM	61
CEFEPIME	17
CEFTAZIDIME	20
CIPROFLOXACIN	19
IMIPENEM	42
MEROPENEM	34
COLISTIN	100
<i>K. pneumoniae</i> (n = 13)	
AMIKACIN	91
AZTREONAM	23
CEFEPIME	34
CEFTAZIDIME	18
CEFOTAXIME	13
CIPROFLOXACIN	27
ERTAPENEM	86
IMIPENEM	100
MEROPENEM	86
PIPERACILLIN/TAZOBACTAM	29
<i>P. aeruginosa</i> (n = 8)	
AMIKACIN	50
AZTREONAM	43
CEFEPIME	63
CEFTAZIDIME	63
CIPROFLOXACIN	50
IMIPENEM	63
MEROPENEM	58
PIPERACILLIN/TAZOBACTAM	67
COLISTIN	100

**Conclusions:** Incidence of surgical site infections relating to implantation of joint prostheses was 6.4%. It was possible to isolate the causative agent in 49% of the cases. The greatest numbers of positive cultures were in cases relating to the hip and the smallest numbers, to the shoulder. Although *S. aureus* was the most frequent agent, the prevalence of GNB was high, and the high resistance profile of these isolates to the antimicrobials that were tested (including carbapenems) was highlighted.

**P1128** Prevalence and risk factors of hospital-acquired infections in intensive care units: retrospective analysis from a USA hospital database

C. Amand-Bourdon\*, A. Stemart, E. Obi-Tabot, F. Joly (Chilly-Mazarin, FR; Bridgewater, US)

**Objectives:** To determine the prevalence of intensive care unit hospital-acquired infections (HAI), identify the risk factors and determine the inpatient consumptions for these infections in a U.S. hospital database.

**Methods:** A retrospective cohort study was undertaken using hospital database from the Premier Perspective of adults ( $\geq 18$  years old) admitted with a stay  $\geq 48$  hours in 2007. Three HAI known to be high drivers of hospital consumption were followed: bloodstream infection (BSI), surgical site infection (SSI), Hospital-acquired pneumonia (HAP) including ventilator-associated pneumonia (VAP). Case-subjects were defined as patients with NI. Control subjects without NI consisted of all patients who did not meet the definition for case-subject. Inpatient consumption was limited to hospital length of stay (LOS) and inpatient mortality rates. Logistic regression for prevalence odds ratio (OR) was used to assess the effects of independent variables as risk factors for the presence or absence of infection.

**Results:** Out of 5 426 276 patients meeting the entry criteria in 2007 in the Premier database, 8.5% of these patients experienced HAI. Focusing on ICU population of 463 491 patients, 119 616 (25.8%) patients developed HAI. HAP/VAP: 16.6%, BSI: 13.9%, and SSI: 1.4%. Patients with HAI were mostly elderly (57% vs. 52%), admitted via emergency room (71% vs. 56%), a high bed occupation, presented with more severe illnesses, more risk of mortality, and often underwent device procedures as: central catheter placements (49% vs. 18%) or mechanical ventilation hook-ups (42% vs. 15%) compared to patients without NI. The inpatient-mortality rate and LOS were higher in patients with HAI (18.5% vs. 4.5% and 15.8 + 17.4 days vs. 8.1 + 7.6 days), respectively compared to patients without HAI. Central catheters and mechanical ventilations were identified as the two main risk factors for HAI with OR = 3.4 CI (3.3–3.4) and OR = 2.8 (2.7–2.8), respectively.

**Conclusions:** Hospital-acquired infections are common and often associated with two main specific risk factors of mechanical ventilations and central catheters, which subsequently lead to longer LOS and higher mortality rates. These findings illustrate the changing nature of hospital patient population over the years that are more vulnerable to nosocomial infections, which demand preventive measures to reduce the prevalence and risk factors of these infections on the elderly.

**P1129** Transmission dynamics of *Staphylococcus aureus* and *Pseudomonas aeruginosa* in a burn centre during a 6-month period of patient monitoring by molecular typing

W.A. van der Reijden\*, S.A. Boers, I.F. van Ess-Visser, A.F.P.M. Vloemans, R. Jansen, B.M.W. Diederens (Haarlem, Beverwijk, NL)

**Introduction:** Patients hospitalized with burn wounds are at increased risk of developing microbial colonization and infection. Infections may lead to prolonged hospitalization, an increased morbidity and mortality and disturbed skin graft acceptance. Knowledge of colonization dynamics is limited and standard bacteriological techniques are not designed to detect and monitor transmission of bacterial strains. Therefore, the use of appropriate molecular typing methods may provide more insight into these dynamics and can result in the design of targeted infection prevention programs.

**Objective:** To obtain more insight into the transmission dynamics of *Staphylococcus aureus* (SA) and *Pseudomonas aeruginosa* (PA) in a burn centre.

**Methods:** From February till August 2011 all (n = 136) patients admitted at the Burn Centre, intake specimens were routinely taken from the nose, throat, and perineum on admission and from wounds and

infection sites on admission and thereafter twice a week. In addition, 56 nurse practitioners and surgeons of the Burn Centre/ICU were screened for SA and PA (nasal) carriage. A cluster was defined as a group of at least two patients carrying an identical SA or PA strain. During a 6 month period, all SA and PA isolates were typed by MLST and AFLP.

**Results:** Forty-eight out of 136 patients (35.3%) were positive for SA at any moment during hospitalization. We identified 27 multilocus sequence types and 38 AFLP types. Ten clusters of SA-positive patients were observed (range 2–8 patients). One third of patients were SA carriers at admission. Half of these carriers became infected by their own endogenous SA strain and in at least 67% of the patients, evidence for exogenous SA infection was observed. Three health care workers (HCWs) from the burn wound department shared an SA-strain with one of the clusters. PA was found in 11.6% of patients. In 50% of them, an identical PA was found in both an intake sample at admission and in a wound, indicating endogenous infections. None of the HCW were PA carrier. In 44% of patients carrying PA, evidence for exogenous infection of PA belonging to two large clusters was observed.

**Conclusions:** The results of this study show a high rate of endogenous and exogenous infections during a 6 month period in burn wound patients. The routine practice of molecular typing demonstrates the endogenous and exogenous spread in a burn centre and opens the possibility of more targeted infection prevention interventions.

**P1130** Evaluation of clinical and economic outcomes associated with infective endocarditis at an academic medical centre

K. Bauer\*, J. West, D. Goff, E. Abel, D. Blais, K. Stevenson, M. Firstenberg (Columbus, US)

**Objectives:** Infective endocarditis (IE) is a prevalent problem in health care associated with increased mortality, resource utilization and costs. We evaluated the epidemiology, clinical outcomes, and costs associated with IE at our institution.

**Methods:** Adult patients (pts) diagnosed with IE (Duke Criteria) were evaluated between January 2009–December 2010. Demographic characteristics, ICU admission, ICU length of stay (LOS), mortality, and hospital costs were evaluated. Statistical analysis included Fisher's exact or Wilcoxon ranksum test. Data are presented as percent or median (IQR).

**Results:** One hundred twenty-eight pts were identified for inclusion: 55% male, age 56 (40–67) years, 54% were admitted to the ICU. Comorbidities included: 74% cardiovascular disease, 38% renal insufficiency, 36% diabetes mellitus, and 19% COPD. Most pts had native valve IE (97%) with the aortic (43%) and mitral (48%) valves most frequently infected. Methicillin-resistant *staphylococcus aureus* (MRSA) (27%), methicillin-sensitive *staphylococcus aureus* (MSSA) (18%), *Enterococcus faecalis* (*E. faecalis*) (10%), and *Streptococcus viridans* (*S. viridans*) (9%) were the most common organisms. Complications included: stroke (13%), embolization other than stroke (5%), heart failure (9%), intracardiac abscess (3%), and  $\geq 1$  complication (17%). Valve replacement was performed in 23%. ICU LOS and hospital LOS were 6 (3–10) and 13 (9–22) days, respectively. Overall, hospital mortality was 23%. Hospital costs were \$39 455 (20 596–82 820). Costs were further analyzed based on valve replacement and organism.

Organism	Surgery (n=29)	No Surgery (n=99)	P-value
MRSA	562,935 (45,648-80,714)	538,828 (18,006-77,870)	0.35
MSSA	581,139 (54,275-95,308)	534,297 (21,900-44,921)	0.01
E faecalis	5204,691 (136,243-439,271)	536,430 (30,188-43,539)	0.02
S viridians	595,691 (74,351-111,471)	526,285 (19,319-33,230)	0.09

**Conclusions:** IE is associated with a high complication rate, increased mortality, and significant health care costs. Successful management of IE requires a multidisciplinary stewardship and surgical approach. Cost

outcome data favored surgery for staphylococci but not for *E. faecalis* or *S. viridans*. The significance of these findings warrants further investigation.

**P1131** Characteristics of meningitis/ventriculitis associated to neurosurgical procedures at a Brazilian teaching hospital: a retrospective analysis from 2005 through 2010

M.M. Alves\*, D.B. Assis, T. Guimaraes, M.P. Freire, F.C.G. Pinto, S.F. Costa, I. Boszczowski (Sao Paulo, BR)

**Objectives:** To describe characteristics of meningitis/ventriculitis associated to neurosurgical procedures at a Brazilian Teaching Hospital. **Methods:** Patients with meningitis/ventriculitis, microbiologically confirmed were included retrospectively from January 2005 through November 2010. Hospital charts were reviewed and liquor characteristics, isolated microorganisms and resistance profile were described.

**Results:** There were 72 microorganisms isolated in a total of 66 episodes of meningitis/ventriculitis. The 66 cases represent 45.8% (66/144) of meningitis/ventriculitis reported in the period. Median between meningitis/ventriculitis occurrence and last neurosurgical procedure was 11 days (range 1–47 days). Glycorrhachia/serum glucose had a median of 0.23, (range 0.0076–0.93). In 88.8% of the episodes this ratio was below 0.66. CSF lactate had a median of 61 mg/dL, range (16–179 mg/dL). The non-fermenting Gram-negative accounted for the majority (40%) of the infections followed by Gram-positive (30%) and Enterobacteriaceae (25%). *Acinetobacter* spp. was the leading pathogen (23.6%), followed by *P. aeruginosa* (12.5%), *Staphylococcus aureus* and coagulase negative staphylococci (11.1% each one). Among *Acinetobacter* sp. isolates, only 37.5% were susceptible to imipenem and 28.6% to meropenem. Among *Pseudomonas aeruginosa*, 22.2% were susceptible to imipenem and 44.4% to meropenem. Before 7 days after hospitalization, all Gram negative isolates were susceptible to ceftazidime. After 7 days, 50% of non-fermenting Gram negatives were cephalosporin resistant and carbapenem susceptible and 50% of them, were multi-drug-resistant. The most prescribed empiric therapy was vancomycin plus meropenem. And the second one was vancomycin plus ceftazidime. The empiric therapy was correct in 65% of the cases. Twenty-eight (42.4%) patients died. Deaths related to non-fermenting Gram negatives were 57% and related to *Acinetobacter* spp. was 47%. *Acinetobacter* spp. was isolated in 25% among patients who died, and all but one were multi-drug-resistant.

**Conclusion:** Differently from other centers, there is a high prevalence of non-fermenting Gram-negative bacteria resistant to carbapenems causing meningitis after the seventh day of hospitalization at our institution. There is a high mortality rate associated to non-fermenting Gram negatives, in special related to *Acinetobacter* spp. Highly effective preventive measures related to this pathogen are needed.

**P1132** Incidence of hospital-acquired pneumonia, bacteraemia and urinary tract infection in patients with haematological malignancies, 2004–2010: a surveillance-based study

C. Huoi\*, P. Vanhems, M.C. Nicolle, M. Michallet, T. Bénet (Lyon, FR)

**Introduction:** Patients with haematological malignancies are at high-risk of hospital-acquired infection (HAI). The objective was to describe the incidence trends of HA pneumonia, bacteraemia and urinary tract infection (UTI) in a university haematology department between 2004 and 2010.

**Methods:** A prospective surveillance of HAI was performed in a university haematology department composed of 42 single-bed rooms. All patients hospitalized between 1 January 2004 and 31 December

2010 for at least 48 hours were included. Definitions of HAI were based on a standardized protocol. The analysis was restricted to the first HAI. The incidence was the number of events per 1000 patient-days at risk. Univariate and multivariate Poisson regressions were fitted to assess temporal trends, adjusted on age, gender, aplasia, exposure to central venous catheter, haematological disease and treatments.

**Results:** Overall, 3355 patients accounting for 58 063 patient-days at risk were included. A total of 1055 (31.4%) patients had at least one HAI. The overall incidence of HA pneumonia, HA bacteraemia, and HA-UTI were respectively 3.3 (95% CI: 2.8–3.8), 12.0 (95% CI: 11.1, 12.9), and 2.9 (95% CI: 2.5, 3.4) per 1000 patient-days at risk. HA bacteraemia incidence increased of 11% (95% CI: +6%, +15%,  $p < 10^{-3}$ ) per year, independently of aplasia, central venous catheter and haematological disease. The incidences of HA pneumonia and HA-UTI were stable. In acute myeloid leukaemia patients, incidences of HA pneumonia, HA bacteraemia and HA-UTI were respectively 4.2, 12.9, and 2.6 per 1000 patient-days at risk. In patients with acute lymphoid leukaemia, incidences of HA pneumonia, HA bacteraemia and HA-UTI were respectively 1.8, 13.4 and 3.5 per 1000 patient-days at risk. The most frequently isolated pathogens were *Aspergillus* spp. (59.2%) and *Candida* spp. (7.8%) for pneumonia, coagulase negative *Staphylococcus* (44.2%) and *Candida* spp. (4.6%) for bacteraemia and enterobacteria (60%) for UTI.

**Conclusion:** Incidence of HA pneumonia and HA-UTI remained stable. The improvement of infection control measures could have been counterbalanced by exposure to more aggressive chemotherapies. Incidence of bacteraemia increased suggesting that other factors than central venous catheter exposure could explain this trend. More investigation are needed to explore in depth such findings.

**P1133** Surveillance of the central venous catheter-related bloodstream infections in haematological patients

M. Giemza, M.M. Wroblewska\*, E. Mik, A. Kuziak, J. Czyz, B. Marianska (Warsaw, PL)

**Objectives:** Analysis of the frequency, risk factors and etiology of the central venous catheter-related bloodstream infections (CVC-BSIs) in haematological patients.

**Materials and methods:** We retrospectively analysed data related to the risk factors and etiology of CVC-BSIs for the time period from January 2006 until September 2011. The duration of catheter insertion, the number of CVC-BSIs and incidence density rates per 1000 catheter-days were calculated. Catheter tip cultures were performed according to Maki's semi-quantitative method. Bacterial strains were isolated and identified according to standard methods. All staphylococcal cultures were subsequently tested for methicillin susceptibility with a cofoxitin disc diffusion test.

**Results:** The total of 2500 central lines were analysed. The mean duration of CVC insertion decreased from 19 days in 2006 to 14.5 days in 2011. During the study period 97 CVC-BSIs were reported. The incidence density rate decreased from 4.5/1000 catheter-days in 2006 to 1.3/1000 catheter-days in 2011. Among cultured microorganisms ( $n = 93$ ) the most common were staphylococci – 67 (72.0%) strains. Methicillin-resistant *S. epidermidis* (MRSE) comprised 42/50 (84.0%) strains, while methicillin-resistant *S. aureus* (MRSA) – 4/13 (30.8%) strains. Enterococci constituted 8/93 (8.6%) isolates, enteric rods – 8/93 (8.6%), and *A. baumannii* – 2/93 (2.1%) strains. Eight strains of *C. albicans* were cultured (8.6% of all isolates).

**Conclusions:** During the observation period the mean duration of CVC insertion decreased from 19 days in 2006 to 14.5 days in 2011. At the same time the incidence density rate decreased from 4.5/1000 catheter-days in 2006 to 1.3/1000 catheter-days in 2011. The main etiological agents were staphylococci; MRSE comprised 84% of *S. epidermidis* strains. *C. albicans* strains amounted to almost 9.0% of all isolates, while no strains of *C. parapsilosis* were cultured. Gram-negative non-fermenting rods were very uncommon (2.1%).

**P1134** A study of microbial aetiology of catheter-associated urinary tract infection in intensive care unit and medical wards from a tertiary care teaching hospital in New Delhi, India

S. Banerjee\*, S.K. Prakash, M.K. Daga, R. Kumar, A. Das, R. Kaur (New Delhi, IN)

**Objectives:** The study aimed to find the rate and microbial agents of Catheter Associated Urinary Tract Infection (CAUTI), but not mere asymptomatic and insignificant bacteriuria, in Intensive Care Unit (ICU) and Medical Wards (MW) as per the CDC CAUTI guidelines.

**Methods:** Two hundred adults with urethral catheters were included with 100 each from the MW and ICU of MAMC and LN Hospital, Delhi, India, from August 2010 to September 2011. Three samples were aseptically collected from each patient – within 24 hours, in the 1st week between 4th and 6th day and beyond 1 week of catheterization. The unbiased allocation of patients was a key step. Everyday, ‘‘Allocation Concealment’’ was done by obtaining initial blanket consent from all eligible and willing patients. Blocked Randomization was performed to include a minimum of one patient each time from each of four block categories, viz. the MW men and women blocks and the ICU men and women blocks. The day for collecting the 1st sample were selected by simple randomization every week, as the patients admitted under different units in the different days of the week were hypothesized to have varying levels of stringency and vigilance regarding catheter care and antibiotic usage. Sixty-five cases were unavailable for the 3rd sample due to catheter withdrawal, death or discharge. Semi-quantitative culture followed by identification of isolates was done by conventional techniques and confirmed by VITEK2 COMPACT<sup>®</sup> (Biomerieux).

**Result:** Only three of 200 (1.5%) patients in the 1st sample, 77 (30) from ICU and 47 from MW) from the 2nd sample (38.5%) and 41 of 135 patients (14 from ICU and 27 from MW) with two isolates from 13 and one isolate from 28 cases from the 3rd sample (30%) fitted to the CDC CAUTI criteria. The isolate characteristics were quite different in 2nd and 3rd samples. 98.7% of the 2nd sample isolates were gram negative rods (N), including *Escherichia coli* (36), *Klebsiella pneumoniae* (19), *Enterobacter* spp. (7), *Pseudomonas aeruginosa* (4), *Acinetobacter baumannii* (3), *Proteus mirabilis* (2), *Providencia stuartii*, *Burkholderia cepacia*, *Serratia fonticola*, *Citrobacter freundii*, *Pantoea agglomerans* and *Strenotrophomonas maltophilia* (one each). Whereas, among the 3rd sample isolates, 57.4% were *Candida* spp. (31), 24% were *Enterococcus* spp. (13) and only 18.5% were gram negative rods.

**Conclusion:** A clear shift from gram negative predominant isolates in the first week to *Candida* and Enterococcal isolates beyond 1st week in CAUTI patients was observed with broad spectrum antibiotic usage.

**P1135** Bloodstream infections in a neonatal intensive care unit: a 2-year study

M. Papadimitriou\*, E. Charachousou, D. Hatzaki, A. Doudoulakakis, I. Parakakis, J. Kapetanakis, E. Lebessi (Athens, GR)

**Objectives:** To present the experience with bloodstream infection (BSI) in a 30-bed, university-affiliated, level III-IV NICU at a large pediatric hospital in Athens.

**Methods:** The charts of all neonates with culture-proven BSI admitted to our NICU over 2 years (2009–2010) were retrieved. Clinical, epidemiologic and microbiologic characteristics were recorded.

**Results:** A total of 787 neonates (58.4% boys) were admitted during the study period. Overall, 128 episodes of BSI, due to 131 pathogens were diagnosed in 88 neonates (63.6% boys, 56.8% preterms). Of those, 28/88 (31.8%) presented congenital anomalies, 22/88 (25%) respiratory distress and 19/88 (21.6%) necrotizing enterocolitis. Average stay before infection was 20.8 days (0–195) and mean hospitalization was 60.4 days (0–396), significantly higher than overall mean hospitalization (18.4 days). The mean incidence of BSI was nine cases/1000 patient days. Overall, 128 bacteria (Gram positive 96 [75%], Gram negative 32 [25%]), and three fungi (*Candida albicans* 2, *Malassezia furfur* 1) were recovered. Analytically, the following pathogens were identified: *Staphylococcus* spp. (81/96, 84.4%), *Enterococcus* spp. (15/96, 15.6%), *Escherichia coli* (8/32, 25%), *Klebsiella pneumoniae* (7/32, 21.8%), *Enterobacter aerogenes* (6/32, 18.7%), *Enterobacter cloacae* (5/32, 15.6%), *Serratia marcescens* (2/32, 6.25%), and *Serratia liquefaciens*, *Klebsiella oxytoca*, *Proteus mirabilis*, *Alcaligenes xylosoxidans* (1/32 each, 3.1%). Polymicrobial bacteremia was diagnosed in three cases. Extended-spectrum beta-lactamases (ESBL) were detected in *K. pneumoniae* (71%), *Escherichia coli* (13%) and *E. cloacae* (80%). Overproduction of AmpC beta-lactamases was identified only in one *E. aerogenes* strain. All coagulase-negative staphylococci (CNS) were susceptible to linezolid and vancomycin, whereas 16/80 (20%) were non susceptible to teicoplanin. Multidrug resistant isolates, such as VRE, MRSA, carbapenemases producers were not identified. A cluster of five nosocomial cases due to *K. pneumoniae* ESBL was detected from February to May 2009, and a cluster of four nosocomial cases due to *E. cloacae* ESBL from July to November 2010. The crude mortality rate was 11.4%, significantly higher than the overall mortality (3.6%).

**Conclusions:** Neonatal bacteremia was mainly caused by CNS. Resistance to commonly used antibiotics was exhibited especially by Gram negative bacteria. Strict infection control measures were important to limit the spread of ESBL producers in the NICU.

**P1136** Hospital-acquired pneumonia in non-ICU patients in a rural general hospital

T. Exiara\*, M. Filippidou, K. Nikolaou, M. Kouroupi, E. Gidaris, A. Konstantis, L. Simoglou, A. Risgits, V. Dendrinos, E. Pigkal, E. Filippidou, S. Saridou, M. Memet, L. Papazoglou (Komotini, Didimoteixo, Alexandroupolis, GR)

**Objectives:** Hospital-acquired pneumonia (HAP) is a major subgroup of all hospital acquired infections and an important public health problem. It usually occurs in patients with underlying diseases, increases nosocomial morbidity and mortality, prolongs hospital stay and raises the cost of health care. The aims of this study were to determine the prevalence, aetiology and outcome of HAP in our rural general hospital.

**Methods:** This is a retrospective and descriptive study. We reviewed the medical files of all inpatients fulfilling clinical criteria of HAP, during last 5 years. Demographical data, co-morbidities, clinical and laboratory findings, pathogens identified and outcome were registered and analyzed.

**Results:** In a total of 3156 patients, 127 (4.02%) had HAP, 76 (59.8%) male and 51 (40.2%) female with mean age of  $74 \pm 7.3$  years. Eighty-four (66.2%) of HAP cases were diagnosed at Internal Medicine wards and 43 (33.8%) at Surgical wards. The main identified co-morbidities were: Stroke (67.7%), diabetes mellitus (42.5%), malignancy (29.9%), heart failure (26.8%), chronic renal failure (25.2%), chronic pulmonary disease (20.5%) and alcohol abuse (10.2%). Etiologic diagnosis was achieved in 62 (48.8%) patients. Mixed aetiology was considered in 7 (5.5%) cases. The most common isolated pathogens were: Methicillin Resistant *Staphylococcus* in 23 (18.1%) patients, Enterobacteria (*E. coli*, *Enterobacter* spp., *K. pneumoniae*) in 22 (17.3%), *Acinetobacter baumannii* in 6 (4.7%), *Pseudomonas aeruginosa* in 12 (9.4%) and

*Enterococcus* spp. in 7 (5.5%) patients. Complications were observed in 61 (48%) cases with respiratory failure in 33 (26%) cases, septic shock in 12 (9.5%), pleural effusion in 11 (8.7%) and renal failure in 5 (3.8%) cases. The mean duration of hospitalization was  $23 \pm 5.6$  days. The mortality rate attributed to HAP was 29.9%.

**Conclusions:** As in other European countries, in our Hospital HAP affects mostly elderly patients with severe underlying diseases predisposing them to aggressive pathogens that vary accordingly to the hospital flora of an institution. Guidelines have been developed in effort to deal with this issue, but as we know, part of the solution to this problem passes through a full commitment to the clinical rules of antibiotics management and microbiological aspects of this disease.

#### P1137 Health-care-acquired pneumonia in internal medicine departments: frequency and risk factors for difficult-to-treat micro-organisms

M. Giannella\*, J.A. Capdevila, B. Pinilla, P. Muñoz, E. Bouza on behalf of the ENEMI study group

**Objective:** To assess frequency and risk factors for difficult-to-treat (DTT) microorganisms in patients with HCAP treated in IMDs.

**Methods:** Seventy-two internal medicine departments (IMDs) reported all patients with pneumonia attended in their department during 1 week in January 2010 and 1 week in June 2010. We analyzed those who fulfilled Health-care-acquired pneumonia (HCAP) criteria (prior hospitalization  $\geq 2$  days or surgery in the past 180 days; residence in a nursing home; chemotherapy, intravenous therapy, wound care or specialized nursing care at home in the past 30 days; attending hospital or hemodialysis clinic). DTT microorganisms were *P. aeruginosa*, Enterobacteriaceae and methicillin-resistant *S. aureus* (MRSA).

**Results:** The 1002 patient records examined revealed 307 (30.6%) cases of HCAP. Prior hospitalization (56%), residence in a nursing home (55%), and attending hospital regularly due to a chronic comorbid condition (55%) were the most common HCAP criteria. An etiological diagnosis was achieved in 65 patients (21.2%): *S. pneumoniae* (38.5%), *P. aeruginosa* (17%), Enterobacteriaceae (12.3%), MRSA (12.3%), *H. influenzae* (5%) and others (11%). Overall, 41.5% of patients with an etiological diagnosis had a DTT microorganism. Differences between patients with difficult-to-treat (DTT) microorganism and those with an easy-to-treat microorganism were chronic obstructive pulmonary disease (70% vs. 43%,  $p = 0.04$ ) and attending the hospital regularly due to a chronic comorbid condition (73.3% vs. 40%,  $p = 0.01$ ). Multivariate analysis adjusted for age, Charlson index, functional status (Barthel index), residence in a nursing home, prior hospitalization, and severity of pneumonia (ATS/IDSA) showed that attending the hospital regularly due to a chronic comorbid condition was the only independent risk factor for difficult-to-treat (DTT) microorganism (OR 4.12, 95%CI 1.43–11.84;  $p = 0.008$ ).

**Conclusions:** HCAP accounts for one third of cases of pneumonia treated in IMDs; up to 40% of those with identified etiology are caused by difficult-to-treat (DTT) microorganisms. Broad-spectrum antibiotics should be considered in this setting especially in patients attending the hospital regularly due to a chronic comorbid condition.

#### P1138 Characterisation of healthcare-associated pneumonia in a Belgian university hospital

C. Theunissen\*, D. De Bels, J. Vanderhulst, I. Gallimoni, G. Herzog, J. Massaut, S. Cherifi (Brussels, BE)

**Objectives:** Healthcare-associated pneumonia (HCAP), referring to patients with frequent healthcare contacts and at higher risk of contracting resistant pathogens, is now recognized as a new category of pneumonia. Evidence regarding its distinct clinical course and microbiological etiology remains controversial. The aim of our study was to compare the clinical and microbiological aspects of HCAP to those of community-acquired pneumonia (CAP) in a Belgian tertiary center.

**Methods:** This prospective observational study included all adult patients hospitalized with pneumonia, admitted between 15 October 2010 and 15 August 2011. Clinical characteristics and culture data of HCAP were determined and compared to CAP.

**Results:** A total of 157 patients (83 women and 74 men) were included. Forty-nine percent of them had HCAP, 51% had CAP. HCAP differed from CAP in age ( $p < 0.001$ ), the presence of cancer ( $p = 0.003$ ), lung disease ( $p = 0.007$ ), cardiac disease ( $p = 0.021$ ), metabolic disease ( $p = 0.025$ ), neurological disease ( $p = 0.001$ ) and immunosuppression ( $p = 0.012$ ). CAP needed more frequently transfer to an intensive care unit (ICU) (27 vs. 16%,  $p = 0.048$ ). Thirty-five percent of HCAP was culture-proven vs. 22% CAP. *Streptococcus pneumoniae* was the major pathogen (32%), followed by *Staphylococcus aureus* (14%) and *Haemophilus influenzae* (14%). No differences in microbiological etiology were detected between both groups except for *Moraxella catarrhalis* (4 in HCAP vs. 0 in CAP,  $p = 0.039$ ). Adequacy of treatment was similar in both groups (80% in CAP vs. 76% in HCAP), as were length of hospital stay (23 days in CAP vs. 21 days in HCAP) and mortality rate at 28 days (9% in CAP vs. 18% in HCAP). Logistic regression analysis revealed that mortality at 28 days was independently related to age (OR = 3.63; 95% CI [0.04–1.16];  $p < 0.001$ ); the presence of cancer (OR = 2.25; 95%CI [0.16–2.40];  $p = 0.025$ ) and the presence of *S. pneumoniae* (OR = 2.17; 95%CI [1.18–3.64];  $p = 0.03$ ).

**Conclusion:** HCAP differs from CAP in age and underlying illnesses. However, the outcome and microbiological etiology were similar in both groups. Mortality was primarily related to underlying patient-related factors rather than the mode of acquisition or the presence of nosocomial pathogens. This study, held in a monocentric setting on a limited number of patients, did not indicate the need to adapt empiric antibiotic treatment in case of HCAP.

#### P1139 A review of the infection control prevention and control interventions during a large outbreak of norovirus infection at a hospital, London

S. Palanivel\*, P.A. Riley (London, UK)

**Background:** An outbreak of norovirus gastroenteritis took place between 15 May and 18 June 2010 at St George's Hospital, a tertiary centre in London. This project describes the outbreak and the strategies implemented to identify and control the infection. Most of these strategies fell in accordance with the current Health Protection Agency (HPA) guidelines written in 2000. However certain aspects were managed differently from the current guidance in order to maintain the acute and routine services of the hospital.

The objectives of this study were to: (i) evaluate if using a 48 hour isolation period rather than 72 hours for symptomatic patients resulted in secondary cases, (ii) Ascertain if modified infection prevention and control measures used by St George's Hospital during the outbreak had a detrimental effect on the running of the hospital. This will help assess if modifying approaches to infection control in the context of a norovirus outbreak is appropriate in hospital outbreaks.

**Methods:** Number and date of clinical and laboratory confirmed diagnoses were used to plot an epidemic curve. Number of secondary hospital cases as a result of reduced isolation period and number of affected wards, closed wards, closed bays and quarantined bays were recorded. Hospital performance data were collected for the epidemic period and compared with a non-epidemic period.

**Results:** The study showed no secondary cases resulted from exposure to patients out of isolation between 48 and 72 hours. There was no reduction in Accident and Emergency attendees seen within 4 hours and patients admitted on the 18-week pathway were better during the outbreak than the following year. The clinical division most affected was Medicine, where there was an increase in last minute cancellations and mean length of stay in acute medicine was higher than the following year.

**Conclusions:** A shorter isolation period did not result in an increase in secondary cases and there was no adverse outcome in hospital performance data over the period of the outbreak other than in the hospital division with the most cases. A reduced isolation period can be recommended for similar tertiary referral centres for management of future outbreaks.

**P1140 A nosocomial outbreak of 2009 influenza A (H1N1) in a haematology ward**

C. Garcia-Vidal\*, I. De la Haba, D. Viasus, J. Niubó, E. Coma, M. Bodro, À. Plans, C. Micheo, J. Trellis, A. Fernández-Sevilla, J. Carratalà (L'Hospitalet de Llobregat, ES)

**Objective:** Data about the measures to adopt in nosocomial outbreaks of 2009 influenza A (H1N1) are scarce, specially in wards with severely immunosuppressed pts.

**Methods:** We describe the characteristics and measures adopted in a nosocomial outbreak of 2009 influenza A (H1N1) that occurred in an hematology ward from 27 January to 4 February 2011. Influenza diagnosis was made by real-time polymerase chain reaction. The hematology ward has three wings (two with rooms with a positive airflow relative to the corridor and frequent air changes).

**Results:** The outbreak involved 15 (56%) of 27 hospitalized pts and six health care workers (HCW). The likely index case was admitted with B cell lymphoma and respiratory infection in a positive pressure room and diagnosed with influenza A (H1N1) 4 days later. All pts but one were diagnosed in the wings with rooms with positive pressure and were transferred after influenza diagnosis to rooms without positive pressure. The median age of pts was 55 years (35–83); most of them had acute leukaemia and five were stem cell transplant recipients. Only 13% of the pts and 12% of the HCW had received the recommended influenza vaccine. There was one case of pneumonia. Seven asymptomatic pts were diagnosed by screening. The main measures adopted were: (i) instituting droplet and contact precautions; (ii) close the ward for new admissions; (iii) restricting visits and avoid patients, family and staff movement between wards, (iv) re-offering influenza vaccination; (v) universal screening and oseltamivir therapy for all hospitalized pts during 14 days; (vi) stop the positive airflow, and (vii) test all symptomatic health care workers. The overall case-fatality rate was 20%.

**Conclusions:** Our study suggests that airflow transmission may play a significant role in nosocomial outbreaks of influenza. The measures adopted merit consideration when facing new outbreaks occurring in hematology wards. Our report reinforces the needed to maximize prevention measures against influenza infection such as annual influenza vaccination.

**P1141 Unusual hospital-related outbreaks due to fungi: the need to improve diagnosis, treatment and prevention**

E. Repetto\*, C. Giacomazzi, A. Traverso, F. Castelli (Brescia, Aosta, IT)

**Objectives:** Fungi are a well known cause of severe infections in immunocompromised patients. Two or more unusual hospital related

fungi infections diagnosed in a short period should be assumed as an epidemic. Outbreak's reports are increasing: the aim of this review is to collect data to improve the management of these infections.

**Methods:** The free online worldwide database for nosocomial outbreaks of the Institute of Hygiene and Environmental Medicine-Charité of the University of Berlin (<http://www.outbreak-database.com>) was used to collect the English literature on unusual fungal infections published from 1990 to 2011 (*Aspergillus* and *Candida* were excluded). For each outbreak the following data were considered: phylum, duration (months), source of infection (identified, not identified, not searched), site of infection (organs, devices), ward (medical, surgical, ICU), risk factors (identified, not identified, not searched), number of patients infected or colonized, treatment (medical, surgical, none), related mortality and type of epidemiological study.

**Results:** Twenty-seven reports were considered: Ascomycetes caused the majority of the reported outbreaks (17/27) and the overall median duration was high (6 months). In one outbreak the infection was limited to prosthetic devices. Six centers did not look for the source of the infection and nine centers were not able to identify it. Statistically significant risk factors were searched and found in 13/27 and 11/13 outbreaks, respectively. In the majority of cases (14/27) only molecular analysis and environmental surveys were performed. The complete results are summarized in Table 1.

Table 1.

Phylum	Duration*	Source	Site	Ward
17 Ascomycetes 5 Basidiomycetes 5 Zygomycetes	6 months (0-45)	12 identified* 9 not identified 6 not searched	26 organ** 1 device	10 medicine 7 surgery 10 ICU
Risk factors	N° patients per outbreak*	Therapy	Mortality*	Type of study
11 identified** 2 not identified 14 not searched	5 (2-379) infections§	17 antifungals 1 surgery 1 no therapy 8 not reported	27% (0-100%)	13 case-control studies 14 other§§

ICU: intensive care unit; \*median and range; \*\*contaminated material or human to human; \*\*\*blood, lung, skin, bowel, central nervous system, eye; \*\*\*\*preterm birth, low birth weight, invasive devices/procedures, co-morbidities; § 12 co-infections; §§ molecular analysis and environmental surveys.

**Conclusions:** Fungal nosocomial outbreaks usually involve few patients but show high mortality (median value: 27%), especially in patients with severe co-morbidities. This fact could be explained by the delay in the diagnosis, the inability of recognizing the source of infection and the challenges of the treatment. In two cases a direct human to human transmission was proved and in seven cases was hypothesized. More efforts should be done to implement the application of proper care and hygiene practices in order to avoid human to human transmission.

**P1142 Reporting observational studies on antibiotic-resistant infections. It is time to improve it**

E. Tacconelli\*, M.A. Cataldo, G. De Angelis, C. De Waure, S. Venturiello, C. Caddeu, E. Milozzi, B. Cookson (Rome, IT; London, UK)

**Objectives:** Several limitations affect observational studies exploring risk factors associated with infection or colonisation due to antibiotic-resistant bacteria (ARB). An attempt to improve the quality of scientific evidence was done with the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) statement. However, we do believe that the peculiarity of the epidemiology of ARB needs specific variables to be considered and included in this score. The main objective of the study was therefore to suggest new items to be considered to improve reporting of observational studies on ARB infections.

**Methods:** The study was designed as a three-step study. Firstly, we reviewed the literature selecting all articles analysing the association between antibiotic exposure and acquisition of MRSA or multidrug-resistant *A. baumannii*. Secondly, all the articles were reviewed

according to the items of the STROBE index. Absolute and relative frequencies were used to describe the results of the judgment of quality of reporting. The impact factor of the journal where the study was published was also reported. Thirdly, a new set of items specifically focused on antibiotic-resistant infections were developed by an Expert panel and tested on the same articles. The Expert panel was composed by the authors and three external reviewers.

**Results:** Seventy-eight studies (39 case-control, 28 cohort, and 11 cross-sectional) were reviewed. Overall the quality of reporting, assessed through the STROBE statement, was poor in most areas. Statistical details, subgroup analysis, sample size calculation and the description of main study objectives were satisfied in <25% of the studies. Linear regression analysis revealed that increase in impact factor was significantly associated with the percentage of satisfaction of the STROBE statement ( $p = 0.01$ ). However, an unexpected low level of quality of high rank journals for major issues such as sample size calculation, bias and confounding analysis was observed. Twelve new items were proposed (Table 1). All the new items were reported in <25% of studies.

Table 1.

Section	New item proposal
Introduction Background /rationale	Report previous in vivo and in vitro studies.
<b>Methods</b>	
Study design	State type of study.
Setting	Specify if setting is epidemic or endemic. Specify type of hospital and characteristics of population served by the hospital. Describe infection control measures applied at the study location.
Participants	Provide clear definition for case and control and give reason for control selection. Give reason for matching criteria.
Variables	Specify antibiotic usage according to: type, dosage, duration and route of administration. Define time at risk for antibiotic exposure. Include among potential confounders: comorbidity, length of hospital stay, previous surgery, presence of devices.
Data sources/measurement	Provide definition of resistance, multidrug resistance, including pattern of co-resistance. Whether variation of resistance is seen in studied pathogens. Whether studies performed to identify location or resistance e.g plasmid, chromosome, integron, transposon.
	Definition of infection and/or colonization. If not a validated reference, evidence of robustness of definition.
Quantitative variables	Provide subgroup analyses for immunocompromised, surgical medical patients and patients in intensive care units.
<b>Results</b>	
Descriptive data	Specify among the exposure: previous stay in long term care facilities, nursing home, and other hospitals.
Other analyses	Report subgroup analysis by type of patients and type of microorganism.
<b>Discussion</b>	
Limitations	Provide description of sources of selection bias, information bias and confounding.
Generalizability	Discuss study setting for the generalizability.

**Conclusion:** There is a significant need to improve the quality of reporting epidemiological studies on infections due to ARB. Since these studies might impact on public health officers decisions to try to reduce the spread of ARB, the application of our modified STROBE score can play a role.

#### **P1143** Predicting a complicated course of *Clostridium difficile* infection using a validated scoring system at patient's bedside

M.P.M. Hensgens\*, O.M. Dekkers, S. le Cessie, A. Goorhuis, E.J. Kuijper (Leiden, Amsterdam, NL)

**Objective:** *Clostridium difficile* infection (CDI) is the leading cause of antibiotic associated diarrhoea. Mortality associated with CDI is high and varies from 6% to 19%. Patient characteristics such as age and comorbidity, laboratory findings and type of *Clostridium difficile* have been used to predict the outcome of CDI. However, no validated prediction rule is available. In this study, we aim to develop such a

scoring system using criteria that are available at the bedside of the patient at time of diagnosis.

**Methods:** Between March 2006 and May 2009, nine hospitals in the Netherlands included patients with a positive toxin test for *C. difficile*. Demographic characteristic, clinical and laboratory parameters were collected using patient records, the electronic medical information system and consulting the physician in charge. We performed univariable logistic regression of putative predictors of a severe course of CDI after 30 days (death, ICU admission or colectomy due to CDI). Multivariable logistic regression and subsequent reduction of the model resulted in a final model. Internal validation was done using bootstrapping techniques. External validation took place using a different cohort of CDI patients, gathered in a different time frame.

**Results:** In total, 395 CDI patients were included of whom 46 had a complicated course within 30 days (11.9%). Seventeen putative predictors were included in univariable analysis. Five variables remained in the final model: age (OR 4.96  $\geq$  85 years; OR 1.83 50–84 years), diagnosis at the ICU (OR 7.03), recent surgery (OR 0.23), hypotension (OR 3.25) and admission because of diarrhoea (OR 3.27). After internal validation, a score was developed with four risk categories on the outcome: no risk (0%), low risk (5%), medium risk (16%) and a high risk (39%). External validation among 140 CDI patients showed that the score was capable of categorizing CDI patients according to their outcome.

**Conclusion:** This prediction rule uses bedside collected criteria to predict a complicated course of CDI after 30 days. Objective categorization of patients is therefore possible, which could have major implications for guidance of treatment decisions and selection of patients for randomized trials.

## Clinical epidemiology of nosocomial infections – Gram-positive infections

### **P1144** Molecular characterisation of VRE from the hospital environment and correlation with clinical VRE samples during an outbreak in a tertiary referral centre

C. Fenelon\*, C. Wrenn, S. Fitzgerald, K. Schaffer, E. O'Mahony, L. Fenelon, D. Keating, D. O'Brien (Dublin, IE)

**Background:** EARS-Net data in 2011 show that Ireland had the highest proportion of enterococcal bloodstream isolates that were resistant to vancomycin (44.0%, quarter 2 2011). St Vincent's University Hospital is a 479 bedded tertiary referral centre and is the National Centre for Liver Transplantation and Pancreatic Surgery. In 2010, the proportion of enterococcal bloodstream isolates that were vancomycin resistant in our hospital was 39%. Almost all of these infections occurred in patients in the intensive care unit (ICU), general surgical and haematology/oncology wards.

**Objectives:** To establish whether there was an environmental reservoir of vancomycin resistant enterococci (VRE) in these wards and to determine whether the clinical and environmental strains were related.

**Methods:** Three hundred and eighty-one environmental samples were taken using flocked swabs (FLOQSwabs™; Copan Flock Technologies). The swabs were taken from specified frequently-touched locations in patient care areas in ICU, general surgical and haematology-oncology wards. Culture specimens were obtained by rubbing premoistened swabs repeatedly over each designated site and placing the swab in liquid transport medium. Specimens were inoculated onto blood agar and VRE chromogenic agar (Biomerieux) and incubated for 48 hours. VRE was confirmed using the VITEK II identification system (Biomerieux). Isolates were tested for antimicrobial susceptibility and typed by PFGE. PFGE was performed on 10 isolates of VRE from patients present in the clinical areas at the time that the environmental swabs were taken.

**Results:** Of the 381 environmental samples taken, 125 (32.8%) were positive for VRE (Table 1). Linezolid resistance was identified in 4%. VRE was most frequently isolated from bed rails, patient tables and

equipment storage units. PFGE analysis yielded a diverse set of isolates with six clonal complexes (EC-6/7, EC-9, EC-10, EC-11, EC-12, EC-13) identified. Five of these were found among both clinical and environmental samples.

**Conclusion:** The hospital environment plays an important role in the transmission of VRE. Frequent transfer of patients between the study areas, a paucity of single rooms and shared toilet facilities may be a factor in the molecular diversity of isolates identified. Strict adherence to infection prevention and control measures and thorough environmental cleaning is necessary to prevent spread following the establishment of successful clones.

**P1145** **Molecular epidemiologic characterisation of *Staphylococcus epidermidis* isolated from prosthetic joint infections**

B. Hellmark\*, B. Söderquist, M. Unemo, Å. Nilsson-Dotter-Augustinsson (Örebro, Linköping, SE)

**Objectives:** *Staphylococcus epidermidis* is a commensal that comprises a substantial part of the normal human skin flora. Nevertheless, this bacterium has emerged as the most important pathogen in infections related to implanted foreign body materials, especially prosthetic joint infections (PJIs). A major problem for the clinical laboratory is to determine whether finding *S. epidermidis* in a sample from a PJI is a true infection or if it is a sampling contamination. The aim of this study was to examine the molecular epidemiology of *S. epidermidis* isolated from PJIs and compare to commensal isolates from skin of healthy, non-hospital individuals.

**Methods:** Sixty-one isolates from PJI and 24 commensal isolates were examined using multilocus sequence typing (MLST) according to the MLST-scheme published by Thomas et al. (Thomas et al., 2007). For studies of relationship between different sequence types (ST) eBURSTv3 were used (<http://eburst.mlst.net>).

**Results:** Two STs dominated among the PJI isolates; ST2 in 28 isolates (45%) and ST215 in 19 isolates (30%). The remaining PJI isolates (n = 14) were assigned as singletons, pairs or triplets of different STs. In contrast, the commensal isolates displayed a diverse picture with mainly singletons and not more than three isolates assigned the same ST. ST2 and ST297 were the only STs found among both groups of isolates.

This is in concordance with previous studies of nosocomial isolates reporting ST2 as the dominant ST among invasive isolates (Li et al., 2009; Miragaia et al., 2007). ST215 is a relatively novel ST that recently has been described in a study of MDR *S. epidermidis* obtained from patients at hospitals in northern Europe, and ST215 was identified

only in isolates from hospitals in Sweden and Norway (Widerström et al., 2009).

**Conclusion:** A correlation between the results of the MLST and the source of the isolates could be seen. ST2 and ST215 dominated among the PJI isolates while only two and no commensal isolates displayed ST2 and ST215, respectively.

**P1146** **The impact of methicillin-sensitive *Staphylococcus aureus* bacteraemia in a UK renal population**

P. Thomson, C. Deighan, S. Hasnie, J. Coia\* (Glasgow, UK)

**Objective:** Infection is the second leading cause of death in patients with established renal failure, comprising 25% of all deaths. (i) *Staphylococcus aureus* is a common cause of bacteraemia and associated with significant mortality and morbidity in this population. (ii) In this study we examine the impact of methicillin-sensitive *Staphylococcus aureus* bacteraemia (MSSAB) in our established renal failure population.

**Methods:** We performed a retrospective study of prospectively recorded data. An electronic patient record search was conducted for all MSSABs in the established renal failure population of the Glasgow Renal Units and outpatient dialysis facilities between 1 January 2010 and 31 December 2010. Events were allied to electronic records of in-patient admissions, antimicrobial therapy, clinical events and mortality.

**Results:** Thirty-eight patients developed 43 episodes of MSSAB. 3/38 (7.9%) occurred in patients with a functioning renal transplant, 6/38 (15.8%) in patients with an arteriovenous fistula, 21/38 (55.3%) in patients with a tunneled venous catheter and 6/38 (15.8%) in patients with a non-tunneled venous catheter. 11/38 (28.9%) patients died within 6 months of MSSAB. 6/38 (15.8%) had metastatic infection including 4/38 (10.5%) with endocarditis.

Average in-patient stay increased from 11.3 to 24.5 days ( $p < 0.001$ ) comparing the periods 6 months before and after MSSAB. 33/38 (86.8%) patients were treated as in-patients. No difference in metastatic infection, hospitalisation or mortality rates was seen when comparing flucloxacillin with vancomycin based treatments.

**Conclusion:** MSSAB confers a significant burden of comorbidity, hospitalisation and death in renal patients. In this analysis, there was no discernible difference in clinical outcomes between flucloxacillin and vancomycin based therapies.

2. Fitzgerald SF, O'Gorman J. A 12 year review of *Staphylococcus aureus* bloodstream infections in haemodialysis patients: more work to be done. *J Hosp Inf* November 2011; 79: 218–221.

**P1147** **First documented nosocomial transmission of MRSA spa type 011 in an Austrian hospital, 2010–2011**

D. Schmid\*, W. Ruppitsch, U. Orendi, U. Zerlauth, F. Allerberger (Vienna, Klagenfurt, AT)

Livestock-associated (1a) methicillin-resistant *Staphylococcus aureus* belonging to multilocus sequence type (ST) 398 was first associated with human disease in 2003 in the Netherlands. MRSA isolates of spa types t011, t034, t108, t567, t571, t588, t753, t898, t899, t1184, t1254, t1255, t1451, t1456, t1457, t2123, t2330, t2383, t2582, or t3013 correspond to ST 398. In December 2010 a cluster of five patients positive for t011 was identified in a 1400 bed – hospital in Austria.

Aim of our investigation was to describe the cluster, to identify the mode of spread and the source(s) of that strain. A cluster case was defined as a person, who stayed as a patient or health-care worker in hospital A between June 2010 and March 2011 with a specimen positive for MRSA t011.

Case finding was performed within routine MRSA screening or infection diagnostics. Data on demographics and livestock contact were ascertained by personal interviews. Six patients (four male, two

**Figure 1;** cases by date of MRSA detection, department (ward) of stay and pig-farm contact

female) and one male nurse fulfilled the cluster case definition (median age: 72 years). The initial MRSA t011 isolates were from nasal ( $n = 7$ ) or skin ulcer ( $n = 1$ ) swabs. None of the cases showed signs of MRSA infection. Figure 1 displays the cases by date of MRSA detection, department of stay and livestock contact. The case-patients I, II and III had a positive history of livestock contact as farmer or by living in the household of a farmer. Case-patient IV shared the patient room with case-patient III. The case-patients V and VI and the case-nurse VII were linked to each other by stay or work within 2 months at the same ward, where the case-patient II had been hospitalized 4 months earlier. In May 2011 dust samples and pig nasal swabs from the pig farm related to case-patient III yielded t011; samples from the pig farm related to case-patient I tested negative for MRSA, and case II refused testing of the involved pig farm. Our findings underline, that regular contact with pigs contributes to transmission of la-MRSA ST398 from animals to humans and to spread of la-MRSA into the health-care-setting. The first described nosocomial outbreak due to la-MRSA affected a Dutch hospital in 2007. In 2008 and 2009, in Austria MRSA t011 was detected in dust samples from pig farms, and in nasal swabs from veterinarians and pig farmers. Efforts of clinicians, infection control practitioners and veterinarians are required to prevent further spread of la-MRSA into health-care settings.

#### **P1148** Use of a novel MRSA strain-typing system to investigate a neonatal intensive care unit outbreak

L. Gilbert\*, A. Pinto, M. O'Sullivan, K. Dempsey, J. Tallon, M. Tracy (Sydney, AU)

**Background:** In May 2011, two 26 week-gestation infants, developed pneumonia, due to a community-type methicillin-resistant *Staphylococcus aureus* (cMRSA) and died within days of each other. They had shared a room, in a 39-bed Neonatal Intensive Care Unit (NICU – 19 ventilator, 20 non-ventilator cots). Previously, MRSA had been isolated rarely from NICU patients. Using a novel MRSA typing system (19-target PCR, reverse line blot assay) the cMRSA was identified as PVL positive, SCCmec type IV. We hypothesised that one infant had acquired cMRSA from her mother and the other by nosocomial transmission.

**Methods:** Enhanced infection control precautions (hand hygiene, contact precautions and environmental cleaning) were implemented. All infants, staff (138 NICU staff) and selected environmental sites were screened for MRSA and routine screening of infants, on admission and weekly, was introduced. Despite this, another 11 infants (all but one of whom had been delivered by Caesarean section) were colonized or infected with MRSA in the next 5 months. One hundred and thirty-four NICU, 19 visiting staff and 52 environmental sites were re-screened and screening of relevant delivery ward and operating room staff is underway (70 screened so far).

**Results:** Ten of 13 colonised infants (including the two index cases) had the same "epidemic" strain; the mothers of two of these 10 infants carried a different strain. Three infants had non-epidemic cMRSA strains, including one whose mother carried a matching strain. Two NICU staff in the 1st and two in the 2nd round of screening were MRSA carriers; only one carried the epidemic strain, but was not thought to be the source. All were successfully decolonized. MRSA was isolated from only one environmental site (blood gas machine). Screening of junior medical staff, who had rotated to other hospitals before screening commenced is still incomplete. Although, no source has yet been found, no newly colonized infants have been identified in NICU since this rotation occurred. Further investigation of the epidemic strain showed that it is a PVL-positive ST22 MRSA, which previously has been identified rarely in Australia.

**Conclusion:** The use of a rapid, sensitive MRSA strain typing system allowed precise characterization of the epidemic and elimination of several potential sources (mothers and staff). There has been no intra-NICU transmission since September. We assume the source is an as-yet-unidentified external staff member; investigations are continuing.

#### **P1149** Is colonisation pressure a predictor of methicillin-resistant *Staphylococcus aureus* transmission in a low prevalence setting?

A. Senok\*, H. Khanfar, A. Anani, V. Zinkevich (Riyadh, Dhahran, SA; Portsmouth, UK)

**Objectives:** Colonization pressure (CP) has been described as a useful predictor of nosocomial transmission of methicillin-resistant *Staphylococcus aureus* (MRSA) in settings of high MRSA rates. This study investigates the role of CP as a predictor of nosocomial MRSA infection in a low prevalence setting.

**Methods:** Retrospective analysis of health care associated MRSA (HA-MRSA) rates from 2004 to 2009 at the Saudi Aramco Dhahran Health Center, Saudi Arabia was carried out. MRSA-patient days, susceptible patient days, nosocomial incidence and colonization pressure were calculated for each month from January 2008 to December 2009.

**Results:** In 2005 and 2006 HA-MRSA accounted for 29.6% and 31.6%, respectively, of the hospital associated infections, declining to 5.1% in 2009. During the study period, MRSA constituted 13.7% of all staphylococcal isolates and was associated with bacteremia and wound infection. All isolates were sensitive to vancomycin. The incidence of nosocomial infection per 1000 susceptible patient days was 1.17 in 2008 and 0.7 in 2009. Monthly colonization pressure ranged from 0.1 to 1.62 across the 2-year period. Nosocomial transmission was observed in 13 out of 24 months; however, no pattern of association between the preceding month's CP and the nosocomial incidence in the subsequent month was demonstrable.

**Conclusion:** These findings indicate that in settings of low MRSA prevalence, nosocomial transmission does occur at low CP levels probably due to lapses in adherence to infection control. However, CP does not appear to be a predictor of transmission and nosocomial incidence. In such settings, strict adherence to infection control policies with a low tolerance approach to lapses in adherence, coupled with adequate staffing, ongoing education, continuous surveillance and feedback measures are recommended.

**P1150** Virulence determinants among coagulase-negative staphylococci recovered from bacteraemias and device-related infections

N. Giormezis\*, A. Foka, E. Drougka, S. Fouzas, G. Dimitriou, E.D. Anastassiou, I. Spiliopoulou (Patras, GR)

**Objectives:** Coagulase-negative staphylococci (CNS), mainly *Staphylococcus epidermidis* and *S. haemolyticus*, are a major etiological agent of neonatal nosocomial sepsis and a major cause of device-related infections in hospitalized patients. Among the various virulent factors potentially implicated, are the adhesion mechanisms used by the bacteria to anchor themselves to the surface of various materials, including medical devices. Of equal importance is the production of an intercellular polysaccharide adhesin (PIA), encoded by the *ica* operon, and biofilm formation. In this study, CNS isolated from bacteraemias and device-associated infections were compared in terms of antibiotic resistance, biofilm formation, *ica* and adhesin's gene carriage.

**Methods:** In total, 313 CNS (161 from infants with bacteraemia and 152 from catheters and other device-mediated infections) were identified at species level by Vitek 2 Advanced Expert System (bioMérieux, France). Biofilm formation was tested by Christensen's method. Antibiotic resistance was tested by the disk diffusion method and Etest, according to CLSI guidelines. Clonality was identified by PFGE analysis of *Sma*I chromosomal DNA digests. The presence of *mecA*, *icaA* and *icaD* (*ica* operon) and adhesin's genes (*atlE*, *fbe*, *bap*, *fnbA*) was tested by PCRs. Data were statistically analyzed using SPSS.

**Results:** One hundred and fifty-nine (98.8%) CNS from blood cultures and 136 CNS (89.5%) from medical devices were *mecA*-positive (MR-CNS). Two major clones were characterized among *S. epidermidis* and one among *S. haemolyticus*. Forty-six (30.3%) CNS from various devices and 76 (47.2%) from blood infections formed biofilm, whereas most strains were multi-resistant. There was a significant difference in biofilm formation ( $p = 0.002$ ), *mecA* ( $p < 0.001$ ), *ica* and *fnbA* ( $p = 0.001$ ) gene carriage in favor of bacteraemic CNS, whereas those from medical devices were more frequently related with the presence of *bap* gene ( $p = 0.031$ ). No difference was found in regards of the adhesins *AtlE* and *Fbe*.

**Conclusion:** In our hospital, multi-resistant CNS, mainly *S. epidermidis* and *S. haemolyticus* are a major cause of neonatal sepsis and device-mediated infections among hospitalized patients. Those isolated from blood cultures carried more pathogenic and antibiotic resistance elements, including methicillin resistance, biofilm formation, *ica* and *fnbA* gene carriage, whereas CNS from medical devices were, in comparison, more related with the adhesin *Bap*.

**P1151** Rapid bench top whole genome sequencing for investigation of a putative MRSA outbreak

N.C. Gordon\*, T. Golubchik, P. Piazza, A. Votintseva, D. Buck, R. Lay, A.M. Kearns, R. Bowden, L. O'Connor, D.C. Crook (Oxford, London, UK)

**Objective:** To investigate the relatedness of atypical methicillin resistant isolates of *Staphylococcus aureus* in an intensive care unit setting using a rapid turnaround bench top sequencer.

**Methods:** Seven cases over a 2 week period were found to be colonised with *S. aureus* on routine screening using MRSA selective agar; however the isolates had an oxacillin MIC of  $< 2 \mu\text{g/mL}$  on routine E-strip testing suggesting that they were methicillin susceptible. These were sent to a reference laboratory and were shown to be spa type t5973 and *mecA* positive by PCR. No further cases were detected on repeated screening of all patients on the unit. Two months later a case grew similar isolates from a blood culture and a screening swab. These were also t5973 and *mecA* positive. These isolates were tetracycline resistant on routine testing whereas the earlier isolates were susceptible. The Illumina MiSeq platform was used to sequence and

assess the relationship between these two later isolates to the seven cases identified 2 months earlier.

Two of the study isolates were sequenced twice and the reference isolate MRSA-252 was sequenced for validation. Four samples were sequenced per run using  $2 \times 150$  bp reads. The sequences were mapped to a reference genome with STAMPHY. Base and variant calls were made using SAMTOOLS, PICARD and bespoke Python scripts. The entire process from the time of culturing the organisms to determining relatedness of strains took  $< 5$  working days.

**Results:** All 12 samples were successfully sequenced with a mean call rate of 81% of the reference genome. No sequence differences were detected in the two pairs of replicates or between the MRS-A252 control sample and reference sequence. Among the test samples, no sequence differences were detected between isolates from six of the original seven cases, and the other isolate differed at a single site. The two isolates from the blood culture positive case yielded identical sequences that differed at two positions from the other isolates.

These data are consistent with recent acquisition from a common source.

**Conclusion:** Rapid bench top whole genome sequencing provided unambiguous evidence of an outbreak of atypical MRSA acquisition in an intensive care unit. This was achieved in a timescale sufficiently rapid to inform case management.

**P1152** Successful implementation of a new MRSA-screening concept

T. Rünz\*, M. Kellner (Sindelfingen, DE)

**Objectives:** To reduce nosocomial infections and colonisations with MRSA at a 1600 bed secondary and tertiary care a six-hospital network in Germany, the department of infection control, in collaboration with the hospital administration and the laboratory introduced a new MRSA screening concept.

**Methods:** A checklist was created to select high risk patients for mandatory MRSA-screening based on 7 points. Instead of the physicians, the nurses were now responsible for this selection process. Patients with prior history of MRSA-colonization or infection were identified by means of a pop-up window on the computer screen with the message "CAVE" (lat.: caution) at the time of admission. To shorten turn-around time, a PCR-based assay for MRSA-detection (Light Cycler MRSA Advanced, Roche Diagnostics) was established with a throughput of up to 100 tests per day. Results were available within 24 hours after receiving the specimen. The MRSA-KISS (KISS = German Hospital Surveillance System) results were to be reported regularly. Three testing phases: (i) real observation, (ii) intensive training and (iii) inspection interval were monitored for number of screenings, nosocomial MRSA infections, nosocomial MRSA colonisations and residence time during which infection control precautions remained unchanged.

**Results:** Screening rates increased from 10% to 15% before introduction of the new screening concept to 31% after the introduction. Turn-around time was reduced for detection of MRSA

Table 1: Facts of the testing phases and development of nosocomial MRSA infections

	Phase 1 'real observation'	Phase 2 'intensive training'	Phase 3 'inspection interval'
Observation period	09/2008 – 03/2009	09/2009 – 03/2010	04/2010 – 12/2011
Number of patients	41,563	41,535	122,676
Decision for screening	Physician	Nurse	Nurse
Checklist	No	Yes	Yes
Screening rates	10-15%	31%	33%
Duration (months)	7	7	21
Number of nosocomial MRSA infections	11	3	-7
Number of nosocomial MRSA infections p.a.	18,0	4	-4,0

colonisations and MRSA infections after compared to before the introduction of the new screening concept. Most importantly, rates of MRSA colonization ( $p < 0.005$ ) and MRSA infection were markedly reduced.

The evaluation of economic data shows that the incremental costs are not fully compensated by the additional DRG (diagnosis related groups) proceeds.

**Conclusions:** The introduction of a new stringent screening concept including checklist, caution label in medical information system, and rapid diagnosis using PCR resulted in a significant reduction in the rates of nosocomial MRSA-infections and MRSA colonisations in the hospital network.

**P1153 Phenotypic and genotypic characterisation of coagulase negative staphylococci bacteraemic isolates from infected very low birth weight neonates: antibiotic and antiseptic susceptibility, biofilm production and clonality**

M. Lepointeur, J.-W. Decousser, G. Royer, O. Romain, F. Doucet-Populaire\* (Clamart, FR)

Very low birth weight neonates (VLBW) are high risk patients to develop hospital acquired infections as catheter related bacteraemia (CRB). Coagulase negative staphylococci (CNS) are the leading cause of CRB.

**Objectives:** To characterize CNS isolated from blood cultures of VLBW hospitalized at the NICU of Antoine Bécélère hospital (Clamart, France).

**Methods:** Forty-nine strains of CNS responsible for clinically relevant CRB among 47 VLBW (median 830 g, range 540–1430 g) were included between January 2009 and September 2011. Species identification was performed using conventional and reference methods. Antimicrobial susceptibility was tested by disc diffusion method and MIC determination (Etest®); mupirocin susceptibility study was completed by mupA PCR. Antiseptic susceptibility was tested by broth microdilution method (chlorhexidine CHX, benzalkonium chloride BZC, acriflavine ACR) and qacA PCR. Biofilm formation was evaluated by the Ring Test method; a PCR targeting IS256 and icaADB was performed. Clonality of *S. epidermidis* and *S. capitis* was studied using PFGE analysis.

**Results:** The species distribution was: *S. epidermidis* (47%), *S. capitis* (37%), others species (16%). The proportion of rapid (<6 hours), slow (6–24 hours) and no biofilm producer was 41%, 37% and 22%, respectively. Antibiotic resistance was common: oxacillin (98%), gentamicin (88%), ciprofloxacin (29%) and mupirocin (61%). The MIC90 of vancomycin, teicoplanin, daptomycin and linezolid was 3, 4, 1 and 1 mg/L, respectively. Among mupirocin resistant strains, all but one harboured a high level resistance and were mupA positive. Antiseptic decreasing susceptibility was identified among 12% of strains for CHX, 22% for BZC and 33% for ACF. Qac A was presented among 63% of the 49 strains. IS256 or icaADB was identified in 92% and 74% of strains, respectively. PFGE analysis pointed out a significant clonality among *S. epidermidis* and *S. capitis* isolates.

**Discussion:** Among this particular population of patient, several clones of CNS were implicated in CRB. They are characterized by a high level of antibiotic and antiseptic resistance, biofilm production and a high prevalence of IS256, icaADB, qacA and mupA. Preventive policies including large use of CHX and mupirocin could have influenced these epidemiologic features. Cross contamination seem to be very common.

**Conclusion:** Some well adapted multi-resistant clones of *S. epidermidis* and *S. capitis* are responsible for the majority of CRB in this NICU.

## Clinical epidemiology of nosocomial infections – Gram-negative infections

**P1154 Multiresistant bacteria obtained from returning travellers: incidence, characteristics, influence on clinical outcome**

J. Nemeth\*, B. Preiswerk, A. Nobile, S. Karrer, C. Ruef (Zurich, CH)

**Background:** Worldwide, the burden of multiresistant bacteria is increasing with strong regional differences. Such bacteria may be introduced into the healthcare system by returning travellers requiring medical care.

**Methods:** Patients transferred from abroad to the University Hospital Zuerich (USZ) routinely undergo screening for possible colonisation with Methicillin resistant *Staphylococcus aureus* (MRSA), Extended-Spectrum Beta-Lactamase producing bacteria (ESBL) and multiresistant gram-negative bacteria (MR-gram negative). Clinical characteristics and outcome of 259 patients transferred between 1 January 2009, and 30 September 2011, were retrospectively analysed.

**Results:** Eighty-six were women (33.2%) and 173 were men (66.8%) with a median age of 56.2 (range: 17.3–96.6). One hundred and sixty-three (62.9%) were hospitalized on surgical wards and 96 (37.1%) on medical wards, respectively.

Forty-six patients (17.7%) were colonized and 9 (3.5%) were infected. Thirty-three (12.7%) were colonized with one bacterial strain, 12 (4.6%) with two different bacterial strains and three (1.2%) were colonized with three different bacterial strains. In total, 36 ESBL expressing bacteria, 21 MR-gram negative and three MRSA were detected. *Escherichia coli* (n = 18), *Klebsiella pneumoniae* (n = 14) and *Acinetobacter baumannii* (n = 14) were most frequently isolated. The most common site of detection was the skin (45 of 46 patients; 97%), and the respiratory tract (19 of 46 patients; 41%).

Travellers transferred from Europe were colonized in 12.4%, from the Americas in 20%, from Africa and Middle East in 39.1%, and from Asia and Australia in 33.3%, respectively.

Being colonized contributed independently to a significantly increased length of stay in ICU at USZ. The mortality rate of colonized patients (10.9%) during hospital stay was significantly higher than the mortality rate of noncolonized patients (2.3%) ( $p = 0.018$ ). Being colonized was independently associated with death (Odds ratio: 5.176 [1.325–20.218]).

**Conclusions:** A substantial proportion of patients transferred from abroad are colonized with multiresistant bacteria, a fact which is associated with poor clinical outcome. Gram negative bacteria with different resistance patterns occurred most frequently and were detected in travellers from every continent. These data mirror the global crisis of emerging, multiresistant gram negative bacteria and the associated clinical impact.

**P1155 Surveillance of *Escherichia coli* bacteraemia in England – preliminary results of the recently introduced mandatory surveillance scheme**

J. Davies\*, J.K. Abernethy, R. Guy, M.C. Muzyamba, A.P. Johnson, E. Sheridan, R. Hope (London, UK)

**Objective:** In June 2011 the English Healthcare Associated Infection (HCAI) mandatory surveillance programme was extended to include the collection of all cases of *Escherichia coli* (*E. coli*) bacteraemia reported by NHS acute Trust hospitals. Surveillance was initiated in response to recent increases in *E. coli* bacteraemia observed across England with the aim of better understanding this national trend. Present work represents preliminary analysis of the early months of *E. coli* surveillance data.

**Methods:** *E. coli* bacteraemia data for the period June to August 2011 were extracted from the Health Protection Agency's mandatory surveillance system. Basic demographic information for each *E. coli* bacteraemia case is captured by surveillance. Organisations also have

the opportunity to submit additional information for each case. This record level information was used to undertake preliminary analysis of the aetiology and underlying risk factors of reported *E. coli* bacteraemia cases.

**Results:** In the first 3 months of surveillance 8165 *E. coli* bacteraemia cases were reported via mandatory surveillance. Fifty percent of cases were reported in patients aged 75 years and over with this pattern being observed for both sexes. Seven thousand nine hundred and seventy-four of the 8165 reported cases were admitted to an acute Trust at the time of specimen collection, with 60% having the specimen taken on the day of admission. A further 20% of cases had the specimen taken within a week of admission with half being taken on the day following admission. Seventy-five percent of *E. coli* bacteraemia patients were admitted from home.

Urinary Tract infections (UTI) were indicated to be the primary source of infection in 45% of cases (3682). Where UTI had been indicated and information on catheterisation was provided 85% of records indicated a catheter was present. In a quarter of cases the primary source of infection was listed as unknown.

Thirty-five percent (2882) of total records suggest one or more predisposing factors to the bacteraemia episode. Vascular access is indicated in 30% of relevant records and surgical procedures in 20%. Invasive devices, neutropaenia and wound ulcers are all cited in 10% of cases. In some instances more than one factor is indicated.

**Conclusion:** Mandatory surveillance of *E. coli* bacteraemia is currently in its infancy with the scheme only commencing in June 2011. Preliminary analysis indicates that enhanced surveillance will provide us with a wealth of useful data/information on this important and currently increasing infection.

#### **P1156** Developments in England's mandatory surveillance programme: targeting *E. coli* and MSSA bacteraemia

*E. Sheridan\*, R. Hope, A. Johnson (London, UK)*

**Background:** Reporting of MRSA bacteraemia and *C. difficile* infection by hospitals is mandatory in England (since 2001 and 2004 respectively). Following reduction in the incidence of these infections, we considered extending the surveillance programme. We describe below the decision-making process regarding which additional pathogens to focus on and which clinical and epidemiological data to collect.

**Methods:** Bacteraemia data are routinely collected by the HPA on a voluntary basis using a database (LabBase2) which enables trends to be followed. However it contains few data on whether infections are healthcare-associated (HCAI) and hence potentially preventable. The LabBase2 data were evaluated to ascertain the predominant pathogens causing bacteraemia. A web-based tool was developed to minimise reduplication of data collection, align with routine information collected by microbiologists and to capture all diagnoses and procedures based on ICD-10 and OPCS codes. Other data sources, in particular Hospital Episode Statistics (HES), a national database covering all NHS admissions, were evaluated with the intention of linking the databases, with only questions not answerable by these asked via the system. The data collection was trialled in a variety of clinical settings.

**Results:** Overall bacteraemia rates were largely static since 2006, with a paradoxical increase in *E. coli* (35% rise 2006 – 2010 to 27 055 cases annually). MSSA, the second most common organism (around 84% of 10 070 *S. aureus* bacteraemia cases), declined slightly but not as fast as MRSA. *E. coli* and MSSA were chosen for enhanced surveillance as the two leading causes of bacteraemia in England. HES data (include dates of admission, clinical diagnoses, procedures etc.) and LabBase2 antimicrobial resistance (AMR) data were identified as datasets to link. Additional data collected by the mandatory system include: probable primary focus of infection; related urinary catheter/other medical devices; clinician opinion: HCAI or not? If yes – primary or secondary care?

**Conclusion:** By establishing this additional surveillance and linking the datasets we hope to ascertain the burden of infection due to *E. coli*

and MSSA bacteraemia, develop means of determining whether the infections are HCAI, review clinical correlates of AMR and guide future interventions to reduce infection rates.

#### **P1157** An nosocomial transmission of IMP-1 producing *K. pneumoniae* in a intensive care unit at a Korean hospital

*J. Park\*, J. You, H. Yang (Busan, Osong, KR)*

**Objectives:** The worldwide emergence of carbapenem resistant Enterobacteriaceae is associated with life threatening infections in hospitalized patients. We describe the emergence and spread of IMP-1 producing *K. pneumoniae* in a medical intensive care unit (MICU) at a Korean hospital.

**Methods:** Carbapenem-resistant *K. pneumoniae* isolates were characterized by standard biochemical methods and disc diffusion susceptibility testing. Genes coding for beta-lactamase were sought by PCR and sequencing. Isolates were compared by PFGE. A point prevalence survey of environmental cultures and health care workers (HCW) was conducted in MICU. Surveillance rectal swab cultures were obtained from all patients and newly admitted patients.

**Results:** In August 2011, the index case was a 79-year-old man who was transferred from another hospital and at MICU admission. The index case was diagnosed of pneumonia treating with ventilator care. He was treated with piperacillin/tazobactam until carbapenemase resistant *K. pneumoniae* was isolated in the follow-up culture of sputum. During active surveillance from August to October, other two cases were colonized with isolates showing the same susceptibility pattern. Patient 1 was with the index case in the MICU about 10 days, and patient 2 was with patient 1, not the index case, in the MICU about 8 days. There was no isolate in follow-up culture in all of them and other MICU-admitted patients. PCR and sequencing identified IMP-1 gene. The PFGE typing showed that all of three isolates was genetically related. There was no isolate in environmental cultures and HCWs' hands. This transmission was controlled by isolation of all patients with IMP-1 producing *K. pneumoniae* as well as strict contract precautions.

**Conclusions:** The emergence of IMP-1 producing *K. pneumoniae* in Korean hospitals creates an important challenge for clinicians and hospital epidemiologists. Combined control measures should be immediately adopted in order to control the cross-transmission of CRE especially in ICU.

#### **P1158** Case-control analysis of Gram-negative catheter-related bloodstream infection in a tertiary care medical centre

*A. Eworo, P. Muñoz\*, M. Rodríguez-Creixems, A. Fernandez-Cruz, E. Reigadas, E. Bouza (Madrid, ES)*

**Objectives:** Data on catheter-related bloodstream infections by Gram-negative pathogens (GN-CRBSI) are scarce and biased. GN-CRBSI seem to be increasingly frequent and may lead to erroneous empirical therapy. We describe the epidemiology, risk factors and clinical characteristics of GN-CRBSI in nonselected patients in a tertiary hospital.

**Methods:** From 2008 to 2010, we compared each patient with proven GN-CRBSI (positive peripheral blood culture and catheter tip or differential blood cultures) with two randomly selected controls (non-GN-CRBSI).

**Results:** We detected 81 episodes of GN-CRBSI (17% of all CRBSI). Incidence/1000 admissions was 0.46 in 2008, 0.66 in 2009 and 0.49 in 2010. The most common microorganisms were *Escherichia coli* (22.5%), *Enterobacter cloacae* (18.5%), *Pseudomonas aeruginosa* (15%) and *Klebsiella pneumoniae* (12.5%). Cases were compared with 162 controls (coagulase-negative staphylococci, 58.7%; *Staphylococcus aureus*, 18.5%; *Enterococcus* spp., 8.6%; *Candida* spp., 14.2%). There were no differences in age, sex, underlying disease, surgery, place of acquisition, type of catheter, lumens, catheter days, maximum severity or hospital stay. The comparison of cases vs. controls revealed the following: Charlson index, 1.56 ± 2 vs. 2.6 ± 2.8, p = 0.003;

neurological disease, 6% vs. 0.6%,  $p = 0.01$ ; intensive care (ICU) stay, 5% vs. 15%,  $p = 0.04$ ; immunosuppression, 17% vs. 32%,  $p = 0.02$ ; time to positive blood culture,  $10.8 \pm 16$  hours vs.  $19.8 \pm 16$  hours,  $p < 0.001$ ; origin in a lower limb catheter, 18.5% vs. 8%,  $p = 0.005$ ; subclavian catheter, 24.7% vs. 39%,  $p = 0.02$ ; previous antimicrobials, 57% vs. 19%,  $p < 0.001$ ; concomitant infection, 57% vs. 42%,  $p = 0.02$ ; empirical antimicrobial therapy, 78% vs. 48%,  $p < 0.001$ ; efficacious empirical therapy, 57% vs. 36%,  $p = 0.004$ ; removal of catheter for therapy, 96% vs. 84%,  $p = 0.004$ ; development of bacteremia-related complications, 16% vs. 8%,  $p = 0.07$ ; admission to intensive care (ICU) due to sepsis, 47% vs. 29%,  $p = 0.007$ ; and mechanical ventilation, 41% vs. 20%,  $p = 0.001$ ; Mortality was similar (21% vs. 26%). Multivariate analysis showed that GN-CRBSI were more common in the following situations: no immunosuppression, underlying neurologic conditions, previous antimicrobial therapy, non-subclavian insertion site, and blood cultures growing before 8 hours.

**Conclusion:** GN-CRBSI account for 17% of all CRBSI and should be taken into consideration in the empirical therapy of patients with the characteristics mentioned above. Mortality and need for admission to the ICU are significant.

**P1159** **Low contribution of ESBL-producing Enterobacteriaceae from long-term care facilities' residents in a tertiary medical centre**

T. Lejko Zupanc, B. Beovic, B. Znidarsic, M. Mueller Premru, M. Pirs\* (Ljubljana, SI)

**Objectives:** New Slovenian guidelines published in mid-2010 have recommended stricter screening policies in order to contain the spread of ESBL-producing Enterobacteriaceae. National guidelines recommend screening of patients upon admission into intensive care units, patients transferred from long-term care/nursing facilities (LTCs), travelers and all of the patients who have previously had an ESBL-producing Enterobacteriaceae isolated from a clinical or surveillance site. It has been suggested that LTCs may act as a reservoir for ESBL-producing Enterobacteriaceae within the community and may significantly contribute to the spread within hospitals. The objective of this study was to determine the mode of acquisition of ESBL-producing *E. coli* (EC) and *K. pneumoniae* (KPN) (community, LTCs, nosocomial) and potential differences in antimicrobial susceptibility.

**Methods:** During the study period from June 2010 to October 2011 data regarding the mode of acquisition was collected prospectively. Hospital and laboratory records of patients with ESBL-producing EC and KPN isolates were reviewed. Antibiotic susceptibility tests were performed using a disk diffusion method or an automated system and interpreted according to CLSI standards.

**Results:** A total of 433 patients with EC-ESBL and 427 patients with KPN-ESBL isolated from a clinical or surveillance sites were included in the study. EC-ESBL was first recovered from surveillance samples in 59.1% of patients and subsequently detected in blood cultures in 2.7%, tracheal aspirate in 5.8% and urine in 10.9% of patients. KPN-ESBL was first recovered from surveillance samples in 53.2% of patients and subsequently detected in blood cultures in 2.2%, tracheal aspirate in 8.8% and urine in 17.6% of patients. The differences in antimicrobial susceptibility test results of community and nosocomial isolates of EC-ESBL and KPN-ESBL are presented in Table 1.

Table 1. Cumulative antimicrobial susceptibility test results of community and nosocomial isolates\*

		AMC	TZP	CAZ	CIP	CTX	FEP	ETP	IPM	AN	GM	SXT
EC-ESBL	community	28.3	80.2	55.7	26.4	0.0	72.6	100.0	100.0	90.6	66.0	27.4
	nosocomial	19.6	78.6	41.1	25.9	0.0	55.4	100.0	100.0	86.6	50.9	21.4
KPN-ESBL	community	6.7	45.0	6.7	5.0	0.0	36.7	95.0	100.0	93.3	48.3	8.3
	nosocomial	5.6	46.9	5.6	5.6	0.0	32.7	95.1	96.8	87.0	66.0	9.9

\* Cumulative antimicrobial susceptibility test results for LTCs isolates are not shown due to small number of isolates

**Conclusions:** Our results suggest that while LTCs may be reservoirs of ESBL-producing Enterobacteriaceae they contributed only 8.3% and 3.3% of the newly discovered patients with ESBL-producing EC and KPN isolated from clinical or surveillance cultures during the study

period. EC-ESBL was community-acquired in 42.7% and hospital-acquired 48.7% of cases. Majority of KPN-ESBL were hospital-acquired (75.9%), while only 20.6% were community-acquired.

**P1160** **Carriage of antibiotic-resistant bacteria in the respiratory tract during SDD and SOD: preliminary results of a cluster-randomised cross-over study**

E.A.N. Oostdijk\*, A.M.G.A. de Smet, J. Kesecioglu, M.J.M. Bonten on behalf of the SDD-SOD study group

**Objectives:** Selective Digestive tract Decontamination (SDD) and Selective Oropharyngeal Decontamination (SOD) aim to eradicate Gram-negative bacteria (GNB) from the respiratory tract in intensive-care-unit (ICU) patients. In both regimens tobramycin and colistin are administered in topical form in the oropharynx four times daily. In a previous study the unit-wide prevalence of ARB in the respiratory tract was lower during SDD/SOD as compared to standard care, but significantly increased in time during these measures (Oostdijk et al. AJRCCM 2010;181:452). We conducted a 16-center cluster-randomized cross-over (CRCO) study in the Netherlands, comparing 12 months periods of SDD and SOD to determine effects on carriage with antibiotic-resistant bacteria (ARB). This is a preliminary analysis on the ecological unit-wide effects of SOD and SDD on respiratory tract carriage with antibiotic-resistant bacteria (ARB).

**Methods:** All patients with an expected ICU-stay of >48 hours were eligible to receive SDD/SOD. Prevalence of respiratory tract carriage with ARB was determined once monthly in all ICU patients (receiving or not receiving SDD/SOD), through inoculating swabs on selective media supplemented with either colistin or tobramycin and a chromogenic ESBL agar. This preliminary analysis includes 265 of the planned 384 point prevalence surveys (69%): 130 during SDD and 135 during SOD, from 14 out of 16 hospitals. Trend analysis was performed of consecutive point prevalence surveys during 24 months of study.

**Results:** Respiratory samples were obtained from 2359 patients (1110 during SOD and 1249 during SDD) of which 236 patients (10%) had growth on selective media with Enterobacteriaceae (209 cultures) or *Pseudomonas aeruginosa* (72 cultures). Completeness of culture taking was 89% based on 100% quality control checks. ESBL production was detected in 1.2% ( $n = 28$ ) of all cultures (SOD vs. SDD  $p = 0.66$ ). Resistance to aminoglycosides, ciprofloxacin and colistin was detected in 88 (3.7%), 71 (3.0%) and 15 (0.6%) cultures, respectively ( $p = 0.22$ ,  $p = 0.38$  and  $p = 0.11$  for SOD vs. SDD). In time, a gradual decrease in the prevalence of aminoglycoside resistance and ciprofloxacin was observed (beta-coefficients  $-0.14$  ( $p < 0.05$ ) and  $-0.83$  ( $p < 0.05$ )), whereas resistance prevalence for ESBL and colistin remained stable.

**Conclusion:** Longitudinal trends in respiratory tract carriage of antibiotic-resistant bacteria (ARB) in patients in 14 Dutch ICUs reflected low prevalence to beta-lactam antibiotics, aminoglycosides and colistin, and no determinable increase of resistance during 24 months of study.

**P1161** **Comparison of MALDI-TOF mass spectra analysis and XbaI-restriction of genomic DNA (PFGE) in evaluation of nosocomial transmission and outbreaks of Escherichia coli and Klebsiella pneumoniae**

M. Pirs\*, T. Cerar, E. Ruzic Sabljic, V. Krizan Hergouth, A. Andlovic, T. Lejko Zupanc, T. Mrvic, K. Seme (Ljubljana, SI)

**Objectives:** Two suspected cases of intra- and interdepartmental outbreak and nosocomial transmission of *E. coli* – ESBL and intra- and interdepartmental nosocomial transmissions of *K. pneumoniae* – ESBL were analyzed. A total of 20 strains of *E. coli* – ESBL from 19 patients and 11 strains of *K. pneumoniae* – ESBL from 10 patients were analyzed.

Genomic DNA restriction presented with pulsed-field gel electrophoresis (PFGE), a genotyping method with a high discriminatory power is

considered a golden standard for determination of genetic relatedness of isolates in investigation of outbreaks; however, the method is time consuming. The aim of this study was to investigate the potential of matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS) for rapid preliminary evaluation of strain relatedness in investigation of an outbreak by comparing both methods.

**Methods:** Two methods were applied. XbaI-digested genomic DNA (PFGE) banding patterns were used for genotyping of the strains. Isolates were also analyzed by whole cell MALDI-TOF MS as recommended by the manufacturer (Bruker Daltonics, Germany). GelComparII software (Applied Maths, Ghent, Belgium) was used to compare banding patterns of PFGE and mass spectra.

**Results:** PFGE analysis has confirmed an outbreak within two affected units and transmission of *E. coli* – ESBL from one unit to the other. In the case of *K. pneumoniae* – ESBL intra- and interdepartmental nosocomial transmissions were confirmed using PFGE analysis. In both cases analysis based upon mass spectra has shown some agreement between the two methods, however there were some notable exceptions. Some strains from non-related PFGE clusters were grouped together while PFGE analysis demonstrated <60% relatedness.

**Conclusions:** Based upon our data MALDI-TOF-based method did not produce satisfactory results in our preliminary evaluation of strain relatedness in investigation of an outbreak. More outbreak strains must be analyzed with both methods for optimization and definitive evaluation of the use of MALDI-TOF for outbreak investigations.

**P1162** **Molecular profiling of nosocomial isolates of *Klebsiella pneumoniae* expressing AmpC beta-lactamase in a tertiary referral hospital of northern India**

S. Upadhyay\*, M.R. Sen, S. Mishra, A. Bhattacharjee (Varanasi, Assam, IN)

**Objective:** *Klebsiella pneumoniae* is considered an important pathogen causing nosocomial and community-acquired infections, often associated with the production of plasmid mediated AmpC beta-lactamases, which are frequently described as a part of complex integrons, facilitate their horizontal transfer to other related and unrelated microbes. The present study was designed to determine the occurrence of AmpC producing clinical isolates of *K. pneumoniae*, their molecular characterization, genetic environment, plasmid profile and transmission dynamics in a tertiary referral hospital in northern India.

**Methods:** A total of 132 consecutive, clinical isolates of *K. pneumoniae* were collected from inpatients and outpatients of S.S. Hospital, Banaras Hindu University, Varanasi India, during April 2008 to September 2009. All the isolates were investigated for the presence of AmpC beta-lactamase. Molecular characterization and genetic association of plasmid mediated AmpC producing isolates was studied by performing multiplex PCR for blaAmpC and integrase gene PCR for the presence of integron among AmpC producers. All the AmpC positive isolates were typed by random amplification of polymorphic DNA. The plasmid-mediated AmpC gene blaCIT was further sequenced. Amplicons of EBC gene were digested with Cfr9I to determine their clonal types. All the ampC harbouring isolates resistant to third generation cephalosporins were selected for plasmid profiling, transformation, and transconjugation.

**Results:** A total of 104 isolates were phenotypically positive for AmpC beta-lactamase. On performing their genotypic characterization, 40 isolates were harbouring different ampC gene. Among them 37 were harbouring class 1 integron. Sequencing results confirmed the presence of CMY-2 variant of AmpC. RFLP pattern demonstrated the presence of blaACT among EBC harbouring isolates. CMY-2 and ACT gene on a 16 kb conjugative plasmid was consistently present in all the screened isolates of *K. pneumoniae*, and was inferred to encode cefoxitin and cephalosporin resistance based on transconjugation experiments. RAPD showed presence of 24 different clones.

**Conclusion:** The presence of integron in AmpC producers and their genetic association with the ampC gene underlines the potential risk of their dissemination in hospital as well as in community. Thus the

acquisition of plasmid-mediated ampC genes by *K. pneumoniae* restricts therapeutic alternatives for combatting infections caused by these organisms.

**P1163** **An outbreak of OXA-48 carbapenemase-producing *Klebsiella pneumoniae* in an Irish tertiary referral centre in 2011**

A. Ronayne\*, D. O'Brien, C. Wrenn, L. Rose, C. Roche, S. Fitzgerald, L. Fenelon, B. Crowley, K. Schaffer (Dublin, IE)

**Background:** Between January and October 2011, 13 isolates of OXA-48 producing *Klebsiella pneumoniae* (*K. pneumoniae*) were detected in the laboratory. The first five cases were found in clinical specimens of inpatients on general surgical wards.

**Methods:** After the second and third isolate had been confirmed as an OXA-48 producing *K. pneumoniae* by an external reference laboratory, the general surgical wards were closed for admissions and an outbreak investigation undertaken. Case patients were isolated with full contact precautions. Weekly screening for rectal carriage of carbapenem resistant Enterobacteriaceae (CRE), which had already been initiated in the ICU, was commenced on all affected surgical wards. A screen of the general and the near patient environment on the ward was undertaken. Intensified cleaning and disinfection was implemented. The isolate was not detected on environmental screening. Six additional patients were identified as carriers on rectal screening. A review of previous *K. pneumoniae* blood culture isolates stored in the laboratory revealed one additional OXA-48 positive *K. pneumoniae* isolate from a patient not linked to the surgical wards.

**Results:** Typing of all isolates by pulse field gel electrophoresis (PFGE) showed the 10 isolates from the general surgical wards to be identical by PFGE. The OXA-48 *K. pneumoniae* from the patient on the medical ward had a unique typing pattern.

Multi-locus sequence typing (MLST) performed demonstrated a unique sequence type (ST 13). To our knowledge, no other OXA-48 producers associated with this ST have been found.

**Conclusion:** The aim of this presentation is to highlight the emergence of this highly resistant organism in the Irish healthcare setting and to discuss the challenges it presents. The experience of our laboratory underlines the importance of maintaining a high level of alert in Irish laboratories to detect carbapenem resistant isolates. As molecular confirmation of CRE isolates is required, the availability of timely laboratory services will be elementary to control further outbreaks.

**P1164** **Risk factors for locally acquired New Delhi metallo-beta-lactamase-1 Enterobacteriaceae in Singapore**

K. Marimuthu\*, J. Teo, V.C. Gan, W.K. Ng, P. Krishnan, B.S. Ang, D.C. Lye (Singapore, SG)

**Objective:** New Delhi metallo-beta-lactamase-1 (NDM-1) was reported in India and the United Kingdom in August 2010. The first case of NDM-1 in this hospital was detected in October 2010. Contact screening by rectal swab and strict isolation was immediately instituted. From October 2010 to October 2011, we detected seven NDM-1 patients with no overseas travel in last 2 years. The objective of this study is to assess risk factors for and treatment outcome of NDM-1 Enterobacteriaceae.

**Method:** We conducted a retrospective case-control (1:4 ratio) study from October 2010 to October 2011 for risk factors and treatment outcome. NDM-1 isolates were screened phenotypically and genotypically for acquired metallo-beta-lactamases (MBL), serine carbapenemases and extended spectrum-beta-lactamases (ESBL).

**Results:** We detected eight NDM-1 bacteria in six patients from clinical cultures (six in urine, one in bile) and one from contact screening; five were *Escherichia coli*, two *Klebsiella pneumoniae* (KP) and one *Enterobacter cloacae*. All isolates were positive for at least two ESBL's (TEM-type, SHV-type and CTX-M-type) and plasmid AmpC (DHA-1 or CMY-type) and negative for VIM-type, IMP-type, KHM-1;

OXA-48, KPC-1 and GES-type beta-lactamases or 16S rRNA methylases. Our NDM-1 isolates were distinct from the Indian NDM-1 by multilocus sequence typing. Cases and controls had similar demographic data, with no cases of Indian race. NDM-1 patients had more dementia (37.5% vs. 6.3%,  $p = 0.05$ ). On univariate analysis, cases were more likely to be exposed to carbapenems within 30 days (OR 1.61, 95%CI 1.6–216.1,  $p = 0.019$ ) and fluoroquinolones within 90 days (OR 7.67, 95%CI 1.3–45.3,  $p = 0.025$ ), have other multi-drug resistant organisms (MDRO) (OR 5.95, 95%CI 1.1–31.2,  $p = 0.035$ ) and ESBL KP (OR 9.67, 95%CI 1.5–60.0,  $p = 0.015$ ) within 12 months. All isolates were resistant to all tested carbapenems, cephalosporins, penicillin-inhibitor combinations, and ciprofloxacin; 100% were susceptible to polymyxin B, 87.5% to amikacin, and 25% to gentamycin and ciprofloxacin. Three cases of urinary infections were cured with amikacin or polymyxin B.

**Conclusions:** Carbapenem and fluoroquinolone exposure, and a history of MDRO and ESBL KP were risk factors for NDM-1 at our centre. Amikacin or polymyxin B may be effective in treating NDM-1 urinary infections.

**P1165** Epidemiological, microbiological and clinical characteristics of an outbreak of colistin-resistant KPC carbapenemase-producing *Klebsiella pneumoniae*

C. Tascini\*, A. Leonildi, I. Ciullo, F. Sbrana, P. Malacarne, S. Flammini, E. Tagliaferri, F. Menichetti (Pisa, IT)

**Objectives:** We aimed at describing the characteristics of an outbreak of KPC carbapenemase – producing *Klebsiella pneumoniae* (KPC-KP), occurring in Pisa Hospital in Italy and still going on.

**Methods:** A boronic acid-inhibition test method was used directly on rectal swabs to detect colonization. Direct Polymerase Chain Reaction (PCR) was also performed on a subset of samples. Susceptibility was tested by the E-test method according to the breakpoints of the European Committee on Antimicrobial Susceptibility Testing (EUCAST). Periodical screening of patients admitted in affected wards was conducted and colonized patients were isolated. Clinical records and laboratory databases were revised.

**Results:** The first case was recorded on April 2010 and data up to the 31st of October 2011 have been revised. One hundred and eighty-eight strains of KPC-KP were isolated from 128 patients. Out of them, 49 had a clinically evident infection: 23 sepsis, 13 respiratory infections, nine abdominal infections, six urinary infections, two other infections. In 79 patients, intestinal KPC-KP colonization occurred asymptotically. Nine patients died. Almost all of them had a long history of hospitalization and serious comorbidity.

PCR confirmed the presence of blaKPC gene. Patients infected by KPC-KP were admitted in the following wards: Intensive Care Units 45, Surgery 18, Neurorehabilitation 9, Infectious Diseases 11, Pneumology 17, Diabetology 8, Haematology 4, others 16.

Number of cases per quarter increased over time with a linear trend. MIC50 and MIC90 of relevant antimicrobials is reported in Table 1. At least half of the strains showed a full or intermediate susceptibility to tygecycline, gentamicin and fosfomicin. Only 30% of strains were non-resistant to colistin or imipenem. Tygecycline and gentamicin were generally used often in association with a third drug, generally fosfomicin. Mortality among patients with sepsis was around 40%.

	Pisa, Italy, 2010-2011		Range		breakpoint EUCAST (mg/L)	
	MIC50 (mg/L)	MIC90 (mg/L)	min (mg/L)	max (mg/L)	≤	>
amikacin	32	>256	1	>256	8	16
gentamicin	1	64	0.19	>1024	2	4
imipenem	24	>32	0.25	>32	2	8
meropenem	>32	>32	4	>32	2	8
ertapenem	>32	>32	0.25	>32	0.5	1
colistin	4	12	0.125	24	2	2
fosfomicin	16	1,024	3	>1024	32	32
tigecycline	1.5	3	0.5	12	1	2
cotrimoxazole	>32	>32	0.049	>32	2	4

**Conclusion:** KPC-KP is spreading in our hospital, especially in ICUs, and is a relevant cause of morbidity and mortality. We suggest treatment to be based on three drugs including imipenem or colistin whenever possible.

**P1166** In vitro activity of colistin and tigecycline against carbapenemase producing *Klebsiella pneumoniae* clinical isolates during 2005–2010 in a university hospital

K. Spyropoulou\*, S. Vamvakopoulou, C. Bartzavali, E. Jelastopulu, E. Petinaki, P. Giakoupi, A. Vatopoulos, E.D. Anastassiou, I. Spiliopoulou, M. Christofidou (Patras, Larissa, Athens, GR)

**Objective:** *Klebsiella pneumoniae*, a pathogen frequently involved in nosocomial outbreaks, constitutes a serious problem because of its virulence and multidrug resistance. Tigecycline (TIG) and colistin (COL) are antibiotics with broad-spectrum activity; appear to be the only therapeutic option for infections of carvapenemases producing *K. pneumoniae* (Kpcp). The aim of this study was to define the susceptibility of such isolates to TIG and COL, during the last 6 years, in Patras University Hospital.

**Methods:** A total of 493 Kpcp isolates were collected during 2005–2010, from inpatients (313 men), hospitalized in ICU (221), Internal Medicine Units (159) and Surgical wards (113), one isolate per patient. Isolates were recovered from cultures of clinical specimens (177 pus, 149 blood, 100 urine, 67 BAL). Identification was performed by standard methods. Antimicrobial susceptibility was carried out by disk diffusion method according to CLSI. Besides standard antibiotics, gentamicin (GEN) was included, whereas, MIC to imipenem (IMP), TIG and COL were determined by E-test. Isolates were tested applying Hodge Test for the presence of carvapenemases according to CDC and by meropenem-EDTA-Boronic acid synergy disk test, for presence of MBL and/or KPC. The presence of blaVIM and blaKPC genes was confirmed by PCR. Molecular typing was performed by PFGE of XbaI restricted genomic DNA.

**Results:** During the study period, Kpcp isolates were 14%, 22%, 33%, 27%, 34% and 46%, accordingly. Resistance rate among standard antibiotics was very high (>90%), while 42% were resistant to GEN, 20% to COL and 7% to TIG. From 2005 to 2008, all Kpcp isolates (197) were MBL producers, sensitive to TIG with 5% resistant to COL. Three KPC producing isolates were isolated in 2008, sensitive to COL. During 2009, 41MBL/66KPC Kpcp were isolated, whereas, in 2010 20 MBL/186KPC. The resistance rates in 2009 were 25% to COL and 7% to TIG, whereas, in 2010 were 31% and 15%, accordingly. blaVIM gene was detected in all MBL (+) isolates, whereas, blaKPC2 was found in all KPC (+). Three isolates carried both genes. All KPC (+) isolates belonged to pulsotype A.

**Conclusion:** Isolation of Kpcp isolates shows a significant increase during the last 6 years ( $p < 0.001$ ). Only GEN, COL and TIG are effective. During 2009–2010 resistance to COL and TIG also rose significantly ( $p < 0.001$ ). These results emphasize the urgent need for implementation of infection control measures and new antibiotic strategies.

**P1167** Gram-negative bacteraemias in elderly ICU patients

M. Katsiari\*, A. Xydaki, I. Strouvalis, Z. Roussou, E. Platsouka, N. Maguina (Athens, GR)

**Objectives:** Bloodstream infections (BSI) from Gram negative pathogens are among the most frequently encountered nosocomial infections in Intensive Care Unit (ICU) patients representing an important cause of morbidity, mortality and excess cost. Aim of this study was to investigate the epidemiology of these infections in ICU elderly patients and identify potential risk factors.

**Methods:** Retrospective study (January 2007–December 2010) including patients >65 years old with ICU-acquired Gram negative bloodstream infection, as identified by positive blood cultures obtained

>48 hours following ICU admission. Patients were classified into two groups, according to BSI diagnosis. Group A included patients who developed BSI (n = 72) and Group B patients who did not (n = 182). Other data collected included: Age, gender, APACHE II score, septic shock on admission, history of chronic obstructive pulmonary disease (COPD), diabetes mellitus (DM), chronic renal failure (CRF), immunosuppression, prior use of antibiotic or surgery, hypoalbuminaemia, preceding ICU length of stay on day of BSI diagnosis, as well as isolated pathogens. We also evaluated the impact of BSI on duration of mechanical ventilation and central venous catheter (CVC) catheterization, ICU length of stay (LOS) and mortality. Data were analyzed using Mann-Whitney rank sum test, Chi-square and Fisher Exact test.

**Results:** Ninety-four BSIs (10 polymicrobial) were identified in 72 patients. Median time for a positive blood culture was 18 days following admission. Isolated pathogens included *Acinetobacter baumannii* (32), *Klebsiella pneumoniae* (30), *Pseudomonas aeruginosa* (10), *Proteus mirabilis* (7), other Gram negative bacteria (25). Demographic data, evaluation of risk factors and impact of BSIs on ICU morbidity and mortality are depicted on Table 1.

	Group A (n=72)	Group B (n=182)	p-value
Age	74 (71-79)	77 (72-81)	0.022
Gender (male)	45 (62.5)	111 (61)	0.796
APACHE II score	21.5 (16.5-25.5)	20 (16-25)	0.293
Septic shock on admission	32 (44)	57 (31)	0.067
Hypoalbuminaemia	43 (60)	99 (54)	0.528
COPD	26 (36)	54 (30)	0.398
CRF	8 (11)	33 (18)	0.194
DM	24 (33)	62 (34)	0.971
Prior surgery	28 (39)	57 (31)	0.315
Immunosuppression	7 (10)	18 (10)	0.847
Prior antibiotic use	30 (42)	58 (32)	0.183
Days on mechanical ventilation	24 (16-39)	7 (5-12)	<0.001
Days on central venous catheterization	33 (20-53)	11 (7-21)	<0.001
ICU length of stay	28 (19-43)	11 (7-17)	<0.001
ICU mortality	32 (44)	32 (21)	<0.001

TABLE 1: Demographic data, risk factors and impact of BSIs on ICU morbidity and mortality  
Data are number (%) of patients, or median value

**Conclusions:** Gram negative bacteraemias were significantly correlated with age. Prolonged ICU stay was identified as risk factor for BSI acquisition. However, no other risk factor was determined. Gram negative bacteremic episodes significantly prolonged ICU length of stay and increased ICU mortality.

**P1168** Virulence factors and clones of multidrug-resistant *Pseudomonas aeruginosa* isolates disseminated among patients in a University hospital

M. Koutsogiannou\*, E. Drougka, E. Jelastopulu, E.D. Anastassiou, I. Spiliopoulou, M. Christofidou (Patras, GR)

**Objectives:** *Pseudomonas aeruginosa* is a cause of serious infections, especially in immunocompromised patients. The high resistance rate to antibiotics, the large number of virulence factors, including the type III secretion system (TTSS) responsible for exotoxins Y, U, T, S, and the frequent spread of endemic strains, constitute this microorganism a major nosocomial pathogen. The association of *P. aeruginosa* isolates carrying TTSS genes recovered from clinical samples of different hospitalized patients during a 2 year period, with respect to antibiotic resistance patterns, serotype and clone dispersal, was investigated.

**Methods:** A total of 220 *P. aeruginosa* isolates recovered from inpatients during 2006-2007 were identified at the species level by standard methods (Oxiferm, BD, BBL). Antibiotic susceptibility testing was performed by the agar disk diffusion method according to CLSI

guidelines. MIC of colistin was determined by the Etest (AB Biodisk). Serotyping was performed using 16 monovalent antisera against the O antigen, according to the International Antigenic Typing Scheme. Clones were defined by PFGE of chromosomal DNA SpeI digests. Exotoxins-gene detection was performed by PCR.

**Results:** Among 220 isolates, 64% were multi or pan-resistant but colistin susceptible. Most isolates were recovered from patients hospitalized in the ICU (55%), followed by the Department of Internal Medicine (26%), Surgery (11%), Outpatients (6%) and Pediatrics (2%). By PFGE, 40 clones were identified, with three predominant: a (50%), d (19%) and b (5%). The majority of isolates (37%) were recovered from respiratory tract samples, followed by wounds (19%), bacteremia (19%), urinary tract (13%), catheters (8%) and stool specimens (4%). The main serotype was O11 (68%) followed by O12 (10%). Most multi pan-resistant isolates (87%) produced one or more toxins: Y (94%), U (94%) and T (87%), while only 37% produced the S toxin.

**Conclusion:** Multi pan-resistant, toxin Y, U, T producing *P. aeruginosa* strains, belonging to two major clones, a and d, have disseminated principally in ICU. Spread of such strains constitute *P. aeruginosa* infections problematic and difficult to treatment, forcing continuous infection control measures and appropriate antibiotic policy.

**P1169** The impact of antimicrobial therapy on survival in patients with nosocomial *Acinetobacter baumannii*-associated infections

Y. Gorbich\*, I. Karpov, O. Kretchikova (Minsk, BY; Smolensk, RU)

The objective of the present study was to assess the impact of appropriate antimicrobial treatment on clinical outcome in patients with *Acinetobacter baumannii*-associated infections.

**Material and methods.** Eighty seven patients treated at nine multi-field hospitals between December, 2008 and November, 2010 with clinically and laboratory confirmed nosocomial infections caused by *A. baumannii* were included in the study. Among them 39 patients had favorable outcome, while 48 patients died within 30 days after pathogen isolation. Both groups were comparable by age, sex and proportion of ICU-hospitalized patients.

Antimicrobial therapy was considered to be appropriate if the list of administered antibiotics included at least one agent that was active in vitro against isolated strain of *A. baumannii* and when the route of administration and the dosage were adequate.

Antimicrobial susceptibility testing was performed by disk-diffusion method. The results were interpreted following the guidelines of the CLSI, 2011. Intermediately susceptible isolates were regarded as resistant.

In order to assess the impact of antimicrobial therapy on the outcome, cases with appropriate antimicrobial treatment from both studied groups were compared with those who receive inappropriate therapy using the odds ratio model. The Chi-squared or Z-test was used to assess differences in categorical variables, as appropriate. Continuous variables were compared using the Mann-Whitney test. The Shapiro-Wilk's test was used to assess normality. Results were considered statistically significant at  $p < 0.05$ . Data was stored and analyzed using Statistica software v.6.0 (StatSoft Inc., USA).

**Results:** Among patients with favorable outcomes four persons received appropriate empirical antimicrobial treatment, while in the other group – only three patients. Odds ratio for favorable outcome was 1.7 (95% confidence interval [CI] 0.4–8.2;  $p = 0.77$ ).

Appropriate antimicrobial agents were administered as a part of causal treatment to 27 patients who survived and to 11 patients who died within 30 days after pathogen isolation. Odds ratio for favorable outcome was 6.7 (95% CI 2.6–17.3;  $p < 0.001$ ).

**Conclusion:** Our study has revealed that appropriate causal antimicrobial therapy has a positive influence on 30-day survival rate in patients with nosocomial infections caused by *A. baumannii*, confirming in this way the statement that *Acinetobacter baumannii* is a real pathogen but not a witness of the lethal outcome.

**P1170 Clinical characteristics and outcome of post-neurosurgical *Acinetobacter baumannii* meningitis: a multicentre cross-sectional study**

C. Moon\*, Y. Kwak, B. Kim, E. Kim, C. Lee (Busan, Seoul, Jeonju, KR)

**Objectives:** *Acinetobacter baumannii* is an important cause of post-neurosurgical meningitis. The emergence of carbapenem-resistant strain in this setting has caused a therapeutic challenge. We investigated the clinical characteristics and therapeutic outcome of the patients with post-neurosurgical *A. baumannii* meningitis.

**Methods:** We retrospectively reviewed medical records of patients with post-neurosurgical *A. baumannii* meningitis diagnosed in five university-affiliated hospitals between January 2005 and May 2011. Only patients older than 16 years of age with positive CSF culture and clinical features compatible with meningitis were included.

**Results:** Forty episodes of post-neurosurgical *A. baumannii* meningitis were reviewed. The mean hospital stay before neurosurgical procedure was 23 days. The most frequent underlying diseases were brain hemorrhage (67.5%), brain neoplasm (7.5%), head trauma (5.0%), and hydrocephalus (5.0%). Eleven patients (27.5%) were treated with intrathecal antibiotics. Thirty-three patients (82.5%) received surgical therapies such as removal of ventricular shunt and lumbar drain. The mortality from meningitis was 35%, which was significantly related to carbapenem resistance ( $p = 0.002$ ). In 22 patients with carbapenem-non-susceptible *A. baumannii* meningitis, colistimethate containing regimen ( $p = 0.040$ ) and intrathecal administration of antibiotics ( $p = 0.001$ ) were significantly associated with recovery from meningitis. During the study period, two patients treated with intravenous colistimethate developed nephrotoxicity. Toxicity related to local administration was not reported in patients treated with intrathecal antibiotics.

**Conclusion:** Carbapenem-non-susceptible *A. baumannii* meningitis showed high mortality in post-neurosurgical patients. Use of colistimethate and intrathecal administration of antibiotics should be considered for the treatment of this infection.

**P1171 Predictors of mortality in multidrug-resistant *Acinetobacter baumannii*: a descriptive study in a long-term acute care hospital**

A. Tedesco\*, S. Mondino, T. Tassoni, P. Calvi, M. Cavallo, R. Cazzaro, L. Dal Sasso, S.A. Bellometti (Lonigo, Arzignano, IT)

**Objectives:** To determine the risk factors for 30-day mortality of multidrug-resistant *Acinetobacter baumannii* (MDRAB) during an outbreak occurred in a non-traditional setting, a 50-bed long-term acute care hospital (LTACH).

**Patients and methods:** From January 2010 to June 2011 an outbreak of 38 MDRAB occurred in a LTACH in Northern Italy. In this descriptive observational study a retrospective chart review was performed to analyse patient demographics, comorbidities and outcome. *Acinetobacter* was identified by automated Vitek2 system (Biomérieux, France). Antibiotic susceptibility was evaluated according to CLSI criteria. A Cox regression model was used for determining risk factors of mortality and a Kaplan–Meier analysis for comparing 30-day survival among subgroups.

**Results:** Mean age of the population was 81.5 years. 94.7% had a comorbidity. Source of isolates was respiratory tract (44.7%), urine (39.5%), blood (7.9%) and wounds (5.2%). All the isolates were resistant to beta-lactams, fluoroquinolones and carbapenems; amikacin and colistin susceptibility was 62% and 100%, respectively. 73.6% had a bacterial coinfection and 47.3% received antibiotic treatment. Colistin monotherapy was the most common (88.9%) antibiotic provided followed by combination therapy with rifampicin and amikacin monotherapy. In bivariate analysis (Figure 1) risk factors significantly associated with 30-day mortality (36.8%) were ischemic encephalopathy or stroke ( $p = 0.041$ ) and presence of central venous catheter (CVC) ( $p = 0.0344$ ). Similarly, the multivariate analysis

exhibited the same variables as the independent risk factors for mortality. Patients with ischemic encephalopathy or stroke and presence of CVC had worse survival than those without ( $p = 0.0286$  and  $p = 0.0252$ , respectively). In addition, there was no statistically significant association between mortality and treatment or coinfection.

\* excluded from the analysis

**Conclusions:** Rare MDRAB outbreaks are described in LTACHs. Our results suggest that neurological comorbidity and invasive procedures, as presence of CVC, have a significant negative impact on survival in MDRAB infections. The treatment and the presence of bacterial coinfection were not associated with mortality, although this study was not powered to assess these covariates adequately. We assume that MDRAB isolation in long-term and post-acute care settings can reflect colonization rather than infection. On the contrary, implementation of infection control measures is mandatory in LTACHs.

**P1172 A multicentre prospective observational study for risk factors and outcome of carbapenem-resistant *Acinetobacter baumannii* bacteraemia**

D.W. Park\*, J.W. Sohn, Y. Kim, C. Lee, M.S. Lee, S. Ryu, Y.J. Choi, H. Jang, C. Kang, H.Y. Kim, H.J. Choi, S.S. Lee, S.W. Kim, S.I. Kim, E.S. Kim, J.Y. Kim, K.R. Peck, M.J. Kim (Ansan, Seoul, Daejeon, Jeonju, Daegu, Goyang, Gwangju, Wonju, Anyang, KR)

**Background:** Risk factors and outcome in patients who acquired healthcare-associated bacteremia due to carbapenem-resistant *Acinetobacter baumannii* (CRAB) are rarely investigated. The aim of this study was to analyze the risk factors and outcome of carbapenem resistance in patients with *A. baumannii* bacteremia.

**Methods:** A multicenter prospective observational study was conducted in 15 teaching hospitals around South Korea from February 2010 to August 2011. Patients who were  $\geq 18$  years old and had healthcare-associated bacteremia due to *A. baumannii* were enrolled. Only one bacteremic episode from one patient was included in the

study. Comparisons were made between patients with CRAB bacteremia and patients with carbapenem-susceptible *A. baumannii* (CSAB) bacteremia.

**Results:** One hundred and ninety-seven patients with CRAB and 69 patients with CSAB were enrolled. Risk factors associated with CRAB bacteremia included prior exposure to carbapenem (Odds ratio [OR] = 5.07; 95% confidence interval [CI] = 1.05–24.62;  $p = 0.044$ ), lower serum albumin concentration prior bacteremia (OR = 0.15; 95% CI = 0.04–0.59;  $p = 0.006$ ), and bacteremia due to pneumonia (OR = 4.58; 95% CI = 1.16–18.07;  $p = 0.030$ ). Patients with CRAB bacteremia had a higher in-hospital mortality rate than patients with CSAB bacteremia (92.4% vs. 7.6%,  $p < 0.001$ ). Multivariate analysis showed that carbapenem resistance (OR = 55.48; 95% CI = 5.05–609.45;  $p = 0.001$ ), prior central venous catheterization (OR = 6.49; 95% CI = 1.19–35.25;  $p = 0.030$ ), PITT bacteremia score (OR = 1.84; 95% CI = 1.20–2.82;  $p = 0.006$ ), and APACHE II score at onset of bacteremia (OR = 1.16; 95% CI = 1.02–1.33;  $p = 0.028$ ) were independent variables associated with in-hospital mortality in patients with *A. baumannii* bacteremia.

**Conclusion:** Prior exposure to carbapenem, lower serum albumin concentration, and pneumonia were associated with the development of CRAB bacteremia. Carbapenem resistance was one of independent risk factors associated with in-hospital mortality in patients with *A. baumannii* bacteremia.

#### **P1173** Bacteraemia caused by multiresistant *Acinetobacter baumannii*: an observational study

A. Rodriguez-Guardado\*, A. Blanco, M. Martinez, F. Pérez, M. Lantero, V. Asensi, V. Carcaba, J. Carton (Oviedo, ES)

**Background:** Multiresistant *Acinetobacter baumannii* is a problem worldwide. The aim of this study is deepening in the knowledge of the risk factors, clinical features, and treatments of this infections.

**Methods:** A observacional retrospective study was performed to describe the characteristics of bacteremia caused by multiresistant *A. baumannii* in Hospital Universitario Central of Asturias, a university hospital in the north of Spain, from January 2000 to December 2010. Antimicrobial susceptibilities were tested using a microdilution commercial system.

**Results:** During the period of study 103 episodios of bacteremia in 103 patients were included. Sixty-eight patients belonged to intensive care unit. The mean time of stay at hospital was 32 days (range 1–213). The most frequent underlying diseases were neoplasm (14.6%), trauma (12%), diabetes (11%), renal insufficiency (11%), trauma (12%), CNS disease (9%) and kidney transplant (7%). Seventy-nine patients had undergone surgical procedures. Ninety-one percent cases had intravascular catheters, 86% had a bladder catheter and 73% cases had undergoing mechanic ventilation. All patients had received previous antibiotic therapy for other infections. The most frequent origin of bacteraemia were: ventilator-associated pneumonia (28%), surgical wound infection (23%), abdominal abscess (17%), catheter (17%), urinary tract infection (11%), meningitis (4%). Forty-nine patients (47.6%) died due to infection. The mortality were associated to inadequate treatment ( $p = 0.0001$ ). In 67 cases, the microorganism isolated was only susceptible to colistin; in 36 cases, the microorganism was susceptible to colistin and carbapenems. All the patients had received empirical antibiotic treatments that were adequate in 42% of the cases. After receiving the antibiogram, the antibiotic therapy was reassessed and was considered inadequate in five patients. Seven patients died before the instauration of a definitive treatment. Forty-three patients received iv monotherapy with colistin, 35 with carbapenems, three ampicillin/sulbactam. In 15 cases, a combined parenteral therapy was used with imipenem (10 cases) or colistin (five cases) plus aminoglycosides.

**Conclusions:** Bacteremia due to multiresistant *A. baumannii* is a frequent problem in intensive care units. The most frequent origin is the respiratory tract. The mortality is highest and associated with inadequate empiric treatment.

#### **P1174** Impact of delayed appropriate antibiotic therapy on mortality in patients with carbapenem-resistant *Acinetobacter baumannii* bacteraemia: a multicentre prospective observational study

D.W. Park, Y.K. Yoon, Y. Kim, C. Lee, M.S. Lee, S. Ryu, Y.J. Choi\*, H. Jang, C. Kang, Y. Kim, Y.H. Jun, S.S. Lee, H.H. Chang, J. Kwon, G.M. Park, J.Y. Kim, K.R. Peck, M.J. Kim (Ansan, Seoul, Daejeon, Jeonju, Daegu, Goyang, Gwangju, Wonju, Anyang, KR)

**Background:** The incidence of carbapenem-resistant *Acinetobacter baumannii* (CRAB) infections is increasing and therapeutic options are limited. However, controversy exists regarding the mortality attributable to delay in starting appropriate antibiotic treatment. The aim of this study was to analyze the clinical features and outcomes of patients with CRAB bacteremia and assess the factors influencing in-hospital mortality, especially in terms of early appropriate antimicrobial therapy.

**Methods:** A multicenter prospective observational study was conducted at 15 teaching hospitals around South Korea from February 2010 to August 2011. Patients who were  $\geq 18$  years old and had nosocomial bacteremia due to *A. baumannii* were enrolled. Only one bacteremic episode from one patient was included in the study. Early appropriate antimicrobial therapy was defined as one or more agents active against CRAB, given with adequate dosage and route of administration, not later than 24 hours after the blood culture was obtained.

**Results:** Of 197 patients with CRAB bacteremia who enrolled in this study, 167 patients were evaluable. The in-hospital mortality rate was 80.2% (134/167). According to univariate analysis, older age, previous central venous catheterization and mechanical ventilation before bacteremia, primary bacteremia, pneumonia, lower serum albumin concentration prior bacteremia, development of severe sepsis or septic shock, higher PITT bacteremia score and APACHE II score, application of mechanical ventilation, and delayed ( $>24$  hours after blood culture obtained) appropriate antibiotic treatment were associated with in-hospital mortality. Multivariate analysis showed that serum albumin concentration prior bacteremia (Odds ratio [OR] = 0.086; 95% confidence interval [CI] = 0.01–0.85;  $p = 0.036$ ) and PITT bacteremia score (OR = 18.14; 95% CI = 2.76–119.40;  $p = 0.003$ ) were independent risk factors for in-hospital mortality.

**Conclusion:** A delay in starting appropriate antibiotic therapy was not associated with higher mortality in our analysis. Our data suggest that severities of baseline condition and infection presentation were major risk factors for in-hospital mortality.

#### **P1175** Risk factors for infection development following an ultrasound guided prostate biopsy procedure and effects of resistant bacteria in the intestinal flora

E. Eruz\*, E. Ozden, H. Aslaner, S. Ogucu Durgun, D. Koseoglu Taymur, K. Memikoglu, H. Kurt (Ankara, TR)

**Introduction:** This study is aimed to define the risk factors of post prostate biopsy infections and to determine whether the intestinal colonization of the resistant bacteria against antibiotics used for prophylactic purposes tend to increase the risk of urinary tract infections (UTI).

**Materials and methods:** The study involved 168 patients who undergone prostate biopsy procedure accompanied by transrectal ultrasonography (TRUSPB) while receiving ciprofloxacin and gentamycin for prophylaxis. Fecal cultures were taken from all of the patients before the prophylaxis and presence of ciprofloxacin resistant bacteria was inspected by antibiogram. Odds ratio was used to evaluate whether the questioned risk factors increase UTI incidence.

**Results:** Ciprofloxacin resistant bacteria were detected in 81 out of 168 stool samples (48.2%) obtained before the procedure. From these 81 isolates, 74 were *E. coli*, five were *Enterococcus*, two were *Klebsiella*. Among the 74 ciprofloxacin resistant *E. coli* strains, 39.2% were detected to produce extended spectrum beta lactamase, and the

sensitivity rates of nitrofurantoin, fosfomycin, and amycacin were found to be relatively high (95%, 98.8% and 100% respectively).

UTI developed in 10.1% of the patients (17/168) who had had TRUSPB. Six patients (3.6%) had the infection accompanied by high fever and urosepsis was found to occur in two patients (1.2%). The findings of the risk analysis revealed that the history of urolithiasis (OR = 2.23, 95% CI 1.06–9.56  $p = 0.03$ ), presence of long term urinary catheterization (OR = 10.64, 95% CI 1.40–81.45,  $p = 0.05$ ), hospitalization preceding the prostate biopsy procedure by maximum 1 year (OR = 3.91, 95% CI 1.10–14.05,  $p < 0.03$ ), history of UTI  $\geq 3$  times in the last 1 year (OR = 4.39 95% CI 1.02–18.84,  $p = 0.03$ ) and recent history of antimicrobial agent utilization (OR = 4.85, 95% CI 1.34–17.59,  $p = 0.009$ ) were determined as the risk factors for infections to develop following a TRUSPB. None of the patients who were not detected to have intestinal fluoroquinolone resistant bacteria colonization developed an infection following TRUSPB ( $p < 0.001$ ).

**Conclusion:** The study conducted shows that the intestinal colonization of ciprofloxacin resistant bacteria increases the risk of infection development following a prostate biopsy procedure under ciprofloxacin prophylaxis.

**P1176 Risk factors for *Burkholderia cepacia* complex bacteraemia among intensive care unit patients in a Greek general hospital**

K. Kontopoulou, K. Tsepanis\*, E. Vasiliagkou, K. Katsanoulas, I. Stoikou, E. Antoniadou, K. Mandavelli (Thessaloniki, GR)

**Objective:** We performed a case-control study to investigate risk factors of bacteremia in non-CF patients and describe the epidemiology of BCC infection in our institution.

**Methods:** In a 16 month-period between January 2010 and April 2011 BCC was recovered from 13 patients without CF admitted to the Intensive Care Unit (ICU) of our hospital. A case of BCC bacteremia was defined as a positive blood culture for the bacteria combined with deterioration of clinical status. Controls (N = 52) were defined as patients who had spent at least 7 days in the ICU within 2 weeks of the primary episode of BCC bacteremia of their matched case but did not have BCC isolated during the study period (N = 52). Risk factors that were investigated were the presence of tracheostomy, malignancies, administration of colistin during the last 10 days, administration of propofol 3 days before the onset of symptoms, administration of central venous catheters, recent abdominal surgery, length of hospitalization, preexisting comorbid conditions, presence of percutaneous feeding tube and renal failure. Multivariate logistic regression analysis (stepwise selection procedure) was performed in order to determine independent risk factors of acquisition of BCC bacteremia. Covariates were included in the model if univariate logistic regression analysis revealed that were significantly associated with BCC bacteremia at an  $p$  value of  $< 0.10$ .

**Results:** Multiple regression analysis (table attached) revealed the presence of tracheostomy, malignancies, length of hospitalization, administration of colistin during the last 10 days and administration of propofol 3 days before the onset of symptoms as independent risk factors for BCC bacteremia. Meropenem and ciprofloxacin and piperacillin-tazobactam were the most active agents against BCC.

RISK FACTOR	ODDS RATIO	ODDS RATIO (95% CI)	P VALUE
Presence of tracheostomy	2,23	1,01-3,45	0,044
Malignancies	3,01	1,4-4,61	0,023
Administration of colistin	4,12	1,53-6,81	0,019
Administration of propofol 3 days before the onset of symptoms	5,23	2,2-8,46	0,012
Length of hospitalization	1,9	1,01-2,78	0,049

**Conclusion:** Because BCC colonizes the respiratory tract, it is not surprising that factors associated with compromised respiratory status, such as tracheostomy emerged as significant risk factor for BCC bacteremia. Underlying malignancy is associated with immunosuppression. The continuous infusion of propofol supports bacterial growth because it is a lipid based emulsion. Other researchers had concluded that administration of antibiotics decrease the risk of BCC bacteremia. However, because of the intrinsic resistance to colistin of BCC, the administration of the antibiotic eliminates the other bacteria responsible for bacteremia and allows the growth of BCC.

**P1177 Outbreak of *Burkholderia multivorans* in non-cystic fibrosis patients hospitalised in intensive care units**

V. Hanulik, M. Chroma\*, R. Uvizl, M.A. Webber, R.N. Whitehead, S. Baugh, M. Sedlakova, M. Kolar (Olomouc, CZ; Birmingham, UK)

**Objectives:** The *Burkholderia cepacia* complex (Bcc) comprises a large group of opportunistic pathogenic bacteria. The epidemiology and role of Bcc as an etiological agent in non-cystic fibrosis (non-CF) patients is poorly understood.

**Methods:** Between 1 February 2011 and 30 September 2011, all Bcc isolates obtained from clinical samples from patients hospitalized in the University Hospital Olomouc were collected. All Bcc isolates were identified and speciated using the Phoenix automated system (Becton Dickinson), the RapID™ System biochemical tests (Remel) and PCR analysis. Genetic relationships between isolates were identified by a random amplified polymorphic DNA (RAPD) method. Multilocus sequence typing (MLST) was used with selected epidemic isolate.

**Results:** A total of 74 Bcc isolates were acquired with 52 non-duplicate isolates from separate patients. Forty five strains (86.5%) were genomovar II (*Burkholderia multivorans*) and all these strains were isolated from patients without cystic fibrosis (CF). RAPD showed 25 different clonal groups (I–XXV) amongst these strains, the largest number of identical strains was in group III (23 strains, 44.2%). In this group, 15 (65.2%) patients were hospitalized in intensive care units (ICU) and strains were most frequently isolated from the lower respiratory tract (53.3%) and upper respiratory tract (26.7%). A phylogenetic analysis of *gyrB* of the epidemic strain showed this strain has previously been isolated from the United Kingdom, USA, New Zealand and recently the Czech Republic and found in environmental samples, CF and non-CF patients.

**Conclusion:** We investigated 52 strains from distinct patients. Most frequently isolated was *Burkholderia multivorans* (86.5%) isolated from patients without CF. Over 44% of these strains were identical by RAPD suggesting an outbreak and more than 65% of them were isolated from ICU patients. Deaths directly associated with group III *Burkholderia multivorans* infection were noted in four cases. Genetic analysis of the epidemic strain suggested a global distribution which now includes the Czech Republic. The rate of 86% of Bcc isolates being *Burkholderia multivorans* is unusual and is a novel observation. The source of the epidemic strains has not been found as yet.

**Acknowledgements:** This study was supported by the Ministry of Education project no. MSM6198959205, project CZ.1.05/2.1.00/01.0030 and research by MAW is supported by a BBSRC David Phillips fellowship.

**International and national resistance surveillance data**

**P1178 Prevalence of extended-spectrum beta-lactamases in Europe: 2004–2011**

M. Hackel\*, D. Hoban, R. Badal, S. Bouchillon, B. Johnson, J. Johnson, S. Hawser, M. Dowzicky (Schaumburg, US; Epalinges, CH; Colleeville, US)

**Background:** Infection by extended-spectrum beta-lactamase (ESBL)-producing bacterial pathogens is increasing worldwide, with the

prevalence of ESBLs in Europe varying greatly from country to country. Patients with infections caused by an ESBL-producing organism are at increased risk of treatment failure. The Tigecycline European Surveillance Trial (TEST), a longitudinal surveillance study, determined the ESBL status and antibiotic susceptibilities to tigecycline and comparator compounds for 21 149 *Escherichia coli*, *Klebsiella oxytoca*, and *Klebsiella pneumoniae*, from 25 European countries from 2004 to 2010.

**Methods:** Twenty-one thousand and seventy-three isolates (10 814 *E. coli*, 2648 *K. oxytoca*, 7687 *K. pneumoniae*) from 14 Western European and 11 Eastern European countries were analyzed in this survey. The isolates were identified to the species level at the participating sites and confirmed by the central laboratory. MICs were determined by each site using supplied broth microdilution panels and interpreted according to EUCAST guidelines. ESBL testing was performed by Laboratories International for Microbiology Studies (LIMS), a subsidiary of International Health Management Associates, Inc. (IHMA, Schaumburg, IL, USA) following CLSI guidelines.

**Results:** Results are shown in the following figure.

**Conclusions:** Linear trends in the prevalence of ESBLs in Eastern and Western Europe for the years 2004 to 2010 continue to increase significantly ( $p < 0.00001$ , Cochran-Armitage test). The percentage of ESBL+ *E. coli*, *K. oxytoca*, and *K. pneumoniae* isolates in 2010 was 16.7% in Western Europe and 24% in Eastern Europe. The percentage varies greatly from country to country, ranging from 0% in Finland to 41% in Italy.

**P1179** Global trends in frequency and susceptibility of extended-spectrum beta-lactamase positive *E. coli*, *K. pneumoniae*, and *K. oxytoca* Isolated from intra-abdominal infections since 2005 – the SMART Study

R. Badal\*, S. Lob, S. Bouchillon, D. Hoban, A. Johnson, M. Hackel (Schaumburg, US)

**Objectives:** The Study for Monitoring Antimicrobial Resistance Trends (SMART) program has been monitoring the activity of ertapenem (ETP), amikacin (AK), cefepime (CPE), ceftazidime (CAZ), ceftazidime (CAZ), ceftriaxone (CAX), cefotaxime (CFT), ciprofloxacin (CP), imipenem (IMP), levofloxacin (LVX), ampicillin/sulbactam (AS), and piperacillin/tazobactam (PT) against gram-negative bacteria isolated from intra-abdominal infections (IAI) since 2002. This report evaluates changes in frequency of ESBL+ *E. coli* (Ec), *K. pneumoniae* (Kp), and *K. oxytoca* (Ko) since 2005, and their impact on susceptibility levels.

**Methods:** Seventy-six (2005) to 155 (2010) labs per year in Asia/Pacific (AP), Latin America (LA), Middle East/Africa (MEA), Europe (EU), and North America (NA) collected 32 605 isolates of Ec/Kp/Ko from IAI. Microdilution minimum inhibitory concentrations (MICs) and extended spectrum beta-lactamase (ESBL) confirmation were done by Clinical and Laboratory Standards Institute (CLSI) methods. % ESBL+ were determined each year, and percent of susceptible strains (%S) to study drugs were compared for ESBL+ vs. ESBL- strains.

Region	2005	2006	2007	2008	2009	2010
AP <sup>1</sup>	23% (782) <sup>2</sup>	27% (1289) <sup>2</sup>	38% (1935)	32% (1871)	35% (2298)	29% (2400) <sup>2</sup>
LA <sup>2</sup>	18% (514)	23% (579)	30% (680)	29% (659)	24% (1176)	33% (1493)
MEA <sup>2</sup>	16% (257)	16% (283)	15% (330)	14% (204)	16% (206)	22% (404)
EU <sup>2</sup>	7% (1635)	8% (1839)	10% (1661)	12% (1938)	12% (2183)	13% (2210)
NA	4% (257)	8% (293)	8% (311)	6% (477)	7% (1240)	8% (1202)

<sup>1</sup> Significant increasing trend ( $p < 0.05$ , Cochran-Armitage test).  
<sup>2</sup> No isolates available from India.

**Results:** Global % ESBL+ (Ec + Kp + Ko) by year:

**Conclusions:** 1 ESBL+ Ec/Kp/Ko have increased sharply since 2005, with statistically significant trends in Latin America, Middle East/Africa, and Europe and decreased %S to many drugs (incl. CP, LVX). Even the increases in North America ( $p = 0.054$ ) and Asia/Pacific ( $p = 0.06$ ) were almost significant, with the trend in Asia/Pacific being confounded by the availability of isolates from India (where ESBL rates are very high) only in 2007–2009.

2 ETP and IMP remain the most effective of the study drugs against ESBL+ strains.

**P1180** Susceptibility of intra-abdominal pathogens and occurrence of extended-spectrum beta-lactamase producers in 13 European countries – the SMART study 2010–2011

R. Badal\*, S. Lob, S. Bouchillon, D. Hoban, S. Hawser, A. Johnson, M. Hackel (Schaumburg, US; Epalinges, CH)

**Objectives:** The Study for Monitoring Antimicrobial Resistance Trends (SMART) has been monitoring the antimicrobial susceptibility of aerobic gram-negative bacteria from intra-abdominal infections (IAI) since 2002. This report compares susceptibility levels of key IAI pathogens in 13 countries Europe to ertapenem (ETP), amikacin (AK), cefepime (CPE), ceftazidime (CAZ), ceftriaxone (CAX), ciprofloxacin (CP), imipenem (IMP), levofloxacin (LVX), ampicillin-sulbactam (AS), and piperacillin/tazobactam (PT) during 2010–2011.

**Methods:** Forty-six labs in 13 European countries each collected up to 100 consecutive gram-negative bacteria/year from IAI in 2010–2011. MICs were determined by broth microdilution, and interpreted using EUCAST guidelines.

**Results:** Four thousand and twenty isolates were collected. The rate of extended spectrum beta-lactamase (ESBL) producers was 9% in Europe overall, with country-specific rates ranging from 1% and 4% in Estonia and France to 16% and 26% in Latvia and Turkey, respectively. The table below shows % susceptible for each drug for all isolates combined for which EUCAST breakpoints were available; values at least 5% less than the European average are shaded.

	n	ESBL <sup>1</sup>	AS <sup>2</sup>	AK	CAX	CAZ	CFT	CP	CPE	ETP	IMP	LVX	PT

EU	4,020	9%	46%	90%	79%	80%	78%	75%	84%	96%	92%	77%	83%

<sup>1</sup> % of all species of IAI isolates that were ESBL+.

<sup>2</sup> Only species for which breakpoints exist were included in the %S calculations for each drug; eg, *P. aeruginosa* was not included in the AS, CAX, CFT, or ETP %S calculations as no breakpoints exist.

**Conclusions:** 1 The susceptibility of IAI pathogens varied dramatically among the 13 European countries that participated in this study, with AK, ETP, and IMP showing the highest % susceptible for all species combined for which EUCAST breakpoints exist.

2 ESBL rates also varied by country, and countries with high rates showed lower overall susceptibilities against IAI pathogens.

3 Surveillance studies such as SMART highlighting current regional ESBL rates and susceptibility patterns are important for guiding empiric therapy for IAI.

**P1181 Susceptibility of intra-abdominal pathogens in Europe, Africa, and the Middle East – SMART 2010/2011**

R. Badal\*, S. Lob, S. Bouchillon, S. Hawser, D. Hoban, M. Hackel (Schaumburg, US; Epalinges, CH)

**Objectives:** The Study for Monitoring Antimicrobial Resistance Trends (SMART) has monitored susceptibility of intra-abdominal infection (IAI) pathogens since 2002. During that time, antimicrobial resistance has increased alarmingly in many regions of the world. This report summarizes European, African, and Middle Eastern data from SMART 2010 and 2011.

**Methods:** Fifty-four hospitals in 18 countries each collected up to 100 consecutive isolates of gram-negative aerobic bacilli from IAI. Isolate identification and susceptibility testing was done at a central laboratory, and interpreted using CLSI M100-S21 guidelines.

**Results:** Four thousand seven hundred and thirty-six isolates were collected, of which almost 70% were *E. coli* (49%), *K. pneumoniae* (11%), and *P. aeruginosa* (8%). Ten percent of all IAI pathogens (13% of *E. coli* and 28% of *K. pneumoniae*) were ESBL+ with the reduced susceptibility profiles normally associated with that phenotype. Regional ESBL+ *E. coli* rates ranged from 3% (Africa, n = 238) to 13% (Europe, n = 1944) and 38% (Middle East, n = 130), with the difference between Europe and Middle East being statistically significant (p < 0.05, Fisher's exact test). Susceptibility of organisms with n > 50, listed by frequency of occurrence, are shown in the table below. Shading denotes % susceptible values ≥90%.

<i>S. marcescens</i>	76	95	14	92	68	43	89	75	83	99	97	95	91

\*Ak=amikacin, AS=ampicillin-sulbactam, Cpe=cefepime, Cft=cefotaxime, Cfx=cefotaxin, Caz=ceftazidime, Cax=ceftriaxone, Cp=ciprofloxacin, Ep=ertapenem, Imp=imipenem, Lvx=levofloxacin, PT=piperacillin-tazobactam, na=no breakpoint defined.

**Conclusions:** ESBL rates varied between the regions with particularly high rates found in the Middle East. Overall only three of the study drugs, ertapenem, imipenem, and amikacin, showed an average % susceptible of ≥90% for the two species accounting for almost 2/3 of all IAI pathogens (*E. coli* and *K. pneumoniae*). These three agents remained effective against most ESBL+ isolates. Although *A. baumannii* represented only 3% of IAI isolates, this species was <40% susceptible to all drugs for which it has breakpoints. Increasing resistance requires ongoing monitoring to help control the rapid spread of multi-drug resistant pathogens.

**P1182 Susceptibility of Gram-negative pathogens isolated from urinary tract infections in Portugal between 2009 and 2010 – the SMART Study**

S. Ferreira\*, J. Diogo, A. Castro, H. Ramos, E. Ramalheira (Aveiro, Lisbon, Porto, PT)

**Objectives:** The Study for Monitoring Antimicrobial Resistance Trends (SMART) has been monitoring activity of ertapenem (Etp), amikacin (Ak), cefepime (Cpe), cefotaxime (Ctx), ceftazidime (Caz), ceftriaxone (Cax), ciprofloxacin (Cp), imipenem (Imp), levofloxacin (Lvx) and piperacillin/tazobactam (PT) vs. gram-negative bacteria from urinary tract infections (UTI) since late 2009. This report summarizes the ESBL prevalence in Enterobacteriaceae as well as susceptibility levels for key UTI pathogens in Portugal during 2009–2010.

**Methods:** Three Portuguese community hospital laboratories, representing North, Center and South of Portugal, each collected up to 25 (in 2009) and 50 (in 2010), consecutive gram-negative bacteria from UTI. MICs were determined by broth microdilution, and interpreted using CLSI guidelines M100-S20U (2010). ESBL production was determined for *Escherichia coli*, *Proteus mirabilis*, *Klebsiella pneumoniae* and *oxytoca* using the CLSI phenotypic method.

**Results:** Two hundred and forty-nine isolates were collected from UTI during the last 2 years. Susceptibility results are shown in Table 1. As expected the most prevalent species were *E. coli* (n = 120) and *K. pneumoniae* (n = 46), composing about 70% of all UTI pathogens. The ESBL rate was very high at 30.3% and 44.6% for those two species.

Drug	Breakpoints (S/I/R)	Susceptibility results 2009			Susceptibility results 2010		
		<i>E. coli</i>	<i>K. pneumoniae</i>	<i>P. mirabilis</i>	<i>E. coli</i>	<i>K. pneumoniae</i>	<i>P. mirabilis</i>
Amikacin	≤16   ≥2   =68	92/88	100	100	97/48	0	95
Cefepime	≤8   ≤8   =82	88/1	100	83/33	100	55/13	0
Ceftriaxone	≤2   ≤4	88/1	100	83/33	100	52/56	0
Cefotaxime	≤4   ≤8   =89	95/48	100	83/33	100	93/18	100
Ceftazidime	≤2   ≤4	88/1	100	83/33	100	52/56	0
Ciprofloxacin	≤1   ≤2   =4	65/9	100	66/67	100	48/72	0
Ertapenem	≤4/25   8/5   =6	100	100	83/33	100	100	100
Imipenem	≤2   ≤4	100	100	100	0	100	100
Levofloxacin	≤2   ≤4   =8	63/9	100	66/67	100	48/72	0
Piperacillin/Tazobactam	≤16/8   ≤2/8/4/4   =128/8	95/34	100	50	100	85/9	0

**Conclusions:** *E. coli* (~50% of all UTI pathogens) susceptibility decreased to almost all the antibiotics tested in 2010. *K. pneumoniae* (~18% of all UTI pathogens) susceptibility also decreased in 2010. The ESBL rates in these two species are disturbing, considering that it causes ineffectiveness of the majority of the antibiotics tested and used in clinical practice. Until definitive identification and susceptibility testing results are known, options for effective empirical therapy of UTI in Portugal have diminished to include very few (e.g., carbapenems, amikacin) of the agents evaluated in this study.

**P1183 Susceptibility of Gram-negative pathogens isolated from intra-abdominal infections in Portugal between 2008 and 2010 – the SMART Study**

S. Ferreira\*, J. Diogo, A. Castro, H. Ramos, E. Ramalheira (Aveiro, Lisbon, Porto, PT)

**Objectives:** The Study for Monitoring Antimicrobial Resistance Trends (SMART) has been monitoring activity of ertapenem (Etp), amikacin (Ak), cefepime (Cpe), cefoxitin (Cfx), ceftazidime (Caz), ceftriaxone (Cax), ciprofloxacin (Cp), imipenem (Imp), levofloxacin (Lvx) and piperacillin/tazobactam (PT) vs. gram-negative bacteria from intra-abdominal infections (IAI) since 2002. This report summarizes the ESBL prevalence as well as susceptibility levels for key IAI pathogens in Portugal during 2008–2010.

**Methods:** Three Portuguese community hospital laboratories, representing North, Center and South of Portugal, each collected up to 100 consecutive gram-negative bacteria/year from IAI during 2008–2010. MICs were determined by broth microdilution in a central laboratory, and interpreted using CLSI guidelines M100-S20U (2010). ESBL production was determined for *Escherichia coli*, *Proteus mirabilis*, *Klebsiella pneumoniae* and *oxytoca* using the CLSI phenotypic method.

**Results:** Seven hundred and sixty-eight isolates were collected from IAI during the last 3 years. The results are shown in Table 1. As expected the most prevalent species were *E. coli* (n = 325) and *K. pneumoniae* (n = 104), representing >50% of all IAI pathogens, and the ESBL rates were, respectively, 12% and 14%; no ESBL was detected for *K. oxytoca* or *P. mirabilis*.

<i>P. aeruginosa</i>	423	80.1				76.4			73.1	74.7		72.3	68.8	74.2											
<i>S. marcescens</i>	56	34.3	100	7.1	85.7	89.3	78.6	89.3	94.6	98.2	100	96.4	89.1												

**Conclusions:** There was no visible alterations in the susceptibility along the timeframe studied (2008–2010) in both *E. coli* and *K. pneumoniae*. Until definitive identification and susceptibility testing results are known, options for effective empirical therapy of IAI in Portugal remain a wide range of antibiotics of the agents evaluated in this study.

**P1184 Comparative in vitro activity of amoxicillin/clavulanate against aerobic Gram-negative pathogens in Spain – SMART 2005–2010**  
*R. Badal\*, S. Bouchillon, D. Hoban, M. Hackel (Schaumburg, US)*

**Objectives:** The Study for Monitoring Antimicrobial Resistance Trends (SMART) has been monitoring worldwide activity of ertapenem (ETP), amikacin (AK), cefepime (CPE), cefoxitin (CFX), ceftazidime (CAZ), ceftriaxone (CAX), cefotaxime (CFT), ciprofloxacin (CP), imipenem (IMP), levofloxacin (LVX), ampicillin/sulbactam (AS), and piperacillin/tazobactam (PT) against gram-negative intra-abdominal infection (IAI) pathogens since 2002, and from urinary tract infection (UTI) starting in late 2009. Additionally, amoxicillin/clavulanate (AUG) was tested specifically against Spanish isolates. This report compares the in vitro activity of these drugs in Spain during this period.

**Methods:** Nine thousand four hundred and sixty-one isolates were collected by 11 Spanish hospitals from IAI (2005–2010) and UTI (2009–2010). Extended spectrum beta-lactamase (ESBL) confirmation and MIC determinations for all drugs except AUG were done following Clinical and Laboratory Standards Institute (CLSI) methods; AUG was tested by Etest using the same inoculum as the other drugs. EUCAST breakpoints were used to interpret MICs.

**Results:** % Susceptible (%S) for all species with n > 10 is shown below. Values ≥90% are shaded.

Note: blanks = no breakpoint established.

ESBL+ rates in 2010 for *E. coli* and *K. pneumoniae* were 8.8 and 13.6%, respectively.

Organism	N	AS	AK	AUG	CAX	CAZ	CFT	CP	CPE	ETP	IMP	LVX	PT
<i>A. baumannii</i>	57												
<i>A. hydrophila</i>	14	42.9	100	50.0	78.6	92.9	85.7	100	100	57.1	64.3	100	78.6

<i>M. morgani</i>	163	3.7	96.9	2.1	84.7	66.9	66.3	80.4	98.2	99.4	66.9	85.3	97.6
<i>P. mirabilis</i>	347	80.4	91.6	92.5	95.7	97.4	96.3	77.0	99.1	99.7	84.2	89.1	99.4
<i>P. vulgaris</i>	58	68.8	98.3	94.4	56.9	86.2	87.9	98.3	95.6	100	81.0	98.3	98.3
<i>P. aeruginosa</i>	423	80.1				76.4			73.1	74.7		72.3	68.8
<i>S. marcescens</i>	56	34.3	100	7.1	85.7	89.3	78.6	89.3	94.6	98.2	100	96.4	89.1

**Conclusions:** 1 AUG was the second least active drug in the study, inhibiting ≥90% of only three relatively minor species causing IAI and UTI (*P. mirabilis*, *P. vulgaris*, and *C. koseri*); only AS was less active. 2 AUG retained marginal activity (72%) vs. ESBL+ *E. coli*, but it only inhibited 48% of ESBL+ *K. pneumoniae*. With nearly 14% of *K. pneumoniae* being ESBL+ in Spain, use of AUG to treat IAI may be unwise until ESBL status of the pathogen is known. 3 Only ETP and IMP inhibited >90% of ESBL+ isolates. ESBL+ *K. pneumoniae* were especially troubling, as other than the carbapenems and AK, no other drug inhibited >50% of these isolates.

**P1185 In vitro susceptibilities of aerobic and facultative Gram-negative bacilli isolated from patients with intra-abdominal infections and urinary tract infections in China: the 2010 Study for Monitoring Antimicrobial Resistance Trends (SMART)**

*Y. Wang\*, H. Xi, Y. Xu, B. Hu, Y. Ni, W. Huang, Y. Wang, A. Wu, Y. Yu, X. Feng, Z. Sun, K. Liao, D. Shen, Z. Hu, Y. Chu (Beijing, Shanghai, Chongqing, Jinan, Changsha, Hangzhou, Zhengzhou, Wuhan, Guangzhou, Tianjin, Shenyang, CN)*

**Objectives:** The Study for Monitoring Antimicrobial Resistance Trends (SMART) is an ongoing study to monitor the worldwide in vitro susceptibilities of aerobic and facultative gram-negative bacilli (GNB) isolated from intra-abdominal infections (IAI). In 2010, isolates from urinary tract infections (UTI) were also included. This report summarizes the most recently completed data in 2010 from SMART study in China.

**Methods:** In 2010, GNB isolates were collected from 13 teaching hospitals in 11 cities of China. Antimicrobial susceptibilities were tested by CLSI broth microdilution method (M07-A8). Extended-spectrum beta-lactamases (ESBLs) were tested by phenotypic confirmatory test recommended by CLSI. Modified Hodge Test (MHT) and PCR amplification for GES-, KPC-, SME-, NMC-, IMP-, VIM-, SPM-, GIM-, SIM- and NMD-encoding genes were performed for Enterobacteriaceae with imipenem MICs ≥ 4 µg/mL and/or ertapenem MICs ≥ 1 µg/mL.

**Results:** One thousand one hundred and forty-two isolates from IAIs and 530 isolates from UTIs were collected. Enterobacteriaceae composed 80.6% of IAI isolates and 88.3% UTI isolates. *E. coli* (53.1%/66.8%), *K. pneumoniae* (13.6%/11.5%) and *P. aeruginosa* (9.5%/5.8%) were the most common isolates from both IAIs and UTIs. Imipenem and ertapenem were the most active agents against Enterobacteriaceae (>96% susceptible) according to the breakpoints of CLSI M100-S20, followed by amikacin and piperacillin/tazobactam. The percentages of ESBL-producers in *E. coli*, *K. pneumoniae*, *K. oxytoca* and *P. mirabilis* for IAIs and UTI were 66.1%/64.5%, 35.7%/56.9%, 52.9%/28.6% and 16.7%/28.6%, respectively. Of the 181 isolates with elevated carbapenem MICs, only 11 were MHT positive. One isolate of *E. coli* and three isolates of *K. pneumoniae* produced KPC-2. One isolate of *M. morgani* produced both IMP-1 and VIM-2. One isolate of *K. oxytoca* produced VIM-1. One isolate of *E. cloacae* produced IMP-2. All four KPC-2-producers and one IMP-2-producer were MHT positive.

**Conclusion:** Enterobacteriaceae were still the main gram-negative pathogens for IAIs and UTIs in China in 2010. The carbapenems were the most active agents in vitro against Enterobacteriaceae. The percentage of ESBL-producers was higher than the previous SMART data in China, especially for *P. mirabilis*. Carbapenem-producing Enterobacteriaceae were still rare in mainland of China.

**P1186 Frequency and antimicrobial resistance of Gram-negative bacilli isolated from Latin America hospitals: results from SENTRY Antimicrobial Surveillance programme, 2008–2010**

*A. Gales, M. Castanheira, R. Jones, H. Sader\* (Sao Paulo, BR; North Liberty, US)*

**Objective:** To provide an update on the frequency and antimicrobial resistance (R) of Gram-negative bacilli (GNB) isolated from SENTRY Program Latin American medical centers (LAMC). This program has monitored antimicrobial R in LAMC since 1997.

**Methods:** Twelve thousand eight hundred and eleven organisms, including 5704 GNB (44.5%), were consecutively collected (one per patient) between January 2008 and December 2010 from 10 LAMC located in Argentina (ARG; 2), Brazil (BRA; 4), Chile (CHI; 2) and Mexico (MEX; 2). The isolates were susceptibility (S) tested by the CLSI broth microdilution method at a central laboratory. *E. coli* (EC),

*Klebsiella* spp. (KSP) and *Enterobacter* spp. (ESP) isolates with MIC,  $\geq 2$  mg/L for imipenem (IMI) or meropenem (MER) were screened for carbapenemases by the Modified Hodge test, PCR for blaIMP, blaVIM, blaKPC, blaSME, blaGES, blaIMI, blaNMC-A, and blaOXA-48, and DNA sequencing. Selected IMI-R *Acinetobacter* spp. (ASP) strains were screened for blaOXA-23, 24, 51, 58, blaKPC and MBLs by PCR.

**Results:** The infection sites included bloodstream (BSI; 52.6%), skin and soft tissue (22.9%) and pneumonia (13.1%), among others. The most common causes of BSI were *S. aureus* (SA; 22%), EC (21%) and KSP (13%); while *P. aeruginosa* (PSA; 33%), SA (21%), ASP (18%), KSP (11%) and ESP (5%) represented the top five organisms from pneumonia. ESBL rates were 18.0%, 12.8%, 23.8% and 48.4% among EC and 60.5%, 49.9%, 59.2% and 33.3% among KSP from ARG, BRA, CHI and MEX, respectively. MER-non-S KSP was highest in BRA (11.1%), followed by ARG (8.2%), CHI (5.0%) and MEX (0.8%). KPC-producing KPN was not detected in 2008, but emerge in 2009 (10 strains) and increased significantly in 2010 (44;  $p < 0.0001$ ). blaKPC-2 was detected in 54 of 85 (65.9%) carbapenem-non-S *K. pneumoniae* (KPN). MER-non-S PSA was observed in 53.8%, 46.7%, 33.3% and 28.8% of strains from ARG, BRA, CHI and MEX, respectively. IMI-S ASP decreased from 38.6%, 83.2% and 91.8% in 2003–2005 to 14.5%, 28.6% and 47.4% in 2008–2010 in ARG, BRA and CHI, respectively. OXA-producing ASP was documented in ARG (OXA-23), BRA (OXA-23 and -24), CHI (OXA-58) and MEX (OXA-24). Colistin was the only compound with reasonable activity against ASP and PSA (Table 1).

Antimicrobial	% susceptible <sup>a</sup> (no. tested)				
	EC (1517)	KSP (1052)	ESP (451)	PSA (1099)	ASP (845)
Ceftazidime	82.1	54.9	63.6	61.1	12.8
Cefepime	84.1	58.8	82.0	61.9	14.8
Piperacillin/Tazobactam	90.5	60.9	74.1	55.6	10.2
Meropenem	99.9	92.2	98.2	57.1	30.3
Ciprofloxacin	59.7	55.9	76.3	56.7	12.5
Gentamicin	81.2	63.1	78.7	63.2	37.8
Amikacin	98.6	86.8	92.2	73.3	29.4
Colistin	99.8 <sup>b</sup>	97.0 <sup>b</sup>	82.7 <sup>b</sup>	99.7	98.1

a. Based on CLSI breakpoint criteria (2011); b. PSA breakpoint was applied.

**Conclusions:** Only COL showed >77% overall coverage against the five most frequently isolated GNB from LAMC participating in the SENTRY Program. Empiric antimicrobial therapy for serious infections caused by GNB requires the combination of two or more agents for adequate coverage.

#### **P1187** Resistance patterns in multi-resistant Enterobacteriaceae: data from the German Antibiotic Resistance Surveillance System (ARS) from 2008 to 2010

B. Schweickert\*, I. Noll, M. Feig, H. Claus, M. Abu Sin, G. Krause, T. Eckmanns (Berlin, DE)

**Objectives:** Multiresistant gramnegative bacteria have emerged as a serious public health problem worldwide requiring consistent and intensified surveillance efforts. Data from ARS, the German Antibiotic Resistance Surveillance system are presented.

**Methods:** ARS is a voluntary laboratory based surveillance system collecting resistance data of all clinical pathogens and sample types. Data are transmitted electronically to the central data-base of the national public health institute (Robert Koch Institute). The development of susceptibility-rates and of resistance patterns of *Escherichia coli* (*E. coli*) and *Klebsiella pneumoniae* (*K. pneumoniae*) from 2008 to 2010 is presented. The panel of antibiotics and antibiotic classes used for the estimation of resistance patterns is presented in Table 1.

**Results:** In hospital care, susceptibility testing was performed in more than 24 000 *E. coli* -isolates and more than 4500 *K. pneumoniae* isolates throughout all 3 years.

From 2008 to 2010, non-susceptibility against cefotaxim (CTX) in *E. coli* rose from 6.9% to 9.3% and in *K. pneumoniae* from 10.4% to

11.4%. In CTX-non-susceptible isolates of both species the most frequent resistance pattern includes non-susceptibility against fluoroquinolones, aminoglycosides, trimethoprim/sulfamethoxazol and tetracyclines. From 2008 to 2010, CTX-non-susceptible *E. coli* isolates comprising four additional antibiotic classes (all betalactams excluded, except carbapenems) have decreased (33.5–27.3%), while non-susceptibility patterns with only one additional non-susceptible antibiotic class increased (12.5–16.6%). In contrast, in *K. pneumoniae* non-susceptibility-patterns of CTX-non-susceptible isolates comprising three additional antibiotic classes have increased (34.3–40.5%) and the patterns with one additional non-susceptible antibiotic sank (11.7–8.3%). In the observed time period non-susceptibility against carbapenems in both species remained under 1%.

Table1: Panel of antibiotics and antibiotic classes used for the estimation of resistance patterns

Antibiotic or antibiotic class	<i>E. coli</i>	<i>Klebsiella pneumoniae</i>
Aminopenicillines	x	
Aminopenicillin-betaactamase inhibitors	x	x
Piperacillin	x	
Piperacillin/Tazobactam	x	x
3. Generation-cephalosporins	x	x
Carbapenems	x	x
Ciprofloxacin	x	x
Trimethoprim/Sulfamethoxazol	x	x
Tetracyclines	x	x
Aminoglycosides	x	x

**Conclusion:** While the overall CTX-non-susceptibility rates in *E. coli* and *K. pneumoniae* show an increase, the patterns of CTX-non-susceptibility combined with non-susceptibility to additional antibiotic classes show different directions with *K. pneumoniae* isolates showing a trend toward more resistant isolates. The analysis of resistance patterns provides a deeper insight into strain characteristics and allows a more differentiate tracing of the development of antibiotic resistance.

#### **P1188** Epidemiology of ESBL-producing Enterobacteriaceae extended-spectrum beta-lactamases in Belgian hospitals: results of nationwide multicentre survey in 2010

Y. Glupczynski\*, C. Berhin, T. Huang, P. Bogaerts, A. Deplano, R. De Mendonça, B. Jans, O. Denis (Yvoir, Brussels, BE)

**Objectives:** We assessed the species distribution and diversity of extended-spectrum beta-lactamases (ESBLs) genes found in Enterobacteriaceae isolates prospectively collected in Belgian hospitals.

**Methods:** Hospital-based laboratories participating to the national surveillance network were requested to send to the reference center five nonduplicate clinical Enterobacteriaceae isolates resistant to 3rd and/or 4th generation cephalosporins (putative ESBL producers), collected during the first trimester of 2010.

Identification was confirmed by MALDI-TOF MS. The presence of ESBL was detected by a positive disk synergy test with clavulanic acid and with phenyl boronic acid (400 µg) disks for AmpC hyperproducers. ESBLs were identified by DNA micro-array (Check-Points, The Netherlands). Typing of selected isolates was performed by PFGE and by semi-automated rep-PCR.

**Results:** Ninety laboratories (43 in Flanders, 30 in Wallonia, 17 in Brussels) sent 433 isolates (400 confirmed as ESBL) from patients (mean age 66 years; range 1–99 years) hospitalized in medical (52%), surgical units (19%) or ICU (18%). ESBLs were isolated from urine (62%), respiratory tract (16%), pus (13%) and blood (6%). *E. coli*, *K. pneumoniae*, *E. aerogenes*, and *E. cloacae* represented 64%, 14%, 13% and 5% of the ESBLs, respectively. *E. coli* accounted for 75% of the ESBLs collected in a community-acquired setting and the proportion and incidence of ESBL-producing *E. coli* rose from 4.1% and 2.2/1000 admissions in 2006 to 6.3% and 4.1/1000 admissions in 2010. The majority of ESBL types were CTX-M (71%; of which 80% were CTX-M-15). Coresistance to ciprofloxacin, cotrimoxazole and

aminoglycosides among ESBL was 75%, 72% and 40% respectively. Spread of CTX-M-15 *E. coli*, *K. pneumoniae* and SHV-12/CTX-M-9 *E. cloacae* belonging to identical or closely related rep-PCR and/or PFGE types was observed in several hospitals in different cities.

**Conclusion:** In comparison to previous surveys carried out in 2006 and in 2008, we observed an increase in the proportion and incidence of CTX-M-15 producing *E. coli*. The spread of epidemic clones of ESBL-producers in Belgium is disquieting and highlights the need for adapted national guidelines in order to limit the cross-transmission of these organisms in Belgian hospitals.

**P1189** Nationwide survey of extended-spectrum beta-lactamases, metallo-beta-lactamases, and oxacillinases produced by multidrug-resistant *Pseudomonas aeruginosa* strains in Belgium in 2010

Y. Glupczynski\*, F. El Garch, A. Deplano, C. Bauraing, C. Berhin, B. Jans, M. Hallin, O. Denis, P. Bogaerts (Yvoir, Brussels, BE)

**Objectives:** The increasing prevalence of nosocomial infections produced by multidrug-resistant (MDR) *Pseudomonas aeruginosa* (PA) strains severely compromises the selection of appropriate treatments and is associated with significant morbidity and mortality. The aim of this study was to determine the frequency and the different types of acquired (and transferable) beta-lactamases in a collection of 111 MDR clinical PA isolates that were isolated in Belgian hospitals in 2010.

**Methods:** During a 3-month period, 54 hospital laboratories participating in the NSIH national surveillance network collected 1080 nonredundant strains of PA. MICs of 12 antipseudomonal antibiotics were determined centrally by microbroth dilution according to CLSI guidelines against MDR PA isolates (defined by resistance to at least three classes of antimicrobials among beta-lactams, carbapenems, aminoglycosides and quinolones). Beta-lactam resistance mechanisms of MDR strains were analyzed by IEF, PCR and sequencing with specific primers targeting most class A, B and D beta-lactamase coding genes. The epidemiological relatedness of the strains was studied by O serotyping, semi-automated Rep-PCR, PFGE and MLST.

**Results:** Overall, 111 MDR PA isolates (10.3%) were found in 36 hospitals (in 24 different cities). Colistin was the only agent tested consistently active against MDR PA (85% susceptibility by CLSI breakpoints). Metallo-beta-lactamases (MBLs) were detected in 55 isolates (VIM-2, n = 47; VIM-4, n = 7; VIM-1, n = 1). ESBLs were found in 13 isolates (BEL-1, n = 7, PER-1, n = 4, SHV-2a and VEB-1, n = 1 each) and OXA/CARB penicillinases in 44 strains (OXA-2, n = 14; OXA-10, n = 11 (9 in association with VIM-2); OXA-31/-35, n = 7; OXA-9, n = 2; CARB-1/-4, n = 6).

Overall, MDR PA strains were distributed among 30 distinct PFGE types and 21 rep-PCR patterns. The 47 VIM-2 producing isolates clustered in three major PGFE types (Q, X and W) were all of serotype O12 and belong to ST111 or ST244. On the other hand, VIM-4 as well as the BEL-1, PER-1 and VEB-1 clustered in several distinct PFGE and rep-PCR types, were predominantly serotype O11 and of ST235 type.

**Conclusion:** The emergence and epidemic diffusion of several clones of MDR PA isolates with acquired and transferable resistance mechanisms in Belgian hospitals is a matter of concern and underlines the need for continuous epidemiological monitoring.

**P1190** Prevalence of plasmid-encoded fosfomycin resistance gene among clinical isolates of extended-spectrum beta-lactamase-producing *Escherichia coli* and *Klebsiella pneumoniae* in Korea and the genetic environment of fosA3

Y.J. Kim\*, S.Y. Lee, J.K. Yu, K.G. Park, Y.J. Park (Seoul, KR)

**Objectives:** The rising rate of multi-drug resistance in Enterobacteriaceae reduces the number of effective drugs that can be used. Fosfomycin, although known for nearly four decades, has been

rarely used in Korea. Although fosfomycin resistance is mostly due to mutation in the chromosomal locus including *glpT*, several, plasmid mediated resistance genes are reported. In this study, we evaluated the prevalence of plasmid-mediated fosfomycin resistance determinants among the ESBL-producing *Escherichia coli* and *Klebsiella pneumoniae* and their genetic environments.

**Methods:** A total of 347 non-duplicate ESBL-producing clinical isolates, including *E. coli* (165) and *K. pneumoniae* (182), collected at 25 hospitals in Korea, from June 2009 to July 2009. The fosfomycin MICs were determined by an agar dilution method according to the CLSI guideline using MH agar supplemented with 25 µg/mL glucose-6-phosphate. PCR was used to detect the presence of ESBLs (*bla*TEM, *bla*SHV, *bla*CTX-M) and plasmid-encoded fosfomycin resistance genes (*fosA*, *fosA3*, *fosB*, *fosC2*). The PCR products were sequenced on a 3730 DNA Analyser (Applied Biosystems, Foster City, CA, USA). The transferability of resistance was studied by the transformation experiments using *E. coli* TOPO10 (Invitrogen, USA) as the recipient strain. From plasmid recovered from the transformants, the sequences of DNAs adjacent to *fosA3* were determined with a series of PCR primers and plasmid replicon typing was performed as described by Carattoli et al.

**Results:** The susceptibility to fosfomycin was 92.9% in *E. coli*, and 95.2% in *K. pneumoniae*. Of the 21 isolates non-susceptible to fosfomycin (eight *E. coli* and 13 *K. pneumoniae*), seven (five *E. coli* and 2 *K. pneumoniae*) isolates harbored *fosA3* and all of them co-harbored *bla*CTX-M-1group or *bla*CTX-M-9group. The transformants were successfully obtained from six isolates and the *bla*CTX-M was always co-transferred to the recipient *E. coli* strain. The replicon type of transformants co-harboring *bla*CTX-M-1group and *bla*CTX-M-9group were IncF and IncN type, respectively. The genetic environment of the *fosA3* carried by IncN and IncF type plasmids are described in Figure 1.

**Conclusions:** The fosfomycin resistance rate in ESBL-producing *E. coli* and *K. pneumoniae* was low in Korea (4.2%, 5.5%, respectively). However, *fosA3* was already indwelling in the transferable plasmid of *bla*CTX-M harboring clinical isolates.

**P1191** Resistance to colistin in *Klebsiella pneumoniae* – a slowly emerging problem in England

R.L.R. Hill\*, R. Pike, K. Patabendige, T. Pillana (London, UK)

**Objectives:** We sought evidence for resistance to colistin amongst all isolates of *Klebsiella pneumoniae* submitted to the national reference service from January to November 2011 and similarly reviewed all isolates collected in 2003 onwards.

**Methods:** Clinical isolates of *K. pneumoniae* from patients throughout England were referred to the HPA reference service for evaluation. Patient details were collated and repeat specimens excluded. MICs of 27 antibiotics, including beta-lactams, aminoglycosides and colistin, were determined for each isolate by agar dilution (BSAC method). Current BSAC/EUCAST breakpoints for all antibiotics tested (e.g. MIC > 2 for colistin) were applied to isolates collected from 2003 to

2011 inclusive. Resistance mechanisms present in 2011 isolates were compared to those of the first colistin-resistant isolates within the 8 previous years (period 2003–2011).

**Results:** There were 28 colistin-resistant *K. pneumoniae* from 29 patients in 19 hospitals during the first 10 months of 2011 compared to three isolates from three patients in two hospitals in 2004 and none in 2003. MICs of colistin were from 4 to >32 in 2011 but all were >32 in 2004. In 2011, there were 18 male (aged 4 weeks to 82 years) and 10 female (aged 18–83 years) patients. Nine isolates were from urine, five from wounds, four each from blood or faeces, two from line tips and one each from umbilicus, sputum or nose. Five patients were from one hospital and two different isolates from one patient in another hospital. Of the 28 isolates, 14 had an ESBL whilst 18 had a carbapenemase of which three were metallo-beta-lactamases (MBL) plus an ESBL. Nine were pan-aminoglycoside resistant and only seven had sensitivity to one aminoglycoside; due to beta-lactamase action + reduced permeability, only two were sensitive to ertapenem (MICs  $\leq$  0.5). Five were sensitive to tigecycline only and one was non-susceptible. One of the 2004 isolates had a ceftazidimase whilst the other two a CTX-M. In 2005 there were nine colistin-resistant isolates (MIC = 32) from six hospitals – two identical strains from one hospital and three from another; all had CTX-Ms and one an MBL. All isolates were pan-resistant to cephalosporins (cefotaxime, ceftazidime, cefpirome; MICs 32 to >256). **Conclusion:** The first isolates of *K. pneumoniae* resistant to colistin occurred in 2004, with an increase of almost ten times that in 2011. Isolates had one or more other significant resistance mechanism. Resistance to Colistin in *Klebsiella pneumoniae* appears to be a slowly emerging problem in England.

#### **P1192** Evolution of *Escherichia coli* susceptibility in the French community from 2004 to 2010

S. Thibaut, J. Caillon, G. Grandjean, F. Ollivier, G. Potel, F. Ballereau\* (Nantes, FR)

**Objectives:** The aim of this study was to determine the susceptibility of bacterial strains isolated from community-acquired infections. Survey was carried out by a network with 100 medical analysis laboratories in France in 2010.

**Methods:** All the strains of *Escherichia coli* isolated in these laboratories over a 7-year period, from January 2004 to December 2010, were included in the investigation.

**Results:** 200276 antibiograms were collected: 97.7% of *Escherichia coli* were isolated from urine. Among fluoroquinolones, the susceptibility of ciprofloxacin was higher than for ofloxacin/norfloxacin. Indeed, during the study period, the susceptibility to ofloxacin or norfloxacin decreased gradually from 91.4% in 2004 to 85.9% in 2010 ( $p < 0.001$ ) and the susceptibility rate to ciprofloxacin has slightly decreased since 2006 (92.7% in 2006 to 90.1% in 2010,  $p < 0.001$ ).

The rate of susceptibility to amoxicillin decreased gradually and significantly over the study period: 60.7% in 2004 and 56.4% in 2010 ( $p < 0.001$ ). Moreover, a slight decrease was observed in the susceptibility rates to amoxicillin-clavulanic acid during the study period, from 77.3% in 2004 to 72.0% in 2010 ( $p < 0.001$ ).

Cefotaxime, Ceftazidime and Ceftriaxone were the most active agents, with more than 97.6% and 97.0% of susceptibility in 2005 and 2010 respectively ( $p < 0.05$ ). The susceptibility of cefixime was stable 96.8% in 2004 and 96.3% in 2010. 2.4% *E. coli* isolated were shown to produce extended spectrum beta lactamases (ESBL).

The susceptibility to Nitrofurantoin was relatively stable over the studied period (98.2% in 2004 and 98.6% in 2010). For the susceptibility to cotrimoxazole, the rates decreased during the studied period from 85.6% in 2004 to 81.7% in 2010 ( $p < 0.01$ ).

**Conclusion:** This study confirms the worrying character of the evolution of resistance of *E. coli* to the quinolones. Quinolones should not be any more recommended to treat urinary infections in the community. A better knowledge of the bacterial epidemiology in the community should contribute to adapt the antibiotics strategies.

MedQual conduct a communication plan with Social Security alongside general practitioners to adapt the prescription of antibiotics to the resistance profile of the community Multi-Resistant Bacteria.

#### **P1193** Phenotypic and genetic screening of beta-lactamases mediated resistance amongst clinical isolates of Gram-negative bacilli from Romanian hospitals

I. Czobor\*, M.C. Chifiriuc, L. Marutescu, A. Cotar, O. Banu, E. Borcan, V. Lazar, G. Mihaescu (Bucharest, RO)

The purpose of this study was the detection of various types of beta-lactamases in Gram-negative rods (GNR) isolated from intensive care units (ICU).

**Material and methods:** A number of 531 GNR strains (334 Enterobacteriaceae and 197 Pseudomonadaceae) were isolated from 1166 positive clinical samples collected from patients hospitalized during 2011, in the ICUs of two big hospital from Buhcarest, Romania. Their resistance phenotypes were established using: disk diffusion test, double-disk diffusion test (DDST) with amoxicillin-clavulanic acid (AMC), cefotaxime (CTX) and ceftazidime (CAZ), DDST with AMC plus EDTA, imipenem (IPM) and IMP plus EDTA, Modified Hodge Test (MHT) and E-test ESBL, MBL and AmpC. The genetic support of the beta-lactam resistance mediated by enzymatic mechanisms was investigated by simple (blaampC, blaTEM grup, blaSHV grup, blaPSE grup, with PSE-1, PSE 4, CARB-3 alleles, blaIMP) and respectively multiplex PCR (blaVIM, blaSIM si blaSPM).

**Results and discussion:** GNR strains constituted the most frequent etiology of infections occurred in hospitalized patients, representing 45.5% from the total number of positive cases. Out of these, 64% of the Enterobacteriaceae and 36% of the Pseudomonadaceae strains expressed resistance to beta-lactam antibiotics. The extended spectrum beta-lactamases (ESBL) phenotype was present in 35.8%, while the metallo beta-lactamases (MBL) one in 34% of the tested GNR strains. A significant percentage (9.4%) of the tested strains exhibited simultaneously ESBL and MBL profiles. Some of the *Enterobacter* sp. strains expressed inducible cephalosporinases and extended spectrum AmpC cephalosporinases. The molecular study revealed, in decreasing frequency order, the presence of blaSHV, blaTEM and blaPSE genes. More than half of the *Pseudomonas aeruginosa* strains resistant to carbapenems exhibited the blaVIM gene.

**Conclusion:** The beta-lactam resistance profiles of Enterobacteriaceae and Pseudomonadaceae strains, mediated by beta-lactamases production, become more complex, especially in hospital units with high selective pressure, such are the ICUs. The high percent of ESBL and MBL producing strains suggests the necessity of resistance genotyping of key Gram-negative pathogens isolated from our geographical area, that will substantially contribute to the understanding of the genetics of antibiotic resistance and of the spread of resistance determinants in the hospital environment.

#### **P1194** Microbiological characteristics of Gram-negative bacteria isolated from patients with intra-abdominal infections in Latvia, 2007–2010

A. Balode, A. Vilde\*, U. Dumpis, T. Obidenova, I. Jansone (Riga, LV)

**Objective:** This study was conducted in Pauls Stradins Clinical University Hospital in order to determine the most common Gram-negative bacteria causing intra-abdominal infections and their susceptibility to commonly used antimicrobials.

**Methods:** Data presented is part of the Study for Monitoring Antimicrobial Resistance Trends (SMART). Microbiological isolates were obtained from intra-abdominal samples by conventional/automated methods. In vitro antibacterial susceptibility was detected using MIC panel against ampicillin/sulbactam, amikacin, ceftriaxone, ceftazidime, cefotaxime, ceftoxitin, ciprofloxacin, cefepime, ertapenem, imipenem, levofloxacin, piperacillin/tazobactam and interpreted according to the CLSI standard.

**Results:** A total of 382 Gram-negative bacteria were isolated in 2007–2010, of which Enterobacteriaceae accounted for 88.7% (339), *Pseudomonas* spp. – 7.1% (27) and *Acinetobacter baumannii* – 4.2% (16) of the species. Majority of Enterobacteriaceae were *Escherichia coli* – 60.5% (205 isolates) and *Klebsiella pneumoniae* – 10.6% (36), extended-spectrum beta-lactamase producers (ESBL-positive) were 12% (25) and 42% (15), respectively. Equally high prevalence of ESBL positive Gram-negative bacteria was observed over the period from 2007 to 2010. Most antimicrobials were effective against non-ESBL *E. coli* and *Kl. pneumoniae* displaying susceptibility >85%, except ampicillin/sulbactam with susceptibility 65.6% and 71.4%, respectively. ESBL-positive *E. coli* and *Kl. pneumoniae* susceptibility to imipenem was 100%, to amikacin – 88% and 86.7%, to ertapenem – 88% and 80%, to ceftoxitin – 84% and 66.7%, to piperacillin/tazobactam – 84% and 53.3%, but <36% and 7% to other tested antimicrobials. The most resistant Gram-negative bacteria isolated from intra-abdominal samples were *Ac. baumannii* (just 62.5% susceptible to amikacin, 25% to imipenem, 18.8% to ampicillin/sulbactam and <13% to other antibiotics).

**Conclusions:** Persistently high prevalence of ESBL producing Gram-negative bacteria in intra-abdominal samples from patients in Latvian multidisciplinary hospital was observed, while high susceptibility to carbapenems was still recorded.

**P1195 Epidemiological data of VIM- and IMP-producing *P. aeruginosa* prevalence in Novosibirsk in patients undergoing cardiosurgery**

V.N. Ilyina\*, A.I. Subbotovskaya, D.S. Sergeevichev, V.S. Kozyreva, A.P. Subbotovsky (Novosibirsk, RU)

**Objectives:** At present day the prevalence of multi-drug resistant strains of *P. aeruginosa* is an increasing therapeutical problem. The acquisition of metallo-beta-lactamases is one of the most common causes of carbapenem resistance in gram-negative bacteria. VIM and IMP-producing *P. aeruginosa* is widespread in Europe. In this work we report the epidemiological data of prevalence and types of metallo-beta-lactamase (MBL) producing strains of *P. aeruginosa*.

**Methods:** Clinical isolates of *P. aeruginosa* obtained from patients admitted in ICU after cardiosurgery from August 2009 to August 2011. Identification and susceptibility of *P. aeruginosa* were tested with the Phoenix device (Becton Dickinson). MBL production was detected by the imipenem-EDTA disk synergy test. Expression of VIM and IMP genes were tested with PCR using melting curve analysis.

**Results:** On routine microbiological examination 19 isolates of *P. aeruginosa* were resistant to all beta-lactams. Presence of MBL production was proven by positive imipenem-EDTA disk synergy test in all 19 cases. Using PCR we found that 11 isolates (58% of MBL-positive strains) were expressed by blaVIM gene and eight isolates (42%) were expressed by blaIMP gene.

**Conclusions:** During the study period 19 carbapenem-resistant MBL-producing strains of *P. aeruginosa* were found. Carbapenem-resistance was defined by blaVIM gene in 58% cases and by blaIMP gene in 42% cases. Surveillance and typing of carbapenem-resistant strains of *P. aeruginosa* is necessary to prevent further spread of these strains.

**P1196 Surveillance of carbapenemase producing Enterobacteriaceae in the Netherlands**

D.W. Notermans\*, K. van der Zwaluw, A. Haenen, M. Leverstein-van Hall, J. Alblas, M. van Santen-Verheuevel, M. Heck, H. Bijlmer, X. Huijsdens (Bilthoven, Utrecht, NL)

**Objectives:** Carbapenemase producing Enterobacteriaceae are an important threat to health care. Besides resistance to the class of beta-lactam antibiotics, associated resistance genes to other classes of antibiotics leave very little possibilities for antibiotic therapy for infections with these strains. In several countries, outbreaks in hospitals

and rapid dissemination through the health care system have been observed; a reason to start surveillance in The Netherlands.

**Methods:** Medical microbiological laboratories in the country were advised to submit all Enterobacteriaceae with an MIC for meropenem >0.25 for phenotypical and genotypical confirmation for carbapenemases. Carbapenemase genes tested by PCR were: KPC, NDM, VIM, GIM, SIM, IMP, SPM and OXA-48. Meropenem MIC was determined with E-test. Further strain and epidemiological information was collected.

**Results:** A large outbreak in one hospital with an OXA-48 positive *Klebsiella pneumoniae* was detected. Data from this hospital is excluded from the description of the surveillance results.

For 2011, up to November, 123 isolates from 97 patients were submitted by 35 hospitals. Twenty-two different CPE were detected from 20 patients. Twice, a patient harboured two different bacterial species (*E. coli* and *K. pneumoniae*) with the same carbapenemase (OXA-48, respectively NDM).

Carbapenemases found were OXA-48 (15x), NDM (4x), KPC (2x) and VIM (1x). Species involved were *K. pneumoniae* (18x), *Escherichia coli* (2x), *Citrobacter freundii* (1x) and *Enterobacter cloacae* (1x). Meropenem MICs ranged from 0.38 mg/L (OXA-48) to >32 mg/L (7x). MICs were within sensitive range ( $\leq 2$  mg/L) in eight isolates and resistant (>8 mg/L) in nine isolates.

Risk factors reported in 13 cases were admission to a foreign hospital in eight cases (Marocco 4x, Turkey, Pakistan) or the Dutch outbreak hospital in five cases.

**Conclusion:** Besides the large OXA-48 outbreak, no other CPE outbreaks were detected in 2011 though the surveillance and a limited number of CPE were seen in The Netherlands. The surveillance is on voluntary base and may therefore not have complete national coverage yet. As far as known, cases could either be related to the outbreak or to admissions in foreign hospitals. *Klebsiella pneumoniae* was the predominant species (82%) and OXA-48 the most frequently encountered (68%) carbapenemase.

**P1197 Evolving epidemiology of carbapenem-resistant Enterobacteriaceae: molecular characterisation of KPC-positive strains and circulating plasmids**

I. Frasson\*, A. Cavallaro, E. Franchin, S. Parisi, G. Palù, S.N. Richter (Padua, IT)

**Objectives:** The worldwide dissemination of carbapenemase-producing MDRO is becoming a crucial public health problem. A large number of plasmid-mediated enzymes with carbapenemase activity has been identified in Enterobacteriaceae, KPC (*Klebsiella pneumoniae* carbapenemase) being the most frequent. The aim of this study was to characterize both at the phenotypic and molecular level carbapenem-resistant strains that caused outbreaks in the Padua Teaching Hospital from January 2009 to October 2011. In particular, we focused on detection of clonal spreading of resistant strains and on sequence modification of KPC-encoding plasmids, monitoring and updating the epidemic spreading for almost 3 years.

**Methods:** Non-repetitive Enterobacteriaceae isolates with an imipenem MIC  $\geq 1$  mg/L were identified by automated systems and collected from intensive care units, surgical and medical wards. The presence of ESBL and carbapenemase genes belonging to Ambler class A, B or D was assessed by PCR. Molecular typing of positive strains was performed by PFGE, MLST and ERIC-PCR. Plasmids conferring carbapenem resistance were extracted and compared by RFLP, southern blot and deep sequenced.

**Results:** The initial outbreak in 2009 of carbapenem-resistant strains was caused by KPC-positive *K. pneumoniae* strains mostly collected from intensive care units. In particular, KPC-3 was associated with ST258 and KPC-2 with ST147. Since the end of 2010, spreading of non-clonally related KPC-3/KPC-2-positive strains (ST37, ST527, ST512, ST554, ST307, ST510 and ST437) was observed in different wards, including general medical ones. All KPC-positive plasmids were collected and sequenced: we found two different plasmid backbones

encoding KPC-3 and one presenting KPC-2. In addition, most of the strains presented TEM-1, SHV-11/12 and OXA-9. Interestingly, four KPC-2 isolates were additionally positive for the metallo-beta-lactamase VIM-1.

**Conclusion:** Our data indicate that few KPC-positive plasmids have rapidly spread in our region with a worrisome highly efficient horizontal transfer. Importantly, carbapenem-resistant strains have not been confined to intensive care units, but have extended to medical wards as well, leading to involvement of the non-hospitalized population with subsequent dangerous community acquisition. Early identification of carbapenemase producers in clinical infections, also at the carriage state, is thus becoming mandatory to prevent and contain further resistance spreading.

#### P1198 Intestinal colonisation by imipenem-resistant Gram-negative bacilli in ICU patients

L. Armand-Lefevre\*, C. Angebault, F. Barbier, E. Hamelet, G. Defrance, E. Ruppe, R. Bronchard, A. El Mniai, R. Lepeule, J.C. Lucet, M. Wolff, P. Montravers, P. Plesiat, A. Andremont (Paris, Besançon, FR)

**Objectives:** The intestinal flora is a major reservoir of Gram negative bacilli potentially pathogenic for ICU patients. Their increasing resistance to cephalosporins leads to increase use of carbapenems. Here, we evaluated the intestinal carriage of Imipenem resistant Gram negative bacilli (IR-GNB) in ICU patients.

**Methods:** During a 6-month period, 523 consecutive ICU patients were screened for rectal IR-GNB colonization upon admission and weekly thereafter. Swabs were plated on Drigalski agar with imipenem E-test strips. MIC to carbapenems were determined in all GNB growing in the inhibition ellipse. Underlying resistance traits of IR-GNB were characterized. Genetic relatedness between IR-GNB was determined using the semi-automated repetitive-sequences-based PCR (rep-PCR) DiversiLab system® (Biomérieux). A case-control study was performed to identify risk factors for IR-GNB acquisition.

**Results:** IR-GNB colonization rate was 2.7% upon admission, increased to 5.6%, 15.1%, 29.7%, 36.8%, 44.7%, and reached 58.6% after 1–6 weeks of ICU stay, respectively. Overall, 56 IR-GNB were collected from 50 patients: 36 *P. aeruginosa*, 12 *S. maltophilia*, 3 *K. pneumoniae*, 2 *A. baumannii*, 1 *E. aerogenes*, 1 *E. cloacae* and 1 *H. alvei*. Imipenem resistance in *P. aeruginosa* was due to (i) an inactivation of the OprD gene alone (n = 19), associated with an overproduction of the MexAB efflux system (n = 6), a hyperexpression of AmpC (n = 6) or a GES-9 production (n = 1) or to (ii) a VIM-2 production (n = 4). Imipenem resistance in Enterobacteria was due to (i) hyperproduction of AmpC alone or with TEM-24 or SHV-12 or to (ii) DHA-1 (n = 2) or CTX-M-15 production, with porin loss. High genetic diversity was observed among the 56 IR-GNB, except for one clone of four VIM-2 producing *P. aeruginosa*, two DHA-1 producing *K. pneumoniae* and two *S. maltophilia* isolates with indistinguishable patterns. In multivariate analysis, the main risk factor for IR-GNB carriage was imipenem exposure with an increased link according to the duration of treatment: aOR = 5.9 (95% CI, 1.5–25.7) for 1–3 days and aOR = 7.8 (95% CI, 2.4–29.8) for >3 days.

**Conclusion:** Intestinal carriage of IR-GNB steadily increased over time. Imipenem resistance determinants were diverse. Exposure to imipenem was the major risk factor for IR-GNB colonization even after short exposure.

#### P1199 Antibiotic resistance trends of urinary ESBL-producing *E. coli* and *Klebsiella* spp. at a teaching hospital in Istanbul, 2004–2010

S. Akcay\*, A. Inan, N. Dosoglu, S. Cevan, D. Engin, S. Aksaray (Istanbul, TR)

**Objectives:** Urinary tract infections treatment has become more complex, not only because of an increasing bacterial resistance to fluoroquinolones, trimethoprim-sulfamethoxazole, or other standard

antibiotics, but also because of the emergence of ESBLs in Enterobacteriaceae. The aim of this study was to detect ESBL prevalence, antimicrobial resistant rates of *E. coli* and *Klebsiella* spp. in hospitalized patients and alterations in years.

**Methods:** This is a retrospective study conducted at a teaching hospital in Istanbul. From 2004 to 2010, we obtained a total of 12092 *E. coli* and 716 *Klebsiella* spp. strains from urine samples. Antibiotic susceptibilities of isolated strains were investigated by disk diffusion method according to CLSI criteria. ESBL production was examined with the double-disk synergy test.

**Results:** From 2004 to 2010 the prevalence of ESBL-producing *E. coli* increased from 5% to 12.2%. The prevalence of ESBL-producing *Klebsiella* spp. increased from 13% to 21.9%. Resistance to certain antibiotics of ESBL(+) *E. coli* was revealed as follows: 42.6%, 100% (p < 0.0001) for amoxicillin/clavulanic acid, 27.8%, 93% (p < 0.0001) for gentamicin, 1.8%, 14.1% (p = 0.004) for amikacin, 44.4%, 100% (p = 0.01) for ciprofloxacin, 27.8%, 72.4% (p < 0.0001) for levofloxacin, 27.8%, 100% (p < 0.0001) for trimethoprim/sulphamethoxazole and 7.4%, 17.2% (p = 0.05) for nitrofurantoin respectively. The resistance rates of ESBL(+) *Klebsiella* spp. were as follows: 60%, 100% (p < 0.0001) for amoxicillin/clavulanic acid, 20%, 64.8% (p < 0.0001) for gentamicin, 20%, 37.8% (p = 0.008) for amikacin, 40%, 91.8% (p < 0.0001) for ciprofloxacin, 20%, 81.4% (p < 0.0001) for levofloxacin, 20%, 100% (p < 0.0001) for trimethoprim/sulphamethoxazole and 20%, 29.7% for nitrofurantoin respectively. For ESBL(–) *E. coli* and *Klebsiella* spp. resistance to quinolones, trimethoprim/sulphamethoxazole decreased. Although nitrofurantoin resistance have increased in ESBL(–) *Klebsiella* spp.; it has decreased for ESBL(–) *E. coli* in years. None of the strains were resistant to carbapenems.

**Conclusion:** The prevalence of ESBL(+) organisms in our hospital was high. Over a time period of 7 years significant changes in the antibiotic resistance of ESBL(+) *E. coli* and *Klebsiella* spp. were observed. A high resistance rate was seen for fluoroquinolones, trimethoprim/sulphamethoxazole and amoxicillin/clavulanic acid.

#### P1200 The trend of selected antimicrobial-resistant pathogens in a tertiary care hospital, Istanbul

T. Haznedaroglu, V. Turhan\*, M. Özyurt, B. Bektöre, O. Baylan, O. Öncül, L. Görenek (Istanbul, TR)

**Background:** The objective of the present study was to analyse secular trends in antimicrobial resistant bacteria (ARB) from a tertiary care hospital from Istanbul-TR.

**Methods:** ARB identified from patients in the ICU with nosocomial infections. For each antimicrobial/pathogen pairs; the pooled mean rate of resistance for January through December of 2003–2010 was recorded and documented. The number of special antimicrobial/pathogens detected along the years of 2003–2010 was analysed and increase (or decrease) in the resistance rates during the 2010 compared with previous 8 years.

Fig. 1 Antibiotic resistance rates among selected pathogens associated with health care related infections in medical ICU and surgical ICU patients, comparing the periods 01 January through 31 December 2010 to 2003 through 2009. MRSA, Methicillin-resistant *Staphylococcus aureus*; MRSE, Methicillin-resistant coagulase-negative staphylococci; MSSA, Methicillin-sensitive *Staphylococcus aureus*; MRSA, Methicillin-resistant *Staphylococcus aureus*; MRSE, Methicillin-resistant coagulase-negative staphylococci; MSSA, Methicillin-sensitive *Staphylococcus aureus*. The percentage increase in resistance rate calculated as (2010 rate - mean rate in 2003-2009) / mean rate in 2003-2009 x 100.

**Results:** The rate of the carbapenem resistant *A. baumannii* (CRAB) was detected very high as well as 81.3% at the year of 2010. There has been up to 61% increase in CRAB when compared with previous years. The rate of the third generation cephalosporin (TGC) resistant *K. pneumoniae* was detected as 45.2%. There has been a nearly 50.7% increase in nonsusceptible *K. pneumoniae* isolates to TGC according to the previous years. The rate of the TGC resistant *E. coli* was detected as 34.3%. There has been nearly 25.2% increase in non-susceptible *E. coli* isolates to TGC according to the previous years. Our clinical and laboratory based data showed the decreasing trend for MRSA. The year of 2010s data set showed a 22.9% reduction in MRSA rates.

**Conclusions:** There is a dangerous trend about ARB in our institution. Especially CRAB, TGC resistant *E. coli* and *P. aeruginosa* are the most important examples. This 8-year study in an institution showed a data of significantly increasing antibiotic resistant pathogens which is limiting the antimicrobial therapy options especially for ICU patients. Strict implementation of infection control policy including appropriate antimicrobial prescription and simple infection control measures are needed. Decreasing resistance trend of MRSA is another reality in our institution as well as widespread phenomenon in a lot of European country but it is difficult to explain this phenomenon at least at this moment.

**P1201** Activity and spectrum of antimicrobial coverage against pathogens collected from patients with hospital-acquired and ventilated-associated bacterial pneumonia in USA medical centres

H. Sader\*, R. Flamm, D. Farrell, R. Jones (North Liberty, US)

**Objective:** To evaluate the frequency of occurrence and antimicrobial susceptibility of bacterial organisms collected from patients with hospital-acquired (HABP) and ventilated-associated bacterial pneumonia (VABP) in USA hospitals. We also evaluated the expected empirical coverage for broad-spectrum antimicrobials alone and two drug combinations.

**Methods:** Organisms were consecutively collected from patients hospitalized with pneumonia in 65 hospitals from all USA nine Census regions in 2010–2011 directed by a common prevalence style protocol. Susceptibility testing was performed by reference CLSI broth microdilution methods.

**Results:** Two thousand six hundred and fifty-seven organisms were evaluated, 2187 from HABP and 470 from VABP. The proportion of Gram-negative/Gram-positive was nearly 60%/40%. 63.6% of patients were male and 36.4% female. The median age values were 57 and 54 for HABP and VABP, respectively. Overall, 53.1% of patients were from ICU, including 44.5% of patients with HABP and 83.9% of patients with VABP. The five most common organisms were (% of total for HABP/VABP): *S. aureus* (36.3%/33.4%), *P. aeruginosa* (20.8%/17.9%), *Klebsiella* spp. (10.1%/10.6%), *Enterobacter* spp. (5.5%/8.3%) and *E. coli* (5.5%/4.9%), and these accounted for 77.6% of the total. 47.1% of *S. aureus* were oxacillin-resistant (MRSA) and 30.1% of *P. aeruginosa* were non-susceptible to imipenem. Among *Klebsiella* spp., 12.6% had an ESBL phenotype and 1.5% of strains were non-susceptible to imipenem. None of the antimicrobials alone provided adequate spectrum against the five most common organisms as a group. The two drug combination with best coverage (susceptibility to at least one of the compounds) for the top five organisms was amikacin plus vancomycin (VAN) or linezolid (LZD); 98.6% coverage), gentamicin plus VAN or LZD (94.9%), meropenem plus VAN or LZD (93.0%) and cefepime plus VAN or LZD (90.4%). The 6th and 7th most frequently isolated organisms were *S. maltophilia* (4.0%) and *Acinetobacter* spp. (3.8%), and exhibited high resistance rates to all antimicrobial agents tested.

**Conclusion:** Empirical antimicrobial therapy for HABP/VABP requires at least two agents to provide adequate coverage for the most common organisms. The best antimicrobial coverage was obtained with the combination of an aminoglycoside (amikacin or gentamicin) with VAN or LZD.

**P1202** Carbapenem-resistant *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Acinetobacter baumannii* clinical isolates in a tertiary hospital

V. Papaioannou, S. Tsiplakou, A. Stylianakis\*, E. Chatziandreou, I. Papadakis, D. Argyris, P. Thomaidis, K. Mouta (Athens, GR)

**Objectives:** Carbapenemase-producing Gram-negative bacteria have increased substantially. The aim of this study was to evaluate carbapenem-resistant *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Acinetobacter baumannii* isolates derived from clinical samples in a tertiary hospital.

**Methods:** A total of 310 strains of *K. pneumoniae*, 224 of *P. aeruginosa* and 324 of *A. baumannii* were studied. Isolates were recovered from blood cultures, body fluids, catheters, pus, bronchial secretions and urine samples derived from hospitalized patients (ICUs and surgical and medical wards), during 1 year, from 1 November 2010 to 31 December 2011. One hundred and eighteen out of 310 *K. pneumoniae* isolates were recovered from ICU patients' samples while the number for *P. aeruginosa* isolates was 96 out of 224 and for *A. baumannii* 209 out of 324 respectively. All isolates had meropenem and/or imipenem MICs > 1 mg/mL. The identification and susceptibility testing was performed via the Vitek II automated system (Biomérieux, France), and when necessary susceptibility results were confirmed with the use of E-test strips (AB Biodisc, Sweden) according to CLSI guidelines. Metallo-beta-lactamase (MBL) production was evaluated using disks containing meropenem with and without EDTA and KPC-production with boronic acid combined-cisk tests, using disks containing meropenem with and without boronic acid.

**Results:** All isolates were multidrug resistant. *K. pneumoniae* isolates revealed 11% resistance to gentamicin, 8% to tigecycline and 40% to colistin. With reference to carbapenemase production, 61 isolates were producing MBL and the rest 249 were producing KPC. Seventy-five out of 310 *K. pneumoniae* isolates were recovered from blood samples. As for *P. aeruginosa* (38 out of 224 being recovered from blood samples), resistance to gentamicin was at 75%, and to colistin at 4%. One hundred and eighty-one out of 224 isolates were producing MBL. *A. baumannii* isolates (72 out of 324 being recovered from blood samples), revealed resistance to gentamicin at 58%, to tigecycline at 39% and to colistin at 2%.

**Conclusion:** It is of great importance to monitor the emergence and prevalence of carbapenem resistant Gram-negative bacteria depending not only on susceptibility testing but on phenotypic detection of carbapenemase production as well, in order to choose appropriate empiric therapy according to existing information and adjust individual antimicrobial chemotherapy when necessary.

**P1203** In vitro activity of fosfomicin in well characterised carbapenem-nonsusceptible *Pseudomonas aeruginosa* isolates recovered from 16 Spanish hospitals

M. Díez-Aguilar, M. García-Castillo, A. Oliver, R. del Campo, R. Cantón, M. Morosini\* (Madrid, Palma de Mallorca, ES)

Multiresistance in clinical *Pseudomonas aeruginosa* isolates is worrying, mainly in severe infections in which few options remain available. Fosfomicin, an inhibitor of peptidoglycan precursor's synthesis, shows no cross-resistance with other antimicrobials and may act synergistically with many antimicrobial compounds. Data suggest that IV fosfomicin can be used in combination to treat infections caused by multidrug-resistant *P. aeruginosa*.

**Objective:** The shortage of new antimicrobials constitutes a challenge that mandates the re-evaluation of existing compounds. With such an aim, fosfomicin MICs against a genetically unrelated collection of clinical carbapenem-non susceptible *P. aeruginosa* from 16 Spanish hospitals were evaluated.

**Methods:** Fosfomicin (FOS) MICs (agar dilution-CLSI; breakpoints-EUCAST) of 63 contemporary carbapenem-nonsusceptible *P. aeruginosa* isolates (16 Spanish hospitals, COMPACT Surveillance

Study) exhibiting 55 PFGE- and 37 MLST-different patterns, were determined. Carbapenem resistance mechanisms (molecular level) and co-resistances were addressed in a preceding study. Results were compared with those obtained in 151 carbapenem-susceptible isolates.

**Results:** A total of 33% of carbapenem-non susceptible isolates were fully susceptible to FOS (MIC  $\leq$  32 mg/L) while median MIC value was 64 mg/L. These figures almost entirely superimposed to that of EUCAST distribution for FOS-*P. aeruginosa* (<http://www.eucast.org>). All sequence types (STs), even the most represented (ST175, ST646, and ST532), were distributed along the whole range of MIC values (1–1024 mg/L). Consequently, the activity of FOS appears to be maintained against *P. aeruginosa* isolates irrespective of their carbapenem resistance status. This trait was reinforced as the same behavior of FOS was observed against the counterpart carbapenem-susceptible *P. aeruginosa* population recovered along the same cited study.

**Conclusion:** Difficult-to-treat infections caused by carbapenem-nonsusceptible *P. aeruginosa* (endocarditis, cystic fibrosis, foreign-body-associated infections) are communicated worldwide. Re-evaluation of already existing antimicrobials like FOS is constantly addressed due to scarcity of treatment options and results appear to be promising as synergy has been confirmed between FOS and betalactams, aminoglycosides and fluoroquinolones. Figures obtained in the present study reinforce the previous statements and warrants further research to confirm the utility of FOS.

**P1204** Impact of ertapenem utilisation on *Pseudomonas aeruginosa* susceptibility to imipenem. Trends in the last decade in a tertiary teaching hospital

D. Sousa\*, J.M. Gutierrez, F. Molina, B. Lopez, L. Carrajo, L. Castelo, E. Sanchez, E. Miguez, G. Bou, P. Linares (La Coruña, ES)

**Objectives:** We sought to determine the impact of ertapenem use on *Pseudomonas aeruginosa* susceptibility to imipenem and on hospital antimicrobial utilization.

**Methods:** Antimicrobial consumption was recorded monthly in defined daily doses (DDD)/100 patient-days from January 2002 to December 2010 in A Coruña Hospital, a tertiary teaching hospital in Spain. Ertapenem was introduced in January 2005. The incidence of susceptibility (CLSI criteria) of *Pseudomonas aeruginosa* to imipenem (proportion of imipenem-susceptible isolates/1000 patient-days) was evaluated. An interrupted time series with segmented regression analysis was performed to determine the change in *Pseudomonas aeruginosa* susceptibility to imipenem pre- and post-ertapenem introduction.

**Results:** During the whole period of study, we documented an imipenem mean consumption of  $3.05 \pm 0.87$  DDD/100 patient-days, of meropenem  $1.14 \pm 0.71$  DDD/100 patient-days and of ertapenem (after introduction)  $0.85 \pm 0.54$  DDD/100 patient-days. Ertapenem use rose steadily once adopted, with a mean of  $0.09 \pm 0.08$  DDD/100 patients-day in 2005 and a mean of  $1.41 \pm 0.20$  DDD/100 patient-day in year 2010 ( $r = 0.919$ ;  $p < 0.001$ ). There was also a steady increase of imipenem ( $r = 0.620$ ;  $p < 0.001$ ) and meropenem ( $r = 0.851$ ;  $p < 0.001$ ) over the study period. After introduction of ertapenem, there was a significant increase in median consumption of imipenem (before  $2.32 \pm 0.52$  vs.  $3.41 \pm 0.77$  after;  $p < 0.001$ ) and meropenem (before  $0.55 \pm 0.25$  vs.  $1.44 \pm 0.68$  after;  $p < 0.001$ ).

We evaluated a total of 5 343 *P. aeruginosa* isolates, of which 3 791 were susceptible to imipenem. Mean incidence of imipenem-susceptible *P. aeruginosa* was  $2.01 \pm 0.25$ . There was a positive correlation between ertapenem consumption and the incidence of imipenem-susceptible *P. aeruginosa* ( $r = 0.462$ ;  $p < 0.001$ ). No correlation was found with the use of Imipenem ( $r = -0.106$ ;  $p = 0.273$ ) or Meropenem ( $r = -0.031$ ;  $p = 0.750$ ). By segmented regression analysis, the susceptibility of *P. aeruginosa* to imipenem increased after the introduction of ertapenem. The increasing trend was significant (slope = 0.018;  $p < 0.001$ ) (Figure)

**Conclusions:** The overall carbapenem consumption steadily increased over the study period. Ertapenem use was associated with improved susceptibility of *P. aeruginosa* to imipenem.

**P1205** Rapid spread of OXA-23-positive *Acinetobacter baumannii* in Greece marking the end of OXA-58 predominance

A. Liakopoulos\*, A. Papaioannou, A. Spliopoulos, C. Konsolakis, S. Vourli, A. Velegraki, L. Zerva, C. Koutsia-Carouzou, I. Spiliopoulos, S. Tzouveleki, V. Miriagou, E. Petinaki (Larissa, Patras, Athens, GR)

**Objectives:** To study the spread of carbapenem-resistant *Acinetobacter baumannii* isolates, collected in Greece during 2011 and identify the respective carbapenemases.

**Methods:** A total of 143 randomly selected carbapenem-resistant *A. baumannii* isolates were included in the study. They were collected during 2011 from various clinical specimens (blood, bronchial secretions, pus, catheters) in four tertiary care hospitals located in Athens (2), Larisa (1) and Patra (1). Identification and susceptibility testing were performed with the Vitek-2 System (BioMerieux, France). Identification of blaOXA-58, blaOXA-23, blaVIM and blaIMP was carried out by PCR and sequencing. Molecular typing was performed by the three loci-sequencing typing scheme according to the protocol described in the *A. baumannii* ST website <http://www.hpa-bioinformatics.org.uk/AB/home.php>.

**Results:** The vast majority (88–98%) of *A. baumannii* isolated in the participating hospitals exhibited resistance to carbapenems. The isolates studied represented 20% of the total isolations. None of the isolates harboured metallo-beta-lactamase genes. One hundred one isolates (70.6%) were blaOXA-23 carriers. The remaining isolates were blaOXA-58-positive. The higher frequency of OXA-23 isolates was observed in Larisa and the lower in the Athens. Molecular typing showed that OXA-23-positive isolates belonged to either the ST101-European clone II or the ST201-European clone I. OXA-58-producers were classified into the ST106-European clone II and into ST201. One isolate of the OXA-58 group displayed a novel allelic profile (2-1-2).

**Conclusion:** Up to 2009, OXA-58 producers were predominant among carbapenem-resistant *A. baumannii* circulating in Greek hospitals. Data presented here indicate a relatively rapid change due to the dissemination of at least two distinct *A. baumannii* clones carrying the blaOXA-23 gene that had not been previously seen in this setting.

**P1206** First identification of colistin and tigecycline-resistant *Acinetobacter baumannii* producing KPC-3 carbapenemase in Portugal

C. Caneiras\*, F. Calisto, G. Da Silva, T. Amores, L. Lito, J. Melo Cristino, A. Duarte (Lisbon, Coimbra, PT)

**Objectives:** Nowadays the carbapenems resistance among *Acinetobacter baumannii* and *Klebsiella pneumoniae* are serious therapeutic and infection control challenge. The aim of this study was to analyse the clinical characteristics and to investigate the genetic basis of the carbapenem resistance of *K. pneumoniae* and *A. baumannii* clinical strains isolated from the same patient.

**Methods:** Antimicrobial susceptibility was determined by disk diffusion (amoxicillin/clavulanic acid, cefotaxime, ceftazidime, imipenem, meropenem, ciprofloxacin, gentamicin, tigecycline and colistin), and interpreted according to CLSI guidelines. The presence of blaTEM, blaSHV, blaCTX, blaKPC, blaIMP and blaVIM was screened by PCR using specific primers. Amplicons were sequenced and compared to sequences available in the GeneBank database.

**Results:** A female patient, with 35 years old, had renal insufficiency, being an immunocompromised host. She had been submitted to ciprofloxacin and meropenem therapy before the identification, in February 2011, of KPC-3 producing *Klebsiella pneumoniae*. *Acinetobacter baumannii* 86982FF was isolated in March 2011. Both isolates were recovered from sputum at surgical ward. *K. pneumoniae* showed susceptibility to colistin, intermediate susceptibility to ciprofloxacin and gentamicin, and resistance to the other antimicrobials, including tigecycline. *A. baumannii* was resistant to all studied antimicrobials and was identified a KPC-3 carbapenemase. The blaKPC-3 gene was part of a plasmid in both isolates and was included in transposon Tn4401.

**Conclusions:** We report for the first time the identification of multidrug-resistant *A. baumannii* producing KPC-3 carbapenemase in Portugal. The report of KPC-3-producing *A. baumannii* isolates is very worrisome, since these strains are resistant to all beta-lactam agents and to other antimicrobials, including colistin and tigecycline.

**P1207** Isolation of anaerobic bacteria and susceptibility pattern to antimicrobial agents from purulent specimens in a Greek hospital, 2008–2010

M. Orfanidou\*, T. Pitsia, T. Christacopoulou, G. Ganteris, E. Vagiakou, E. Malamou-Lada (Athens, GR)

**Objectives:** To study the occurrence of anaerobic bacteria isolated from purulent samples and their susceptibility to antibiotics, during a 3 year period, in a tertiary hospital of Athens

**Methods:** During the study period 499 anaerobic strains were isolated from 6313 purulent samples. The samples were cultured on appropriate media. The identification was performed by Gram staining, colony morphology, hemolysis, fluorescence, special potency antimicrobial agent disks and by the use of API rapid 32 A and Crystal ANA. MICs were determined by E-test method, according to CLSI instructions

**Results:** Out of 6313 purulent samples, submitted to the laboratory, bacteria were isolated in 4414 (70%) ones. Anaerobic bacteria were isolated from 419 purulent samples, which consisted a 6.6% of the total cultures and 9.5% of the positive cultures. Polymicrobial cultures were 355/419 (85%) and monomicrobial were 64/419 (15%). The infection origins of the samples were: soft tissue and extremities (181/419, 43%), head and neck (97/419, 23%), abdomen (65/419, 16%), surgical wound (63/419, 15%), genital track (13/419, 3%)

Out of 499 anaerobic isolated strains *Bacteroides fragilis* group was 34% (169/499), *Prevotella* spp. 33% (166/499), *Peptostreptococcus* spp. 11% (37/499), *Bacteroides* spp. non fragilis group 6% (30/499), *Fusobacterium* spp. 5% (27/499), *Clostridium* spp. 4% (18/499), *Propionibacterium acnes* 3% (17/499), *Porphyromonas* spp. 2% (10/499), others 1% (5/499)

*B. fragilis* group revealed resistance 13% to moxifloxacin, 12% to co-amoxiclav and 1% to meropenem. *Prevotella* spp. was 45% resistant to ampicillin, 33% to clindamycin, 3% to moxifloxacin, 0.7% to meropenem and 0.6% to co-amoxiclav. *Peptostreptococcus* spp. was resistant to clindamycin (16%) and penicillin (6%), while it was fully susceptible to moxifloxacin. None of the above strains appeared resistant to metronidazole.

**Conclusions:** Anaerobic infections are ~10% of positive purulent cultures. More than half of the anaerobes were isolated from soft tissue and head and neck infections. The most prevalent anaerobic species isolated were *B. fragilis* group and *Prevotella* spp. All strains were susceptible to metronidazole and with low resistance ratio to meropenem, which suggests a good alternative for empirical therapy in our hospital, in addition with co-amoxiclav and moxifloxacin for head and neck infections, where *Prevotella* spp. and *Peptostreptococcus* spp. were predominant.

**P1208** Reduced carbapenem susceptibility in the *Bacteroides fragilis* group – findings from the TEST programme 2007–2010

M. Hackel\*, S. Bouchillon, R. Badal, S. Hawser, D. Hoban, M. Dowzicky (Schaumburg, US; Epalinges, CH; Collegette, US)

**Background:** *Bacteroides fragilis* group organisms are important anaerobic co-pathogens in many polymicrobial infections. Reduced susceptibility to carbapenems in *B. fragilis* group is due primarily to the metallo-beta-lactamase CfiA gene (meropenem MICs 1–4) with high-level resistance secondary to acquired upstream insertion sequences (IS) causing expression of CfiA (MICs > 16).

**Methods:** The Tigecycline European Surveillance Trial (TEST) evaluated 164/1842 (8.9%) *B. fragilis* group organisms with reduced susceptibility to carbapenems (meropenem MIC  $\geq$  1 mg/L) from a collection of anaerobes spanning 4 years, 2007–2010. The isolates were identified to the species level at the participating sites and confirmed by a central laboratory. MICs were determined by the central laboratory using agar dilution according to CLSI guidelines.

**Results:** MIC<sub>90</sub> (mg/L)/% susceptible\* of *B. fragilis* group with meropenem MICs of  $\geq$ 1 mg/L by year (n/n total *B. fragilis* group isolates): \*EUCAST breakpoints used where available; CLSI breakpoint used for cefoxitin; FDA breakpoint used for tigecycline (Tygacil<sup>®</sup>, 2009).

	2007(40/506)	2008(33/430)	2009(45/541)	2010(46/365)
Tigecycline	2/100	4/97.0	2/97.8	4/93.5
Metronidazole	2/100	2/100	1/100	1/97.8
Pip-Tazo	16/80.0	32/84.9	64/77.8	32/78.3
Meropenem	8/70.0	8/54.6	>8/42.2	>8/52.2
Clindamycin	>8/65.0	>8/60.6	>8/64.4	>8/56.5
Cefoxitin	>32/52.5	>32/57.6	>32/55.6	>32/43.5

**Conclusions:** *B. fragilis* group isolates with reduced susceptibility to meropenem increased significantly between 2007 and 2010 ( $p < 0.05$ , Fisher's exact test). Greater than 93% of these isolates were susceptible to tigecycline and metronidazole, with no significant reduction in susceptibility for any of the compounds tested over the 4 years of analysis.

**P1209** An age analysis of the susceptibility of Gram-positive and Gram-negative pathogens from centres in the USA: TEST programme 2008–2010

D. Hoban\*, S. Hawser, M. Hackel, S. Bouchillon, B. Johnson, J. Johnson, M. Dowzicky (Schaumburg, US; Epalinges, CH; Collegette, US)

**Background:** Tigecycline has been shown to have potent broad spectrum activity against most commonly encountered species

responsible for community and hospital acquired infections. The Tigecycline Evaluation and Surveillance Trial (TEST) program determined the in vitro activity of tigecycline compared to most commonly prescribed broad spectrum antimicrobials against gram-negative and gram-positive species collected in the United States during 2008 to 2010. This report analyzes differences in susceptibilities in different age groups from this study.

**Methods:** A total of 12 852 clinical isolates from 131 cumulative United States testing sites were identified to the species level. Age groups are defined as Pediatrics: 0–17; Young Adult: 18–34; Adult: 35–64; and >65; Geriatrics. Minimum Inhibitory Concentrations (MICs) were determined by each site using supplied broth microdilution panels and interpreted according to CLSI/FDA guidelines.

**Results:** In general, tigecycline %S was very similar in the four age groups (pediatric, young adult, adult, and geriatric). Levofloxacin showed reduced activity against adult vs. pediatric isolates of *Acinetobacter* spp., Enterobacteriaceae, ESBLs, *Enterococcus* spp. and MRSA. *S. pneumoniae* penicillin susceptibility ranged from 63% for geriatric isolates to 60% for adults. All agents were active against *H. influenzae* and *S. agalactiae*.

**Conclusion:** Although many drugs showed little difference in activity among patient age groups, overall susceptibility levels were generally higher in the pediatric and young adult groups than in adults and geriatrics. Some of the problematic therapy issues seen in older patients (VRE, reduced fluoroquinolone efficacy) are not as prevalent in younger patients, while others (ESBLs, MRSA) can be found across all age groups. Although the effectiveness of tigecycline in patients <18 years of age has not been established, tigecycline in vitro activity in this study demonstrates potent activity against ESBL, MRSA and enterococci often associated with serious infections of the various age groups evaluated.

**P1210** Resistance phenotypes observed from amongst *Staphylococcus aureus* and pneumococci isolated from USA paediatric patients during the 2009 AWARE surveillance programme

K.M. Krause\*, D. Biek, R.N. Jones, H.S. Sader, I.A. Critchley (Oakland, North Liberty, US)

**Objectives:** Ceftaroline (CPT), the active form of CPT fosamil, is a new broad-spectrum cephalosporin with bactericidal activity against Gram-positive pathogens, including MRSA and penicillin-resistant pneumococci, as well as common Gram-negative pathogens. CPT fosamil is approved in the USA for treatment of adults with acute bacterial skin and skin structure infections or community-acquired bacterial pneumonia. The AWARE surveillance program is a global initiative that monitors susceptibility of key target pathogens to CPT and other clinically important antibacterials. This study analysed 2009 data for resistance (R) patterns among *S. aureus* (SA) and *S. pneumoniae* (SPN) by age.

**Methods:** Consecutive SA (n = 2311) and SPN (n = 1222) were collected from 52 sites from all nine USA census regions. Isolates were grouped by patient age (SA, SPN): ≤2 years (y) (n = 195, 170), 3–5 (n = 52, 82), 6–14 (n = 122, 94), 15–17 (n = 47, 14), 18–64 (n = 1232, 578), ≥65 (n = 663, 284). MICs were determined centrally by CLSI methods.

**Results:** MRSA rates were 42.3% (3–5 years) to 53.2% (15–17 years). Multidrug resistance (MDR; resistant to ≥2 classes) was most common in the very young and adults (50.4%) and least common in patients aged 3–17 years (38.5%). Nosocomial or community-acquired source was available for 1511/2311 SA. Within this subset, patients ≤2 (19%) and ≥18 (19.3%) y were ~3× more likely to have nosocomial infection than children and adolescents (7.2%). Levofloxacin R increased with age. CPT was consistently active (MIC90, 1 mg/L) against isolates from all age groups and resistant phenotypes.

PRSP rates were 0% in patients aged 15–17 years to 4.3% in 6–14 year-olds. MDR was most common in patients ≤14 years (50%), decreased to 21.4% in 15–17 year-olds, and was 26% in

adults. Amoxicillin-clavulanate R was most common in patients ≤2 years (30%) and decreased to 8.8% in patients ≥65 years. Ceftriaxone-R occurred in 5.9% of paediatric patients. Inverse correlations between age and resistance to clindamycin, tetracycline, and trimethoprim-sulfamethoxazole were noted. The CPT MIC90 was 0.25 mg/L against isolates across all age groups.

**Conclusion:** Observed R patterns suggest differences in profiles of SA and SPN isolated from US adult and paediatric patients during the 2009 AWARE Program. These differences possibly reflect antibiotic prescribing habits, frequency of hospital stay, and the use of the pneumococcal conjugate vaccine in the USA. CPT was consistently active against all isolates recovered in this study.

**P1211** Emergence of high-level mupirocin resistance in non-aureus staphylococci associated with increased mupirocin use

E. Bathoom\*, D.J. Hetem, J.G. Kusters, M.J.M. Bonten (Utrecht, NL)

**Background:** In our hospital, mupirocin has increasingly been used for eradication of nasal *S. aureus* carriage in patients scheduled for certain surgical procedures over the past 6 years. The target for mupirocin is isoleucyl transfer RNA synthetase (ileS). High-level resistance to mupirocin is conferred by acquisition of plasmids expressing a distinct ileS-gene (ileS-2).

**Objectives:** To assess the frequency of occurrence of high-level mupirocin resistance and look for a putative association with mupirocin use.

**Methods:** We assessed mupirocin resistance in Staphylococcal bloodstream isolates from 2006–2011, that had routinely been tested by Phoenix automated testing (PAT). In a sample survey, we evaluated reliability of PAT results using e-test in the first 40 consecutive non-aureus blood isolates of each year. Species determination was performed by maldi-TOF. We tested for presence of ileS-2 in the first 100 consecutive non-aureus bloodstream isolates of each year using RT-PCR. Data on mupirocin use was acquired from Utrecht Patient Oriented Database.

**Results:** High-level mupirocin resistance of non-aureus blood isolates increased from 13% in 2006 to 19% in 2011 (n = 2149, PAT results). Only two high-level mupirocin resistant *S. aureus* isolates were found. Sample survey (n = 237): Sensitivity and specificity of PAT to detect high-level mupirocin resistance was 0.97 and 0.97, respectively. Two isolates did not grow and PAT testing could not provide a result for one isolate. IleS-2 RT-PCR was performed on 598 isolates. In four phenotypically high-resistant ileS-2 RT-PCR was negative; three of these were *Rothia mucilaginosa*, *Kuceria* species, and *Micrococcus* species, known to be intrinsically resistant to mupirocin by other mechanisms than ileS-2. In three isolates ileS-2 was detected (all with C<sub>t</sub>-values <30), but were tested sensitive to mupirocin.

The yearly amount of mupirocin prescribed in our hospital increased from 3.6 kg in 2006 to 13.3 kg in 2010, and correlates with the increase in % non-aureus Staphylococci carrying ileS-2 (8% in 2006 to 22% in 2011; Spearman's rho 0.135, p = 0.01).

**Conclusion:** We observed a significant increase of high-level mupirocin resistant non-aureus Staphylococci, all linked to presence of ileS-2. This increase coincides with an increased use of mupirocin.

**P1212** A 5-year study of antimicrobial resistance of enterococcal isolates in a tertiary hospital

S. Tsiplakou, A. Stylianakis\*, V. Papaioannou, A. Panagopoulou, K. Ntetsika, I. Papadakis, D. Argyris, K. Mouta (Athens, GR)

**Objectives:** The aim of the present study was to assess resistance rates to various antimicrobials of *Enterococcus* sp. clinical isolates for a period of 5 years, and to characterize the mechanism of resistance to glycopeptides.

**Methods:** During a 5-year period, from 2006 to 2010, 846 *Enterococcus* isolates, one per patient, were collected from patients

hospitalized in different wards of our hospital. Enterococci were isolated from 185 blood, 340 pus, and 321 urine cultures. Identification and susceptibility testing were performed using the Vitek 2 automated system (bioMérieux, France). The antimicrobials tested were ampicillin, penicillin, ciprofloxacin, levofloxacin, high-level gentamicin, linezolid, tigecyclin, vancomycin and teicoplanin. MICs for vancomycin and teicoplanin were confirmed by E-test (AB Biodisk, Sweden), according to CLSI guidelines. Further analysis of the vancomycin resistance genes (vanA, and vanB) was performed by sandwich hybridization (EVIGENE VRE detection kit, Statens Serum Institut, Denmark).

**Results:** Identification yielded 646 *E. faecalis*, 183 *E. faecium*, nine *E. casseliflavus*, five *E. avium*, and three *E. gallinarum*. *E. faecium* isolates showed the highest level of resistance to ampicillin (77%), penicillin (78%), ciprofloxacin (72%), levofloxacin (78%) and high-level gentamicin (38%), while rates for *E. faecalis* isolates were 12%, 22%, 41%, 39% and 47% for ampicillin, penicillin, ciprofloxacin and levofloxacin and high-level gentamicin respectively. Twelve *E. faecalis* isolates and three *E. faecium* isolates were resistant to linezolid (2%). Tigecycline was the most active antimicrobial, all isolates being susceptible. Fifty-seven (6.7%) enterococcal isolates were glycopeptide-resistant (GRE), including 11 of 646 (1.7%) *E. faecalis* isolates, and 46 of 183 (25%) *E. faecium* isolates, half of which derived from blood cultures. MIC values for vancomycin were 64 mg/L or higher and 32 mg/L or higher for teicoplanin. Genotypic analysis of the isolates yielded that all glycopeptide resistant enterococci possessed the vanA gene.

**Conclusion:** High levels of resistance were observed among *E. faecium* isolates that also exhibited significant resistance to glycopeptides. Both *E. faecalis* and *E. faecium* isolates showed low level resistance to linezolid. Tigecycline was the most active agent against *E. faecalis* and *E. faecium* including GRE. Antimicrobial resistance surveillance and prudent use of antibiotics is mandatory for the management of life-threatening infections.

#### PI213 Susceptibility of *Enterococcus* species including vancomycin-resistant phenotypes: Asia/Pacific, 2006–2010

D. Hoban\*, R. Badal, M. Hackel, S. Bouchillon, M. Dowzicky (Schaumburg, Collegetown, US)

**Background:** *Enterococcus faecium* and *E. faecalis* are significant pathogens both in community and hospital patients. The increasing prevalence of vancomycin-resistant *Enterococcus* spp. (VRE) worldwide dictates the continued monitoring of these phenotypes. The Tigecycline Evaluation and Surveillance Trial (TEST) has monitored the activity of tigecycline and comparators globally since 2004.

**Methods:** Forty-three sites in 10 Asia/Pacific countries collected 1004 *E. faecalis* and *E. faecium* isolates between 2006 and 2010. MICs were performed as specified by CLSI at each site using prepared broth microdilution panels and interpreted according to CLSI/FDA guidelines. Linear trends over time in % susceptible/resistant were assessed with the Cochran-Armitage test.

**Results:** In 2006–2010, two of 613 *E. faecalis* (0.3%) and 86 of 391 *E. faecium* (22%) were vancomycin-resistant. The overall VRE rate increased from 7% to 9% between 2006 and 2010, however this trend was not statistically significant ( $p > 0.05$ ). The in vitro activity of five agents are shown in the following table for 2006 and 2010 only, although the statistical test was applied to all 5 years studied.

Note: No statistically significant trends in % susceptible were found for any agents studied ( $p > 0.05$ ).

Drug	MIC <sub>50</sub> (mg/L) / % Susceptible					
	<i>E. faecalis</i>		<i>E. faecium</i>		VRE	
	2006	2010	2006	2010	2006	2010
Ampicillin	1/100	2/100	>16/11.5	>16/10.7	>16/0	>16/0
Levofloxacin	>32/62.5	32/72.0	>32/10.3	>32/5.4	>32/0	>32/0
Penicillin	4/100	4/98.8	>8/14.9	>8/10.7	>8/5.9	>8/0
Tigecycline	0.25/100	0.25/100	0.12/100	0.25/100	0.12/100	0.12/100

n	144	82	87	56	17	12

**Conclusions:** Tigecycline demonstrated potent in vitro activity against *E. faecalis* and *E. faecium* isolates including vancomycin-resistant phenotypes with 100% of isolates remaining susceptible in 2010 and an MIC<sub>90</sub> of 0.12–0.25 mg/L that was unchanged between 2006 and 2010.

#### PI214 Primary investigation of the virulence factors of vancomycin-resistant *Enterococcus faecium* in a tertiary-care hospital of Sichuan, China

Y. Deng, Z. Li, Y. Huang, Y. Xiao, C. He, Y. Xie, M. Kang\*, H. Fan (Chengdu, CN)

**Objective:** To analyze the phenotypic and molecular characterization of vancomycin-resistant *Enterococcus faecium* (VREFm) isolates, and figure out the potential association of the three virulence factors: enterococcal surface protein (esp); hyaluronidase (hyl); adhesin of collagen from *E. faecium* (acm) with the colonization or infection of *E. faecium*.

**Methods:** VREFm isolates (n = 45) from intestinal colonization of patients in Intensive Care Unit (ICU) had been screened by VRE chromogenic agar and identified by multiplex polymerase chain reaction (PCR) for the D-Ala-D-Ala ligase gene (ddl gene). Infective ampicillin-resistant vancomycin-susceptible *E. faecium* (VSEFm) isolates (n = 60) and infective VREFm isolates (n = 8) had been identified by Vitek II compact. Use E-test to detect the minimum inhibitory concentrations (MICs) of VREFm. The vancomycin-resistant genes and the virulence factors (hyl, esp, acm) were detected by PCR.

**Results:** Fifty-three VREFm strains (eight infective strains and 45 intestinal colonization strains) and 60 VSEFm strains over 1 year period were collected. Thirty-four VSEFm strains from blood, other 26 VSEFm strains from pleural fluid and CSF. All the 53 VREFm isolates harbored the vanA gene and exhibited the VanA phenotype. Thirty-seven of 45 (82.22%) intestinal colonization VREFm strains, all the eight clinical infective VREFm strains and 32 of 60 (53.33%) clinical infective VSEFm strains carried the esp gene. Twenty-one of 45 (46.67%) intestinal colonization VREFm strains, three of eight (37.5%) clinical infective VREFm strains and 17 of 60 (28.3%) clinical infective VSEFm strains carried the hyl gene. Forty-one of 45 (91.11%) intestinal colonization VREFm strains, six of eight (75%) clinical infective VREFm strains carried the acm gene, compared with 55% acm-positive in clinical infective VSEFm strains. In VREFm group, 21 of 24 (87.5%) hyl-positive strains carried the esp gene, however, in VSE group, only five of 17 (29.41%) hyl-positive strains carried the esp gene. In addition, the positive rate of acm gene in VSEFm strains from blood (32.35%) is much lower than that from the pleural fluid and CSF (84.62%).

**Conclusion:** Esp, hyl and acm are highly related to the infection of *E. faecium*. Especially for VREFm, the esp and acm gene are more related to its infection or colonization than hyl gene. A further research will be carry out to confirm whether esp can help the *E. faecium* resistant to antibiotic in hyl-positive strains and whether acm can help the *E. faecium* invading the serous cavity.

#### PI215 Vancomycin MICs compared between MRSA and MSSA in nine countries

R. Reynolds\*, R.N. Jones, M.G. Stilwell, G. Zhanel, R. Hope and BSAC Working Party on Resistance Surveillance

**Objective:** Raised vancomycin (VAN) MICs in nominally susceptible *S. aureus* are suspected of contributing to less successful clinical outcomes. We reported previously that MICs were slightly, but significantly and consistently, lower for MRSA than MSSA in the UK and Ireland. We extended our focus to eight other countries to test the generality of this surprising result.

**Methods:** The SENTRY, CANWARD and BSAC resistance surveillance programmes contributed data on 33 978 *Staphylococcus aureus* (31 181 from blood) collected between 2001 and 2010. VAN

MICs were measured by the CLSI broth microdilution or BSAC agar dilution method. Data for the UK and Ireland were combined and counted as one country. Comparison of unimodal MIC distributions was by interval regression of  $\log_2$  MIC.

**Results:** SENTRY data for the UK and Ireland confirmed the BSAC observation of slightly but significantly lower VAN MICs for MRSA, but this was unique among the countries studied. Seven showed higher MICs for MRSA, statistically significant in six, while Germany showed no difference. These differences in MIC were small (up to 1.15-fold increase in geometric mean), but were generally consistent across years. The US results were replicated consistently in each of four census regions (West, MidWest, NorthEast and South). In all countries except the UK and Ireland, VAN MICs of 2 mg/L ("raised but susceptible") were significantly more common in MRSA than MSSA, generally seen for 3–10% of isolates vs. 1–4%. Only 16 of 33 978 isolates (0.05%) were nominally non-susceptible to vancomycin, all with MIC of 4 mg/L.

Country	No. of isolates		Geometric mean MIC, mg/L			% with MIC $\geq$ 2mg/L		
	MSSA	MRSA	MSSA	MRSA	P	MSSA	MRSA	P
Australia <sup>1</sup>	739	206	1.00	1.12	0.002	3	22	<0.001
Brazil <sup>1</sup>	1354	730	0.93	1.00	<0.001	4	8	<0.001
Canada <sup>2</sup>	3518	1110	0.87	0.94	<0.001	1	3	<0.001
France <sup>1</sup>	1797	658	0.89	0.99	<0.001	1	7	<0.001
Germany <sup>1</sup>	1390	273	0.86	0.85	0.88	1	5	<0.001
Italy <sup>1</sup>	556	343	0.87	0.94	0.16	1	10	<0.001
Spain <sup>1</sup>	675	170	0.88	0.98	0.011	1	5	<0.001
UK & Ireland <sup>1</sup>	1263	866	0.88	0.66	<0.001	2	3	0.17
UK & Ireland <sup>2</sup>	2094	1027	1.32	1.13	<0.001	42	23	<0.001
USA <sup>1</sup>	8086	7123	0.89	0.96	<0.001	2	6	<0.001

<sup>1</sup>SENTRY (2001–2010, blood, CLSI broth, <sup>†</sup>not 2005). <sup>2</sup>CANWARD (2007–2010, blood & other sources, CLSI broth). <sup>3</sup>BSAC (2001–2010, blood, BSAC agar dilution).  
Note: MICs for UK/Ireland are 1.6-fold higher in BSAC (agar) study than SENTRY (broth)

**Conclusion:** Frank vancomycin non-susceptibility (MIC  $\geq$  4 mg/L) is extremely rare in these nine countries (0.05%). Subtle differences in MICs between MRSA and MSSA exist and differ between countries; they may depend on clonal composition of local *S. aureus* populations. Their clinical significance remains uncertain.

#### P1216 Susceptibility of routine MRSA isolates to a series of antibiotics in the Netherlands

T. Bosch\*, A. Nijmeijer, M.E.O.C. Heck, H.A. Bijlmer (Bilthoven, NL)

**Objective:** Methicillin-resistant *Staphylococcus aureus* (MRSA) is a pathogen that is associated with serious infections. In The Netherlands, the incidence of MRSA infections remains low due to the restricted use of antibiotics. Although The Netherlands has a successful surveillance system for typing MRSA, very little is known about the incidence of resistance to antibiotics other than methicillin in these isolates. Therefore, susceptibility to a series of antibiotics was tested for randomly chosen MRSA isolates to investigate the susceptibility of these isolates and compare these results with our typing data.

**Methods:** A total of 249 *S. aureus* isolates from our national MRSA surveillance were used in this study. All isolates were typed with multiple-locus variable number of tandem repeat analysis (MLVA). Susceptibility was tested for; cefuroxime, ciprofloxacin, clindamycin, erythromycin, gentamicin, meropenem, mupirocin, oxacillin, rifampicin, tetracycline, tigecycline and vancomycin. The isolates were tested according to the EUCAST criteria.

**Results:** All 249 isolates were resistant against to at least one antibiotic and resistance was found against all antibiotics except for tigecycline and vancomycin. Most isolates (86, 35%) were resistant to four antibiotics. Six isolates (2%) showed the broadest resistance (eight antibiotics). Most resistance was found against gentamicin (243 isolates, 98%) and oxacillin (222, 89%). Resistance was also found against cefuroxime (222, 89%), erythromycin (121, 49%), tetracycline (112, 45%), ciprofloxacin (96, 39%), clindamycin (67, 27%), meropenem (27, 11%), mupirocin (18, 7%) and rifampicin (2, 1%). MLVA-typing resulted in 225 complete MLVA-profiles. MLVA complex (MC) 398 was predominant with 76 (34%) isolates, followed by MC5 (37, 16%) and MC8 (28, 12%). No correlations were found

between MLVA-typing results and the presence of antibiotic resistance, except for the presence of tetracycline resistance among MC398 isolates.

**Conclusion:** Our results show that most *S. aureus* isolates are resistant to four or more antibiotics and resistance levels to some antibiotics were 89% and higher. Only tigecycline and vancomycin had a 100% sensitivity rate. These results show that, despite the restricted use of antibiotics, antibiotic resistance among *S. aureus* isolates is widely present in The Netherlands and that a good surveillance system is necessary to monitor possible changes in antibiotic resistance in the future.

#### P1217 Activity of vancomycin, linezolid and daptomycin against staphylococci and enterococci isolated in Greek hospitals, 2008–2010

I. Spiliopoulou, Z. Florou, M. Papadimitriou-Olivgeris\*, M. Economou, E. Drougka, K. Ziva, N. Giormezis, E. Petinaki (Patras, Larissa, Athens, GR)

**Objectives:** Evaluation of the activity of vancomycin, linezolid and daptomycin against staphylococci and enterococci collected from three tertiary Greek hospitals (Central and Southwestern Greece) from 2008 to 2010.

**Methods:** A total of 1052 staphylococci (831 *Staphylococcus aureus* and 221 Coagulase Negative Staphylococci, CNS) and 553 enterococci (353 *Enterococcus faecalis* and 200 *E. faecium*) recovered from clinically significant specimens (blood, urine, pus, etc) were included. Identification and susceptibility testing was performed using the automated Vitek 2 System (bioMérieux). Determination of MICs to linezolid, vancomycin and daptomycin was performed by Etest according to CLSI guidelines. Methicillin resistance among staphylococci and vancomycin resistance among enterococci were detected by PCR for *mecA* and *vanA/vanB* respectively.

**Results:** The majority of vancomycin-resistant enterococci (VRE: 287 isolates) were *E. faecium* (196 isolates, carrying *vanA* gene). Among *S. aureus* and CNS 512 and 166 were *mecA*-positive respectively (MRSA and MR-CNS). Table 1 represents the mean MIC values among the tested isolates. The mean MIC values did not differ significantly during the study period. Elevated MIC mean values of vancomycin were determined among MRSA and MR-CNS. The average values of linezolid MICs among MR-CNS differed among the participating hospitals (14.38, 7.95 and 1.5) corresponding to a variable number of linezolid-resistant isolates recovered from hospitalized patients.

Table 1. Mean values of MICs of vancomycin, linezolid and daptomycin among enterococci (VRE: vancomycin-resistant enterococci), staphylococci (MSSA, methicillin-sensitive *S. aureus*; MRSA, methicillin-resistant *S. aureus*; MR-CNS: methicillin-resistant coagulase-negative staphylococci; MR-CNS: methicillin-resistant coagulase-negative staphylococci).

Year	Vancomycin						Linezolid						Daptomycin					
	VRE	VRE	MSSA	MRSA	MR-CNS	MR-CNS	VRE	VRE	MSSA	MRSA	MR-CNS	MR-CNS	VRE	VRE	MSSA	MRSA	MR-CNS	MR-CNS
2008	2.00	2.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
2009	2.00	2.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
2010	2.00	2.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00

**Conclusions:** Daptomycin remains active against the majority of Gram-positive cocci isolated in Greek clinical settings. The elevated levels of MICs to vancomycin among staphylococci above the therapeutic limit of the antibiotic, renders often this drug inactive. Additionally the detection of linezolid-resistant isolates, reflecting the differences in antibiotic usage in the participating hospitals, emphasizes the need of the development a drugs' restriction policy.

#### P1218 Continued decline of macrolide-resistant *Streptococcus pyogenes* in Portugal

C. Silva-Costa\*, M. Ramirez, J. Melo-Cristino (Lisbon, PT)

**Objectives:** In Portugal, we noted a steady decrease in macrolide resistance among *Streptococcus pyogenes* (GAS) causing pharyngitis in 1999–2006, accompanied by large fluctuations of the macrolide

resistance phenotypes, and changes in the clonal composition of the population. To establish if these have continued, we characterized the isolates recovered in 2007–2009.

**Methods:** Antimicrobial susceptibility testing and macrolide resistance phenotype were determined by disk diffusion. All macrolide-resistant isolates were further characterized. Macrolide resistance genotype was determined by PCR. A combination of T typing, emm typing and pulsed-field gel electrophoresis profiling (PFGE) was used to identify clones.

**Results:** During the 3 years of the study, the overall rate of erythromycin resistance was 6.8% (n = 106), much lower than the one reported in the previous period. A continuous decline in macrolide resistance was noted (12.4% in 2006 to 3.3% in 2009,  $p < 0.001$ , Cochran-Armitage test) and this was accompanied by fluctuations in the prevalence of the macrolide resistance phenotypes. PFGE identified seven major lineages, containing 79 isolates (78.2%), each exclusively associated with a single macrolide resistance phenotype. Two major clones were found among MLSB isolates characterized by T11/emm11 and T12/emm22 whereas among M isolates three clones were identified, characterized by T1/emm1, T4/emm4 and T25/emm75, including each approximately the same number of isolates. All clones identified had already been found in Portugal, but these changed in prevalence during the study period.

**Conclusion:** The decline in macrolide resistance among GAS causing pharyngitis in Portugal continued in 2007–2009, despite high macrolide use. Although the reasons behind these changes remain unidentified, they were accompanied by alterations in the prevalence of the resistance phenotypes and of the clonal composition of the population.

#### **P1219** Antimicrobial resistance prevalence at the United Kingdom's first academic health science centre

*L.S.P. Moore\*, C.P. Thomas, E. Brannigan, A.H. Holmes (London, UK)*

**Objective:** To examine current bacterial resistance rates from two central London hospitals, a multisite renal unit and surrounding community 4 years after becoming part of the first UK AHSC.

**Method:** Imperial College Healthcare NHS Trust supplies microbiology services to five central London hospitals, a multisite renal unit in North West London and additionally to primary care practices across this area. Infection advice is provided by an integrated team of infection specialists with an established antimicrobial policy. Laboratory operating procedures are uniform for samples received from two of these hospitals and from the renal sites and community samples. The laboratory information management system was interrogated for these four subsets of the AHSC for all susceptibilities performed in a 1 year period from March 2010 to February 2011 providing 502 315 antibiograms. Sub group analysis for resistance rates in high intensity (level 2 and level 3 care) vs. low intensity areas (level 0 and level 1 care) were calculated for each hospital and the renal unit and compared to that in the community. Resistance rates were identified for AmpC and ESBL producing Enterobacteriaceae, glycopeptide resistant enterococci and *Pseudomonas aeruginosa*.

**Results:** We find that in North West London there are significant variations in resistance rates between geographically close units. Of 20 142 Enterobacteriaceae isolates we find 9.4% of isolates from the community display ESBL/AmpC phenotypes, rising to 22.4–25.6% ( $p = 0.173$ ) in low intensity inpatient areas and 28.1–56.5% ( $p < 0.001$ ) in high intensity areas. Of 5277 enterococci isolates we find community GRE rates of 0.5%, with 7.7–17.3% 9 ( $p = 0.005$ ) in low intensity inpatient areas and 34.5–59.5% ( $p < 0.001$ ) in high intensity areas. Of 3777 *Pseudomonas aeruginosa* isolates we find carbapenem resistance in the community of 3.2%, with rates from 7.1% to 9.8% ( $p = 0.370$ ) in low intensity inpatient areas and 19.7–34.7% ( $p = 0.005$ ) in high intensity areas.

**Conclusion:** Despite unified antimicrobial and infection control policies, standardised laboratory practice and integrated infection specialists there is significant variation in antimicrobial resistance between high intensity areas within the AHSC. Variations in antimicrobial use and specific clinical drivers of second and third line antimicrobial therapies must be considered as causative factors and may warrant unit specific policies allowing for these variabilities.

#### **P1220** National MRSA rates run along with fair play – European championship 2008

*E. Meyer\*, P. Gastmeier, F. Schwab (Berlin, DE)*

**Objective:** To assess the relationship between national MRSA rates and indicators for fair play in the European Football Championship 2008.

**Methods:** National MRSA rates were retrieved from the European Resistance Surveillance System (EARSS) in 2008. All teams which qualified for the final tournament and had reported data to EARSS were included in the analysis. Hosting countries were excluded. The number of yellow and red cards was calculated per 100 min as an indicator for fair play. Red cards were weighted like yellow cards. MRSA rates and the fair play indicator were calculated by Spearman correlation index and p-value was set  $< 0.05$ .

**Results:** In 2008, 16 countries qualified for the European Football Championship. Five countries (Turkey, Switzerland, Croatia, Russia and Austria) did not contribute MRSA rates to EARSS and/or were hosting countries. MRSA rates, entire playing time and number of cards are listed in the Table 1.

Correlation was highly significant ( $p = 0.038$ ) with a correlation coefficient of 0.632.

	MRSA%	entire playing time	red cards	yellow cards	cards/ 100 min
Czech Republic	14.6	270		4	1.48
France	22.8	270	1	7	2.96
Germany	18.4	540	1	7	1.48
Greece	40.4	270		8	2.96
Italy	37.4	390		9	2.31
Netherlands	1.0	300		5	1.67
Poland	20.2	270		7	2.59
Portugal	49.1	360		8	2.22
Romania	34.4	270		7	2.59
Spain	26.0	480		8	1.67
Sweden	1.0	270		3	1.11

**Conclusion:** Demographic and socioeconomic factors as well as safety culture are known to influence the MRSA situation. Other socio-psychological factors used to measure non-adherence with MRSA guidelines are scarce. Interestingly, indicators for fair play in the European national football correlated highly with national MRSA rates: Sweden and the Nederland played the fairest and had the lowest MRSA rates. It remains to be proven (e.g. in the Championship 2012) whether this factor indeed can serve as an indicator for adherence with MRSA guidelines or whether this correlation cannot be substantiated.

#### **P1221** ABSTRACT WITHDRAWN

## Highlights of the molecular bases of antimicrobial resistance in Enterobacteriaceae

### P1222 Efflux inhibitors induce ramA expression

A.J. Lawler\*, V. Ricci, L.J.V. Piddock (Birmingham, UK)

**Objectives:** The aim of this work was to identify compounds that influenced the expression of ramA, which encodes RamA, a regulator of the AcrAB-TolC efflux pump in *Salmonella enterica* serovar Typhimurium (SL1344). AcrAB-TolC is the major efflux pump in Enterobacteriaceae, and exports a wide range of substrates. One of the physiological functions of this pump is export of chemicals which are toxic to the bacterium. It was hypothesised that increased expression of acrAB and/or tolC could be via induction of ramA in response to hostile environments. As over-expression of AcrAB-TolC can lead to multidrug resistance (MDR), increased production, via the induction of ramA, could also lead to transient MDR.

**Methods:** The promoter of ramA was fused to gfp on the reporter plasmid pMW82. The GFP is unstable and so allows changes in expression to be measured via fluorescence. The ramA reporter plasmid was transformed into SL1344 and assays were carried out using a 96 well plate format. The response of ramA to sub-MIC of different antibiotic classes, biocides and efflux inhibitors (EIs) was determined.

**Results:** The efflux inhibitor (EI) PAbetaN, a competitive inhibitor of AcrB, caused a two fold increase in fluorescence. A similar increase was also observed with another EI, CCCP; which disrupts the proton motive force required for functional efflux. The greatest increase in fluorescence achieved was in response to chlorpromazine (CPZ), a compound with EI-like activity. At 50 µg/mL of CPZ a 6.3 fold increase in GFP fluorescence was observed, however, of the six antibiotics tested, all of which are substrates of acrB, four caused no significant increase in expression. Chloramphenicol and ciprofloxacin caused a modest increase in fluorescence of 1.48 and 1.18 fold, respectively.

**Conclusions:** Our data demonstrated that in this system compounds which act as EIs increased ramA expression. Antibiotics belonging to a number of classes had minimal or no influence on the level of ramA. This work was funded by MRC grant No G0801977.

### P1223 MDR efflux pumps have overlapping and distinct roles in antibiotic resistance and virulence

J.M.A. Blair\*, A.M. Bailey, H.E. Smith, L.J. Thompson, A.J. Lawler, L.J.V. Piddock (Birmingham, UK)

**Objectives:** Antibiotic efflux is responsible for the intrinsic resistance of Gram-negative bacteria to many classes of antibiotics and biocides. *Salmonella* have several efflux pumps system of which AcrB mediates clinically relevant levels of resistance. The aim of this study was to investigate whether the roles of these efflux pumps overlapped or were distinct.

**Methods:** *S. enterica* mutants lacking combinations of efflux genes were constructed. The transcriptome of mutants lacking AcrB, AcrD or AcrF were studied using the Pan-Salmonella Generation IV array (Wellcome Trust Sanger Institute). The phenotype of all single, double and triple mutants was determined by MIC testing, efflux assays and infection assays. Real time RT-PCR was used to study the transcription levels of the pump genes after inactivation of one or more homologous system.

**Results:** Inactivation of single RND pump genes, acrB, acrD or acrF, caused multiple changes in the transcriptome. As shown previously, genes required for virulence had decreased expression after acrB inactivation. Expression of virulence genes from SPI-1, 2 and 3 was also decreased in an acrD mutant. Strains lacking AcrB, AcrD, AcrF, or combinations thereof, all invaded human intestinal cells poorly showing that these efflux systems each have a distinct role in virulence. As previously shown, inactivation of

acrB caused multi-drug hypersusceptibility while inactivation of AcrD or AcrF alone had no effect on susceptibility to the drugs tested. However, strains lacking two or three efflux pump components became increasingly susceptible to antimicrobials and effluxed less Hoescht dye than strains with intact efflux systems. Real time RT-PCR showed that transcription levels of efflux pump genes were adapted to compensate for loss of other efflux pumps.

**Conclusion:** AcrB, AcrD and AcrF have some overlapping functions because an increase in the transcription level of intact efflux pumps was able to partially compensate for loss of homologous systems. However, loss of any of the pumps inhibited the ability to invade host cells showing that up-regulation of other pumps cannot compensate for all the functions normally performed by other systems. These data are critical for the design of effective efflux pump inhibitors.

### P1224 Stress response and resistance of *Salmonella enterica* serotype Enteritidis to the efflux pump inhibitor neuroleptic drug thioridazine

G. Spengler\*, L. Rodrigues, M. Martins, M. McCusker, S. Santos Costa, E. Ntokou, Á.M. Szabó, Á. Horváth, Z.G. Varga, S. Fanning, J. Molnár, L. Amaral (Szeged, HU; Lisbon, PT; Dublin, IE; Larissa, GR)

**Introduction:** The main reason for problematic therapy lies in the variety of responses that *Salmonella* activates when in a noxious environment, rendering the organism quite resistant to most antibiotics. Multidrug resistant (MDR) phenotype of most clinical bacterial isolates is due to the over-expression of multidrug efflux pumps. Compounds that are efflux pump inhibitors (EPIs) reduce or reverse resistance to antibiotics to which the bacterial strain is initially resistant.

**Objectives:** In the present study, thioridazine (TZ)-induced accumulation of the universal efflux pump substrate ethidium bromide and its subsequent efflux by *Salmonella enterica* serotype Enteritidis strains was investigated under different physiological conditions.

**Methods:** Concentrations of TZ were evaluated for activity against over-expressed MDR efflux pumps of *Salmonella* strains with the aid of the automated ethidium bromide (EB) real-time fluorimetric method. The activity of genes that regulate and code for the AcrB transporter, was demonstrated by real-time reverse transcription quantitative polymerase chain reaction (RT-qPCR).

**Results:** *Salmonella enterica* serotype Enteritidis cultured in medium containing increasing concentrations of TZ does not grow during the first 6–8 h, after which time its growth is similar to unexposed controls. At the end of a 16-hour exposure period, the organism is resistant to >250 mg/L TZ. The TZ promoted increase of accumulation of EB that is followed by efflux may be the reason for the resistance of Salmonellae to this phenothiazine.

The genetic response against TZ treatment was assessed by real-time reverse transcription quantitative polymerase chain reaction (RT-qPCR) at periodic intervals. It is demonstrated that a sequence of activation beginning with the stress gene soxS, followed by the global regulator ramA, then by the local regulator marA and then by the transporter acrB which remains over-expressed by the end of the 16 h culturing period.

**Conclusions:** TZ seems to present an environmental challenge to the organism, namely TZ induces resistance to the agent as a consequence of the activation of genes that regulate and code for the main efflux pump AcrAB. Furthermore, TZ also activates the two-component regulon PmrA/B and because the activation of pmrA/B also activates acrB, the development of high resistance to TZ during a 16-hour culture period is in part due to activation of the two-component regulon.

### P1225 Genomic evolution of antibiotic resistance in *Salmonella enterica* serovar Typhimurium following biocide challenge

R.N. Whitehead\*, L.J.V. Piddock, M.J. Pallen, M.A. Webber (Birmingham, UK)

**Objectives:** Biocides are essential in preventing infection or microbial contamination in a range of environments. There are concerns that

biocide exposure is helping drive selection of antibiotic resistant bacteria due to common mechanisms of resistance. The aim of this study was to identify the genetic basis of antibiotic resistance in mutants selected after biocide exposure.

**Methods:** *S. Typhimurium* was challenged continuously for 5 days with four separate biocides with differing modes of action. Throughout the challenges, each population was sampled and screened for the emergence of antibiotic resistant mutants. Resistant mutants were characterised phenotypically and the genomes of four mutants from each biocide challenge were sequenced, mutations identified and investigated.

**Results:** The earliest mutants had appeared by the second sub-culture in some biocides but not until the fifth in others. The biocides Superkill and AQAS selected mutants that exhibited a low level multi-drug resistant phenotype consistent with de-repression of efflux pumps. Trigen selected mutants that were specifically resistant to high-levels of quinolones and triclosan.

Genome sequencing identified a ramR mutation in the mutants isolated from Superkill and AQAS, consistent with the low-level MDR phenotype. Mutations within both *gyrA* and *fabI* were present in mutants isolated after exposure to Trigen; these mutations have previously been associated with quinolone/triclosan resistance respectively. Additional mutations were also consistently identified in *rpoA* from mutants isolated after exposure to AQAS and in *zur* in mutants recovered from the trigen challenge. These mutations have not previously been linked to drug resistance and suggest new roles for these genes in the regulation of multidrug resistance.

**Conclusions:** All biocides tested could select antibiotic resistant mutants however their propensity to do so differed. Some biocides selected resistance to specific antibiotics rather than generic multi-drug resistance. Next generation sequencing allowed us to identify genes involved in biocide-antibiotic cross resistance, some of which have been previously linked to drug resistance and some of which are novel. This knowledge will provide useful insights when designing new biocides or dictating policies to minimise selection of antibiotic resistant mutants.

**P1226** Characterisation of mechanisms of resistance and determination of plasmid incompatibility group of *E. coli* and *Salmonella* strains isolated from healthy food animals with decreased susceptibility to cefotaxime

V. Thomas, A. de Jong\*, P. Butty, K. Godinho, M. Vallé, P. Nordmann (Brussels, BE; Paris, FR)

**Objectives:** In a trans-European surveillance programme (European Antimicrobial Susceptibility Surveillance in Animals; EASSA), 4501 *Escherichia coli* isolates and 659 *Salmonella* spp. isolates have been recovered between 2002 and 2006 from cattle, pigs and chickens. Screening of this collection resulted in 116 *E. coli* isolates (MICs 0.5–>64 mg/L) and 19 *Salmonella* isolates (MICs 1–8 mg/L) showing decreased susceptibility or resistance to cefotaxime (CTX). The purpose of this study was to characterize the  $\beta$ -lactamases and to determine the plasmid incompatibility group (Inc) of plasmids encoding those resistance genes.

**Methods:** Whole-cell DNA of each isolate was used in standard PCR experiments with sets of primers designed for detection of class A or D  $\beta$ -lactamases and plasmid-mediated class C (AmpC) cephalosporinases. PCR products were sequenced for obtaining the entire sequence of each  $\beta$ -lactamase gene. Sequencing of the AmpC-type  $\beta$ -lactamase gene was also performed for the *E. coli* isolates without transferable  $\beta$ -lactamase genes. Plasmid identification was performed by extraction of plasmid DNA from transconjugants and amplification by PCR. Amplicons were subsequently sequenced and typing was confirmed by Southern blot hybridization.

**Results:** Overall, 90 of the 116 *E. coli* and three of the 19 *Salmonella* isolates investigated, exhibited plasmid-mediated ESBLs or AmpC (Table 1). For 26 strains (MICs 0.5–1 mg/L) penicillinases-, narrow-spectrum oxacillinase or outer-membrane permeability defect were

found. The vast majority of the ESBL producers were from chicken (90%) and from Spain and the Netherlands. All ESBLs, with the exception of few SHV enzymes, and plasmid mediated AmpC conferred resistance to CTX with MICs  $\geq$  4 mg/L. In most cases, ESBL genes were harboured on IncI1 plasmids and AmpC on IncA/C plasmids.

Bacterial species	Resistance mechanism	Animal species (number of isolates)			CTX MIC range (mg/L)	Plasmid Inc group
		Chicken	Pigs	Cattle		
<i>E. coli</i>	<b>ESBLs</b>					
	SHV-12	10	1	0	2-16	I1
	SHV-2a	2	0	0	1	nd
	TEM-52	12	0	0	4-32	I1 or neg
	CTX-M-1	9	0	0	16-64	I1
	CTX-M-2	9	0	0	$\geq$ 64	P
	CTX-M-14	8	0	0	4-32	neg
	CTX-M-9	2	0	0	4-8	F/P
	CTX-M-32	2	0	0	32	neg
	CTX-M-3, -51	2	0	0	4	neg
	<b>AmpC</b>					
	Plasmid-mediated	8	0	0	4-16	A/C
Non plasmid-mediated	14	6	5	1-8	nd	
<i>Salmonella</i> spp.	<b>ESBLs</b>					
	CTX-M-9	2	0	0	16	nd
	SHV-12	0	1	0	32	N

nd: not determined ; neg: no plasmid incompatibility group identified

**Conclusions:** Enterobacterial isolates with reduced susceptibility to cefotaxime were mainly recovered from poultry across the EU. High MIC values to cefotaxime were associated with ESBLs or AmpC cephalosporinases whereas low MICs values were associated penicillinases, oxacillinases or permeability defect. None of the identified ESBLs were of the CTX-M-15 type widely identified among human isolates.

**P1227** A mutation upstream of a chromosomal parMR locus is responsible for antibiotic resistance gene silencing in *Escherichia coli* 345-2

B. Humphrey, D. Walker, N.R. Thomson, V.I. Enne\* (Bristol, Cambridge, London, UK)

**Objectives:** We previously reported the naturally occurring silencing of antibiotic resistance genes encoded on the IncN plasmid pVE46 in *Escherichia coli* 345-2RifC, a wild-type strain of porcine origin. In affected isolates transcription of *aadA1*, *blaOXA-2*, *su11* and *tet(A)* was absent but intact wild-type genes were retained, following passage through the pig gut. The phenomenon was reversible at frequencies of approximately  $10^7$  and likely due to a mutation elsewhere on the genome of 345-2RifC. Here, we aim to identify the mutation responsible for transcriptional silencing.

**Methods:** The complete genome sequences of the wild-type *E. coli* 345-2RifC/pVE46, a strain with a silent phenotype, L5, and a revertant of L5 back to resistance were obtained by 454 sequencing. Sequence analysis was carried out using Artemis. Mutations were confirmed by PCR amplification followed by Sanger sequencing. Transcription was assessed by RT-PCR. The role of the parMR mutation in silencing was investigated by deleting the locus using a lambda red recombinase system.

**Results:** Whole genome coverage was obtained and revealed the genome of *E. coli* 345-2RifC to be 5.2 megabases in size. There were just two polymorphisms between 345-2RifC/pVE46 and the sequenced silent isolate, L5; an ACCA nucleotide substitution in the *tuf* gene and a TA mutation in the upstream region of a chromosomal parMR locus. The parMR mutation returned to the wild-type T in the revertant isolate. PCR amplification and

independent re-sequencing by Sanger sequencing was unable to reproduce the mutation in *tuf* whilst the mutation upstream of *parMR* was confirmed. *parMR* is believed to encode a type II plasmid partitioning system which has become embedded in the chromosome of *E. coli* 345-2RifC through insertion by the CP-933T phage. It is not related to the pVE46 plasmid. The expression of the *parR* and *parM* genes was approximately 10-fold higher in the silent isolate L5 than in 345-2RifC/pVE46. Deletion of the *parMR* locus in L5 obliterated the silencing phenotypes and restored the antibiotic resistance phenotype conferred by pVE46.

**Conclusion:** Up-regulation of a chromosomal *parMR* plasmid-partitioning locus, likely due to a point mutation in its upstream region, appears responsible for the silencing of antibiotic resistance genes on plasmid pVE46. The mechanism by which this occurs is as yet unknown, but other plasmid-partitioning genes have previously been implicated in transcriptional gene silencing.

**P1228** **In vivo selection of a complex mutant TEM allele (TEM-158) from an inhibitor-resistant TEM allele (TEM-35) producing *E. coli* strain**

H. Jacquier\*, G. Marcadé, E. Raffoux, J.L. Donay, G. Arlet, E. Cambau (Paris, FR)

**Objectives:** Many alleles of the penicillinase TEM-1 or TEM-2 were described so far in clinical isolates. Their spectrum of resistance varies with regard to point mutations in the *bla* sequence, with some mutations leading to extended spectrum beta-lactamase (ESBL) and others to inhibitor-resistant TEM (IRT). These IRT enzymes can broaden their spectrum to third generation cephalosporins by the occurrence of additional mutations: they are commonly referred to as “complex mutant TEM” or CMT. If many studies have shown that modifications of the spectrum of TEM-type enzymes is driven by antibiotic selection pressure, no study has ever described a CMT derived from an IRT by in vivo selection.

**Methods:** We describe the case of a patient hospitalized for an acute myeloid leukemia in the Haematology ward at Saint-Louis University Hospital in Paris. During hospitalisation, the patient was treated with ceftazidime for a bacteremia due to an *Escherichia coli* strain expressing an IRT phenotype (strain EC1). After 8 days of treatment, there was no clinical improvement and new blood cultures yielded a strain of *E. coli* with an IRT phenotype but with resistance extended to ceftazidime (strain EC2).

**Results:** ERIC-PCR analysis showed the clonality of the two strains. PCR-sequencing of the TEM allele from EC1 identified the mutations M69L and N276D, corresponding to the TEM-35 allele also known as IRT-4. TEM gene sequencing from EC2 identified the additional mutation R164S, which was previously reported for the TEM-158 allele already described as a CMT allele (CMT-9).

**Conclusions:** to our knowledge, this is the first report of in vivo selection of a complex mutant TEM allele from an inhibitor resistant TEM allele producing *E. coli* strain. This event occurred during a treatment with ceftazidime.

**P1229** **Carbapenem-hydrolysing GES-5-encoding gene on different plasmid types from a sewage treatment plant**

D. Girlich\*, L. Poirel, R. Szczepanowski, A. Schlüter, P. Nordmann (Le Kremlin Bicêtre FR; Münster, Bielefeld, DE)

**Objectives:** The aquatic environment may be considered as a reservoir for dissemination of antibiotic resistance determinants. Two plasmids, pRSB113 and pRSB115, conferring decreased susceptibility to carbapenems in *Pseudomonas* sp. were isolated from bacterial communities residing in the activated sludge compartment of a wastewater treatment plant in Germany. The aim of this work was to characterize the beta-lactamase resistance genes involved and to identify the genetic structures involved in their mobilization and expression.

**Methods:** *Pseudomonas* sp. B13 GFP1 was used as host for electroporation of plasmids recovered from bacteria of activated sludge. Plasmid DNA was extracted from two carbapenem-non-susceptible *Pseudomonas* sp. B13 GFP1 (pRSB113/pRSB115) transformants. A PCR-based approach was used with primers specific to seek for the most common carbapenemase genes. The genetic environment of the *bla*GES-5 gene was determined by using a primer-walking approach. Plasmid size was determined after extraction by the Kieser method. Direct transfer of the *bla*GES-5 determinant was attempted by conjugation and electroporation experiments in *Escherichia coli*.

**Results:** The *bla*GES-5 gene was identified on both pRSB113 and pRSB115 plasmids, in a form of a gene cassette of a class 1 integron. Beta-lactamase GES-5 is a point mutant derivative of the extended-spectrum beta-lactamase GES-1. In addition, to broad-spectrum cephalosporins, it hydrolyses cephamycins and carbapenems. The class 1 integrons were inserted in two distinct structures comprising transposase genes (IS1326 and a novel insertion sequence, named ISUnCu16), a mercuric operon, and a truncated gene of restriction/modification system (*pacR7IR*). The 30-, and 40-kb plasmids both replicated in *E. coli*, but were not self-transferable. Pairwise comparison of the amino acid sequence of RepA and MobA showed that pRSB113 and pRSB115 belonged to two distinct clades of the MobP plasmid family.

**Conclusion:** The *bla*GES-5 gene was identified on two different plasmids belonging to distinct incompatibility groups, that could replicate in both *Pseudomonas* sp. and *E. coli*, and that are mobilizable. This study emphasizes that aquatic environment may be the reservoir of clinically-significant carbapenemase genes.

**P1230** **Multidrug resistance IncHII plasmids carrying blaCTX-M-1 from equine *Escherichia coli* from the Czech Republic**

M. Dolejska\*, L. Villa, A. Carattoli (Brno, CZ; Rome, IT)

**Objective:** Plasmids of incompatibility group HII are important vectors of antibiotic resistance in *Salmonella Typhi* and *S. Paratyphi* A, the major causal agents of enteric fever.

It has been demonstrated that IncHII plasmids allow these pathogens to acquire genes available in the environment. We have previously described IncHII plasmids carrying *bla*CTX-M-1 gene in *Escherichia coli* isolates disseminated in an equine clinic in the Czech Republic (Dolejska et al. 2011, JAC 66:757–64). The aim of this study was to compare, by plasmid MLST (pMLST), four representative CTX-M-1-positive IncHII plasmids from *E. coli* isolated between 2008 and 2010 in the clinic with those found in *S. Typhi* and *S. Paratyphi* A and to perform complete sequencing of selected IncHII plasmids.

**Methods:** Three conjugative IncHII and one IncHII/X1 plasmids ranging 220–285 kb in size, harbouring *bla*CTX-M-1 were purified from *E. coli* transconjugants and compared by restriction fragment length polymorphism (RFLP) and pMLST. Complete nucleotide sequencing of one 220 kb IncHII and a fused 285 kb IncHII/X1 plasmid was performed by the 454-Genome Sequencer FLX procedure on a library constructed on plasmid DNA purified from the *E. coli* transconjugants.

**Results:** All plasmids showed closely related RFLP, identical pMLST profiles and nucleotide sequence homology. One plasmid showed a higher molecular weight because of the fusion with an IncX1 plasmid carrying the *qnrS1* plasmid mediated quinolone resistance (PMQR) gene. Five loci HCM1.043, HCM1.099, HCM1.116, HCM1.178ac, and HCM1.259 showed the allele 1 as also seen in IncHII plasmids of sequence types (ST) 1 and 2 found in *S. Typhi* and *S. Paratyphi*. The gene HCM1.064 coding RepHIIA replication initiation protein in equine isolates showed a new allele with 99.8% nucleotide similarity to previously described allele 2, establishing a new ST for these plasmids.

**Conclusion:** Our data show successful dissemination of *S. Typhi* and *S. Paratyphi* A IncHII plasmid variants to *E. coli* from animals. Up to date the IncHII plasmid type was only identified in *Salmonella* sp. and

lacked ESBL and PMQR genes. Our results show that these plasmids are rapidly evolving toward a larger antimicrobial gene content by mutation, acquisition of resistance determinants and plasmid fusion with other resistance plasmids.

This study was funded by FEMS Advanced Fellowship Grant 2011; Czech Science Foundation (P502/10/P083) and CEITEC (CZ.1.05/1.1.00/02.0068).

**P1231** Development during therapy of carbapenem resistance in *Salmonella enterica* serotype Typhimurium

L.-H. Su\*, T.-L. Wu, C.-H. Chiu (Taoyuan, TW)

**Objectives:** Multidrug-resistant *Salmonella* infection is a global problem and carbapenems may serve as the last therapeutic choice. The emergence of carbapenem resistance in *Salmonella*, therefore, represents a serious problem due to the lack of other therapeutic choices. Here we report the identification and characterization of a clinical isolate of carbapenem-resistant *Salmonella enterica* serotype Typhimurium.

**Methods:** Genetic relatedness of the isolates was analyzed by pulsed-field gel electrophoresis. PCR and sequencing were used to detect the presence of specific resistance genes. The expression and deficiency of outer membrane proteins (Omps) were studied by reverse-transcription (RT) PCR and DNA sequencing. Replicon and sequence types of the resistance plasmids were characterized by published methods.

**Results:** A patient with urinary tract infection was hospitalized for treatment. The urine culture yielded multi-resistant *S. Typhimurium* (U1) susceptible only to carbapenem. The patient was discharged after ertapenem therapy. Two months later, the patient was hospitalized again due to leg injury. The initial wound culture yielded ceftriaxone-resistant *Proteus mirabilis* and ertapenem was prescribed. Wound debridement was performed and the wound pus yielded *S. Typhimurium* (W1) showing the same antibiogram as those of the U1 strain. The patient developed diarrhoea during the therapy. The stool culture grew *S. Typhimurium* (S1) multiply resistant to all antibiotics including carbapenem. The patient was still on ertapenem therapy and was discharged after appropriate wound debridement. All isolates were found to have the same PFGE patterns and carried a blaCMY-2-containing, self-transferable IncII plasmid that belonged to the sequence type ST54. OmpD deficiency due to IS1 insertion at 88 bp upstream of the ompD gene was found among the isolates. In the carbapenem-resistant strain S1, OmpC deficiency through a point mutation, leading to amino acid change from tryptophan (TGG) to a stop codon (TGA) at codon 77, was further identified. No other known carbapenemases, including IMPs, KPCs, VIMs, and OXAs, could be identified from the carbapenem-resistant strain.

**Conclusion:** Development of OmpC deficiency in the OmpD-deficient, CMY-2-producing *S. Typhimurium* resulted in the carbapenem resistance. *Salmonella* appears very adaptive to antimicrobial selection pressure. Caution must be taken by physicians when treating multidrug-resistant *Salmonella* infection.

**P1232** ABSTRACT WITHDRAWN

**P1233** Occurrence of carbapenemase-producing Enterobacteriaceae in Sultanate of Oman

L. Dortet\*, L. Poirel, F. Alyaouqi, P. Nordmann (Le Kremlin Bicêtre, FR; Muscat, OM)

**Background:** Carbapenemase-producing Enterobacteriaceae are increasingly identified worldwide and represent a major public health

concern. The most clinically significant carbapenemases are KPC, IMP, VIM and more recently NDM and OXA-48.

**Methods:** Our study focused on a retrospective collection of enterobacterial isolates recovered at the Royal Hospital, Muscat, Sultanate of Oman. Twenty-two multidrug resistance Enterobacteriaceae (15 *Klebsiella pneumoniae*, five *Escherichia coli*, one *Citrobacter freundii*, one *Serratia marcescens*) isolated over a 5-month period (November 2010 to March 2011) were selected, all showing decreased susceptibility to carbapenems. The MICs were determined by Etest and PCR assays followed by sequencing were carried out for detection and identification of carbapenemase genes. Multi locus sequence typing (MLST) and pulsed-field electrophoresis (PGFE) were performed to evaluate the clonal relationship. Plasmids were isolated by mating-out assays and typed by PCR-based replicon typing (PBRT).

**Results:** Twelve non-clonally related carbapenemase-producing isolates were identified. Seven produced NDM-1 and four produced OXA-48. One *K. pneumoniae* isolate co-produced NDM-1 and OXA-181, which is a point-mutant derivative of OXA-48. With the exception of a single *K. pneumoniae* isolate that only expressed OXA-48, all other isolates co-produced an extended-spectrum beta-lactamase.

In all NDM-1 producers, the blaNDM-1 gene was plasmid-located and bracketed upstream by insertion sequence ISAbA125 (entire or partial) and downstream by the bleMBL gene encoding resistance to bleomycin.

In OXA-48 producers, the blaOXA-48 gene was always associated to insertion sequence IS1999. A single IncLM plasmid of ca. 62-kb was responsible for the acquisition of the blaOXA-48 gene among all OXA-48 producers, whereas the blaNDM-1 gene was identified on different plasmid backbones.

**Conclusions:** This study emphasizes the dissemination of carbapenemase-producing enterobacterial isolates in the Middle East and especially in Gulf countries where populations from the Indian subcontinent and North African countries (respectively important reservoirs of NDM-1 and OXA-48 producers) are important.

**P1234** Importation of OXA-48-producing and carbapenem-resistant *Klebsiella pneumoniae* from Kuwait to France

L. Poirel\*, E. Carbone, S. Bernabeu, L. Gutmann, P. Nordmann, L. Gutmann (Le Kremlin Bicêtre, Paris, FR)

**Objectives:** The aim of this study was to investigate the mechanisms responsible for carbapenem resistance in one *Klebsiella pneumoniae* isolate recovered from Kuwait.

**Methods:** The strain was first screened using primers designed to PCR amplify known carbapenemase genes. The genetic environment of the blaOXA-48 gene was studied by PCR combination using specific primers of IS1999 followed by sequencing. The plasmid scaffolds were typed by using primers specific for the blaOXA-48-bearing plasmid known to circulate in different countries.

**Results:** *K. pneumoniae* ALI was recovered from rectal swabs performed at the hospital entrance of a diabetic woman transferred from Kuwait to France. She had been amputated in Kuwait City from her left leg and was hospitalized in France for a prosthesis surgery. *K. pneumoniae* ALI was resistant in particular to piperacillin-tazobactam and carbapenems, with MICs of IMP, MER, ERT being at 32, 24, and >32 mg/L, respectively. It produced the class D carbapenemase OXA-48, together with a naturally-occurring narrow-spectrum class A  $\beta$ -lactamase SHV-28. Noteworthy, *K. pneumoniae* ALI did not produce any extended-spectrum beta-lactamase, and MICs of CAZ and CTX were at 2 and 4 mg/L, respectively. Plasmid analysis identified a ca. 62-kb plasmid, that does not harbor other resistance determinants and possessed the same genetic profile than blaOXA-48-positive plasmids identified in most OXA-48 producers.

**Discussion:** This study identified the first OXA-48 producer in the Gulf region, whereas carbapenemases of the VIM, NDM, and OXA-181 types had been already described. These findings extend the knowledge on the current diffusion of OXA-48 producers that now also includes the Arabic peninsula.

**P1235** Detection of *Acinetobacter baumannii* derived oxa-51 and oxa-58 carbapenemase genes in enteric bacteria: a new dimension on carbapenemase resistance

S. Budak, Z. Aktas\*, O. Oncul, A. Acar, M. Ozyurt, V. Turhan, L. Gorenek (Istanbul, TR)

**Objectives:** We investigated the occurrence of genes associated with the production of carbapenem hydrolysing carbapenemases in *Escherichia coli* and *Klebsiella pneumoniae* isolates recovered from two ICU patients.

**Methods:** Antimicrobial susceptibility testing was performed and resistance genes were characterized by PCR amplification and sequencing. The Modified Hodge Test (MHT), MBL E-test, EDTA and boronic acid combined disk diffusion method, and a disk enzymatic assay were performed for the screening of carbapenemases.

**Results:** For *K. pneumoniae*, MICs of carbapenems were as follows (mg/L) ertapenem 8, meropenem 1, imipenem 0.25 and doripenem 0.5. This isolate demonstrated positive results in the ESBL, EDTA and APBA combine tests, and disk enzymatic assay. PCR and sequencing revealed the presence of, blaOXA-51 and blaCTX-M-15 beta-lactamase genes. For *E. coli*, MICs of carbapenems were as follows (mg/L) ertapenem and meropenem 0.06, imipenem 2 and doripenem 0.25. *E. coli* strain showed positive results in the ESBL, MHT and disk enzymatic assay tests. PCR and sequencing revealed the presence of, blaOXA-58 and blaCTX-M-15 beta-lactamase genes. Plasmids from both strains were not transferred by conjugation to recipient *E. coli*. In conclusion, we report on the first detection of the OXA-51 and OXA-58 harboring *K. pneumoniae* and *E. coli* isolates and co-produced a CTX-M-15 beta-lactamase.

**P1236** Naturally – occurring metallo-beta-lactamases in *Erythrobacter* sp.

D. Girlich\*, L. Poirel, P. Nordmann (Le Kremlin Bicêtre, FR)

**Objectives:** In-silico analysis identified a metallo-beta-lactamase (MBL) in *Erythrobacter litoralis* HTCC2594, sharing 55% amino acid identity with NDM-1. *Erythrobacter* sp. are strict aerobic bacteria, most frequently found in nutrient-rich coastal seawaters. The aim of this work was to characterize the chromosomally-encoded MBL from several *Erythrobacter* species, that may represent potential reservoirs of acquired MBLs.

**Methods:** *Erythrobacter citreus*, *E. flavus*, *E. longus*, *E. aquimaris*, and *E. vulgaris* were from the collection strains. DNA was extracted and used as template for shotgun cloning experiments. Corresponding beta-lactamase genes were expressed in *E. coli*. Resulting recombinant strains *E. coli* (pCIT-1), *E. coli* (pFLA-1), *E. coli* (pLON-1), *E. coli* (pAQI-1), and *E. coli* (pVUL-1) were selected onto amoxicillin (50 µg/mL) and kanamycin (30 µg/mL) agar plates. MICs were determined by E-test. The deduced amino acid sequences were analyzed and compared with the BLASTP database. Enzymatic activity of bacterial extracts from recombinant *E. coli* strains was determined by UV spectrophotometry with imipenem (100 µM) as substrate.

**Results:** Sequencing of the inserts of the *E. coli* recombinant strains identified hypothetical MBL-encoding genes. MICs of beta-lactams showed a decreased susceptibility to carbapenems only for *E. coli* (pFLA-1) and *E. coli* (pLON-1), expressing the MBL from *E. flavus* and from *E. longus*, respectively. MBLs from other *Erythrobacter* species conferred resistance or reduced susceptibility to amino- and carboxypenicillins, to narrow- and broad-spectrum cephalosporins, but not to carbapenems. MBLs from these different *Erythrobacter* species shared a weak amino acid identity ranging from 45% to 75%. MBLs from these *Erythrobacter* species differed significantly from acquired MBLs, including NDM-1, VIM-1, IMP-1, sharing only 11–23% amino acid identity. Enzymatic activity against imipenem was detectable but weak in all these recombinant *E. coli* strains, except for *E. coli* (pFLA-1), in which the specific activity against imipenem was higher (90 nmol of imipenem hydrolyzed/min/mg of protein).

**Conclusion:** *Erythrobacter* species harbour chromosomally-encoded MBLs showing a wide diversity of amino acid sequences and surprisingly, only few of them exhibited significant carbapenemase activity. None of these species could be considered as a progenitor of any known plasmid-mediated carbapenemase disseminating worldwide.

**P1237** Description of IMP-31, a novel metallo-beta-lactamase very divergent from other known IMP carbapenemases

N. Pfennigwerth\*, S.G. Gatermann, M. Kaase (Bochum, DE)

**Introduction:** The worldwide increase of multidrug-resistance in gram-negative bacteria has become an important clinical challenge. Carbapenem resistance can be caused by a variety of mechanisms, however the worldwide spread of carbapenemases is especially important. A worrying trend is the dissemination of Ambler class B metallo-beta-lactamases (MBL). Here we describe a novel IMP-type MBL, IMP-31, that was found in an outbreak of multidrug resistant *P. aeruginosa* in Germany.

**Methods:** Susceptibility to antibiotics was determined by disk diffusion and Etest. The presence of a MBL was determined by EDTA combined-disc-tests, MBL Etest and by a bioassay based on cell-free extracts. A modified Hodge-Test was performed. PCRs and subsequent sequencing were performed for VIM, IMP, NDM, GIM, SIM, SPM, AIM, DIM and KHM. Clonal relatedness of the isolates was determined by RAPD-PCR and PFGE. Integron structures were analysed by PCR and sequencing. The IMP-31 encoding sequence was cloned into the pBK-CMV vector and transformed into *E. coli* DH5alpha for activity analysis. Localisation of the gene was determined by PFGE and Southern blotting.

**Results:** Clonally related strains from an outbreak of *P. aeruginosa* in Germany were sent to the National Reference Laboratory for Multidrug-resistant Bacteria for further characterisation. The isolates were resistant to piperacillin, piperacillin/tazobactam, ceftazidime, cefepime, aztreonam, imipenem, meropenem and doripenem as well as to gentamicin, tobramycin, amikacin, ciprofloxacin and levofloxacin. The modified Hodge-test was positive for imipenem, meropenem and ertapenem. The isolates showed synergy with EDTA in the combined disk test and the MBL Etest. A chromosomally integrated class I integron was identified, harbouring the IMP-31 gene, a OXA-10 gene and the gene for an aminoglycoside adenylyltransferase (aadA6). The sequence of IMP-31 showed only 85% homology with its closest relatives IMP-8 and IMP-24. It mediates resistance to all carbapenems and most other beta-lactams.

**Conclusion:** The strains harbour a novel IMP-type metallo-beta-lactamase very divergent to any other known IMP variant. Its closest relatives are IMP-8 and IMP-24 with 39 and 40 amino acid substitutions, respectively. Regarding the amount of mutations, it is likely that the source of IMP-31 is a so far unknown environmental bacterium and that it was mobilised quite recently as IMP-31 was only found in German isolates up to date.

**P1238** Characterisation of carbapenemase IMI-2 in *Enterobacter* spp. clinical isolates from France

S. Bernusset, T. Naas\*, D. Tandé, H. Biessy, L. Poirel, M. Henry, C. Cattoen, G. Cuzon, P. Nordmann (Le Kremlin Bicêtre, Brest, La Rochelle, Valenciennes, FR)

**Objectives:** The Ambler class A IMI carbapenemase was first described in 1996 in *E. cloacae* isolates. Three variants have been reported from clinical isolates but also from environment (US rivers) and are either chromosome- or plasmid-encoded. IMI enzymes remain rare in clinical practice. Here, we describe four clinical imipenem-resistant strains of *Enterobacter* spp. isolated between 2007 and 2011, in France.

**Methods:** Carbapenem-resistant *Enterobacter* spp. isolates were characterized by standard biochemical methods, RpoB sequencing,

disc diffusion susceptibility testing, and E-tests. Genes coding for beta-lactamases and the genetic structure surrounding bla<sub>IMI</sub> were sought by PCR and sequencing. Isolates were compared by PFGE, RAPD, Rep-PCR and by their plasmid content.

**Results:** Imipenem-resistant *E. asburiae* BRE-1, PAR-1 and ROC-1 were isolated from patients hospitalized for bone infection and for pneumoniae. Two of these patients had in common a recent contact with an aquatic source. A fourth imipenem-resistant strain of *Enterobacter cloacae*, VAL-1, was isolated from blood culture. These four isolates were identified in four different hospitals located in different French cities (400–1000 km apart from each other). All isolates were resistant to carbapenems but remained susceptible to extended-spectrum cephalosporins. Imipenem hydrolysis was detected in all isolates. A clavulanic acid-inhibited beta-lactamase IMI-1 was identified in VAL-1 and its variant IMI-2 was found in BRE-1, PAR-1 and ROC-1. The latest were genetically indistinguishable by RAPD and Rep-PCR analysis, but different from IMI-2-isolates of US rivers. The bla<sub>IMI-2</sub> gene was located on a self-transferable 90-kb plasmid, whereas bla<sub>IMI-1</sub> was chromosome-encoded. Plasmid migration profiles of BRE-1, PAR-1 and ROC-1 after enzymatic restriction were similar. A LysR-type regulator gene, IMIR-2, involved in inducible expression of IMI-2 was identified upstream of bla<sub>IMI-2</sub>, along with an IS2-like element and a transposase gene tnpA from Tn2501 (Tn3 family). The immediate genetic environment was similar to that described in IMI-2-isolates of US-rivers.

**Conclusion:** This study highlights that IMI carbapenemase-producers may be responsible of human infections in Europe. Furthermore, we have shown that a single *E. asburiae* clone producing IMI-2 may be responsible of infections, and these isolates likely originate from an aquatic source.

#### **P1239** Detection and characterisation of a new VIM-31 variant in *Enterobacter cloacae*

P. Bogaerts\*, C. Bebrone, W. Bouchahrouf, T.-D. Huang, Y. DeGheldre, K. Hoffman, Y. Glupczynski (Yvoir, BE; Aachen, DE; Brussels, BE)

**Objectives:** To characterize a new VIM-2-derived variant, VIM-31, detected in carbapenem-non susceptible (CNSE) *Enterobacter cloacae* (Eclo11236) isolated in a Belgian hospital.

**Methods:** Antimicrobial susceptibility testing was performed by Etest and microdilution according to CLSI guidelines. Resistance genes and their genetic environment were characterized by Check-points CT102 array and by PCR-sequencing. Plasmids were extracted by Kieser method, typed by PCR-based replicon typing and transferred by mating-out assays and transformation. VIM-31 was cloned in pET-28a and purified by ion-exchange chromatography and gel filtration. Kinetic parameters of VIM-31 were determined against various beta-lactams and a 3D homology model was constructed using EsyPred3D server.

**Results:** A CNSE isolate (Eclo11236) was recovered from several blood cultures of an 87-year old female who underwent colectomy for intestinal adenocarcinoma and who subsequently developed a recto-vaginal fistula and secondary peritonitis. Eclo11236 was intermediately susceptible to imipenem (IMI) (MIC = 3 µg/mL) and resistant to ertapenem (MIC = 6 µg/mL) while remaining susceptible to meropenem (MIC = 0.5 µg/mL), aztreonam, tigecycline, amikacin and ciprofloxacin. The presence of an MBL in this isolate was evidenced by a positive double disc synergy test with imipenem (IMI) and EDTA; the patient gradually improved following treatment with ciprofloxacin, but she remained persistently colonized with the same Eclo11236 in urine. PCR-sequencing revealed a new bla<sub>VIM-31</sub> allele coding two Tyr224His and His252Arg mutations in comparison to VIM-2 and located upstream to aacA4' gene in a class 1 integron (In669) carried on a 42-kb non-typeable but transferable plasmid.

VIM-31 presents a broad-spectrum activity, affecting all beta-lactam compounds except aztreonam. Comparatively to VIM-2, VIM-31 exhibits a lower catalytic activity (lower  $k_{cat}$  and higher  $K_m$  values)

against beta-lactams with  $k_{cat}/K_m$  ratios ranging from 4.5 (ceftazidime), 900 (ampicillin), 1900 (cefotaxime) to 2400/mM/s (imipenem). **Conclusion:** We described here a new VIM-31 variant with 2 point mutations leading to modifications of its catalytic properties in comparison to VIM-2. The fact that this VIM-31-expressing *E. cloacae* isolate was detected in a patient who had not traveled abroad and who remained colonized after hospital discharge underlines the risk of silent spread of CNSE in the community.

#### **P1240** Retrospective search for NDM-1 reveals Indian origin of DIM-1 metallo-beta-lactamase

M. Castanheira\*, L. Deshpande, L. Woosley, R. Prochaska, R. Jones (North Liberty, US)

**Objectives:** To assess the early occurrence of NDM-1 and other carbapenemases in a collection of Gram-negative bacilli (GNB) isolates collected in India during 2000. We previously demonstrated that NDM-1-producing isolates were present in India as early as 2006, but no data is available for prior sample years.

**Methods:** Among 220 GNB isolates collected in India during 2000, 22 strains showing elevated imipenem MIC values ( $\geq 0.5$  mg/L) were further evaluated for the presence of carbapenemases. Modified Hodge test (MHT) was performed. Isolates were tested by PCR for genes encoding KPC, IMP, VIM, NDM, SPM, SIM, KHM, DIM, BIC, GIM, SME, IMI, NMC-A, GES and OXA-48. DIM-1-producer was compared to index strain (kindly supplied by L. Poirel, Bicetre Hospital, France) by PFGE and integron structures were amplified using primers located in the conserved sequences (CS).

**Results:** Twenty-two GNB tested belonged to eight bacterial species, including five *E. cloacae*, four *P. aeruginosa*, four *P. fluorescens*, two of each *K. pneumoniae*, *A. baumannii*, *C. freundii*, *P. stutzeri* and one *P. vulgaris*. These strains were collected in five cities: Mumbai, Vellore, New Delhi, Lucknow and Indore. Only one strain yielded positive PCR results for bla<sub>DIM</sub> primers. No isolates were positive for NDM-1 or other carbapenemase-encoding genes. The *P. stutzeri* strain carrying bla<sub>DIM-1</sub> was genetically distinct from the index *P. stutzeri* strain carrying this gene previously described in The Netherlands. Integron structure showed that bla<sub>DIM-1</sub> was located in the second position of a class I integron downstream of aadB and an intact 3'-CS structure (qacEdelta1/sul1). In contrast the index strain carried bla<sub>DIM-1</sub> in the first position followed by aadB and qacH, but no 3'-CS.

**Conclusions:** NDM-producing strains were not detected in this bacterial collection from five Indian cities in 2000, narrowing the interval for the emergence of NDM-producing strains in India. On the other hand, the detection of a DIM-1-producing *P. stutzeri* from India collected many years prior to the finding of this gene in the Dutch strain, suggests that the Indian subcontinent could be the source of another metallo-beta-lactamase gene. Further studies should be performed to investigate the origin of DIM-1 and its prevalence in India.

#### **P1241** Biochemical characterisation of GES-18 carbapenemase with an additional Val80Ile substitution compared to GES-5

C. Bebrone\*, P. Bogaerts, H. Delbrück, R. Rezende de Castro, M. Kupper, Y. Glupczynski, K. Hoffmann (Aachen, DE; Yvoir, BE)

**Objectives:** GES-1 is a class A beta-lactamase conferring resistance to penicillins, first-, second-generation cephalosporins and to ceftazidime. However, GES-1 does not hydrolyze aztreonam, cephamycins or carbapenems. Until now, 17 GES variants differing by 1–3 amino acid residues and with differences in the substrate spectra have been reported. A carbapenemase activity has been demonstrated only in some variants, including GES-5, with a substitution at the Gly170 residue. Here, we investigated the biochemical and structural characteristics of a new GES-18 variant.

**Methods:** Susceptibility profile was determined by disc diffusion and microbroth dilution MIC method according to CLSI guidelines. GES-18 was identified by PCR-sequencing. GES-18 was purified from *Escherichia coli* BL21 (DE3) (pET28a/blaGES-18) by ion-exchange and gel filtration chromatography. Steady-state kinetic parameters for the hydrolysis of beta-lactam antibiotics were determined by measuring spectrophotometrically the initial reaction rates. Inhibition by tazobactam and clavulanic acid was investigated using nitrocefin as reporter substrate. Crystallographic study was also performed.

**Results:** blaGES-18 is an integron-borne allele found in a multidrug-resistant *Pseudomonas aeruginosa* clinical isolate. GES-18 has an additional Val80Ile change compared to GES-5. Compared to GES-1, GES-18 shows an increased activity against carbapenems and cephamycins but presents a reduced activity against ceftazidime and cefotaxime. Aztreonam is a poor substrate of GES-18 with very low *k<sub>cat</sub>* and relatively high *K<sub>m</sub>* values. GES-18 was less susceptible than GES-1 to inhibition by tazobactam and clavulanic acid. The crystal structure of GES-18 was solved by molecular replacement using the structure of GES-1 (PDB code 2QPN) as model.

**Conclusion:** GES-18 is a new GES variant which displays a carbapenemase activity very similar to that of GES-5. We obtained the first crystallographic structure of a Ser170-possessing GES-type carbapenemase.

#### P1242 Identifying *terIS* of ISCR1 and new ISCR elements

*S. Partridge\** (Sydney, AU)

**Objectives:** ISCR elements are responsible for capturing and mobilising certain antibiotic resistance genes. They are unusual insertion sequences, related to the IS91 family, that have *oriIS* and *terIS* motifs at their outer ends and move by rolling circle replication catalysed by the Rcr protein encoded within the element. Continuation of replication beyond the *terIS* end allows capture of adjacent DNA segments. ISCR1 is always found adjacent to the same position of the 3'-conserved segment of class 1 integrons, possibly explained by a deletion encompassing part of an ancestral ISCR element and part of the 3'-CS. However, at 2154 bp ISCR1 appears longer than related elements and could contain captured segment(s) adjacent to *terIS*. Here, searches with the Rcr1 protein of ISCR1 were used to identify related elements to try and shed light on this. Searches with the sequences of selected ISCR and Rcr proteins were also carried out to identify new ISCR-like elements.

**Methods:** The sequences of selected, known ISCR1 elements and their Rcr proteins were used in BLASTn, BLASTp and tBLASTn searches (<http://blast.ncbi.nlm.nih.gov/Blast.cgi>). The nucleotide sequences of these putative elements and/or regions containing putative *rcr* genes were analysed to try and identify element boundaries.

**Results:** Searches identified a protein 87% identical to Rcr1 from ISCR1 in pHH1107, from an uncultured bacterium isolated from manure in Germany. An alignment of the nucleotide sequences revealed 79% identity over 1811 bp and short inverted repeats, a characteristic of *terIS* of IS91-like elements, were identified near to the end of this match in ISCR1. An element encoding a protein 84% identical to Rcr20 in a region 85% identical to ISCR20 is associated with a cat-like gene and inserted in a class 1 integron. Part of the same region is also present upstream of the *armA* gene in the composite transposon Tn1548, found on a number of plasmids, and upstream of the *sul3* gene found beyond the cassette array in some class 1 integrons.

**Conclusions:** Identification of elements related to the region currently defined as ISCR1 appears to support the hypothesis that this element may contain an ancestral ISCR plus additional segments adjacent to *terIS*. Identification of fragments of a previously unrecognised ISCR-like element adjacent to known antibiotic resistance genes suggests they may have had a role in the original capture of these genes.

#### P1243 Discovery of a new 16S rRNA methylase, RmtF, conferring high-level aminoglycoside resistance in human Enterobacteriaceae isolates from India

*L. Hidalgo\**, *K. Hopkins*, *A. San Millan*, *J.A. Escudero*, *B. Gutierrez*, *L. Carrilero*, *C. Martinez*, *A. Santos*, *K. Prasad*, *N. Woodford*, *B. Gonzalez-Zorn* (Madrid, ES; London, UK; Lucknow, IN)

**Objectives:** 16S rRNA methyltransferases (ArmA, RmtA-E, NpmA) have been described in recent years as an emerging mechanism conferring high-level resistance to clinically relevant aminoglycosides. These genes are usually borne by mobile genetic elements and they have been associated with several important resistance mechanisms such as Qnr, ESBLs or more recently the newly discovered carbapenemase NDM-1. A total of 35 Enterobacteriaceae strains (three *Citrobacter freundii*, three *Enterobacter cloacae*, one *Enterobacter aerogenes*, 11 *Escherichia coli* and 17 *Klebsiella pneumoniae*) isolated from human specimens from an Indian hospital were analysed for their high level resistance (MIC  $\geq$  200 mg/L) to gentamicin and amikacin.

**Methods:** PCR screening for the known methylase genes was performed on the 35 isolates. Cloning experiments and subsequent sequencing were performed using plasmid extractions from some of the strains negative for the all the known methylase genes. NDM-1 gene was sought by PCR in strains highly resistant to carbapenems. Plasmids with the new methylase gene were classified according to a PCR-based replication typing and pMLST, as well as by determination of their size by S1-PFGE technique.

**Results:** All the 35 Enterobacteriaceae isolates carry a new 16S methylase gene, named *rmtF*, which is able to confer by itself high-level resistance (MIC  $\geq$  200 mg/L) to the 4,6-disubstituted aminoglycosides (such as gentamicin, amikacin or tobramycin) and shared the highest amino acid identity (46%) with RmtD. In some cases, this new methylase has been found in the same strain (but not on the same plasmid) with another 16S rRNA methylase: ArmA (29% of the strains), RmtB (6%) or RmtC (9%). NDM-1 has been detected in 57% of the strains. Replicon typing revealed that in many strains *rmtF* is borne by an IncN plasmid of approximately 400 kb in size, whereas in others the plasmid is non-typable.

**Conclusions:** This study reports the discovery of a new 16S rRNA methylase, RmtF, which confers high-level resistance to most clinically relevant aminoglycosides. This resistance determinant seems to be spreading quickly among enterobacteria associated with other emerging resistance mechanisms, including NDM-1 carbapenemase. A detailed characterization must be done in order to elucidate the basis of this new resistance determinant. Further surveillance of RmtF among human, animal and food isolates will be needed to track its path worldwide.

#### P1244 Co-linkage of novel extended spectrum beta-lactamase VEB-5 and 16S rRNA methyltransferase ArmA in *Salmonella enterica* from the United Kingdom

*L. Hidalgo\**, *K. Hopkins*, *D. Wareham*, *A. San Millan*, *J.A. Escudero*, *B. Gutierrez*, *L. Carrilero*, *C. Martinez*, *A. Santos*, *B. Gonzalez-Zorn* (Madrid, ES; London, UK)

**Objectives:** Methylation of the aminoacyl site of bacterial 16S rRNA confers high-level resistance to clinically important aminoglycosides. Seven 16S rRNA methyltransferase genes, *armA*, *rmtA*, *rmtB*, *rmtC*, *rmtD*, *rmtE* and *npmA*, have been identified to date. The aims of this study were to investigate the occurrence of 16S rRNA methyltransferases in *Salmonella enterica* isolates selected from the Health Protection Agency (HPA) Laboratory of Gastrointestinal Pathogens culture collection expressing high-level resistance to aminoglycosides.

**Methods:** One *S. enterica* serovar Thompson and three *S. enterica* serovar Worthington isolates were selected based on ability to grow on 500 mg/L of amikacin. PCR screening of the four isolates for the known methylase genes was performed. A series of multiplex PCRs was used to screen for the presence of genes encoding TEM, SHV, OXA 1/4/30/48, CTX-M-1,3,9,8/25, ACC, FOX, MOX, DHA, CIT, EBC, GES, PER, VEB, IMP, VIM and KPC beta-lactamases. Conjugation was attempted in broth culture and transconjugants were selected on Brain Heart Infusion agar plates containing nalidixic acid (50 mg/L) and gentamicin (50 mg/L). Plasmid profiles of the wild-type strains and the transconjugants was analysed by S1-PFGE method. PCR mapping for Tn1548 was performed using plasmid extractions as templates.

**Results:** armA was identified in the four isolates. Multiplex PCRs for the presence of the main beta-lactam resistance genes resulted in identification of blaVEB and blaCMY in *S. Worthington*. The nucleotide sequence of the blaVEB gene shared 100% sequence identity with blaVEB-5 originally identified in *Escherichia coli* in the United States. Furthermore, blaVEB-5 alone was confirmed to confer high-level resistance to aztreonam. The CMY gene was identified as blaCMY-2. Conjugation assays showed the association of armA, blaVEB-5 and blaCMY-2 on the same plasmid in *S. Worthington*. A genetic structure related to Tn1548 was found in both *S. Thompson* and *S. Worthington* to be the mobile element responsible for armA spread.

**Conclusion:** Here we describe for the first time the co-linkage of armA with a VEB beta-lactamase. This is also the first report of blaVEB-5 in *Salmonella enterica*. These findings are relevant due to the combined presence of resistance to aminoglycosides and monobactams. Ongoing surveillance of these genes in bacteria will help to slow down resistance to these clinically relevant antibiotics.

#### P1245 Characterisation of two new variants of 16S rRNA methylase encoding genes, rmtB2 and rmtB3

M. Castanheira\*, L. Deshpande, R. Melano, R. Mendes, R. Jones (North Liberty, US; Toronto, CA)

**Objectives:** To characterize two G1405 16S rRNA methylase encoding genes showing 3–4 amino acid changes compared to rmtB from Enterobacteriaceae isolates collected in 2005 and 2006.

**Methods:** Genes encoding RmtB-like were sequenced on both strands. Clinical strains carrying these genes were analyzed. Primers comprising the open reading frame of the rmtB-like genes were used to amplify the entire gene and amplicons were cloned into PCRScript/XL1 Blue *E. coli* kanR. *E. coli* DH5alpha was used as a secondary host and transformation plated onto selective media containing 30 mg/L of chloramphenicol. Plasmid preparations of clinical strains were transformed into *E. coli* DH5alpha by electroporation and selected in media containing 4 mg/L of kanamycin. Susceptibility testing was performed according to CLSI reference broth microdilution methods using extended MIC dilution ranges for amikacin, tobramycin, gentamicin, arbekacin, apramycin, kanamycin, neomycin and streptomycin.

**Results:** rmtB was sequenced in nine strains initially positive by PCR using primers targeting this gene. Six strains carried variants of the rmtB gene: rmtB2 showing three amino acid changes A41T, I124V and I132V and rmtB3 showing one additional alteration at position 82 (A–V). rmtB2 was detected in three isolates from Mexico (two *E. cloacae* strains; two hospitals) and one *E. coli* from Brazil. rmtB3 was detected among three strains from USA (Texas; *E. coli*) and Mexico (one *E. cloacae* and one *K. pneumoniae*). Susceptibility testing demonstrated that isolates carrying rmtB, rmtB2 and rmtB3 had elevated MIC values for amikacin (32–256 mg/L), tobramycin (16–64 mg/L), gentamicin (4–64 mg/L), arbekacin (16–64 mg/L) and kanamycin (64–256 mg/L) when compared to the *E. coli* host carrying PCRScript plasmid without insert. RmtB-variant produced MIC values for apramycin, neomycin and streptomycin modestly higher (4–8 mg/L) when compared to rmtB (0.25–2 mg/L) expressed in the same genetic background. Plasmids from three of the six clinical strains were transferred to *E. coli* and

MICs were elevated for aminoglycosides (8–256-fold) that are susceptible to G1405 methylation.

**Conclusions:** Two G1405 16S rRNA methylase genes similar to rmtB were detected among several Enterobacteriaceae isolates collected during 2005–2006 from different countries in Latin and North America, suggesting that these variants could be widespread in this geographic region.

Epidemiology and molecular antimicrobial resistance of *Acinetobacter* sp.

#### P1246 Carbapenem and fluoroquinolone resistance in *Acinetobacter radioresistens*

P.G. Higgins\*, E. Zander, H. Seifert (Cologne, DE)

**Objectives:** *Acinetobacter radioresistens* is increasingly found in hospitalised patients where it may be cause of catheter-related bloodstream infections. Although in possession of an intrinsic blaOXA-23, *A. radioresistens* is usually carbapenem-susceptible. However, blaOXA-23 is the commonest acquired carbapenem-resistance determinant in *Acinetobacter baumannii* and is associated with insertion elements (IS) that provide strong promoters leading to overexpression. We recovered two *A. radioresistens* isolates from a patient 17 days apart. Ciprofloxacin (CIP) therapy was administered over this time. Both isolates were carbapenem-resistant. The pre-CIP therapy isolate was fluoroquinolone- (FQ) susceptible and the post therapy isolate was FQ-resistant (Table 1). We investigated the epidemiology and mechanisms of carbapenem- and FQ-resistance in these isolates.

**Methods:** Strain identity was confirmed using rep-PCR (DiversiLab). Carbapenem and FQ MICs were determined by E-test. Carbapenem-resistance was investigated by sequencing blaOXA-23 and its genetic environment. To investigate expression of blaOXA-23, qRT-PCR was performed and compared to the carbapenem-susceptible *A. radioresistens* SH164 isolate. The blaOXA-23 environment including the novel ISAcra1 (see Results) was cloned into shuttle plasmid pWH1266 and transformed into carbapenem-susceptible *A. baumannii* ATCC 17978. FQ-resistance was investigated by sequencing gyrA and parC.

**Results:** The isolates were found to be identical by rep-PCR. A novel IS element was found upstream of blaOXA-23 and was termed ISAcra1 by the IS Database (<http://www-is.biotoul.fr/>). qRT-PCR showed that blaOXA-23 was overexpressed in both isolates compared to control strain SH164. *A. baumannii* ATCC 17978 transformed with ISAcra1-blaOXA-23 had imipenem and meropenem MICs of >32 mg/L (Table 1). Sequencing of gyrA revealed a mutation in the post-CIP therapy isolate, leading to a Ser83-Phe substitution, and was associated with FQ resistance (Table 1). No changes were found in parC.

Table showing carbapenem and fluoroquinolone MICs in *A. radioresistens* strains 1 and 2 and the amino acid substitution in GyrA. Carbapenem MICs of *A. baumannii* ATCC 17978 and *M. luteus* transformant are shown.

Strain	MIC (mg/L)				GyrA
	IPM	MEM	CIP	MOX	
<i>A. radioresistens</i> 1	>32	>32	0.25	<0.094	Ser-83
<i>A. radioresistens</i> 2	>32	>32	>32	2	Phe-83
<i>A. baumannii</i> ATCC 17978	0.25	0.25	at	at	at
<i>A. baumannii</i> ATCC 17978 (pOXA-23)	>32	>32	at	at	at

IPM, imipenem; MEM, meropenem; CIP, ciprofloxacin; MOX, moxifloxacin; at, not tested

**Conclusion:** This study shows that carbapenem-resistance was mediated through overexpression of the intrinsic blaOXA-23 and was associated with the novel ISAcra1. FQ resistance developed during CIP-therapy and was associated with a gyrA mutation. These data highlight the ability of *A. radioresistens* to develop fluoroquinolone resistance during therapy. ISAcra1 has the potential to spread OXA-23 mediated carbapenem-resistance in *A. radioresistens* and *A. baumannii*.

**P1247** Epidemiology of multidrug-resistant *Acinetobacter baumannii*/hemolytic complex in the largest Russian cancer hospital

Z. Grigoryevskaya\*, N. Dmitrieva, S. Dyakova, I. Petukhova, N. Bagirova, E. Kulaga, E. Sokolova, T. Kalinchuk (Moscow, RU)

Multidrug-resistant (MDR) *A. baumannii* is widely spread in nature and in the hospital environment and often causes a variety of difficult-to-treat hospital infections.

**Objective:** To identify clones of *A. baumannii* in the hospital environment and to trace the relationship with the nosocomial infections in cancer patients.

**Methods:** Between March and September 2011, 123 strains of *A. baumannii*/hemolytic complex (ABHC) were isolated, including 101 strains from 54 cancer patients (48% from bronchoscopic swabs, 41% from wounds, 11% from other biomaterials [67% of all strains were from ICU patients]) and 26 strains from hospital environment objects. Identification, antimicrobial susceptibility testing and biotypes were determined with automated system MicroScan (WalkAway, Siemens) with 8-digit level of expertise.

**Results:** Seventeen different biotypes of ABHC were revealed in patients. Five biotypes were presented as “wild” strains and 12 biotypes – as MDR strains. Fifteen biotypes occurred once or twice and two biotypes occurred frequently: 57 of 101 (56%) strains had biotype 00062730 and 26 of 101 (26%) strains had biotype 00062720. According to identification code, the two biotypes differed only in susceptibility to tobramycin 4 mg/mL concentration.

Environmental strains of ABHC (22 strains) were presented with nine biotypes. Two biotypes (one strain each) were “wild” strains and seven biotypes (20 strains) were MDR. The most frequent biotypes were 00062720 (eight strains) and 00062730 (seven strains), the same as biotypes most frequently encountered in patients.

Thus total 34 strains of 00062720 biotype and 64 strains of 00062730 biotype of ABHC with different antimicrobial susceptibility were isolated. 00062720 biotype was more sensitive to antibiotics than 00062730 biotype. Proportion of susceptible strains to cefepime was 50% vs. 0%, ceftazidime – 15% vs. 0%, gentamicin – 53% vs. 0%, levofloxacin – 94% vs. 48%, moxifloxacin 88% vs. 51%, tetracycline 100% vs. 23%, tobramycin – 100% vs. 0%, trimethoprim/sulfamethoxazole – 94% vs. 0%, ampicillin/sulbactam – 0% vs. 8%, respectively. All strains of both biotypes were susceptible to colistin ( $p < 0.05$ –0.0001).

**Conclusion:** Two biotypes of MDR *A. baumannii*/hemolytic complex (00062730 and 00062720) are nosocomial and are identified from the objects of hospital environment and cancer patients with infectious complications. Interruption of transmission is the main task and will be an effective method for preventing nosocomial infections.

**P1248** Diversity in *Acinetobacter baumannii* isolates from paediatric cancer patients in Egypt

L. Al-Hassan\*, H. Mehallawy, S. Amyes (Edinburgh, UK; Cairo, EG)

**Objectives:** Cancer patients are at a higher risk from serious infections because they are immuno-compromised and many causative organisms are multi-drug resistant. In this study we report the genetic and epidemiological diversity of *Acinetobacter baumannii* isolated from paediatric cancer patients in Egypt, an emerging problem in cancer centres.

**Materials and methods:** Thirty-four *Acinetobacter baumannii* strains were collected from the Children’s Cancer Hospital (CCH) 57357 and the National Cancer Institute (NCI) in Cairo from March 2010–June 2011. They were initially identified phenotypically and then genotypically by PCR amplification and sequencing of blaOXA-51-like, and restriction analysis of 16s–23s rRNA spacer sequences using AluI and NdeII. Minimum inhibitory concentrations (MIC) of imipenem and meropenem was performed and interpreted according to BSAC guidelines. Isolates were also screened for the presence of

class D carbapenamases: blaOXA-23, blaOXA-24 and blaOXA-58 by PCR amplification and sequencing.

**Results:** Sequencing of blaOXA-51-like gene revealed a large diversity among the strains with eight different genes identified: blaOXA-64, blaOXA-65, blaOXA-66, blaOXA-69, blaOXA-71, blaOXA-78, blaOXA-94 and blaOXA-100. This large diversity showed the presence of the three major sequence groups (blaOXA-66, blaOXA-69, and blaOXA-71) in addition to other unrelated clones. Overall carbapenem resistance was 47% in all isolates (MIC  $\geq$  8 mg/L), with resistance to meropenem being slightly higher than Imipenem in most strains. All three class D carbapenamases were detected in the isolates, with blaOXA-23 being most common (18 isolates), whereas seven isolates harboured the blaOXA-58 and two isolates had blaOXA-40. Seven blaOXA-23 isolates had ISAbal inserted upstream and this correlated with higher resistance to carbapenems. Two isolates had the unusual combination of both blaOXA-23 and blaOXA-58.

**Conclusion:** The two Egyptian hospitals are tertiary referral centres and these results show that the *A. baumannii* isolated from their patients had diverse origins although they included the three major European clones. The data strongly suggest that many of the strains have been brought to the hospital by the patients themselves rather than acquired by the more usual method of transmission through patient-to-patient cross infection. The results also show how these patients can serve as reservoirs for the survival and eventual dissemination of *A. baumannii*.

**P1249** Emergence of multi-resistant *Acinetobacter baumannii* among Libyan military personnel during the recent Libyan conflict

M.A. Daw\*, A.A. Dau, H. Elasifer, S. Tloba (Tripoli, LY)

Multidrug-resistant (MDR) *Acinetobacter* infections are occurring at alarming rates in traumatic war injuries. The recent Libyan crises have resulted in heavy war wound infection caused by highly-resistant pathogens that Libyan hospitals are not familiar with; among them MDR *Acinetobacter baumannii*. The objectives of this study were to determine (i) Epidemiological manifestations of *A. baumannii* among injured military personnel admitted to Tripoli Medical Centre (ii) Antimicrobial resistance patterns of this pathogen (iii) Phenotypes and molecular characteristics of such pathogen.

**Methods:** A total of 498 patients with wounds classified as war wound associated infections (WWAI) showed positive bacterial cultures isolated from the swabs or the wound debridement were studied. Off these 144 culture showed *A. baumannii* according the standard microbiological identification methods antimicrobial susceptibility tests were carried out using, ceftazidime, gentamicin, Amikacin, ciprofloxacin and Imipenem. Pulsed-field gel electrophoresis (PFGE) analysis were carried to determine clonality.

**Results:** *A. baumannii* infection were more likely to be associated with gunshot wounds (70%), external fixators (55%), Blast (30%), blunt (20%), fragmentation (15%). Antibiotic resistance rates vary according to the antibiotic used, ceftazidime (90%), gentamicin (95%), amikacin (85%), ciprofloxacin (95%) and Imipenem (45%). PFGE analysis showed four different heterogeneous patterns with no occupational transmission was proofed.

**Conclusion:** *A. baumannii* was found to be an emerging problem among Libyan patients particularly those associated with Trauma. This is an alarming issue as preventive measures and specific guide lines should be implemented both for infection control and empiric therapy for suspected infected patients with *A. baumannii*

**P1250** Epidemiology of *Acinetobacter* species infection in a gastroenterology and liver transplant ICU in a multi speciality hospital in India

R. Bagga\*, U. Baveja, A. Rattan (Gurgaon, IN)

**Introduction:** Infections influence the outcome of the critically ill patients and are more common in immunosuppressed individuals. Multi

drug resistant *Acinetobacter* species are emerging as one of the most dreaded bacteria and leads to increase in mortality.

**Hypothesis:** Microbiological data of 759 patients admitted from June 2010 to May 2011 in a Gastroenterology and Liver transplant ICU was analysed.

**Methods:** Results of all the culture samples were retrieved. Blood, urine, Endotracheal/Tracheal secretion and body fluid cultures which are positive for *Acinetobacter* species were analysed. Antibiotic sensitivity pattern were also documented.

**Results:** Fifty eight samples from forty two patients were positive for *Acinetobacter* species.

Thirty two samples (55.2%) were positive from respiratory secretions with radiological confirmation of consolidation, fifteen samples (25.8%) were positive from body fluids (Ascitic, Pleural fluid, Pus) and eleven blood culture samples (18.9%) were detected positive for *Acinetobacter* species. Out of 42, 12 patients had positive cultures from two sites, two patients from three sites and rest 28 patients had culture positivity from single site. Out of 58 *Acinetobacter* isolates, 54 (93.1%) were identified as of *A. baumannii*, two (3.4%) as of *A. hemolyticus* and one (1.7%) each as of *A. lwoffii* and *A. junii*. All these *Acinetobacter* isolates were showing high resistant to carbapenems, cephalosporins, aminoglycosides and fluoroquinolones. All the isolates (100%) were sensitive to Colistimethate sodium with MIC < 0.5. Tigecycline was sensitive in 53 isolates (91.0%) and MIC range was <0.5–4. Out of 58 only eight isolates (13.7%) were sensitive to carbapenams, six (10%) to cefepime-sulbactam combination and aminoglycosides, and three (5%) to fluoroquinolones. Twenty-one (48.8%) out of 43 culture positive patients died within 28 days of detection of positive cultures. Incidence of *Acinetobacter* species infection is 5.6% in our ICU.

**Conclusions:** Despite a reputation of being relatively low virulence *Acinetobacter* infections pose a formidable threat especially to compromised patients. *A. baumannii* is a highly resistant pathogen and carries a high mortality. In our ICU Colistimethate sodium shows excellent sensitivity followed by Tigecycline.

#### **P1251** Surveillance of *Acinetobacter baumannii* isolates resistant to carbapenems during 10-year period (2001–2010) in Aveiro, Portugal

S. Ferreira\*, R. Diaz, S. Rocha, A. Paradela, E. Ramalheira (Aveiro, PT)

**Objectives:** *Acinetobacter* spp. (Aba) is an important nosocomial pathogen worldwide and exhibits high rates of acquired resistance to many antimicrobial agents. It is also responsible for a high number of reported outbreaks worldwide. The aim of this work was to evaluate the temporal evolution of antimicrobial resistance among *Acinetobacter* spp. isolated in a central region of Portugal (Hospital Infante D. Pedro, Aveiro).

**Methods:** Consecutive non-duplicate bacterial pathogens were collected in the last 10 years from hospitalised patients in the Hospital Infante D. Pedro. Sites of isolation included: Skin and soft tissue, bloodstream, urinary tract and lower respiratory tract. The isolates were identified by the automatic VITEK 2 system and Advanced Expert System (VITEK 2 AES) (BioMérieux, Marcy L'Étoile, France). The antimicrobial susceptibility profile to >20 antimicrobial agents was evaluated by CLSI broth microdilution methods and interpreted by CLSI M100-S20 (2010).

**Results:** A total of 440 isolates were collected during the 10 years period. The highest number of isolates was collected in 2004 (11.6%), 2006 (12.5%), 2009 (13.6%), 2010 (28%). Most of the isolates were collected from respiratory tract followed by urinary tract and bloodstream infections. From November 2009 to February 2010, 36 Aba isolates were isolated from samples collected from patients hospitalized in the ICU, causing an outbreak. This Aba clone was endemic in 2006, and had also produced an outbreak in 2007, in the same ward.

**Conclusions:** Polymyxin B remains the most active drug against *Acinetobacter* spp. in the isolates collected in our hospital and

tigecycline was also active. An important reduction in the susceptibility rates to some broad-spectrum antimicrobials was observed, limiting therapeutic options available. Proper control of this multidrug-resistant Aba will require a multidisciplinary approach, including identification of resistance mechanisms, optimizing antibiotic use based on local epidemiology and vigorous implementation of infection control procedures.

#### **P1252** Use of DiversiLab repetitive-sequence-based PCR for epidemiologic analysis of *A. baumannii* from Australia and Asia

H.E. Sidjabat\*, A. Silvey, W. Kamolvit, N. Runnegar, C. Huber, D.L. Paterson (Brisbane, AU)

**Objectives:** A commercial repetitive-sequence-based PCR (rep-PCR) technique (DiversiLab system, bioMérieux, Marcy l'Etoile, France) was used to assess the molecular epidemiology of *A. baumannii* from Australia and Asia. The aim of this study was to assess whether DiversiLab was a reliable diagnostic tool for clonal analysis.

**Methods:** A total of 140 non-repetitive *A. baumannii* isolates (46 from Australia, 54 from Thailand, 25 from Singapore, nine from Malaysia and six from Japan) were analysed by the rep-PCR method using the DiversiLab system. Representative isolates determined by DiversiLab patterns from the five countries were also analysed by multilocus sequence typing (MLST).

**Results:** *A. baumannii* clonal complex (CC) 92 was the predominant clone in all five countries. The DiversiLab patterns of CC92 were relatively specific for each country. *A. baumannii* CC92 was the only clone present amongst carbapenem resistant *A. baumannii* from Thailand (similarities  $\geq 95\%$ ). Two isolates from Thailand had only 90% similarities to the major clone, one belonged to a novel ST and another isolate belonged to ST195. *A. baumannii* from Queensland, Australia, were also predominantly CC92 (78%); and all except one were carbapenem resistant. In contrast, the isolates from Western Australia were diverse and with variability in carbapenem resistance. ST73, 125, 126, 127, 128 and ST129 were non-CC92 of Queensland *A. baumannii*. ST130 belonged to CC92; however, it was susceptible to carbapenems. All but one *A. baumannii* from Japan were closely related by  $\geq 95\%$  and clustered together. Interestingly, the DiversiLab patterns of CC92 from Malaysia were closely related to Thailand *A. baumannii*; whereas, the CC92 from Singapore were closely related to Australian *A. baumannii*.

**Conclusion:** The rep-PCR assay with the DiversiLab system used for *A. baumannii* proved to be a rapid and reliable method for molecular analysis of nosocomial outbreaks as well as for epidemiologic analysis for routine purpose. The rep-PCR assay could also differentiate the country of origin of *A. baumannii* based on their typical DiversiLab patterns. It is likely that evolution of common global clonal clusters has occurred in each country.

#### **P1253** Comparison of carbapenem-resistant *Acinetobacter baumannii* isolates from various body sites of colonised patients

J.H. Yoon\*, S.J. Jin, M.G. Kim, H.W. Kim, N.S. Lee, S.H. Han, J.Y. Choi, D.E. Yong, Y.G. Song, J.M. Kim (Seoul, Jeonju, KR)

**Objectives:** There is no standard surveillance culture method for carbapenem-resistant *Acinetobacter baumannii* (*A. baumannii*). Before selection of culture site and method for surveillance culture, it should be confirmed that the strains obtained from all the body sites are identical. Therefore, we took cultures from multiple body sites of patients with carbapenem-resistant *A. baumannii* colonization and performed pulsed-field gel electrophoresis (PFGE).

**Methods:** From 1 September to 14 September 2011, five patients colonized with carbapenem-resistant *A. baumannii* in intensive care unit (ICU) were included. The strains from their sputum cultures were regarded as results of colonization because there was no clinical or

radiological evidences of pneumonia. We took cultures from six different body sites for each patient, which were buccal mucosa, nostril, axilla, upper arm, groin, thigh and rectum. All the specimens were enriched in nutrient broth in 37°C for 1 hour. Next, 100 µL of the broth was taken from each specimen and inoculated onto CHROMagar™ *Acinetobacter* (CHROMagar, Paris, France). The plates were then incubated at 37°C for 24 hours before reading. Antimicrobial susceptibility testing was performed by disk diffusion and interpreted in accordance with the Clinical and Laboratory Standards Institute guidelines. PFGE was performed on all the strains obtained from sputum and seven body sites.

**Results:** Carbapenem-resistant *A. baumannii* was found in specimens from following sites: buccal mucosa, three specimens, nostril, 5, axilla, 2, upper arm, 5, thigh, 1, and rectum, 2. However, it was not obtained from the groin specimens. For four patients, all the strains in each patient were identical and for one patient, one isolate were classified as closely related with the others (one band difference). The PFGE data are summarized in Figure 1.

Figure 1. Pulsed-field gel electrophoresis of carbapenem-resistant *Acinetobacter baumannii* strains from various body sites. Capital letters indicate case patients and numbers indicate strains obtained from each site of body.  
A-1: sputum, A-2: nostril, A-3: upper arm.  
B-4: sputum, B-5: nostril, B-6: buccal mucosa, B-7: axilla, B-8: rectum, B-9: upper arm, B-10: thigh.  
C-11: sputum, C-12: nostril, C-13: buccal mucosa, C-14: axilla, C-15: upper arm.  
D-16: sputum, D-17: nostril, D-18: buccal mucosa, D-19: upper arm.  
E-20: sputum, E-21: nostril, E-22: rectum, E-23: upper arm.

**Conclusion:** Our results showed that *A. baumannii* isolated from any sites of body in carbapenem-resistant *A. baumannii* colonized patients were identical. Based on this result, we can select candidate site for surveillance culture by higher culture sensitivity. Larger studies would be needed to determine most pertinent surveillance culture site.

#### P1254 Preceding colonisation of carbapenem-resistant *Acinetobacter baumannii* in respiratory tract of sepsis patients

J.H. Yoon\*, S.J. Jin, M.G. Kim, H.W. Kim, N.S. Lee, S.H. Han, J.Y. Choi, D.E. Yong, Y.G. Song, J.M. Kim (Seoul, Jeonju, KR)

**Objectives:** We compared the genetic relations of carbapenem-resistant *Acinetobacter baumannii* (*A. baumannii*) isolated from respiratory specimen and blood to determine whether colonization on respiratory tract precedes bacteremia.

**Methods:** We reviewed 141 carbapenem-resistant *A. baumannii* bacteremia patients who had prior respiratory cultures (e.g., sputum, transtendotracheal aspirates, bronchial washing and bronchoalveolar lavage) with the same organism from 1 January 2009 to 31 November 2010, at Severance hospital. Among them, we excluded cases with blood and respiratory culture in the same day or cases with pneumonia. Finally 32 cases which had carbapenem-resistant *A. baumannii* respiratory tract colonization prior to bacteremia were included. We reviewed their medical records and laboratory findings. Pulsed-field gel electrophoresis (PFGE) was performed on the blood isolates and corresponding respiratory ones.

**Results:** The average interval between the first isolation from respiratory specimens and blood culture with carbapenem-resistant *A. baumannii* was 11.5 days (Range: 1–51 days). Twenty-four of 32 patients had identical PFGE band pattern between isolates from blood

and respiratory specimens. Carbapenem-resistant *A. baumannii* strains from six patients were determined as closely related. The strains from two patients showed different PFGE pattern. The PFGE data are summarized in Figure 1.

Figure 1. Pulsed-field gel electrophoresis of carbapenem-resistant *Acinetobacter baumannii*. Numbers indicate case patients. Each case patient has 2 PFGE results, R and B. "R" is a PFGE result from respiratory specimen and "B" is from blood. Twenty six patients (except 3,25,26,27,28,29,30 and 31) had identical PFGE band pattern between R and B. PFGE patterns of R and B are similar in 9,25,26,27,28 and 29 and different in 30 and 31.

**Conclusion:** This study suggests that colonization of carbapenem-resistant *A. baumannii* in respiratory tract may precede bacteremia. Further investigation about the frequency of colonization prior to infection, the most common site of colonization and the outcome benefits related to early detection would be needed to make more efficient carbapenem-resistant *A. baumannii* infection control strategy.

#### P1255 Identification of a clinical isolate of *Acinetobacter* genomic species 10 with an integron-borne blaVIM-2 gene flanked by miniature inverted-repeat transposable elements

S. Domingues\*, A. Duarte, K.M. Nielsen, G.J. Da Silva (Coimbra, Lisbon, PT; Tromsø, NO)

**Objective:** Reports on carbapenem-resistance in species other than *Acinetobacter baumannii* are rare. As part of our ongoing study of integrons, we have examined a Portuguese collection of *Acinetobacter* spp. isolates. We found a *A. junii* (Api20NE) strain with reduced susceptibility to imipenem. We report the molecular identification and characterization of the mechanism underlying this unusual phenotype in a rarely found clinical species, describing also the genetic basis and flanking regions of an integron.

**Methods:** The clinical strain 118FFC was isolated in March 1998 from the blood of an inpatient of a Surgery ward of the University Hospital of Coimbra. Re-identification was performed by ARDRA and AFLP. Antimicrobial susceptibility was determined by the disc diffusion and by E-test. Results were interpreted according to the CLSI guidelines. The beta-lactamase activity of bacterial extracts was determined by spectrophotometry, using imipenem and nitrocephin as substrates in the presence and absence of EDTA and zinc. Metallo-beta-lactamase production was detected by a microbiological method with EDTA. Screening for class 1 integron and Miniature Inverted-Repeat Transposable Elements (MITEs) were done by PCR, followed by sequencing of amplicons.

**Results:** Strain 118FFC was identified as *Acinetobacter* genomic species 10 (proposed *A. berezinae*). It showed resistance to ampicillin, cefotaxime, ceftazidime, sulphonamides, netilmicin and tobramycin, and reduced susceptibility to imipenem (MIC = 8 mg/L). Beta-lactamase activity and phenotypic test suggested the production of a metallo-beta-lactamase. PCR and sequencing revealed the presence of a class 1 integron (2.2 kb) with the resistance genes cassette aacA7-blaVIM2-aacC1. MITE-like structures (439 bp) flanked the integron on both sides. These were 100% identical to the only two previously identified MITEs, found in *A. baumannii* 65FFC isolated from the same hospital, and in *A. johnsonii* recovered from a prawn in Australia.

**Discussion:** The results showed that an uncommon clinical species of *Acinetobacter* carries a carbapenemase gene, blaVIM-2, without showing resistance to carbapenems. There may be an underestimated prevalence of metallo-beta-lactamases in *Acinetobacter*. The reported resistance genes are embedded in an integron, and the newest reported MITE-like structures, which may facilitate their dissemination. This is the first report of an integron with this gene cassette array, and flanking MITE-like sequences.

**P1256** **Molecular epidemiology and mechanisms of carbapenem-resistant *Acinetobacter baumannii* in a Saudi Arabia hospital**

A. Ribeiro, M.H. Al-Agamy, A.M. Shibl, A.F. Tawfik, P. Courvalin, K. Jeannot\* (Paris, FR; Riyadh, SA; Besançon, FR)

**Objectives:** *Acinetobacter baumannii* (AB) may become highly resistant to carbapenems and almost all of the  $\beta$ -lactams by production of carbapenemases. This study was set up to investigate the molecular epidemiology of carbapenem-resistant *A. baumannii* isolates (CRAB) collected at the Prince Suleiman hospital in Riyadh (Saudi Arabia) from January through December 2010.

**Methods:** The resistance levels to antibiotics were determined in a collection of 27 CRAB by the E-Test method and interpreted according to the EUCAST breakpoints. Acquired beta-lactamases were identified using phenotypic (Double Disk Synergy Tests) and genetic (PCR amplification followed with DNA sequencing) methods according to standard protocols. The clonal relatedness of the strains was investigated by multilocus sequence typing (MLST) according to the Pasteur Institute scheme.

**Results:** The whole collection was highly resistant (MIC<sub>90</sub> > 256  $\mu$ g/mL) to ceftazidime (CAZ), cefepime, and piperacillin-tazobactam. Although all the strains were intermediate or resistant to meropenem (4 to >32  $\mu$ g/mL), two of them appeared susceptible to imipenem (2 to >32  $\mu$ g/mL). DDST using CAZ and clavulanic acid indicated production of a class A extended-spectrum beta-lactamase (ESBL) in 13 isolates contrasting with the detection of genes encoding enzymes PER-1 (n = 13), GES-1 (n = 6), GES-5 (n = 1), and GES-11 (n = 3) in 23 strains. Carbapenemases OXA-51, OXA-23 and OXA-40 were produced by 27, 16 and one isolates, respectively; the ISAbal element was systematically found upstream of the corresponding genes blaOXA-51, blaOXA-23, and blaOXA-40. Of note, 13/27 CRAB coproduced an ESBL and a carbapenemase. As shown by MLST analysis, the 27 strains distributed in eight sequence types (STs). Only 11 isolates belonged to the two most prevalent Clonal Complex in the world, CC1 (ST1, ST7) and CC2 (ST2). Five singleton STs were identified including ST15 and ST113 to ST116, which were new ST identified in this study.

**Conclusion:** The emergence of CRAB is becoming a major concern in Saudi Arabia. Unlike in many other countries, the spread of the OXA-23 enzyme in Saudi strains occurs across different STs.

**P1257** **Molecular analysis of *A. baumannii* isolated from invasive infections in 2009 in Poland**

R. Izdebski\*, I. Letowska, A. Skoczynska, E. Stefaniuk, D. Zabicka, W. Hryniewicz, M. Gniadkowski (Warsaw, PL)

**Objectives:** To characterize *Acinetobacter baumannii* strains causing invasive infections in Polish hospitals.

**Methods:** Thirty clinical isolates of *A. baumannii* from bloodstream infections and meningitis were collected in 2009, during the national surveillance program. They were recovered in 16 hospitals in 13 towns all over Poland. Identification to the *A. calcoaceticus*-*A. baumannii* complex was done by API32GN tests or Vitek2 system (bioMérieux). Species identification was performed by sequencing the 16S-23S rRNA intergenic spacer. Susceptibility to expanded-spectrum cephalosporins and carbapenems was evaluated by disc-diffusion (according to EUCAST); the presence of ESBLs, MBLs and AmpC overexpression was assessed by

specific phenotypic tests. Typing was performed by PFGE and MLST. beta-Lactamases were profiled by isoelectric focusing; genes coding for OXA-23-, OXA-40-, OXA-51- and OXA-58-like CHDLs, PER-1 ESBL and TEM-1-like enzymes were identified by PCR and sequencing. Presence of the ISAbal element upstream of the blaOXA-51-like and blaADC-like natural beta-lactamase genes was analyzed by PCR.

**Results:** The majority of isolates (90%) belonged to two STs: ST2 (European clone II; n = 21) and ST1 (European clone I; n = 6); the remaining clones were ST5 and ST12. PFGE revealed 24 patterns, grouped into six types, and correlating well with STs. All but one of the isolates tested positive for the ADC cephalosporinase overexpression which correlated with the presence of ISAbal upstream of the blaADC genes. Among the 21 ST2 isolates, a diversity of beta-lactamase profiles was observed, with 14 isolates carrying blaPER-1 and 16 having blaTEM-1. Carbapenem non-susceptibility in these isolates correlated either with blaOXA-23- (n = 6), blaOXA-40- (n = 1) or blaOXA-58- (n = 1) like genes; in one OXA-23 producer ISAbal was inserted upstream of the blaOXA-51-like gene blaOXA-66. Among six ST1 isolates, the five carbapenem-non-susceptible isolates carried ISAbal integrated upstream of blaOXA-51-like genes (blaOXA-69) and had no acquired CHDL genes. No MBLs were observed.

**Conclusions:** This is the first detailed molecular analysis of a bigger collection of *A. baumannii* isolates in Poland, and one of the first in Central/Eastern Europe. Similar to observations from other countries, a high representation of the international clones was revealed, as well as the high heterogeneity of beta-lactamase-associated mechanisms of resistance to newer beta lactams.

**P1258** **A novel and hybrid composite transposon at the origin of acquisition of the blaCARB-14 gene in *Acinetobacter baumannii***

R. Bonnin\*, L. Poirel, P. Nordmann (Le Kremlin Bicêtre, FR)

**Background:** Carbenicillin-hydrolyzing beta-lactamases (also named CARB enzymes) are narrow-spectrum class A penicillinases sharing <50% amino acid identity with SHV and TEM. CARB enzymes are known in *Salmonella* sp. and *Pseudomonas* sp. and more rarely in *Acinetobacter* sp.

**Methods:** *A. baumannii* RAB was identified by using the API20NE system (bioMérieux) and confirmed by 16S rDNA gene sequencing and culture at 44°C. MICs were determined by using Etest strips. PCR approaches with standard conditions were used to search for blaTEM, blaSHV, blaCARB genes, blaAmpC, and blaOXA-51. Whole-cell DNA of *A. baumannii* RAB was used to perform shotgun cloning. To compare the hydrolytic spectrum of CARB-14 in comparison to narrow-spectrum CARB-8 and extended-spectrum CARB-10, the corresponding genes were cloned and expressed in an isogenic *E. coli* background under the control of the same promoter.

**Results:** *A. baumannii* RAB was recovered from urine in a 55-year-old patient hospitalized in a French University hospital in 2008. It was resistant to penicillins, cefotaxime, cefepime, of intermediate susceptibility to ceftazidime, and was susceptible to imipenem and piperacillin/tazobactam. It harboured a blaCARB-like gene encoding CARB-14 which is a novel variant exhibiting two amino acid substitutions compared to the closest CARB-5 enzyme. CARB-14 possessed a narrow spectrum hydrolysis profile. Attempts to transfer this resistance determinant by electroporation and by mating out assays failed, suggesting a chromosomal location of the blaCARB-14 gene. Sequence analysis of the region flanking the 5'-end of blaCARB-14 identified a novel insertion sequence ISAb21 belonging to the IS3 family. Downstream of blaCARB-14, another IS belonging to IS3 family named ISAb14 was identified, being in the same orientation as compared to ISAb21. Its inverted repeats shared significant homologies with those of ISAb21. Analysis of the left-end extremity of ISAb21 and the right-end extremity of ISAb14 identified direct repeat (DR) sequences of 3 bp, being the likely signature of a transposition process. Both IS were therefore forming a composite transposon named Tn2114 likely at the origin of the blaCARB gene acquisition.

**Conclusions:** We report here a very peculiar composite transposon made of different IS bracketing a gene coding for a novel carbencillinase, CARB-14. This transposon was made of one copy of ISAb21 and one of ISAb14 belonging to the same IS family.

**P1259** Conversion of OXA-66 into OXA-82 in clinical *Acinetobacter baumannii* isolates and association with altered carbapenem susceptibility

E. Zander\*, P. Higgins, A. Chmielarczyk, H. Seifert (Cologne, DE; Krakow, PL)

**Objectives:** Carbapenem resistance in *Acinetobacter baumannii* is most frequently conferred by carbapenem-hydrolysing OXA enzymes. *A. baumannii* possess an intrinsic blaOXA-51-like, with 68 variants identified. Over-expression of blaOXA-51-like is associated with carbapenem resistance which is commonly mediated by an upstream located insertion element (ISAb1). Reduced expression of the porins CarO, OprD-like and 33–36 kDa Omp is also associated with carbapenem resistance. The aim of this study was to investigate altered carbapenem susceptibility in three clinical *A. baumannii* isolates which were part of an outbreak.

**Methods:** Three *A. baumannii* isolates were recovered from three separate patients (Table 1). Carbapenem susceptibility was determined by Etest. Molecular relatedness was investigated by rep-PCR (DiversiLab) and blaOXA-51-like typing. Presence of acquired OXAs was tested by multiplex PCR. Expression of blaOXA-51-like, carO, oprD-like and 33–36 kDa omp was investigated using qRT-PCR. rpoB was used as a housekeeping control gene.

**Results:** Results are summarised in the Table 1. Clinical isolates A, B and C were clonally related (>98% similarity) as assessed by rep-PCR. blaOXA-51-like typing confirmed affiliation to worldwide clonal lineage WW2. Isolates B and C showed reduced carbapenem susceptibility compared to susceptible isolate A (Table 1). Isolate C was resistant to both carbapenems, whereas isolate B was intermediate to imipenem but resistant to meropenem. Isolate A had OXA-66 while isolates B and C had OXA-82 (L167V) which was also associated with ISAb1. qRT-PCR revealed blaOXA-82 genes were >40-fold over-expressed compared to blaOXA-66. Comparison of porin expression revealed that isolates B and C had reduced expression of carO and oprD-like compared to isolate A (Table 1). Expression of 33–36 kDa omp was reduced in carbapenem-resistant isolate C and was increased in isolate B. Therefore the major difference between isolates B and C was expression of 33–36 kDa omp.

Table: phenotypical and genotypical characterisation of clinical isolates

Isolate	DOI	OXA-51 variant and presence of ISAb1	MIC [mg/L]		Difference in gene expression* [x-fold]			
			IPM	MEM	blaOXA-51-like	carO	oprD-like	33-36 kDa omp
A	30/01/09	OXA-66	4	2	1	1	1	1
B	15/09/10	ISAb1-OXA-82	8	16	16.5	0.79	0.61	2.05
C	09/09/10	ISAb1-OXA-82	>32	>32	46.5	0.22	0.23	0.14

\*compared to gene expression in isolate A; DOI, date of isolation; IPM, imipenem; MEM, meropenem

**Conclusions:** Decreased carbapenem susceptibility in two outbreak-related isolates was associated with conversion of OXA-66 into OXA-82 and its over-expression mediated by ISAb1. However, carbapenem resistance was only found in the blaOXA-82 over-expresser with reduced expression of the three outer-membrane proteins. Therefore carbapenem resistance was not solely associated with an enzymatic mechanism but with a combination of reduced permeability and over-expression of blaOXA-82.

**P1260** Investigation of repetitive PCR results and diversity of oxacillinases among invasive *Acinetobacter baumannii* isolates through 6 years (2004–2010) in a Turkish university hospital

A. Ergin\*, Ö. Köseoglu Eser, G. Hasçelik (Ankara, TR)

**Objectives:** *Acinetobacter baumannii* is a nosocomial pathogen which needs to be investigated by molecular epidemiologic tools for determining appropriate therapeutic regimen especially when multidrug resistance exists. The aim of the study was to evaluate molecular relationship of blood culture isolates of *A. baumannii* with repetitive PCR and search diversity of oxacillinases (OXA) through 2004–2010.

**Methods:** A total of 100 non-duplicate *A. baumannii* blood culture isolates diagnosed with conventional methods and BD Phoenix automated system between 2004 and 2010 in Hacettepe University, Ankara were evaluated. Of these, 87 *A. baumannii* isolates were analyzed using rep-PCR (DiversiLab, bioMerieux, FR). Antimicrobial susceptibility for piperacillin, amikacin, gentamicin, imipenem, meropenem, cefotaxime, ceftazidime, cefepim, ciprofloxacin and levofloxacin was determined by broth microdilution according to CLSI. Colistin, doripenem and tigecycline susceptibilities were performed by E-test. Presence of OXAs, OXA23-like, OXA24-like, OXA51-like and OXA58-like was investigated by PCR.

**Results:** Forty-four (44%) of the isolates were from intensive care units. Nineteen major rep-PCR clusters (A–T) were defined: A (11 isolates), B (nine isolates), C (eight isolates) and D (six isolates) being the most prevalent groups. Overall, 100% of the isolates were resistant to at least three classes of antibiotics. Colistin (98% susceptible) and tigecycline (94% susceptible) were the most susceptible antibiotics tested. Among 100 isolates, there was no significant difference between imipenem, meropenem (17%, both) and doripenem (18%) susceptibility. Carbapenem resistance was mostly associated to the presence of OXAs; OXA23-like (31%) and OXA58-like (23%). All the isolates harboured OXA51-like and none yielded OXA24-like. OXA23-like positive isolates had higher MIC90 levels, 64 mg/L for both imipenem, meropenem and 32 mg/L for doripenem. The occurrence of OXA58-like has increased through 2004–2009 (n:23) until 2010 (n:0), in contrast OXA23-like increased in 2008–2010 (n:31) period. Occurrence of OXA58-like and OXA23-like were more frequent among isolates of cluster A and D, respectively.

**Conclusion:** Analysis of cluster patterns and oxacillinases during 6 years demonstrated a high carbapenem resistance coherent with the replacement of isolates positive for OXA58-like to OXA23-like carbapenemase which highlights the monitoring of epidemic resistance control against *A. baumannii* invasive isolates.

**P1261** blaOXA-24/40-carrying plasmids have an important role in the dissemination process of carbapenem-resistant *Acinetobacter* spp.

F. Grosso\*, S. Quinteira, . Novais, L. Peixe (Porto, Famalicao, PT)

**Objectives:** The spread of OXA-24/40-producing *Acinetobacter* spp. has been strongly influenced by clonal expansion, but the role of horizontal gene transfer (HGT) has scarcely been explored. We studied the diversity of OXA-24/40 encoding plasmids and genetic environment of the blaOXA-24/40 genes among *Acinetobacter* spp. clinical isolates from two Portuguese hospitals.

**Methods:** blaOXA-24/40-carrying plasmids and genetic environments were characterized in representative *A. baumannii* (AB, n = 13) belonging to ST2/ST98 and *A. haemolyticus* (AH, n = 2) (2001–2007), selected from a collection of 157 carbapenem-resistant *Acinetobacter* spp. clinical isolates. AB were chosen on the basis of their ApaI-PFGE patterns (A, A1, A3 and A4). Electroporation was conducted using *A. baylyi* ADP1 as a recipient strain. blaOXA-24/40 genetic location was assessed by hybridization of I-CeuI and S1 gels with specific probes. Plasmid characterization was further accomplished by AB-PBRT, sequencing, and RFLP. The obtained sequences were compared with blaOXA-24/40-harbouring plasmids deposited in GenBank database, following a systematic in silico analysis.

**Results:** Transformants of two AB (PFGE A and A4) and one AH were resistant to all b-lactams except to ceftazidime, aztreonam and cefepime. Highly related 30 kb blaOXA-24/40-carrying plasmids (RFLP pattern A) identified in nine AB (PFGE A, A3 and A4) and

two AH, presented the replicase gene repA\_AB (GR12) and the sequences surrounding blaOXA-24/40 gene were identical to those of the blaOXA-24/40-carrying pAB02 plasmid. An OXA-24/40-encoding plasmid with 10 kb (RFLP pattern B) harbouring the replicase gene aci2 (GR2) was identified in five AB (PFGE A1, A3 and A4) and the blaOXA-24/40 genetic environment was closely related with that from pABVA01 and pMMC3 blaOXA-24/40 carrying plasmids. The two types of plasmids were observed in one AB (PFGE A4). Both blaOXA-24/40 and larger contiguous modules were flanked by XerC/XerD-like binding sites which might be responsible for their mobilization and identification of blaOXA-24/40 and/or common modules in either different plasmid types or in the chromosome.

**Conclusion:** The circulation of common genetic backbones and plasmids (30 kb-repA\_AB; 10 kb-aci2) harbouring blaOXA-24/40 among different AB PFGE-types and species of *Acinetobacter*, along with some previous evidences for HGT of blaOXA-24/40-carrying modules, strongly supports the role of particular platforms and plasmids in the dissemination process of OXA-24/40.

**P1262 Comparison of blaVIM, blaIMP, OXA-58, and OXA-23 real-time PCR results with various phenotypic methods in carbapenem-resistant *Acinetobacter baumannii* and *Pseudomonas* spp.**

S. Bilgi\*, G. Bahar, O. Gurbuz, M. Cagatay (Van, Ankara, TR)

**Objectives:** The aim of this study was to determine the prevalence of carbapenemase production among *Acinetobacter baumannii* and *Pseudomonas* spp. with modified Hodge test, combined disk, and double disk synergy tests, and compare the results with real time PCR. **Methods:** The study was conducted at our hospital between November 2008 and May 2009. Non-repeat 100 carbapenem resistant *A. baumannii* and *Pseudomonas* spp. isolated from clinical specimens were included in the study.

Strains were tested for carbapenemase production with modified Hodge test, imipenem, imipenem-EDTA combined disk, and ceftazidime-2MPA double disk synergy tests. blaVIM, blaIMP, OXA-58, and OXA-23 genes were investigated with real time PCR.

**Results:** Eighty-two of all carbapenem resistant strains were also resistant to ceftazidime. Either one of the genes were detected in 95 of the strains. BlaOXA23 was the most common type of carbapenemases detected. The most sensitive phenotypic method was IMP-IMP + EDTA, on the other hand the most specific phenotypic method was CAZ-2MPA.

The overall results of MHT, IMP-EDTA, CAZ-2MPA disk tests, real time PCR results, and sensitivity, specificity, positive and negative predictive values of phenotypic methods are presented in Tables 1, 2 and 3.

Table 1. Results of MHT,IMP-EDTA,CAZ-2MPA disk tests.

	IMP-EDTA positive	IMP-EDTA negative	CAZ-2MPA Positive	CAZ-2MPA negative	MHT positive	MHT negative
<i>A.baumannii</i> (n:66)	-	100%	10.6%	89.4%	81.8%	18.2%
<i>P.aeruginosa</i> (n:33)	45.5%	54.5%	-	100%	9.1%	90.9%
<i>P.flourescens</i> (n:1)	100%	-	-	100%	-	100%

Table 2. Real time PCR results.

	IMP	OXA-23	OXA-58	OXA-23 IMP	OXA-23 OXA-58	OXA-58 IMP	OXA-23 VIM	OXA-23 IMP VIM
<i>A.baumannii</i>	-	40	1	4	18	-	1	1
<i>P.aeruginosa</i>	3	21	-	-	4	1	-	-
<i>P.flourescens</i>	-	1	-	-	-	-	-	-

Table 3. Sensitivity,speciicity,PPV,and NPV of phenotypic methods

	Sensitivity	Specificity	PPV	NPV
MHT	57.8%	60.0%	96.5%	6.9%
IMP-IMP+EDTA	93.6%	20.0%	95.6%	14.2%
CAZ-2MPA	7.4%	100.0%	100.0%	5.3%

**Conclusion:** Rapid detection of carbapenemase-producing *A. baumannii* and *Pseudomonas* spp. is critical to prevent their widespread dissemination in intensive care units. Thus far, no standardized phenotyping method is available, and sensitivities and specificities of them are variable. According to results of this study high PPVs of all three phenotypic methods make them adequate for detection of carbapenemases in *A. baumannii* and *Pseudomonas* spp.

**P1263 A new method for studying efflux and membrane permeability in *Acinetobacter* species by measuring accumulation of Hoechst 33342 (bis-benzamide)**

G.E. Richmond\*, L.J.V. Piddock (Birmingham, UK)

**Objectives:** Multidrug resistant *Acinetobacter* species are an increasing problem in the hospital setting and nosocomial infection with these pathogens is becoming more and more common. Increase in efflux and loss of outer membrane porins in these bacteria can contribute to resistance to a wide range of clinically relevant antibiotics. The objective of this study was to develop an assay to measure accumulation of Hoechst (H) 33342 to study active efflux and membrane permeability in *Acinetobacter*.

**Methods:** H33342 is a fluorescent probe which permeates the cell membrane and fluoresces when intercalated with DNA or bound to a lipid membrane. The assay was carried out using various clinical and non-clinical and resistant and susceptible isolates of *Acinetobacter baumannii* inoculated into a black 96 well microtitre tray, and intracellular accumulation of the probe was measured in the FLUOstar using excitation and emission filters of 355 and 460 nm respectively. Concentrations of various efflux pump inhibitors (EPIs) non-inhibitory to growth of all isolates tested were determined by growth kinetics and the effect of addition of these EPIs on the accumulation rate of H33342 was studied.

**Results:** Addition of H33342 to *Acinetobacter* cells grown to mid-log phase produced a rapid increase in fluorescence when measured in the FLUOstar. This increase varied between strains, reflecting differing levels of efflux activity and membrane permeability. Addition of efflux inhibitors such as CCCP, a disruptor of the proton motive force, and PABN, a competitive inhibitor of RND pumps, gave rise to increased fluorescence levels reflecting higher levels of accumulation in cells due to reduced efflux activity, confirming H33342 as a substrate of *Acinetobacter* efflux pumps.

**Discussion:** By studying the intracellular accumulation of H33342 in real time, this assay allows the levels of efflux activity to be inferred. It provides a simple and efficient method for comparing efflux and membrane permeability in clinical isolates of *Acinetobacter*, a species in which efflux is a major contributing factor to multidrug resistance. This work was supported by MRC grant G0801977.

**P1264 Deletion of AdeFGH pump increases susceptibility of multidrug-resistant *Acinetobacter baumannii* to carbapenems**

I. Amin, P. Sen, T.H. Koh, G.E. Richmond, L.J.V. Piddock, K.L. Chua\* (Singapore, SG; Birmingham, UK)

**Objectives:** *Acinetobacter baumannii* is a major etiological agent of nosocomial infection worldwide and is becoming increasingly resistant to multiple antibiotics, including carbapenems. The objective of this study is two-fold: to develop a genetic tool for creating gene deletions in multidrug-resistant (MDR) *A. baumannii* and to identify an efflux pump that confers resistance to carbapenems.

**Methods:** *A. baumannii* R2 (TTS6013 654325/03) is a MDR isolate from a collection by the Network for Antimicrobial Resistance Surveillance (Singapore). The adeFGH operon was deleted using a modified markerless gene replacement approach. DNA fragments flanking the deletion was cloned into a mobilizable suicide plasmid, pMo130TelR, and introduced into *A. baumannii* R2 by biparental conjugation. Transconjugants were selected on LB agar containing

tellurite and R2 that had undergone allelic exchange to produce the adeFGH deletion was selected by passaging in LB containing sucrose. The adeFGH deletion in R2 was confirmed by PCR. Antimicrobial susceptibility of the mutant and parental strain was determined using BSAC standard agar dilution and NCCLS broth microdilution methods.

**Results:** The R2Delta adeFGH mutant was created using a modified markerless gene replacement methodology. Incorporation of a tellurite-resistance cassette into pMo130 facilitated selection of MDR *A. baumannii* harboring the plasmid construct. Subsequent passages in LB containing 10% sucrose yielded R2 mutants with deletion of adeFGH. Deletion of adeFGH was confirmed by PCR. Antimicrobial susceptibility testing revealed at least 64-fold increase in susceptibility to meropenem and imipenem in R2Delta adeFGH compared to the parental R2 strain. Susceptibility to aminoglycosides, tetracyclines, chloramphenicol, fluoroquinolone, macrolide, beta-lactams and trimethoprim were unaffected by deletion of adeFGH in MDR *A. baumannii* R2.

**Conclusion:** We have successfully modified a markerless gene replacement strategy and used it to generate efflux pump deletion in MDR *A. baumannii* R2. Deletion of the AdeFGH efflux pump specifically increases susceptibility of MDR *A. baumannii* R2 to carbapenems but not other classes of antibiotics.

This work was supported by a Singapore-UK grant: A\*STAR-UK MRC JGC1366/G0801977.

#### **P1265** Evaluation of colistin-resistant *Acinetobacter* strains

I. Baran\*, I. Mumcuoglu, N. Aksu, A. Yetkin, F. Coskun, D. Kanyilmaz, H. Bodur, Z. Karahan (Ankara, TR)

**Objectives:** *Acinetobacter baumannii* is an important pathogen in ICU patients. In nosocomial *A. baumannii* isolates resistance to extended spectrum beta-lactams, carbapenems, aminoglycosides and fluoroquinolones are widespread. Recently, colistin seems last resort for therapy. The first colistin resistant *A. baumannii* isolate was reported in March 2011 in our hospital and followed by repeated isolation of other resistant strains. In this study phenotypic and genotypic properties of colistin resistant *A. baumannii* strains was investigated.

**Methods:** Nine colistin resistant *A. baumannii* strains isolated from seven patients were included the study. We included more than one isolates some of the patients because they were from different body sites with different MIC concentrations. Hospital Infection Control Committee explained two of this isolates were colonization and seven were pathogens. Identification and antimicrobial susceptibility of isolates were determined by VITEK2 (bioMerieux/France) system. Confirmation was done by E-test. Clonal analysis were evaluated by PFGE. Environmental culture specimens from related clinics were investigated.

**Results:** Three different groups were identified by PFGE as group A, B and C. There was blood and tracheal aspirate specimens of the first patient in group A. MICs of this strains were found to be 4 and 32 µg/mL respectively. There was seven specimens of six patients from same ICU in group B. MIC concentrations were 64 µg/mL of all strains. One patient from burn unit was in group C. MIC of this isolate was 7 µg/mL. Isolates in group B and C was only susceptible to trimethoprim-sulphametaxazole. Five of this patients were dead before their therapy were changed. One patient was not given therapy because the strain was determined as colonisation. The other patient was the first resistance case and cured by colistin therapy. No *A. baumannii* was isolated from environmental cultures.

**Conclusion:** Six patients in group B was considered as a cluster formation. After taking proper precautions no other cases has been seen. It was interesting that all strains in this group were susceptible to trimethoprim-sulphametaxazole and it is needed to investigate in vivo study. Resistance to colistin for multidrug resistant *Acinetobacter* strains is a very important problem. In order to prevent spread of this resistance health workers should strictly abide infection control precautions and rational antimicrobial usage should be applied.

#### **P1266** Involvement of the outer membrane protein OmpW in colistin resistance of *Acinetobacter baumannii*

M. Catel-Ferreira, S. Marti, G. Coadou, T. Jouenne, J. Vila, E. Dé\* (Mont-Saint-Aignan, FR; Barcelona, ES)

**Objectives:** The increasing number of *Acinetobacter baumannii* multi-drug resistant isolates, especially the carbapenem-resistant ones, has converted colistin in a drug of last resort to treat severe infections caused by this emerging pathogen. The objectives of this study were to decipher the mechanisms that could develop *A. baumannii* at the outer membrane (OM) level to resist to the activity of colistin.

**Methods:** Colistin mutant production was undertaken by consecutive passages on media with increasing concentrations of colistin sulphate salt. The comparison of OM protein profiles between the colistin-resistant mutant (MIC > 256 µg/mL) and the susceptible strain, was performed by SDS-PAGE and protein identification by mass spectrometry. Production of *A. baumannii* OmpW was achieved via overexpression in *Escherichia coli* BL21, purification by affinity chromatography and refolding by a dilution method. Functional analyses, single-channel conductance and colistin, Fe<sup>3+</sup> and LDAO specificity measurements, were performed by reconstitution in artificial planar lipid bilayers. The crystal structures of *Pseudomonas aeruginosa* OprG and *E. coli* OmpW were used as template structures for creating an homology model of the *A. baumannii* OmpW generated by the Modeler 8v1 program.

**Results:** Comparison of OM protein profiles allowed us to identify a loss of expression of the outer membrane OmpW in the colistin-resistant mutant. After purification of a recombinant *A. baumannii* OmpW, functional reconstitutions determined a single-channel conductance value of 23 pS (in 1 M KCl), and highlighted a marked specificity of OmpW towards Fe<sup>3+</sup>, LDAO and colistin. The predictive OmpW 3-D model envisaged an eight beta-stranded beta-barrel in which the structural features of *P. aeruginosa* OprG and *E. coli* OmpW were conserved, i.e., a hydrophobic entrance of the channel and a lateral opening that could allow the small hydrophobic compound diffusion.

**Conclusion:** Taken together, these results allowed to conclude that OmpW from *A. baumannii*, as do OmpW proteins from other bacteria, could participate to the assimilation of iron and hydrophobic compounds in *A. baumannii*. Moreover, the structural features of this hydrophobic channel might explain its capacity to bind the colistin. Its loss in the OM could be one of the means, together with lipopolysaccharide modifications, for *A. baumannii* to develop colistin resistance.

#### **P1267** High-throughput mass spectrometry analysis reveals alterations in iron acquisition systems in meropenem heteroresistant *Acinetobacter baumannii*

A. Ikonomidis\*, M. Panopoulou, G. Panayotou, M. Samiotaki (Alexandroupolis, Athens, GR)

**Objectives:** To further investigate the proteomic profile of a characterized meropenem heteroresistant *Acinetobacter baumannii* isolate using high-throughput mass spectrometry analysis.

**Methods:** Sodium-dodecyl-sulfate (SDS) polyacrylamide gel electrophoresis (PAGE) of protein crude extract, in-gel protein digestion of bands of interest, nano-high performance liquid chromatography and high – throughput mass spectrometry (MS/MS) analysis for protein identification were performed. All techniques were applied to both the native and the meropenem heteroresistant populations of a previously characterized meropenem heteroresistant *A. baumannii*. The MS raw file was searched using the SEQUEST algorithm against ATCC 17978 *A. baumannii* protein database.

**Results:** A putative siderophore receptor (MW: 55.2; pI: 5.57), two ferric enterobactin receptor precursors (MW: 57.7; pI: 5.28 and MW: 19.4; pI: 8.78 respectively) as well as two putative ferric siderophore receptor proteins (MW: 81.2; pI: 6.05 and MW: 80.0; pI: 6.23 respectively) were not present in the meropenem heteroresistant

populations in contrast to the native population. On the other hand a putative ferric siderophore receptor protein (MW: 85.4; pI: 7.80) was present in the meropenem heteroresistant populations but not in the native population.

**Conclusion:** The siderophore mediated iron acquisition systems may play a role in the meropenem heteroresistant phenotype of *A. baumannii*.

**P1268** **Modelling in vitro time growth to predict the fitness cost of drug-resistant *Acinetobacter baumannii* and *Pseudomonas aeruginosa***

B. Guo, K. Abdelraouf, K.R. Ledesma, M. Nikolaou, V.H. Tam\* (Shanghai, CN; Houston, US)

**Objectives:** It has been proposed that antimicrobial resistance is usually associated with a fitness cost. The fitness is often determined by competition experiments between isogenic strains (wild-type and resistant mutant). However, this approach is time-consuming and labor-intensive. An alternative method was developed to assess fitness cost in drug-resistant bacteria.

**Methods:** Time-growth studies were performed with 10<sup>5</sup> CFU/mL of *Acinetobacter baumannii* or *Pseudomonas aeruginosa* at baseline. Serial samples were obtained to quantify the bacterial burden over 24 hours. The in vitro growth rates (Kg) of isogenic strains were determined individually in full- and 0.1-strength broth. The relative abundance of the two strains in a co-culture over time was predicted based on the difference in Kg, and subsequently validated by in vitro growth competition experiments for up to 144 hours.

**Results:** The in vitro growth rates of *A. baumannii* were not significantly different in different strengths of broth; the Kg for the wild-type and resistant mutant was 2.38 and 1.23 per hour, respectively. In contrast, the difference in Kg for the wild-type and resistant mutant was not as great in *P. aeruginosa* (1.22 per hour vs. 1.07 per hour). For both bacteria, the proportion of the resistant mutant in the competition co-culture gradually diminished. These experimental observations were in general agreement with the model predictions, suggesting good predicting ability of the mathematical model.

**Conclusion:** The model was found to be reasonable in characterizing in vitro bacterial growth and predicting the fitness cost of resistance. The simple method appeared robust in the assessment of fitness cost associated with drug resistance.

## Epidemiology and molecular resistance of *Staphylococcus* sp. and *Enterococcus* sp.

**P1269** **Spread of methicillin-susceptible *Staphylococcus aureus* ST398 in patients, health care workers and environment in an intensive care unit**

A.S. Brunel\*, A.L. Bañuls, H. Marchandin, D. Morquin, E. Jumas-Bilak, P. Corne (Montpellier, FR)

**Objectives:** An increasing number of human infections with livestock-associated *Staphylococcus aureus* sequence type (ST) 398 has been recently reported. Here, *S. aureus* ST398 isolated from patients, health care workers (HCW) and environmental samples in an Intensive Care Unit (ICU) of Montpellier Hospital were characterized with the aim to understand the circulation of this pathogen into the ICU.

**Methods:** One hundred and twenty-five *S. aureus* were isolated between February and June 2011 in the ICU from patients, HCWs and environment, and typed by MultiLocus Sequence typing (MLST). *S. aureus* ST398 strains were analyzed by double-locus sequence typing (DLST) and accessory gene regulation (agr) typing. Resistance to antibiotics was detected by disk-diffusion method. Macrolide-lincosamide-streptogramin type B (MLSB) resistant strains were screened by PCR for erm(A), erm(C), erm(T) and msr(A) genes. Virulence genes were detected by specific PCRs.

**Results:** Out of the 125 isolates, 29 methicillin-susceptible *S. aureus* (MSSA) ST398 or variant were isolated in nasal carriage and invasive

diseases in five patients (n = 12), nasal colonization of two HCWs (n = 2) and environmental samples (n = 15). For the first time, four isolates were identified as variant of ST 398 with a mutation in the pta gene. All isolates were agr1 and DLST-type 144–186. Erythromycin resistance and inducible MLSB phenotype were observed for 76% of the isolates. Seven environmental isolates showed additional resistance to Kanamycin, Tobramycin and Gentamicin. All strains harbored the erm(T) gene and different combinations of erm(A) and erm(C) and the absence of msr(A). No isolate contained the genes encoding the Pantone Valentine Leukocidin, TSST-1 and Staphylococcal Enterotoxin A. No history of contact with livestock was identified in patients and HCWs. Two patients presented nosocomial pneumonia after acquired-nasal colonization.

**Conclusion:** Isolation of MSSA ST398 strains in patients, HCWs and environment in an ICU during short time period underlines the capacity of this emerging pathogen to rapid person-to-person transmission and the role of the environment as potential reservoir. Despite the absence of large antibiotic resistance and virulence traits, MSSA ST398 can lead to severe infections in critically ill patients. Evolutionary capacity of ST398 genotype is underlined here by description of a mutated genotype, the impact of the mutation on the phenotypic and spreading properties of ST398 genotype has to be investigated.

**P1270** **Modulating activity of vancomycin and daptomycin on the expression of autolysis cell-wall turnover and membrane charge genes in hVISA and VISA strains**

V. Cafiso\*, T. Bertuccio, D. Spina, S. Purrello, S. Stefani (Catania, IT)

**Objectives:** Emerging resistance to glycopeptides in Methicillin-Resistant *Staphylococcus aureus* (MRSA) poses a great threat to antimicrobial chemotherapy worldwide. Recent publications have added to the knowledge of the complex changes taking place in *Staphylococci* evolving towards the reduced glycopeptide susceptibility phenomenon that involves different genetic loci (regulatory, autolytic, cell-wall turnover and cell-envelope positive charge genes). In addition, reduced susceptibility to vancomycin can influence the development of resistance to daptomycin.

**Methods:** The aim of our study was to investigate, by real time RT-PCR, the relative quantitative expression of genes involved in autolysis (atl-lytM), cell-wall turnover (sceD), cell-envelope charges (mprF-dltA) and regulatory mechanisms (agr-locus-graRS-walKR), in heterogeneous Vancomycin-Intermediate-*S. aureus* (hVISA), i.e. Mu3 and three clinical isolates, and Vancomycin-Intermediate-*S. aureus* (VISA) i.e. Mu50, cultured with or without vancomycin and daptomycin.

**Results:** Our results show that hVISA and VISA presented an up-regulation of sceD, and mprF or dltA (in Mu3 and Mu50, respectively) together with a progressive agr-locus down-regulation with respect to Vancomycin Susceptible *S. aureus* (VSSA). Indeed, VISA showed an atl/lytM down-regulation with respect to hVISA and obviously VSSA. The addition of vancomycin or daptomycin sub-inhibitory concentrations to the growth-medium with respect to the free-drug conditions, determined an atl/lytM down-regulation in hVISA, whereas only daptomycin up-regulated the mprF expression both in hVISA and VISA.

**Conclusions:** hVISA and VISA present common features that distinguish them from VSSA, responsible for the intermediate glycopeptide resistance i.e. an increased cell-wall turnover, an increased positive cell-envelope charge responsible for a repulsion mechanism towards vancomycin and daptomycin, and reduced agr-functionality. Vancomycin and daptomycin, acting in a similar manner in hVISA and VISA, can influence their cross-resistance mechanisms promoting VISA behavior in hVISA and enhancing the cell-wall pathways responsible for the intermediate vancomycin resistance in VISA. Daptomycin can also induce a charge repulsion mechanism both in hVISA and VISA increasing the mprF activity.

**P1271** Staphylococcal chromosome cassette mec stability in major endemic methicillin-resistant *Staphylococcus aureus* clones over 20 years.

M. Camoetz\*, J. Sierra, T. Conceição, M. Miragaia, H. De Lencastre, R. Martín, M. Domínguez (Barcelona, ES; Oeiras, PT; New York, US)

**Objectives:** Hospital acquired-Methicillin-Resistant *Staphylococcus aureus* (MRSA) clones are defined by the combination of genetic background and Staphylococcal chromosome cassette mec (SCCmec) type. However in some cases the same clone may be associated to different SCCmec types or variants of the initial type. The aim of this study was to analyze the stability of the SCCmec element among MRSA representative of major endemic clones in the Hospital de Bellvitge (HB) over the last 20 years (1990–2010).

**Methods:** A collection of 166 isolates from bacteremic patients and belonging to three major clones was selected for study: 100 isolates belonged to Clonal Complex (CC) 5 (ST5, ST125, ST146 and ST228); 58 to CC8 (ST8, ST247 and ST1819); and 8 to CC22 (ST22). Isolates were chosen to include the highest variability of PFGE subtypes and antibiotic resistance profiles (ARP) identified for each clone. All selected isolates were typed by SCCmec, agr, spa, ACME (detection of arc and opp3 genes), ccrB sequencing and MLST.

**Results:** The Iberian clone (ST247-SCCmecI-agr-I) was the most prevalent from 1990 to 2000 and no change was observed in its SCCmec structure. Forty-eight isolates from this pandemic clone, showed a single ARP and four different spa types, spa t051 being the most frequent (65%). Between 1996 and 2003, isolates of CC5 rapidly increased and have remained dominant through 2010. All 82 CC5 isolates analyzed showed SCCmec type IVc and were distributed in three clones: ST5-IVc-agr-II; ST125-IVc-agr-II and ST146-IVc-agr-II. CC5 isolates showed 11 ARP and 16 spa types: t002 (32%) and t067 (47%) accounting for 79% of the isolates. Other important endemic clones found in the 2004–2010 period were: ST8-IVc-agr-I, spa t008 (n = 10); ST228-I-agr-II, spa t041 (n = 18) and ST22-IVh-agr-I, spa t032 (n = 8). The ccrB sequencing confirmed the SCCmec type obtained by the multiplex strategy. Gene clusters arc and opp3 were not found in any of the studied isolates.

**Conclusion:** The SCCmec element has remained highly conserved in isolates of a given clone over extended time intervals. Isolates of CC5 in our setting have shown significant stability of SCCmec type IVc in spite of variable antibiotic resistance and spa types.

**P1272** MRSA harbouring mecA-LGA251, a new highly divergent mecA variant: performance of the methods used in routine labs to screen, detect and confirm methicillin resistance

F. Laurent\*, R. Skov, B. Pichon, C. Teale, G. Edwards, M. Holmes, A. Tristan, R. Hill, M. Bes, J.-W. Decousser, A. Petersen, A. Kearns, F. Vandenesch, A.R. Larsen (Lyon, FR; Copenhagen, DK; London, Shrewsbury, Glasgow, Cambridge, UK; Clamart, FR)

**Background:** A new mecA variant, named mecA-LGA251, showing <70% homology with the classical mecA gene, has recently been described in methicillin-resistant *Staphylococcus aureus* (MRSA) isolates from human and animal. We investigated the performance of different phenotypic and genotypic methods routinely used in microbiological labs to screen, detect, and confirm the presence of isolates harboring such a methicillin-resistance (MR) mechanism.

**Methods:** A large collection including 111 mecA-LGA251-positive isolates were collected in UK, Scotland, Denmark and France. Four chromogenic MRSA selective media (MRSA Select (bR), ChromID MRSA (bM), BBL CHROMagar MRSA II (BD), Brilliance MRSA 2 (Oxoid)) were tested for screening. Antimicrobial susceptibility tests (AST) included MIC for FOX and OXA using BMD, AST-P581 (Vitek), PMIC/ID-60 (Phoenix), Pos MIC Panel Type 31 (Microscan). Immunological detection of additional PBP were performed using Clearview Exact PBP2a (Alere) and PBP2a agglutination (Oxoid).

Finally, molecular tests, including “homebrew” mecA PCR, BD GeneOhm StaphSR assay (BD), Xpert MRSA/MSSA SSTI and nasal (Cepheid), NucliSENS EasyQ MRSA (bM) and DNA microarray StaphyType (Alere), were performed.

**Results:** The 111 isolates belonged to CC130 (n = 92, agr 3, 16 spa-types), CC1943 (n = 14, agr 4, four spa-types) and CC425 (n = 5, agr 2, four spa-types). All were MR but susceptible to all the other antibiotics tested.

Data highlighted a highly variable sensitivity for the various selective media and AST tested (see Table 1). Clearview Exact PBP2a test, performed after cefoxitin induction (disc), were the only method allowing the confirmation of expression of additional PBP in all isolates. None of the homebrew mecA PCR or commercial molecular kits currently available was able to identify these isolates. Using DNA microarrays (n = 37), assignment to the specific clones known to be positive for mecA-LGA251 gene were achieved and data revealed the seldom presence of some toxins and virulence genes: tst (n = 7), egc (n = 9), edinB (n = 8), sec (n = 3), sel (n = 3).

CC	agr	n	Number of different spa	Antimicrobial susceptibility test						Immuno (chromatography)		Screening selective media (number of MRSA detected after 24h)

Table 1: Data obtained for a collection of 111 European MRSA isolates harboring mecA-LGA251 gene.

**Conclusion:** The data presented demonstrates that (i) the ability of commercial methods used to screen, identify or confirm mecA-LGA251-positive isolates is highly variable, (ii) such isolates may be missed depending on the used algorithms. The only ways to definitively confirm the methicillin-resistance in such isolates are the use of specific mecA-LGA251 PCR or Clearview Exact PBP2a after cefoxitin induction.

**P1273** A new mechanism for the mobilisation of mecA independent of the action of cassette chromosome recombinase

Z. Zong\* (Chengdu, CN)

**Objectives:** To investigate the genetic context of mecA in a methicillin-resistant *Staphylococcus haemolyticus* isolate, WCSH1, in which no cassette chromosome recombinase (ccr) genes could be detected.

**Methods:** mecA and ccr genes were screened using primers published previously. The region between mecA and orfX, the insertion site of the staphylococcal cassette chromosome (SCC), was amplified using long-range PCR and then sequenced. The region downstream of mecA was obtained using a few inverse PCR with self-ligated enzyme-restricted WCSH1 genomic fragments as the template and PCR mapping. Linkages between different genetic components were confirmed using overlapping PCR and sequencing.

**Results:** A 46-kb region containing mecA was obtained from WCSH1, bounded by orfX at one end and several orfs that were present on the chromosome of the completely-sequenced *S. haemolyticus* JCSC1435 at the other (Figure 1). Of note, orfX was located at the left side of mecA rather than at the right side as seen in almost all contexts of mecA. This 46-kb region was very complex in structure with five copies of IS431 and contained multiple genetic components with different origins. For instance, the 3.7-kb structure adjacent to orfX was almost identical to that on the chromosome of *Staphylococcus epidermidis* RP62A but was absent from *S. haemolyticus* JCSC1435. Sequences resembling the terminal inverted repeats of SCC were found but no ccr genes could be detected. mecA was bracketed by two copies of IS431 and a 8-bp (CTTTTTGC) direct target repeat sequence (DR) was

identified flanking this IS431-mecA-IS431 structure. The 8-bp DR was part of the spacer sequence between *arsR* (encoding the arsenical resistance operon repressor) and *copA* (encoding a copper-exporting ATPase).

**Conclusion:** The presence of 8-bp DR indicates that the two copies of IS431 composed a composite transposon that mobilised *mecA* into the spacer between *arsR* and *copA*, which is independent of the action of cassette chromosome recombinase. This finding is of significance as multiple copies of IS431 are commonly present in the contexts of *mecA* and might form various composite transposons for mobilising *mecA*. The fact that genetic components with different origins were separated by multiple copies of IS431 suggests that IS431 served as the “adapter” facilitating the formation of large mosaic contexts containing *mecA* by promoting the joining of different regions.

**P1274** Emergence of high-level mupirocin resistance in hospital- and community-acquired methicillin-resistant *Staphylococcus aureus* in Pontevedra, Spain

E. Pérez-Roth\*, C. Potel-Alvarellos, X. Espartero, L. Constela-Caramés, S. Méndez-Álvarez, M. Álvarez-Fernández (La Laguna, Vigo, Santa Cruz de Tenerife, ES)

**Objectives:** Mupirocin is used to control the prevalence of methicillin-resistant *Staphylococcus aureus* (MRSA). High-level mupirocin resistance (Hi-MupR, MICs  $\geq 512$  mg/L) is of particular concern, having been frequently associated with treatment failure. The aim of this study was to determine the emergence and mode/s of spread of Hi-MupR in the MRSA population recovered from 2002 to 2009 in four medical centers in Pontevedra, Galicia, Spain.

**Methods:** All hospital- and community-acquired MRSA isolates were included and screened for mupirocin resistance. High-level mupirocin resistant MRSA were characterized by antibiotyping, genotyping (multilocus sequence typing, *spa* typing and pulsed-field gel electrophoresis), and plasmid analysis.

**Results:** Thirty-one single patient high-level mupirocin resistant (MICs  $\geq 1024$   $\mu$ g/mL) MRSA isolates were identified. Four main clonal types, as defined by molecular typing were recognized: ST8/t008/PFGE types H and I (four isolates), ST36/t018/PFGE types E and F (seven isolates), ST72/t148/PFGE type G (three isolates), and ST125/t067/PFGE types A to D (15 isolates). The high-level mupirocin resistance *ileS2* gene was harbored by nine plasmid types (i.e., pCPEP\_1 to pCPEP\_9) based on distinct IS257-*ileS2* spacer configurations that correlated with *ileS2*-locus hybridization polymorphs. Some plasmid types were present in different MRSA clonal types and were recovered from patients treated in distinct medical centers over several years. pCPEP\_1 (configuration UpR882-DnR267/hybridization polymorph I) and pCPEP\_4 (configuration UpR319-DnR267/hybridization polymorph IV) were the most prevalent and were dispersed among clonal complexes (CCs) 5, 8, and 30. Furthermore, diverse plasmid types were recovered from isolates of the same clonal type. Remarkably, seven plasmid types were recovered from ST125 MRSA isolates. Plasmid types pCPEP\_5, 7, 8, and 9 were associated with unique clonal types.

**Conclusions:** This study remark the utility of typing IS257-*ileS2* spacer regions for the rapid differentiation of *ileS2*-encoding plasmid types. Horizontal transmission of a diverse set of plasmids promoted the emergence of Hi-MupR. Clonal expansion of MRSA hardly contributed to the dispersion of the resistance. This valuable epidemiological information is of great importance for the design of appropriate containment epidemiology strategies to preserve the effectiveness of mupirocin.

**P1275** Molecular analysis of high-level mupirocin-resistant methicillin-resistant *Staphylococcus aureus* recovered in Ireland between 1998 and 2009

O.M. Brennan\*, A.C. Shore, K. Kadlec, S. Schwarz, D.C. Coleman (Dublin, IE; Neustadt-Mariensee, DE)

**Introduction:** High-level mupirocin resistance (Hi-MupR) in methicillin-resistant *Staphylococcus aureus* (MRSA) is mediated by the plasmid-encoded *ileS2* (*mupA*) gene. In Ireland, the incidence of Hi-MupR MRSA from bloodstream infections increased from 1.4% to 3.1% between 2005 and 2009. Isolates exhibiting antibiogram-resistogram (AR) and pulsed-field gel electrophoresis (PFGE) types indicative of ST8-MRSA-IIA-E predominated among Hi-MupR MRSA between 1999 and 2005 and those indicative of the current endemic clone, ST22-MRSA-IV, predominated since 2006. The majority of Hi-MupR ST22-MRSA-IV isolates also exhibited aminoglycoside resistance.

**Objective:** To undertake comparative genetic analysis of Hi-MupR MRSA recovered from patients in Irish hospitals between 1998 and 2009.

**Materials and methods:** A total of 109 isolates, representative of the different AR-PFGE patterns of Hi-MupR MRSA recovered from patients in Irish hospitals between 1998 and 2009, were analysed by DNA array profiling (Alere, Germany). Hi-MupR-conferring conjugative plasmids from MRSA, representing the main genotypes prevalent among the Hi-MupR isolates, were subjected to fingerprinting with BglIII, EcoRI and HindIII, Southern hybridisation with an *ileS2* probe and sequence analysis of the *ileS2* flanking regions.

**Results:** The 109 Hi-MupR MRSA isolates were assigned to five genotypes, namely ST22-IV (53%), ST8-IIA-E (38%), ST36-II (7%), ST239-III (1%) and ST5-IV (1%). Plasmid analysis of the three main genotypes revealed a distinct ca. 40 kb *ileS2*-encoding conjugative plasmid and a second large plasmid harbouring *aacA*-aphD. The trimethoprim resistance gene *dhfr*S1 was detected on a Hi-MupR-encoding plasmid in one ST22-MRSA-IV isolate.

**Conclusion:** This study has so far revealed the presence of large distinct conjugative plasmids encoding Hi-MupR in Irish MRSA isolates representative of three distinct genotypes. Significant spread of these plasmids into hospital-associated and community-associated MRSA may compromise our ability to eradicate nasal colonisation of MRSA using mupirocin.

**P1276** Role of insertion sequence IS257 in the dissemination of high-level mupirocin resistance *ileS2* gene in staphylococci: a preliminary study

E. Pérez-Roth, J. Martín-Padrón\*, E. Martín-Núñez, S. Méndez-Álvarez (La Laguna, Santa Cruz de Tenerife, ES)

**Objectives:** Our previous comparative analysis of four completely sequenced pSK41-like plasmids showed that the DNA segments containing the high-level mupirocin resistance *ileS2* gene flanked by copies of insertion sequence IS257 occupy a unique position within each plasmid backbone. These findings imply independent acquisition events through the activity of IS257 and the data suggested that transposition has contributed to the process. In this preliminary study the aim was to obtain further information on the role of IS257 to mediate the genetic capture and dissemination of the *ileS2* gene.

**Methods:** A total of 55 high-level mupirocin resistant (MICs  $\geq 1024$  mg/L) staphylococci containing non-sequenced *ileS2*-carrying plasmids were included. These plasmids were classified into distinct structural groups based on different IS257-*ileS2* spacer configurations. For each isolate the insertion site of segments containing the *ileS2* gene into the plasmid backbone was determined through PCR amplification and subsequent sequencing of amplicons using primers specific to the up- and downstream IS257-*ileS2* spacer regions. Additionally, comparative analyses of DNA sequences of

ileS2-flanking IS257s and adjacent regions were determined in order to obtain insights about the integration mechanisms.

**Results:** Our strategy allowed us to get the adjacent DNA sequences outside to flanking IS257 copies to precisely locate the insertion sites of ileS2-encoding segments within the pSK41-like conserved backbone without the need to conduct comprehensive plasmid sequencing. This analysis mapped several integration sites of IS257-ileS2-IS257 segments. As expected, an identical integration site was found for plasmids belonging to the same structural group. However, structurally different plasmids also shared the location of ileS2-encoding segments. As previously observed, for some plasmids, the existence of flanking 8-bp target duplications adjacent to flanking IS257s imply that transposition has contributed to the process and this was supported by the identity or near-identity of the IS257 sequences. In other plasmids, there was no evidence of a transposition event.

**Conclusions:** Results allowed to conclude that the number of insertion sites of ileS2-encoding segments is smaller than expected based on the IS257-ileS2 configurations. As noted previously, our data suggested that a transposition mechanisms mediated by IS257 participate in the movement of the ileS2 gene.

#### **P1277** Characterisation of a cfr-positive methicillin-resistant *Staphylococcus epidermidis* strain of the lineage ST22 implicated in a life-threatening human infection

C. Lozano, M. Ruiz-García, P. López-García, G. Royo-García, M. Zarazaga, C. Torres\* (Logroño, Elche, ES)

**Objectives:** The gene cfr encodes a methyltransferase which produces the methylation of the 23S rRNA leading to a multiresistant phenotype. This gene was identified in Methicillin resistant *Staphylococcus epidermidis* (MRSE) isolates from a very serious human case. The aim was to characterize the cfr positive MRSE isolates and to determine the localization and the genetic environment of this gene.

**Methods:** Three MRSE isolates were detected in samples from cerebrospinal fluid, pleural drainage and vascular catheter of the patient. Antibiotic susceptibility testing was performed by Wider system and for nine agents also by the agar dilution method (chloramphenicol, clindamycin, erythromycin, lincomycin, linezolid, tetracycline, tiamulina, trimethoprim and virginiamycin). The three MRSE isolates were typed by MLST, PFGE and SCCmec-typing. The presence of resistance genes was studied by PCR. The presence of mutations in 23S rRNA, L3, L4, L22, grlA, gyrA and fusA was investigated by PCR and sequencing. The three MRSE isolates were tested by PCR for the genes lukF/lukS-PV, icaA, icaB, icaC and for the IS256 element. Plasmid or chromosomal gene location was determined by S1-PFGE and I-CeuI-PFGE hybridization. Genetic environment was studied by PCR-mapping and sequencing. Conjugative transfer of cfr gene was performed.

**Results:** The three MRSE strains showed the same PFGE-pattern, belonged to ST22 and had SCCmec-type III. All of them were resistant to 10 antimicrobials groups. The presence of cfr, fexA, aac(6')-aph(2), dfrA, icaA, icaB and icaC genes was confirmed by PCR. Mutations mediating quinolone resistance revealed the S80F and D84N exchanges in GrlA and S84F in GyrA. MRSE isolates possessed L101V and A58T substitutions and 135QGRGPM136 insertion in L3 and N64K and N158S exchanges and 71G72 insertion in L4. The sequencing of 23S rRNA revealed the mutation C2534T. No mutations were identified in L22 and in fusA. Hybridization experiments revealed the presence of the cfr gene in a plasmid of 45-kb and in chromosomal DNA. One transconjugant was obtained and the genetic environment was similar to pSCFS7 (FR675942.1), including the gene fexA. PVL and the IS256 element were not detected.

**Conclusion:** We describe a fatal human case in which cfr-positive MRSE ST22 isolates were detected. The spread of this resistance mechanism is especially worrisome due to this gene lead to simultaneous resistance for several antimicrobials.

#### **P1278** New MLSB resistance gene in *Staphylococcus lentus*

S. Schwendener\*, V. Perreten (Berne, CH)

**Objectives:** One *S. lentus* isolated from a healthy dog displayed resistance to macrolides, lincosamides and streptogramins B (MLSB). Resistance to lincosamide was inducible. However, the underlying mechanism of resistance remains unknown. The aim of the study was to identify and characterize the MLSB resistance determinant in *S. lentus*.

**Methods:** Antibiotic susceptibility was determined by the measurement of the MIC by broth dilution. Inducible resistance was determined by D-test and in broth in the presence of 4 mg/L erythromycin. The genome of *S. lentus* SD952 was sequenced by 454 technology and analyzed for putative erm genes. An erm candidate gene was cloned into the *E. coli* – *S. aureus* shuttle vectors pBUS1 and pRB474 and electro-transformed into susceptible *S. aureus* RN4220.

**Results:** A new Erm determinant was identified by whole genome sequencing of *S. lentus* SD952. The new Erm determinant showed the closest identity to Erm(A) of *S. aureus* with 60% amino-acid identity and 40% DNA identity. Expression of the new erm gene in RN4220 showed an increase of resistance to the macrolide erythromycin (MIC > 64 mg/L) and an inducible increase of resistance to the lincosamide clindamycin (MIC > 128 mg/L) and to the streptogramin B pristinamycin IA (MIC > 64 mg/L). PCR analysis using primers specific for the new erm gene revealed that it was also present in methicillin-resistant *S. lentus* isolates from poultry and slaughterhouse employees.

**Conclusion:** This study identified and characterized a novel inducible resistance gene. Genetic relationship and phenotypic resistance showed that this new gene belongs to the Erm determinant conferring resistance to MLSB antibiotics. This study showed that this gene is also widespread in *S. lentus* isolates from healthy animals and humans working in animal environment.

#### **P1279** Fluoroquinolone recognition by prokaryotic *S. aureus* NorA and eukaryotic murine Mrp4 efflux transporters: a combined experimental and structural study

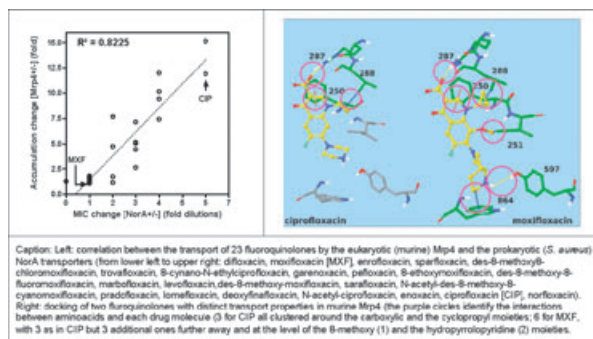

J. Dupont, C. Vallet, P. Tulkens\*, M. Prévost, F. Van Bambeke (Brussels, BE)

**Objectives:** Efflux of antibiotics from prokaryotic cells is a well-known mechanism of resistance. Antibiotic transporters, however, are also found in eukaryotic cells where they modulate the distribution of these drugs. Our objective was to compare the *S. aureus* NorA and the mouse macrophage Mrp4 transporters with respect to recognition of fluoroquinolones (FQ).

**Methods:** A panel of 23 FQ (see Table and JAC 2011, 66:2801–8) with distinct logP and logD at pH 7 (calculated with the Reaxys web-based software [http://www.reaxys.com]) was tested (i) for NorA efflux: by the ratio of MIC observed with the SA-1 *S. aureus* strain overexpressing NorA (AAC 2006, 50:1931–6) to that of the reference strain ATCC 25923 (the latter in the presence of reserpine [10 mg/L] to fully inhibit the basal constitutive expression of NorA); (ii) for Mrp4 efflux: by the ratio of accumulation observed in J774 macrophages overexpressing this transporter (AAC 2009, 53:2410–6) to that observed in wild-type cells (the latter with of the Mrp4 inhibitor gemfibrozil [0.5 mM] to also fully inhibit the basal expression of Mrp4). In parallel, three-dimensional models were constructed by homology modelling using the crystal structures of the prokaryotic lactose permease (LacY) for NorA and of the eukaryotic P-glycoprotein for Mrp4. Docking was performed using an induced fit procedure in the 3D models. The putative binding site of NorA was defined as that of the lactose analog in LacY complex structure and that of Mrp4 identified using mutagenesis data (*Mol Pharmacol* 2008; 74: 964–971).

**Results:** The left panel of the Figure shows that there is a significant ( $p < 0.0001$ ) correlation ( $p < 0.0001$ ) between transport of the fluoroquinolones tested by NorA and Mrp4. However, no correlation

was evidenced between transport and global lipophilicity (log P or logD at pH 7). In the structural analysis, molecules poorly transported established more interactions with the binding sites of both NorA and Mrp4, as illustrated with CIP and MXF for Mrp4 (right panel of the Figure).

**Conclusions:** Although phylogenetically very different from each other, NorA and Mrp4 show similar recognition properties for fluoroquinolones, with those undergoing little efflux actually featuring more numerous interactions in the binding sites. This suggests that the lack of transport is not due to poor recognition but rather to the inability of tightly bound drugs to progress for efflux within the transporter.

#### P1280 The role of NorA in the adaptative response of *Staphylococcus aureus* to stress stimuli

S.S. Costa\*, M. Viveiros, L. Amaral, I. Couto (Lisbon, PT)

**Objectives:** Efflux of antimicrobial compounds is a first-line defence mechanism towards chemical stress. We have shown that adaptation to ethidium bromide (EtBr) of the pan-susceptible *S. aureus* ATCC25923 (ATCC) yielded the progeny strain, ATCC-EtBr, with increased resistance to EtBr, fluoroquinolones and biocides, associated with overexpression of the efflux pump gene *norA*. We now continued this study by reversing the EtBr adaptation process and comparing the parental and derivative strains, in order to understand the importance of the efflux pump NorA to the adaptative response of *S. aureus* to EtBr.

**Methods:** Reversion process of ATCC-EtBr was done by serial passages in EtBr-free media, resulting in ATCC-Rev. Susceptibility profile of the parental and derivative strains was assessed by minimum inhibitory concentration determination for several antimicrobial compounds. Efflux activity was evaluated by real-time fluorometry and RT-qPCR used to analyze gene expression of *norA* and other efflux pump genes (*norB*, *norC*, *mepA* and *mdeA*), as well as of the global regulator *mgrA*. The *norA* gene was sequenced and its transcription initiation site determined by 5'-RACE PCR. *norA* mRNA half-life was determined for ATCC and ATCC-EtBr.

**Results:** The ATCC-EtBr overexpressed *norA* presented a new transcription initiation site, but no alteration was detected on the *norA* mRNA stability, since both ATCC-EtBr *norA* mRNA and ATCC *norA* mRNA showed comparable half-lives. ATCC-EtBr *norA* also carried a mutation leading to the substitution Phe303Tyr. The global regulator *mgrA* was also found to be overexpressed. ATCC-Rev showed a complete reversion of the increased resistance profile presented by ATCC-EtBr, linked to the loss of efflux activity. This was accompanied by a decrease of both *norA* and *mgrA* expression levels and the introduction of a stop codon in *norA*, originating a NorA truncated at the aminoacid 274.

**Conclusion:** This work highlights the importance of efflux pumps in the response of *S. aureus* to stress stimuli. The presence/withdrawal of EtBr led to an increase/decrease in the expression of *norA* and of the regulator *mgrA*. However, we found that other factors, such as alterations at the transcription initiation site or in the aminoacid sequence are also to be considered when analyzing differences in NorA

expression and/or activity. All these factors interplay in an intricate network of cellular responses to chemical stress.

#### P1281 Resistance to biocides conveyed by efflux pumps in clinical isolates of MRSA

S.S. Costa\*, C. Mourato, M. Viveiros, J. Melo-Cristino, L. Amaral, I. Couto (Lisbon, PT)

**Objectives:** Biocides, compounds with antiseptic and disinfectant properties, have a central role in the prevention and control of nosocomial infections, being largely used in health-care settings and more recently, also in the community. Resistance to these compounds can be bestowed by chromosomal and plasmid-encoded efflux pumps (EPs). In this study, we evaluate the response of clinical isolates of *S. aureus* harbouring plasmid-encoded efflux pumps to the selective pressure of biocides.

**Methods:** The biocide resistance profile of two clinical methicillin-resistant *S. aureus* (MRSA) isolates carrying plasmids harbouring the efflux pumps *Smr* and *QacA* was assayed by minimum inhibitory concentration (MIC) determination for the quaternary ammonium compounds cetrimide (CET), cetylpyridinium chloride (CPC), benzalkonium chloride, chlorhexidine, ethidium bromide (EtBr), among others. The efflux activity was evaluated by real-time fluorometry. Expression analysis by RT-qPCR of the plasmid-encoded efflux pump genes *smr* and *qacA* and of the chromosomal efflux pump genes *norA*, *norB*, *norC*, *mepA* and *mdeA* was evaluated in the presence of sub-lethal concentrations of CET, CPC, EtBr and the fluoroquinolone ciprofloxacin. Two antibiotic pan-susceptible reference strains were used as controls.

**Results:** Clinical isolates carrying the *qacA* or the *smr* genes presented higher MIC values for the biocides tested than the reference susceptible strains. Real-time fluorometry also detected a pronounced efflux activity in those isolates in opposition to the reference strains. RT-qPCR assays revealed that the expression of efflux pump genes varied according to the agent tested. In particular, EtBr induced the overexpression of *smr* and *qacA* genes; whereas CET or CPC induced the joint overexpression of *smr* and other chromosomal efflux pump genes; ciprofloxacin, which is not a substrate for plasmid-encoded efflux pumps, triggered the expression of the chromosomally-encoded efflux pumps only.

**Conclusion:** The diversity in the efflux pump gene expression pattern observed might reflect the different mode of action of each agent tested. While EtBr binds to DNA, both CET and CPC are membrane-active detergents, with a more immediate effect on the *S. aureus* cell. Therefore, these two biocides may trigger a global stress response, in which chromosomal and plasmid-encoded efflux pumps may act together to detoxify the cell from these noxious compounds.

#### P1282 Role of resident and acquired multi-drug efflux pumps in reduced susceptibility to cationic biocides in *Staphylococcus aureus*

L. Furi, M.L. Ciusa, D. Knight, V. Di Lorenzo, F. Decorosi, J. Coelho, A.T. Freitas, C. Viti, G. Orefici, I. Morrissey, M.R. Oggioni\* and the BIOHYPO consortium

**Objectives:** In view of the requirements posed by licensing process of disinfectants according to the EC biocide directive, we evaluated the possibility to devise an in vitro test for evaluation of resistance to cationic antibacterial compounds including quaternary ammonium compounds and bisbiguanides.

**Methods:** In three strains of *S. aureus* mutants were selected in vitro with benzalkonium chloride (BZC; quaternary ammonium compound), chlorhexidine (CHX; bisbiguanide), acriflavine (AF) and ethidium bromide (EB) and their phenotypes and *norA* promoter sequences were determined. Data on laboratory mutants was compared to molecular data from of 246 clinical *S. aureus* strains showing decreased susceptibility to BZC or CHX.

**Results:** A survey for susceptibility to EB, AF, BZC and CHX on 75 clinical *S. aureus* isolates showed a bimodal distribution of susceptibility profiles for EB and AF and a normal distribution of susceptibility profiles to CHX and BZC. Mutation frequency in vitro to these compounds was found to be around  $1E-10$  for EB and AF, while no mutants could be selected in a single step protocol for BZC and CHX. Multiple passages on selective plates allowed to select also mutants with BZC and CHX. Irrespective the selective agent all mutants showed important increases in MIC and MBC to norfloxacin, ciprofloxacin, EB and AF. For BZC and CHX the MIC and MBC did either not change or increased by a single dilution. All mutants showed mutations in the promoter region of the NorA MDR efflux pump. Upon the 246 clinical isolates with reduced susceptibility to BZC or CHX, 77 were positive for qacA, 13 for qacC and 1 for qacG and all of these had increased MIC for EB. For 35 clinical strains with reduced EB or BZC susceptibility the norA promoter was sequenced. Out of these nine had a short duplication, five a mutated and 21 a wt norA promoter region. In only one case a clinical strain matched to a mutation also generated in vitro.

**Conclusion:** Our data show (i) that EB and AF are suitable agents for monitoring efflux phenotypes and related genotypes, while BZC and CHX not, (ii) that standard mutation selection assays cannot be performed for BZC and CHX, (iii) and that the mutations selected in vitro by BZC and CHX do not match those detected in clinical isolates. Summarised these data indicate that for *S. aureus* an in vitro test for prediction of resistance development to BZC and CHX is not feasible and, in any case, would yield results of no clinical relevance.

**P1283** *Staphylococcus aureus* mutants and clinical isolates with reduced susceptibility to the biocide triclosan differ in phenotype and genotype

M.L. Ciusa, L. Furi, D. Knight, F. Decorosi, C. Raggi, J. Coelho, A.T. Freitas, L. Baldassarri, C. Viti, G. Orefici, I. Morrissey, M.R. Oggioni\* and the BIOHYPO consortium

**Objectives:** In view of the requirements posed by licensing process of disinfectants according to the EC biocide directive, we evaluated the possibility to devise an in vitro assay for testing the bacterial resistance to the biocide Triclosan. Triclosan is a synthetic bisphenol compound and active ingredient in many human hygiene biocidal products, targeting specifically the bacterial fabI gene encoding a enoyl-[acyl-carrier-protein] reductase.

**Methods:** Starting from five *S. aureus* reference strains 32 mutant were selected in vitro by culturing strains in medium containing triclosan. Mutants were both selected by single exposure on selective media or by cycling on increasing conditions of the biocide. The phenotypes and fabI sequences were determined in all mutants and compared to data from of 76 clinical *S. aureus* strains showing decreased susceptibility to Triclosan.

**Results:** The frequency of selection of *S. aureus* mutants in vitro for triclosan was between  $2 \times 10^9$  and  $3 \times 10^{10}$  depending on the strain. The single passage mutants showed an MIC of 4–8  $\mu\text{g}/\text{mL}$  and MBC of 8–16  $\mu\text{g}/\text{mL}$ , while the multi-passage mutants all showed a MIC of 16–32. In contrast the clinical isolates had a variable range of MIC values (0.125–4  $\mu\text{g}/\text{mL}$ ). All except three in vitro selected mutants showed mutations in the fabI coding region. In contrast only half of the clinical isolates showed mutations in fabI. Except for two mutations, none of the mutations selected in vitro matched to those found in clinical strains.

**Conclusion:** Both the MIC and MBC profiles and the mutations of in vitro selected triclosan resistant mutants differed from those detected in clinical isolates with reduced susceptibility to triclosan. In addition our data clearly indicate that there are additional and yet undescribed mechanisms of resistance to triclosan in clinical isolates of *S. aureus*. Summarised these data indicate that for *S. aureus* an in vitro test for prediction of resistance development to triclosan is not feasible and, in any case, would yield results of no clinical relevance.

**P1284** Genetic basis for in vitro and in vivo resistance to lincosamides and streptogramins A (LSA phenotype) in *Enterococcus faecium*

B. Malbruny, R. Leclercq, V. Cattoir\* (Caen, FR)

**Objectives:** As opposed to *Enterococcus faecalis*, which is intrinsically resistant to lincosamides and streptogramins A (LSA phenotype) by production of an ABC protein named Lsa(A), *Enterococcus faecium* is naturally susceptible. The LSA phenotype may be selected by lincosamides or streptogramins in *E. faecium* both in vitro and in vivo. The aim of the study was to investigate the molecular mechanism of resistance in strains of *E. faecium* with acquired LSA phenotype.

**Methods:** Six LSA-resistant mutants of *E. faecium* HM1070 selected in vitro by using lincomycin (LIN), clindamycin (CLI) and dalfopristin (DAL) were studied. Three different pairs of clinical isolates (pre- and post-exposure to quinupristin-DAL) were also included. Full genome sequence of one lincomycin-selected mutant (*E. faecium* HM1070/LSA) was determined using the 454 sequencing technology, and was compared with that of wild-type *E. faecium* HM1070. The detection of a single mutation putatively responsible for the LSA phenotype was performed by PCR for all strains. Single-nucleotide allelic replacement was carried out to confirm the role of this mutation. DNA fragments comprising resistance and susceptibility mutations were cloned into the thermosensitive vector pG1KT and introduced into *E. faecium* HM1070 and HM1070/LSA strains, respectively. MICs were determined by using the microbroth dilution method.

**Results:** By comparison of the two entire genomes, 50 point mutations were identified, including one within a 1503-bp gene coding for an ABC homologue showing 66% amino-acid identity with Lsa(A). This mutation corresponded to a transition (C1349T) leading to an amino-acid substitution (Thr450Ile) within the Walker B motif of the second nucleotide-binding domain. Strictly identical mutations were identified for in vitro and in vivo resistant strains, but none for susceptible strains. The introduction of the allele from *E. faecium* HM1070/LSA into *E. faecium* HM1070 conferred the LSA phenotype with an increase of MICs of LIN (0.25–8 mg/L), CLI (0.12–2 mg/L) and DAL (4 to >64 mg/L) whereas that of the allele from *E. faecium* HM1070 into *E. faecium* HM1070/LSA restored susceptibility to LIN (8–0.25 mg/L), CLI (2–0.06 mg/L) and DAL (>64–4 mg/L).

**Conclusion:** We identified the molecular mechanism responsible for the acquired LSA resistance in *E. faecium*. Characterization of the biochemical mechanism of resistance and the physiological role of this ABC protein will need further investigations.

**P1285** Identification of the *Enterococcus faecalis* SOS regulon

S. Matrat\*, I.F. Nes, B. Gonzalez Zorn (Madrid, ES; As, NO)

Several antibiotics, such as fluoroquinolones and  $\beta$ -lactams, are known to induce in bacteria a survival mechanism, called the SOS response which is a complex, graded response to DNA damages or stalled replication forks that includes induction of gene products blocking cell division and promoting mutations, recombination and DNA repair. The SOS activator, RecA, after the recognition of DNA damage, cleaves the transcriptional repressor LexA that induces the expression of the genes taking part of the SOS regulon. These genes are not only involved in bacterial survival but also in formation of antibiotic resistance due to the expression of low-fidelity DNA polymerases. In *Enterococcus faecalis*, the second most frequent bacteria involved in nosocomial infections (after *Staphylococcus aureus*), the genes engaged in the SOS mechanism have not been identified to date. We present here the first study to identify the SOS regulon in *E. faecalis*.

An *E. faecalis* LexA mutant was shown to produce constitutively an induced SOS response. This mutant was constructed by a plasmid insertion in the lexA gene preventing the synthesis of the repressor. Microarray experiments were performed to compare the transcriptome

of the wild type and of the constitutive SOS-induced mutant in order to identify LexA regulated genes. The experiment was followed by in silico analysis of the presence of a LexA-box in the promoter region of the regulated genes.

A total of 41 genes (30 up- and 11 down-regulated) were identified as taking part of the SOS regulon of *E. faecalis*. Among these genes, some were known to take part of other bacteria SOS regulon but some genes appear to be unique for the SOS response in *E. faecalis* such as the upregulation of two phage integrases, the downregulation of the eight genes involved in the synthesis of aromatic amino acids and the absence of low fidelity polymerase gene regulation.

This study identified for the first time the SOS regulon of *E. faecalis* with some apparent unique features. The number of genes whose expression is modified by the cleavage of LexA is concordant with previous studies in other bacteria. This study permitted also to identify precisely the *E. faecalis* LexA-box consensus sequence and to open the door for the discovery of new antimicrobial drugs targeting this survival mechanism.

**P1286 Growth condition-dependant cell surface proteome analysis of *Enterococcus faecium***

J.C. Sinnige\*, R.J. Willems, M.J.M. Bonten, J. Top (Utrecht, NL)

**Objectives:** Over the last 30 years *Enterococcus faecium* (Efm) has become the third most common nosocomial pathogen in hospitals worldwide. The aim of current study was to obtain insight in cell surface expression of Efm proteins when grown in physiological and clinically relevant conditions.

**Methods:** Cell surface protein expression of a clinical blood stream Efm isolate, E1162, grown until mid-log phase in brain heart infusion medium including 0.02% bile salts (BHI-bile), urine and biofilm was compared with BHI grown cells. After washing the cell pellet, the cell surface was "shaved" using immobilized trypsin in 50 mM sodium-bicarbonate for 45 min at 37°C. The protein fragment containing supernatant was subsequently further digested using trypsin and peptides were identified using tandem mass spectrometry. The identified peptides were matched against the EfmE1162 whole genome sequence. Finally, LocateP was used to predict the subcellular location of the identified protein. All growth conditions were performed in six biological replicates.

**Results:** For the different growth conditions a total of 15, 11, 13, 13 and 11 proteins, in at least three of the six biological replicates, were identified in BHI-bile, urine, biofilm, TSB 1% glucose, and BHI respectively. Prediction of the subcellular location of identified proteins revealed that for BHI-bile 84%, urine 67%, biofilm 76% and BHI 67% belong to either lipid anchored, n-terminally anchored, secreted, multi-transmembrane or LPxTG anchored group of proteins. In general, the expression of proteins at the cell surface was very comparable with 10 proteins, including two ABC transporters, being expressed and detected in at least three of the studied growth conditions. Differentially expressed proteins included the Penicillin binding protein 5 (PBP-5), which was not identified in urine, a hypothetical lipoprotein that was only identified in urine, and a hypothetical lipid anchored surface protein that was only identified in BHI-bile.

**Conclusion:** This study revealed that proteolytic shaving of Efm cells identified cell surface proteins expressed during growth under different conditions. Differentially expressed proteins are of special interest as they might be involved in the interaction of Efm with the human host and may represent interesting candidate targets for vaccine development. Functional characterization of these proteins will provide more insight in the adaptive mechanisms of this emerging pathogen.

**P1287 Emergence of plasmid-mediated fosfomycin resistance gene, fosB, among *Enterococcus faecium* clinical isolates**

X. Xu, Q. Gu, C. Chen, D. Zhu, M. Wang\* (Shanghai, CN)

**Objectives:** Fosfomycin is used alone or in combination with other antimicrobials for the treatment of infections caused by multi-drug

resistant Gram-positive bacteria, and fosfomycin resistance (FR) in *E. faecium* increased from 20.4% in 2007 to 32.1% in 2009 in China. Plasmid-mediated FR determinants, fosA, fosB and fosC, have been discovered and found to be present in fosfomycin-resistant *Escherichia coli* (fosA, fosC), *Enterobacter cloacae* (fosA), *Klebsiella pneumoniae* (fosA), *Staphylococcus* spp. (fosB). In a recent study on vancomycin-resistant Enterococci (VRE), we found that fosB was present in an *E. faecium* isolate (GenBank: HQ219726). In this study, we determined the prevalence of fosA, fosB and fosC genes in *E. faecium* clinical isolates.

**Methods:** A total of 148 clinical strains of *E. faecium* were isolated from patients in 10 cities of China between 2008 and 2009. Antimicrobial susceptibility testing was performed by agar dilution method according to the Clinical and Laboratory Standards Institute (CLSI). fosA, fosB and fosC were detected by PCR amplification. Multilocus sequence typing (MLST) of *E. faecium* isolates was performed and the sequence types (STs) were analyzed through the MLST database (<http://efaecium.mlst.net/>).

**Results:** Of the 148 isolates, 12 (8.1%) were resistant to (MIC  $\geq$  256 mg/L) and 28 (19%) were intermediate (MIC 128 mg/L) to fosfomycin. fosB gene was present in 10 FR isolates with fosfomycin MICs  $\geq$  1024 mg/L, but not in other two strains with MICs of 256 mg/L or 512 mg/L. Among 10 fosB positive strains, six were VRE with vancomycin MICs  $\geq$  256 mg/L, while three of 138 fosB negative strains were VRE. The 10 fosB positive strains were analyzed by MLST and showed seven STs, including STs 18, 34, 78, 203, 389, and 559. No fosA and fosC were found in any of the isolates.

**Conclusion:** Plasmid-mediated FR gene, fosB, is emerging in *E. faecium* clinical isolates, and spreading by horizontal transfer and clonal dissemination. This is the first report of plasmid-mediated FR gene fosB in *E. faecium*.

**P1288 Contact isolation for vancomycin-resistant enterococci?**

N. Mutters\*, R. Brooke, K. Heeg, U. Frank (Heidelberg, DE; Utrecht, NL)

**Background:** Vancomycin-resistant enterococci (VRE) are primarily opportunistic pathogens with variable virulence and incalculable clinical significance. Many containment strategies lack VRE specific interventions often due to the lack of relevant and reliable epidemiological data.

The primary goal of this study was to estimate the transmissibility of in-patients with VRE bacteraemia to other hospitalized patients. The secondary goal was to document reliable epidemiological data on all VRE cases in a tertiary healthcare centre.

**Methods:** A prospective survey on in-patients colonized and/or systemically infected with VRE was conducted at a 2000-bed university hospital in Germany. All contact patients of bacteraemic VRE patients were analysed. Pulsed-field gel electrophoresis was performed to assess clonal relatedness.

**Results:** A total of 16 507 screening tests were carried out, on 9258 screened patients, of which 557 patients tested positive for VRE (6.0%). Nineteen patients suffered from VRE bacteraemia, an incidence of 0.21%. Co-morbidity was highly frequent in this cohort and exposure rates to external risk factors were high (e.g. previous hospital stay prior to admission 78.9%). The transmission rate to contact patients was low (3.6%). Contact time of negative contact patients was significantly lower than that of VRE-positive contact patients (19.3 hours vs. 72.0 hours,  $p < 0.006$ ).

**Conclusions:** Systemic VRE infection was found exclusively in multi-morbid patients, transmission occurred seldom and average contact time of positive patients was very high. Our data provide evidence that not all carriers of VRE require contact isolation, since therapeutic options are available and given that transmission is not likely. Isolation consumes massive amounts of hospital resources and inflicts psychological stress on patients.

**P1289** Prevalence of phenotypically vancomycin susceptible, but vanB-PCR positive, *Enterococcus faecium*. Do we overlook VRE vanB carrying strains in our hospitals?

J.P. Arends\*, X. Zhou, G. Kampinga, A. Sabat, N.E.L. Meessen, A.W. Friedrich (Groningen, NL)

**Objectives:** Prevalence investigation of vanB positive *E. faecium* in large university hospital in the northern part of the Netherlands.

**Methods:** We screened retrospectively 108 phenotypically vancomycin susceptible *E. faecium* isolates identified by standard protocol from blood culture. In addition, we performed a prospective prevalence study, were 446 rectal swabs collected from 294 patients were cultured. Swabs were grown in BHI broth for 24 hours containing amoxicillin 16 mg/L, amphotericin B 20 mg/L, aztreonam 20 mg/L, colistin 20 mg/L. Different to usual selective detection strategies and in order to increase sensitivity for detection no vancomycin was added to the broth. BHI was subcultured on Brilliance VRE Agar (Oxoid) and read after 48 hours. Blue colonies were subcultured on blood agar and identified by MALDI-TOF MS analysis. All *E. faecium* and *E. faecalis* strains were tested for vanB and TN5382 with PCR and resistance was determined by VITEK® 2. PCR products from three selected isolated were sequenced for confirmation.

**Results:** Three out of 108 (2.7%) vancomycin susceptible clinical blood culture isolates were positive for vanB. The screening results from the prevalence screening showed that, nine patients had an *E. faecium* isolate positive for both vanB and TN5382. Hereof, three patients (1%) were identified phenotypically by Vitek as VRE with a MIC value of 8, the six other isolates (2%) were not identified as VRE by Vitek, these six strains had an MIC value of 1. Etest confirmed the low MIC values. Three sequenced vanB PCR products matched with vanB2. In total, 63 *E. faecium* and 38 *E. faecalis* strains were negative for vanB. These vanB negative strains could be distinguished on Brilliance VRE agar by limited growth.

**Conclusion:** VanB positive *E. faecium* with an MIC value of 1 are likely to be missed in routine practice. The clinical relevance of these low MIC vanB positive *E. faecium* needs further research.

**P1290** Global dissemination of vancomycin-resistant VanB *Enterococcus faecium* causing outbreaks in different countries is mainly associated with chromosomal Tn1549/5382-like platforms

A.R. Freitas\*, A.P. Tedim, C. Novais, P. Ruiz-Garbajosa, L. Peixe, F. Baquero, T.M. Coque (Porto, PT; Madrid, ES)

**Objectives:** Dissemination of VanB *Enterococcus faecium* (Efm) results from transfer of plasmids or, more often, large chromosomal elements. We analysed the genetic context of representative isolates recovered from different continents in order to better understand the global epidemiology of VanB-Efm.

**Methods:** We analysed 20 Efm collected in Australia, Chile, Denmark, Finland, Hungary, Italy (IT), Singapore (SI), Spain (SP), and USA (1992–2008), representative of VanB clinical outbreaks in these areas. Clonality was established by PFGE/MLST. vanB was amplified using specific primers and transposons were discriminated by comparison of DNA profiles after digestion of 5959-bp vanRSYWHBX amplicons with BspHI/DraI enzymes. Distinction between vanB1-Tn1547 and vanB2-Tn1549/Tn5382 was established by specific sequences (right junction of Tn5382; vanSB-vanYB intergenic region; pbp5-Tn5382 association). Genomic location and transfer of vanB was determined by standard procedures. Plasmid analysis included determination of size (S1-PFGE), relaxases, rep initiation proteins, and toxin-antitoxin systems (PCR, hybridization, sequencing).

**Results:** Sixteen clones (11 STs, all but one belonging to CC17) were identified. vanB1 isolates (n = 3) showed RFLP-1 associated with Tn1547 (two USA; early 1990s) and RFLP-3 linked to a new vanRSYWHBX variant (one IT; 2002). This vanB1 variant resulted from recombination between Tn1549 (vanRS) and Tn1547 (vanS), with

ends of both flanking genes (vanR, vanX) being identical to those of pMG2200::vanB2-Tn1549 from *E. faecalis* in Japan. The vanB2 (n = 17) showed RFLP-2 (n = 13) linked to Tn1549/5382 and was predominant and widespread in different continents. Variants of this platform caused by insertions of ISEnf110 or ISEnf200, and the presence of pbp5 (RFLP2\*, n = 4) were detected in Europe, America and Australia. All but the 2 RFLP-1-isolates contained rel-Tn1549. vanB was transferred in 30% of the cases. Most were located on chromosome (n = 16). The four vanB2-conjugative plasmids (50–60 kb) from SP and SI carried rep-pRUM, rep-Inc18 and/or rel-pEF1. **Conclusions:** Global dissemination of VanB enterococci is mostly due to vanB2-Tn1549/Tn5382 carried by CC17 Efm. A Tn1547-Tn1549 (vanB1) hybrid is firstly reported highlighting frequent lateral gene processes among enterococci. Differences among similar transposons indicate evolution of these elements in different locations. Predominance of vanB2 over vanB1 transposons among Efm requires further studies.

**P1291** Microbiologic and clinical characteristics of vancomycin-resistant *Enterococcus faecium* bacteraemia in Taiwan: a retrospective cohort study

C. Lu\*, Y. Chuang, Y. Chen, S. Chang, J. Wang (Hsin-Chu, Taipei, TW)

**Objective:** Bacteremia caused by vancomycin-resistant *Enterococcus faecium* (VREfm) increased rapidly in our institute recently. We aimed to evaluate if there were newly introduced VREfm clones contributing to this increase and the risk factors for 14-day mortality of VREfm bacteremia.

**Methods:** Between January 2003 and December 2010, all patients with VREfm bacteremia were enrolled to analyze the clinical features and antibiotic susceptibility, genotype of vancomycin resistance, and multilocus sequence typing (MLST) of the relevant VREfm isolates were analyzed. Primary end-point was all-cause mortality within 14 days of bacteremia.

**Results:** Vancomycin resistance among non-duplicated blood enterococcal isolates during the study period increased significantly from 3.9% to 18.9% (p < 0.0001). There were 149 episodes of VREfm bacteremia noted. One hundred and two VREfm isolates were available for further analysis. Ninety-three isolates carried the vanA gene. All isolates were susceptible to daptomycin and linezolid. Only two isolates belonging to ST18 were intermediately resistant to tigecycline. ST18 and ST414 were the emerging predominant sequence types (20.6% and 17.6%, respectively). Using of immunosuppressant agents, thrombocytopenia, high Charlson comorbidity index, and septic shock were independently associated with 14-day mortality of VREfm bacteremia. In contrast, male sex, patients received adequate treatment, and whose VREfm isolates belonged to ST414 had a significantly lower in-hospital mortality rate.

**Conclusions:** Vancomycin resistant rate increased in blood enterococcal isolates causing bacteremia. Among tested VREfm isolates, the susceptible rate to daptomycin, linezolid, and tigecycline remains high. Clonal spread of VREfm belonging to ST18 and ST414 might contribute to the increase of VRE. The sequence type of VREfm may play an important role in 14-day mortality of patients with VREfm bacteremia.

**P1292** Molecular characterisation of vancomycin-resistant *Enterococcus faecium* from a tertiary care centre in Saudi Arabia

M. Al-Ahdal, S. Abuzaid, H. Al-Shammary, M. Bohol, S. Al-Thawadi, A. Al-Jabri, A. Senok\*, A. Shibl, A. Al-Qahtani (Riyadh, SA)

**Objective:** There remains a paucity of data on the molecular epidemiology of Vancomycin resistant enterococci in the Arabian Gulf Region. This study was carried out to characterize the vancomycin genotype/phenotype, carriage of putative virulence genes and genetic

relatedness of *E. faecium* isolated in a tertiary care center in Saudi Arabia.

**Methods:** From January 2009 to April 2010, *E. faecium* isolates from inpatients at the King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia were studied. Antimicrobial susceptibility testing to ampicillin, linezolid, teicoplanin, quinupristin/dalfopristin, tetracycline and ciprofloxacin was determined using Microscan Walkaway, disk diffusion and E-test. PCR assays for detection of Van genes and virulence genes for aggregation substance (Agg, Asa1), enterococcal surface proteins (esp); cytolysin (cylA, cylL, cylM), gelatinase (gelE), cell wall adhesin (EfaAfm), hyaluronidase (hyl), surface antigens (Ef) and collagen adhesin (Ace) were carried out. Genetic relatedness of isolates was determined using pulsed field gel electrophoresis (PFGE).

**Results:** The twenty-nine *E. faecium* isolates mostly stool isolates (n/N = 22/29; 75.8%) were found to show seven PFGE banding patterns (A–G). Majority of isolates (n/N = 25/29; 86%) were in three predominant pulsotypes. All isolates were positive for VanA gene and 13 exhibited VanA+/VanB+ genotype. Of these, 10 exhibited VanB phenotype and three had VanA phenotype. Eight isolates with VanA+/VanB– genotype exhibited a VanB phenotype with six of them belonging to the same PFGE pulsotype. All isolates were positive for gelE, esp and EfaAfm genes. All isolates were negative for Ace, Agg, Asa1 and CylL genes while five were positive for the CylA. The hyl and Ef genes were present in 24 and eight isolates respectively. Of the eight isolates positive for a combination of gelE, esp, EfaAfm, hyl and Ef genes, four showed VanB phenotype VanA genotype incongruence.

**Conclusions:** The findings demonstrate the first report of the emergence of VanB phenotype-vanA genotype incongruent *E. faecium* isolates in the Middle East region. Molecular typing suggests a clonal spread of these isolates. The high occurrence of virulence genes especially esp genes associated with epidemic *E. faecium* isolates is a cause for concern.

## Epidemiology of antimicrobial resistance

### P1293 In vitro activity of rifaximin against *Escherichia coli* with prevalent ESBLs and carbapenemases

S. Mushtaq\*, K.L. Hopkins, J.F. Richardson, E. de Pinna, T. Cheasty, J. Wain, D.M. Livermore, N. Woodford (London, UK)

**Objectives:** Rifaximin, a semi-synthetic rifamycin antibiotic, is licensed for treatment of travellers' diarrhoea in the USA and many European countries. As it is poorly absorbed from the gut, there is a theoretical potential for its use to select rifamycin-resistant strains in the gut flora, and for these to have resistance determinants of greater public health significance. We assessed the in-vitro activity of rifaximin and comparators against 90 clinical isolates of *E. coli* that produced ESBLs and/or carbapenemases.

**Methods:** The 90 non-diarrhoeal isolates of *E. coli* produced CTX-M-15 (n = 52), CTX-M-14 (7) or CTX-M-2 (1) ESBLs, or NDM-1 (16), OXA-48 (9), KPC-2 (2), IMP-type (2) and VIM-type (1) carbapenemases. MICs were measured by CLSI agar dilution methodology. Comparator agents were rifampicin, ciprofloxacin, azithromycin, co-trimoxazole and doxycycline. All isolates non-susceptible to either rifamycin (MIC > 32 mg/L) were screened by PCR for arr genes, which encode rifamycin ADP-ribosyltransferases.

**Results:** Rifaximin was active at  $\leq 32$  mg/L (vs. mode = 16 mg/L) against 84/90 (93.3%) of the *E. coli* isolates, but MICs were >128 mg/L for 3/16 isolates with NDM-1 carbapenemase, 1/9 with OXA-48 carbapenemase, and 1/52 with CTX-M-15 ESBL. One isolate with CTX-M-15 ESBL was borderline non-susceptible (MIC 64 mg/L). Seven isolates, including the above six, were non-susceptible to rifampicin (MICs > 32 mg/L vs. mode = 16 mg/L) whilst 63.3% of the isolates were non-susceptible to ciprofloxacin (MICs > 0.5 mg/L) 44.4% to azithromycin (MICs > 16 mg/L; BSAC ECOFF for *S. Typhi*), 81.1% to doxycycline (MICs > 4 mg/L; EUCAST ECOFF for *E. coli*) and 84.4% to co-trimoxazole (MICs > 2 mg/L). Of the

seven isolates with rifamycin MICs > 32 mg/L, only two (both with NDM carbapenemase) had arr-2/-3 genes.

**Conclusion:** Rifaximin was active against most ESBL- and/or carbapenemase-producing *E. coli*. However, high-level resistance was detected in three isolates with NDM-1 metallo-beta-lactamase, one with OXA-48 carbapenemase, and one with CTX-M-15 ESBL. Rifaximin might select such strains in the gut flora of travellers to countries where these resistance mechanisms are prevalent, but there were stronger associations between ESBLs/carbapenemases and resistance to ciprofloxacin or azithromycin implying greater selectivity with these latter alternatives.

### P1294 Evolution of antimicrobial resistance of *Escherichia coli* isolates causing obstetric infections: relationship with virulence and clinical features

E. Guiral\*, J. Bosch, J. Vila, S. Soto (Barcelona, ES)

**Objectives:** *Escherichia coli* is a Gram-negative bacilli that can colonize the female genital tract and become implicated in different infections in pregnant women, both from genital and urinary foci, causing septicaemia or not. The aim of this study was to determine the evolution of the antimicrobial resistance of *E. coli* isolates causing obstetric infections as well as to compare the relationship between resistance profiles, virulence factors and clinical features caused by these strains.

**Methods:** Seventy-eight *E. coli* isolates from women in the Hospital Clinic of Barcelona collected from 1987 to 2010 were included in the study. Among these strains, 24 caused genital-focus sepsis (GFS), 32 UTI-related sepsis (URS) and 22 non-bacteraemic intraamniotic infection (NII). Virulence profiles were analysed by PCR and sequencing using gene-specific primers for 17 virulence genes. Resistance profiles were determined by minimal inhibitory concentrations using the MicroScan-Negative MIC Panel Type 37. *E. coli* phylotype screening was carried out by multiplex PCR.

**Results:** The percentage of resistance in *E. coli* strains has increased for several antimicrobial agents over the years, mainly for nalidixic acid but also for ciprofloxacin, tetracycline and cotrimoxazole. There has also been a significant increase in resistant strains belonging to phylotype D ( $p = 0.04$ ). Compared to clinical features, the resistance profiles from strains causing GFS showed a greater percentage of nalidixic acid, gentamycin and kanamycin resistance compared to strains causing URS or NII. The most virulent strains were those causing septicaemia, as they possess significantly more virulence factors such as hly, cnf, papA, iha, fyu or papG3, all contained within pathogenicity islands. Regarding virulence factors related to iron recruitment, it was of note that the iut (aerobactin-siderophore receptor) was significantly more frequently found in septicaemia-causing strains ( $p < 0.0001$ ), whereas in non-bacteraemic strains iroN (catechol-siderophore receptor) was the most frequent ( $p = 0.041$ ).

**Conclusions:** The increasing percentage of resistance to quinolones in strains causing obstetric infections is a matter of concern. *E. coli* strains causing GFS are more resistant than other strains. Further studies are necessary to elucidate the role of the iron recruitment systems used by the microorganism depending on the environment it colonises.

### P1295 Clonal structure of invasive *Streptococcus pneumoniae* collected from adult patients in Spain

C. Ardanuy\*, A. Fenoll, J. Liñares, E. Cercenado, F. Marco, A. Fleites, B. Buendía, M. Zuñiga, B. Palop, C. Mendez on behalf of the ODIN Study Group

**Objectives:** To analyze the clonal composition of invasive *Streptococcus pneumoniae* collected from adult invasive pneumococcal disease (IPD) in seven Spanish hospitals.

**Methods:** A prospective, active, hospital-based surveillance of all culture-confirmed IPDs in adults ( $\geq 18$  years) was performed in seven Spanish hospitals from August 2010 to June 2011. IPD was considered

isolation of *S. pneumoniae* in normally sterile fluids (blood, cerebrospinal fluid, pleural fluid...). Serotyping was performed by the Quellung reaction, dot blot assay or real-time PCR. All isolates were genotyped PFGE (SmaI). A selection of 37 isolates representative of major PFGE pattern were selected for MLST.

**Results:** A total of 191 cases were identified. The most frequent serotypes were: 3 (11.5%), 19A (9.4%), 7F (8.4%) 1 (6.3%) and 14 (5.8). A total of 72 PFGE patterns were found among 191 pneumococci analyzed, of them 19 accounted for three or more isolates and were selected for MLST. Regarding PFGE and MLST results the most frequent clones among invasive pneumococci were: Netherlands-7F-ST191 (8.4%), Netherlands-3-ST180 (7.3%), Denmark-14-ST230 (6.3%; serotypes 24F and 19A), Sweden-1-ST306 (5.2), Sweden-15A-ST63 (5.2%; serotypes 15A, 19F and 8), Spain-9V-ST156 (4.7%; serotypes 9V and 14), and ST260 (3.7%, serotype 3). Resistance to three or more antimicrobial groups, was detected in 53 isolates (27.7%) and was associated with genotypes CC230 (serotypes 24F, 19A; n = 10), CC63 (serotypes 8, 15A, 19F; n = 10), CC156 (serotypes 9V, 14; n = 5), ST386 (serotype 6C; n = 5), and ST320 (serotype 19A; n = 4).

**Conclusion:** Two antibiotic susceptible clones, Netherlands-7F-ST191 and Netherlands-3-ST180, were the most frequent cause of adult IPD in Spain. One fourth of multidrug-resistant invasive pneumococci belonged to five genotypes. Capsular switching was observed in three multidrug-resistant clones (CC230, CC63 and CC156).

#### P1296 The impact of efflux activity on drug resistance of *Burkholderia cepacia* complex isolated from non-cystic fibrosis patients

V. Hanulik\*, M.A. Webber, R.N. Whitehead, S. Baugh, M. Chroma, M. Sedlakova, M. Kolar (Olomouc, CZ; Birmingham, UK)

**Objectives:** *Burkholderia multivorans* is an opportunistic pathogen with a remarkable capacity to develop resistance to an extensive range of antibiotics and disinfectants.

The aim of this study was to determine the contribution of efflux to antimicrobial resistance in a panel of highly drug resistant *B. multivorans* isolated from non-cystic fibrosis (non-CF) patients.

**Methods:** In our study we tested efflux activity of 46 strains of *B. multivorans* which were obtained from clinical specimens of patients hospitalized from 1 February to 30 September 2011 in University Hospital in Olomouc, Czech Republic. All strains were unique, obtained from different patients.

Susceptibility of isolates to tigecycline (TIG), piperacilin (PIP), ciprofloxacin (CIP) and chlorhexidine was determined according to the guidelines of the British Society of Antimicrobial Chemotherapy. Experiments were repeated in the presence of Phe-Arg beta-naphthylonide dihydrochloride (PABN) as an inhibitor of efflux. Accumulation of Hoescht 33342 was also determined fluorimetrically in the presence and absence of PABN and used as a measure of efflux activity.

**Results:** Hoescht accumulation experiments defined the optimum PABN concentration required for inhibition of efflux to be 100 mg/L. Whilst accumulation of Hoescht varied between the isolates all isolates exhibited low accumulation of the dye when compared to other proteobacteria. There were no obvious correlations between efflux activity and antibiogram of the isolates suggesting all *B. multivorans* exhibit an intrinsically high efflux activity (Table 1). The isolates demonstrated a high degree of tolerance to chlorhexidine with MIC50 and MIC90 values of 100 mg/L an MBC50 of 100 mg/L and MBC90 of more than 100 mg/L of chlorhexidine.

Table: MIC50, MIC90 and range of MICs with and without PABN of 46 *Burkholderia multivorans* strains

Drug	CIP	CIP+PABN	PIP	PIP+PABN	TIG	TIG+PABN
MIC50	0,06	0,06	1	1	1	2
MIC90	0,125	0,125	2	1	4	4
Range	0,06 - 2	0,06 - 2	1 - 4	0,5 - 1	0,5 - 8	1 - 8

Legend: CIP-ciprofloxacin, PIP-piperaciline, TIG-tigacycline, PABN-Phe-Arg beta-naphthylonide dihydrochloride

**Conclusion:** In 46 clinical isolates of *B. multivorans* there was a high degree of efflux activity in all strains, differences in resistance to TIG, PIP and CIP in these strains are not likely to be due to differential efflux activity. Clinical strains of *B. multivorans* are highly resistant to chlorhexidine, which may have a clinical impact for anti-epidemic management and allow survival and spread of these strains in the hospital environment.

**Acknowledgements:** This study was supported by the Ministry of Education project no. MSM6198959205, project CZ.1.05/2.1.00/01.0030 and research by MAW is supported by a BBSRC David Phillips fellowship.

#### P1297 Faecal carriage of *Escherichia coli* O25b:h4/ST131: preliminary results of a survey in nosocomial and community settings

E. Torres\*, L. López-Cerero, M. Bellido, M.D. Navarro, J. Rodríguez-Baño, A. Pascual (Seville, ES)

**Objectives:** Intercontinental *Escherichia coli* clonal group producing different extended-spectrum beta-lactamases (ESBLs) and carbapenemases has been reported recently. This clonal group belongs to the B2 phylogenetic group, to the serotype O25b:H4 and to the multilocus ST131 and causes approximately one in every 10 extraintestinal infections at this moment in Spain, with and without multiresistant pattern. The aim of this study was to determine the prevalence of faecal carriage of this clone in hospital and community settings.

**Methods:** From April 2010 to October 2011, all clinical *E. coli* isolates recovered from hospitalized and emergency room-attended patients were screened for O25b and pabB by using PCR method. Positive isolates were studied for B2 phylogroup by multiplex PCR assay. Rectal swabs were obtained from all participants who agreed to participate. Four groups were studied: cases with infections caused by O25b/pabB/B2 positive isolates, roommates of hospitalised patients or patients who shared nursery care with the case, household members of community cases and 50 healthy volunteers. Rectal swabs were inoculated on Brilliance UTI agar and 4 mg/L cefotaxime Mac Conkey agar. All distinct morphotypes of lactose-positive colonies were selected for screening of O25b/pabB/B2.

**Results:** A total of 27 cases were included in this study: 16 inpatients and 11 patients with community-acquired infections (17 had UTI infections, six suffered bacteraemia and four soft tissue infections). Besides, 30 hospitalised roommates and 25 healthy household members were also studied. The prevalence of faecal carriage of this clone was 60% in hospitalized patients and 42% in community cases (p = 0.45). The faecal O25b *E. coli* colonization was higher in household contacts (36%) than in hospitalised contacts (13.3%) (p = 0.05) and 2% of volunteers were found to be positive. Household contacts of patients with infection who harboured this clone in the rectal flora were found to be more frequently positive for ST131, 50% vs. 23%, but not statistically significant (p = 0.23).

**Conclusions:** The prevalence of faecal carriage of ST131 clone is higher in healthy relatives of infected patients than roommates of inpatients and healthy volunteers. These preliminary results suggest transmission or common acquisition of ST131 within households.

#### P1298 The development of antimicrobial resistance patterns of commonly Gram-negative bacteria isolated from bronchial secretions in intensive care unit in anticancer hospital Thessaloniki GR

S. Karampa\*, S. Kostopoulou, A. Domoktsi, V. Zioutas, S. Ganta, V. Anagnostou, I. Diamanti, P. Kazila, E. Kaita (Thessaloniki, GR)

**Objectives:** The study and evaluation of the resistance rates development of the most frequently Gram(-) bacteria isolated from bronchial secretions in intensive care unit (ICU) patients.

**Methods:** The period 2007–2010, 297 Gram(–) bacterial agents from bronchial secretions were isolated. Identification of microorganisms and susceptibility testing were performed using the WIDER semi-automatic system. Carbapenemase were detected using Hodge test with ertapenem disk and E-test (Imipenem (IMP)/IMP + EDTA). Analysis of data was performed using the WHONET software and statistical analysis with  $\chi^2$  Yates' Correction test ( $p < 0.05$  was considered as significant).

**Results:** Out of 297 Gram(–) species, the predominant pathogen was *P. aeruginosa* ( $n = 113$ ), *A. baumannii* ( $n = 69$ ) and *K. pneumoniae* ( $n = 56$ ) followed. 52/113 (46%) *P. aeruginosa* isolates presented resistance to IMP which from 50% in 2007 decreased to 38% in 2010. Metallo-beta lactamases (MBL) were detected in 33/52 (63%) strains. Statistically significant (S.S.) decrease in resistance to ciprofloxacin (CIP) observed since 2007 (45%) to 2010 (19%) ( $p = 0.003$ ). Gentamicin (GEN) showed a S.S. increase in resistance rates from 2007 (15%) to 2008 (43%) ( $p = 0.03$ ) and reduction from 2009 (19%) to 2010 (3%) ( $p = 0.04$ ). During the 4-year period all isolates were sensitive to colistin (COL). High resistance rates were observed for multidrug-resistant isolates *A. baumannii* to IMP from 2007 to 2009 (84–81%) while in 2010 turned into 30%. A S.S. reduction in Carbapenems resistance exhibited the years from 2009 to 2010 ( $p = 0.008$ ). No strain was resistant to COL. Among *K. pneumoniae* strains 28/56 (50%) were resistant to IMP. Resistance to Carbapenems increased successively from 17% in 2007 to 59% in 2010. All resistant strains had a positive Hodge test. Twelve percent (3/28) were MBL(+) while the rest possibly produce KPC Carbapenemase and requires further testing. Resistance rates to CIP increased from 17% in 2007 to 64% in 2010 ( $p = 0.04$ ). Amikacin resistance from 50% in 2008 reduced to 18% in 2010 while GEN from 19% in 2009 was reset in 2010 ( $p = 0.04$ ). All isolates were susceptible to COL.

**Conclusion:** High rates of MDR (*P. aeruginosa*, *A. baumannii*, *K. pneumoniae*) strains in ICU are threatening fact. COL remains the unique antibiotic with no resistance. Significant reduction in GEN resistance recorded in 2010. In order to reduce resurgence of multi-drug-resistant isolates, judicious selection of antibiotics is required.

#### P1299 Clinical features and outcome of infections due to panderug-resistant Gram-negative bacteria

D. Kofteridis\*, D. Dimopoulou, S. Maraki, A. Valachis, M. Giaka, C. Alexopoulou, A. Andrianaki, G. Giourgouli, G. Samonis (Heraklion, GR)

**Objectives:** Infections caused by panderug-resistant (PDR) gram-negative bacteria are of particular concern due to lack of therapeutic options. The purpose of this study was to describe the characteristics and outcome of gram-negative PDR bacterial infections cared for at a Greek University Hospital.

**Methods:** A series of patients with infections due to PDR gram-negative pathogens hospitalized between December 2009 and June 2011 is presented. An isolate was considered as PDR if resistant to all classes of antimicrobial agents available.

**Results:** In total 17 episodes of infection with PDR bacterial infections occurring in 17 patients have been studied. Their median age was 58 (range: 30–81). Eleven patients (65%) had been treated in the Intensive Care Unit (ICU) during the current hospitalization. Eleven patients (65%) had more than three co-morbidities. Nine patients (53%) had been treated with antimicrobials the previous 3 months including colistin in 5 (38.5%) and tigecycline in 2 (15%). The median duration of hospitalization before the isolation of the PDR microorganism were 25 days (range: 2–91). The PDR microorganisms isolated included 14 *K. pneumoniae* (74%), 3 *A. baumannii* (16%) and 2 *P. aeruginosa* (10.5%). One patient had a polymicrobial infection with three PDR bacteria (*K. pneumoniae*, *A. baumannii*, *P. aeruginosa*). The PDR bacteria were isolated from blood (five patients), pus (4), urine (3), peritoneal fluid (3) BAL (1) and cerebrospinal fluid (1). Treatment was based mainly on colistin (11 patients), tigecycline (10), carbapenem (8) and aminoglycosides (6). The median length of antimicrobial therapy was 44 days (range: 9–162) and the median

duration of hospitalization 45 (range: 2–168). The overall in-hospital mortality was 41% (seven patients), with an infection-related mortality 23.5% (4).

**Conclusions:** The study presents characteristics and outcome of infections due to PDR gram-negative bacteria associated with considerable mortality and prolonged hospitalization. Most of the patients were characterized by multiple co-morbidities, prior hospitalization and ICU admission as well as previous treatment with colistin or tigecycline. These characteristics seem to enhance the risk for developing PDR infections.

#### P1300 Invasive pneumococcal disease in HIV-infected patients in France from 2000 to 2011. Antimicrobial susceptibility and implication of serotypes for vaccination

A.-L. Munier, V. de Lastours\*, E. Varon, J.-L. Donay, J.-M. Molina (Paris, FR)

**Objectives:** Invasive pneumococcal diseases (IPD) remain frequent and severe in HIV-infected subjects. Changes in antimicrobial susceptibility may challenge empirical antibiotic choices. The polysaccharide 23-valent vaccine (PPV23) is recommended in HIV infected subjects, although not fully efficient. Whether PPV23 and the pneumococcal conjugate vaccine (7-valent; PCV7 or 13-valent; PCV13) cover the serotypes most frequently isolated in HIV-infected patients is unclear.

**Methods:** We retrospectively analysed all *S. pneumoniae* isolated from blood cultures, synovial fluid or CSF between 2000 and 2011 in HIV-infected patients from a single reference centre for the management of HIV infection in Paris. MIC of antibiotics were determined by E-test and serotyping was performed by the antiserum agglutination method.

**Results:** Forty HIV patients presented with IPD during the study period. Eighty percent were men, median age was 42 years (23–62), mean CD4-cell count: 251/mm<sup>3</sup>. Half were receiving antiretroviral therapy and 25% had plasma HIV-RNA <400 copies/mL. Only 5% had been vaccinated by PPV23. Resistance rates of *S. pneumoniae* to penicillin G, cefotaxime, cotrimoxazole and levofloxacin were 16.3%, 2.4%, 31.6% and 29.4%, respectively.

Serotyping was performed on 27 strains; 18 different serotypes were observed. 19A, 14, 7F and 6A serotypes were the most frequently represented (6, 3, 2 and 2 strains, respectively), which is a similar pattern to the epidemiology of IPD in the French population. The PCV7, PCV13, PPV23 vaccines and both PCV13 + PPV23 would have covered 26%, 70%, 78% and 85% of the serotypes found, respectively.

**Conclusions:** Resistance to antibiotics and in particular fluoroquinolones is of particular concern in HIV infected patients with IPD. Pneumococcal serotypes are theoretically well covered by both PPV23 and PCV13 vaccinations. Recommended pneumococcal vaccination should be more thoroughly implemented in this population.

#### P1301 Haemophilus haemolyticus as a potential reservoir for ftsI gene mutations and altered penicillin-binding protein 3 mediated resistance in Haemophilus influenzae

E. Witherden\*, S. Tristram (Launceston, AU)

**Objectives:** B-lactamase-negative ampicillin-resistant (BLNAR) strains of *H. influenzae* are being increasingly recognised. BLNAR strains are characterized by specific ftsI gene mutations and associated amino acid substitutions in the encoded penicillin binding protein 3 (PBP3). The N526K (BLNAR defining) PBP3 substitution occurs in almost all BLNAR strains and resistance is enhanced by further substitutions (BLNAR associated) at other sites. It is generally accepted that most BLNAR strains emerge from de novo ftsI mutations in previously susceptible strains although there is some evidence of inter-strain horizontal transfer of mutated ftsI genes. Significantly, there has been one report of horizontal transfer of the ftsI gene from the respiratory commensal *H. haemolyticus* to *H. influenzae*. A role was

proposed for *H. haemolyticus* as a reservoir of *ftsI* genes to mediate BLNAR type resistance in *H. influenzae* through recombination and formation of mosaic *ftsI* genes. Little is known about the frequency, nature or effect on susceptibility of *ftsI* mutations in *H. haemolyticus* and the aims of this study are to investigate this.

**Methods:** A collection of 349 strains of XV dependent *Haemophilus* spp. from a geographically restricted cohort of children with otitis media were further identified by 16sRNA PCR. Subsequently, all isolates of *H. influenzae* and *H. haemolyticus* were tested for susceptibility to ampicillin and amoxicillin-clavulanate using CLSI broth dilution, and screened for N526K associated *ftsI* mutations using single nucleotide specific PCR. The *ftsI* genes of all *H. haemolyticus* and PCR screen positive *H. influenzae* were sequenced.

**Results:** Of the 349 strains, 33 were confirmed as *H. haemolyticus*, and 248 confirmed as *H. influenzae* by 16sRNA PCR. The remaining 68 strains gave equivocal 16sRNA PCR results and were excluded from further analysis. A significantly higher proportion of *H. haemolyticus* (19/33) had the BLNAR defining N526K genotype than *H. influenzae* (80/248) and the presence of this mutation was associated with raised MICs compared to the ATCC strain. Furthermore, a range of BLNAR associated substitutions were seen in strains of *H. haemolyticus* with and without N526K, and appear to represent part of the baseline genotype.

Table 1: Deduced amino-acid substitutions in PBP3 of the 33 *H. haemolyticus* strains compared to *H. haemolyticus* ATCC and *H. influenzae* Rd control.

Strain genotype (n) <sup>1</sup>	Amino Acid at position										MIC (mg/L)	
	274	350	352	377	389	449	490	502	526	547	AMP	AMC
<i>H. influenzae</i> RD	E	D	S	M	L	I	G	A	N	V	0.5	2
<i>H. haemolyticus</i> ATCC 3390 <sup>2</sup>	D	N	G	I	L	I	G	A	N	I	0.5	0.5
<i>H. haemolyticus</i> BLNAs (n=14)	D	N	G	I	L	I	G/E	A	N	I	0.25-1	0.25-2
<i>H. haemolyticus</i> BLNAR <sup>3</sup> (n=7)					F	V		T	K	T	0.25-1	0.25-1
(n=1)							E	V	K		0.5	0.5
(n=3)	E							V	K		0.25-1	1-2
(n=2)	E		T	M				T	K		1	2
(n=2)	E	D	T	M				T	K	V	1	1-4
(n=5)									K		0.5	2

<sup>1</sup> Total number of *H. haemolyticus* strains = 33

<sup>2</sup> Boldface underlined type; known BLNAR associated substitutions in *H. influenzae*.

<sup>3</sup> Shows the deduced amino acid substitutions in PBP3 when compared to the baseline *H. haemolyticus* ATCC 3390 sequence.

**Conclusions:** There is a high prevalence of BLNAR defining and associated PBP3 substitutions in the *H. haemolyticus* strains studied here, with potential to be a reservoir for inter-species transfer of resistance to *H. influenzae*.

### P1302 Are biocides and antibiotic resistance driving the emergence of *Salmonella enterica* serotype 4,[5],12:i:- (monophasic variant of *S. Typhimurium*)?

J. Mourao, L. Dias, L. Ferreira, T. Alves, J. Machado, C. Novais, L. Peixe, P. Antunes\* (Porto, Lisbon, PT)

**Objectives:** *Salmonella enterica* serotype 4, [5],12:i:-, a monophasic variant of serotype *S. Typhimurium*, has become one of the most worldwide common serotypes related to human infections transmitted by food chain. In order to better understand if the rampant emergence of this serotype was linked to particular bacterial features we evaluate the clonal relationship and characterize the phenotype and genetic determinants associated with antibiotic (AB) and biocide (B) resistance of *S. enterica* serotype 4,[5],12:i:- from different sources.

**Methods:** Isolates from humans (n = 115), food (n = 9), environment (n = 4) and piggeries (n = 4) recovered in Portugal (2002–2010) were studied. The serotype was confirmed by PCR (fljA, fljB, hin and fljA-fljB). Susceptibility to 10 AB was tested by disk diffusion (CLSI). Clonality was studied by PFGE and MLST. Analysis of *pcdD* copper efflux, *merA* mercuric reductase, *silA* silver efflux system, AB resistance genes, plasmid and integron backbones (PCR, RFLP and/or sequencing), transferability and genomic location (I-CeuI/S1 nuclease hybridization) was performed.

**Results:** All but two isolates (99%) were resistant to AB, with 94% of multidrug-resistance (MDR, 3–8 AB). Resistance to sulfamethoxazole

(Su, 92%), tetracycline (T, 91%), streptomycin (S, 88%), ampicillin (A, 67%), chloramphenicol (C, 45%), trimethoprim (Tr, 35%), gentamicin (G, 27%), nalidixic acid (4%) or kanamycin (3%) was detected. Isolates were divided in three groups according to their features: (i) European clone (n = 48; four PFGE-types/ST34 that is a SLV of ST19)-ASSuT type (*bla*TEM, *strA*-*strB*, *sul2*, *tetB*), *pcdD*+ and *merA*+, all chromosomally located; (ii) MDR Spanish clone (n = 45; two PFGE-types; ST19 and phagetype DT104/U302) mostly ACGSSuTTr phenotype (n = 27; *bla*TEM, *cmlA1*, *aac(3)*-IV, *aadA*, *sul1*-*sul2*-*sul3*, *tetA*, *dfrA12*), with *merA*, atypical (*estX*-*psp*-*aadA2*-*cmlA1*-*aadA1*-*IS440*-*qacH*-*sul3*) and conventional (*dfrA12*-*orfX*-*aadA2*-*qacEd1*-*sul1*) class 1 integron on large non-conjugative *IncA/C* plasmids; (iii) CSSuTTr type (n = 15; ST19; *cmlA1*, *aadA*, *sul3*, *tetB*, *dfrA12*), carrying an atypical class 1 integron (*dfrA12*-*orfF*-*aadA2*-*cmlA1*-*aadA1*-*IS440*-*qacH*-*sul3*) on large, non-conjugative *IncR* plasmids.

**Conclusions:** Three MDR genotypes of globally spread clonal lineages are involved in the emergence of *S. enterica* serotype 4,[5],12:i:- in Portugal. Besides MDR, resistance to biocides used in animal production or linked to environmental pollution could account for the recent success of this serotype.

### P1303 The role of plasmids in the control of antibiotic resistance in *Escherichia coli* and *Klebsiella pneumoniae* isolated in a London hospital

M. Alqurashi\*, J. Dave, M. Pond, S. Amyes (Edinburgh, London, UK)

**Objectives:** The aim of this study was to investigate the infiltration of extended-spectrum beta-lactamases and their association with individual clones of Enterobacteriaceae isolated from blood cultures within a London teaching hospital.

**Methods:** One hundred Enterobacteriaceae, isolated sequentially in August–October 2009 from blood culture specimens, were obtained from St George's Hospital London. Antimicrobial susceptibility testing was determined by disc diffusion and agar dilution was used to measure the MICs of Cefotaxime, Ceftazidime, and Ceftriaxone; all tests were interpreted according to the BSAC guidelines. Multiplex PCR was used to identify CTX-M and AmpC enzymes. Pulsed-field gel electrophoresis (PFGE) with XbaI restriction was used to genotype the strains. Plasmid profiles were determined using S1 nuclease and alkaline lysis extraction and examined by PFGE. Furthermore, PCR-based replicon typing was used to identify individual plasmid types.

**Results:** Six isolates showed resistance to cefotaxime, ceftazidime and ceftriaxone, five were *Escherichia coli* and one was *Klebsiella pneumoniae*. All of them possessed the CTX-M-15 beta-lactamase gene but none of the strains harboured any of the known transferable AmpC beta-lactamases. Genotyping by PFGE revealed that two of the CTX M-15 beta-lactamase-containing isolates of *Escherichia coli* were closely related but the remaining isolates were <80% identical. In the six isolates, the plasmid profiles were not identical, ranging from 97.0 to 145.5 kb though four isolates of *Escherichia coli* did have the same plasmid of 145.5 kb.

**Conclusion:** Our data indicate the presence of plasmids carrying the CTX-M-15 beta-lactamase within this Enterobacteriaceae population and suggest that the dissemination of CTX-M-15 beta-lactamase gene is linked to both the transfer of these genes between plasmids and the transfer of those plasmids between the individual strains.

### P1304 Resistance mechanisms to amoxicillin-clavulanate in *Escherichia coli*: molecular epidemiology of inhibitor-resistant TEM and OXA-1-producing isolates

A. Ortega\*, V. Bautista, R.M. Bartolomé, E. Cercenado, M.C. Conejo, L. Martínez-Martínez, M. Merino, B. Mirelis, I. Weber, J. Campos, J. Oteo (Madrid, Barcelona, Sevilla, Santander, La Coruña, Palma de Mallorca, ES)

**Objectives:** Resistance to amoxicillin-clavulanate (AMC) in *E. coli* isolates is increasing in last years in Spain. The aims of this study are to

characterize the mechanisms of resistance to amoxicillin-clavulanate (AMC) in *Escherichia coli* in Spain, and to study the molecular epidemiology of OXA-1- and inhibitor resistant TEM (IRT)-producing isolates.

**Materials and methods:** A prospective multicenter study was designed to collect AMC-resistant *E. coli* isolates from clinical samples between January 2010 and May 2010. Seven hospitals members of the Spanish network for infectious disease research (REIPI), and representing six geographical areas, participated. Each hospital collected a maximum of 44 isolates (22 community and 22 nosocomial-acquired). Susceptibility testing was carried out by the microdilution method (CLSI). Mechanisms of resistance were characterized by PCR and sequencing. Molecular epidemiology was carried out by pulsed field gel electrophoresis (PFGE) and by Multilocus Sequence Typing (MLST).

**Results:** Two hundred and fifty-eight isolates were collected. AMC resistance mechanisms were: OXA-1 (26%), plasmidic AmpC (19.4%), hyperproduction of AmpC<sub>Cc</sub> (18.2%) and IRT (17.4%). Fifty-nine isolates (22.9%) had an antibiotic resistant profile compatible with hyperproduction of penicillinase, of them 54 (21.31%) produced blaTEM-1 and five (1.5%) blaSHV-1. The IRTs identified in this study were blaTEM-40 (33.3%), blaTEM-30 (28.9%), blaTEM-33 (11.1%), blaTEM-32 (4.4%), blaTEM-34 (4.4%), blaTEM-35 (2.2%), blaTEM-54 (2.2%), blaTEM-76 (2.2%), blaTEM-79 (2.2%), and the new blaTEM-185 (8.8%). PFGE analysis of IRTs-producing isolates showed a high genetic diversity, with 43 PFGE different patterns among 45 isolates. Two well-defined clusters were detected in the 67 OXA-1-producing isolates, cluster C1 made up of 19 phylogroup A isolates, and cluster C2 made up of 19 phylogroup B2 isolates (16 produced CTX-M-15). MLST results showed 16 different STs among OXA-1-producing isolates, being the majority ST88 (37.3%) and ST131 (32.8%). C1 and C2 isolates belonged to ST88 and ST131, respectively. In IRTs isolates, 20 different STs were found, mainly ST131 (17.8%), ST23 (11.1%), ST73 (11.1%) and ST38 (6.7%).

**Conclusions:** A great diversity of mechanisms of AMC resistance in *E. coli* was detected. Clonal dissemination of OXA-1-producing isolates linked to ST88 and ST131 clones was observed. ST131 clone was detected in the 26.8% of all 112 IRTs or OXA-1-producing isolates studied.

#### **P1305** Resistance to aminoglycosides in *Corynebacterium striatum*

J. Navas\*, R. Duran, S. Martinez, C. Salas, L. Martinez-Martinez (Santander, ES)

**Objectives:** Coryneform bacteria are aerobic Gram-positive, non-spore forming bacilli increasingly recognized as pathogens of clinical relevance, particularly as a cause of opportunistic infections. They are mostly associated with soft-tissue infections, respiratory tract infections, bacteraemia and endocarditis. Corynebacterial infections are usually treated with glycopeptides, mainly vancomycin. Most of *Corynebacterium* are highly resistant to several antimicrobials. Corynebacteria are considered as a possible reservoir of antibiotic resistance genes, that could be transmitted to other saprophytic or pathogenic bacteria colonizing the human skin or other tissues. The objectives of this work have been: To study the susceptibility to aminoglycosides of a collection of *Corynebacterium striatum* clinical strains isolated from different origins and patients at the Hospital Marqués de Valdecilla, Santander, Spain, during the period 2006–2010. The elucidation of their resistance mechanisms.

**Methods:** Seventy-four *C. striatum* clinical isolates were included in the study. MICs were determined using the E-test system. The following antimicrobial drugs were tested: amikacin, gentamicin, kanamycin, netilmicin, streptomycin and tobramycin. Search for aminoglycoside resistance genes were performed by PCR using specific primers for aphA1, aadA1, aadB, aadD, aac(6′)-II, ant(4)-IIa, strA and strB genes. Amplification products were sequenced.

Sequences were analyzed with the BLAST tool at the website of the National Center for Biotechnology Information, USA

**Results:** Forty-five *C. striatum* strains were resistant to at least one of the tested aminoglycosides. Forty-two percent of the isolates were resistant to kanamycin, 30% to streptomycin, 18% to tobramycin, 3% to amikacin and 1% to gentamicin. Nine different resistance profiles were observed. The four most frequent profiles were: resistance to kanamycin and streptomycin (18% of the isolates), resistance to kanamycin (12%), resistance to streptomycin (12%) and resistance to kanamycin and tobramycin (8%). Thirty-three *C. striatum* carried the aphA1 gene, encoding an aminoglycoside phosphotransferase that confers resistance to kanamycin. Three strains carried the genes strA and strB, encoding resistance to streptomycin.

**Conclusion:** A high percentage of our *C. striatum* clinical isolates were resistant to aminoglycosides. Most of the resistant isolates carried the gene aphA1.

#### **P1306** Broad host-range transferable high-level gentamicin resistance in group B *Streptococcus*

A. Tazi, A. Firon, H. Poupet, N. Dmytruk, M. Longo, P. Trieu-Cuot, C. Poyart\* (Paris, FR)

**Objectives:** A screening for Group B *Streptococcus* (GBS) highly resistant to gentamicin (HGR) collected by the National Reference Centre for Streptococci between 2007 and 2011 retrieved three unrelated clinical isolates. The aim of our study was to confirm and to characterize the genetic support of HGR of these GBS strains.

**Methods:** Gentamicin resistance was determined using disk diffusion and minimal inhibitory concentrations (MICs) were measured by E-test®. Sequencing of PCR products as well as direct chromosomal sequencing were performed to identify the aac(6′)-aph(2) gene and to determine its genetic environment. Intra- and inter-species resistance transferability was assessed by conjugation experiments.

**Results:** Three unrelated GBS isolates of capsular serotype II, III, and V were recovered. Two of these strains were responsible for invasive infection (neonatal n = 1, adult n = 1) whereas the remaining was a vaginal colonizing strain. All strains were highly resistant to gentamicin with MIC > 128 mg/L and the presence of the aac(6′)-aph(2) gene encoding the bifunctional aminoglycoside-inactivating enzyme was confirmed by PCR and sequencing. This analysis revealed that the resistance determinants were carried by a classical Tn4001 transposon in one isolate and by truncated Tn4001-like transposons in the remaining two. Resistance of the strains carrying the truncated transposons was intra- and inter-species transferable at a high (10<sup>4</sup>) and a low (10<sup>7</sup>) frequency, respectively, for one strain and intra-species transferable at a low frequency (10<sup>6</sup>) for the other one.

**Conclusion:** We described chromosomally HGR mediated by Tn4001-like transposons in three unrelated GBS isolates. Such resistance has already been reported in other *Streptococcus* species. Yet, to our knowledge, this is only the second report of HGR in GBS, stressing that it is still very rare. However, we characterize one strain displaying a broad host range of conjugal transfer, a feature which might favour the spreading of the aac(6′)-aph(2) gene to other bacteria, as already observed with other antibiotic resistance genes. Thus, continuous surveillance of gentamicin susceptibility in GBS remains necessary.

#### **P1307** Antimicrobial susceptibility and molecular characterisation of metronidazole resistance in *H. pylori* isolated from Thai patients

T. Chatsuwana\*, P. Prasurthisin, R. Vilaichone, D. Thong-Ngam, V. Mahachai (Bangkok, TH)

**Objectives:** To investigate the prevalence of antimicrobial resistance in *H. pylori* isolated from Thai patients and to determine the mechanisms of metronidazole resistance including mutations in the rdxA gene, encoding oxygen-insensitive nitroreductase and efflux pump.

**Methods:** A total of 102 *H. pylori* isolates were obtained from patients at King Chulalongkorn Memorial Hospital and Thammasat University Hospital between August 2003 to January 2007. The MICs were determined by E-test. Mutations in *rdxA* were detected by PCR and DNA sequencing. The role of efflux pump was investigated by using efflux pump inhibitor, CCCP.

**Results:** Prevalence of antimicrobial resistance in *H. pylori* was 0.98% to amoxicillin, 20.59% to ciprofloxacin, 8.82% to clarithromycin, 0.98% to tetracycline and 19.6% to metronidazole. Amoxicillin was the most potent antibiotic against *H. pylori* (MIC<sub>90</sub> = 0.047 mg/L). Sequencing analysis of the *rdxA* gene was determined in three metronidazole-sensitive and 14 metronidazole-resistant *H. pylori*. The results showed 15 amino acid changes in RdxA in metronidazole-sensitive and 28 in metronidazole-resistant *H. pylori* isolates when compared with those of *H. pylori* 26695 from GenBank. No particular amino acid substitution was associated with metronidazole resistance. Three metronidazole-resistant *H. pylori* isolates contained nonsense mutations, leading to a stop codon at either amino acid position seven or 65. One isolate had a deletion of A522 in the *rdxA* gene, leading to frameshift mutation at amino acid position 175. The remaining 10 isolates had missense mutations at various sites (5–12 sites). The efflux pump mechanism was not detected in any isolates.

**Conclusion:** These results suggest that mutations in the *rdxA* gene are associated with metronidazole resistance. However, other mechanisms must be involved in the development of resistance.

#### **P1308** *Escherichia coli* as reservoir for macrolide resistance genes

A. Ferjani\*, A. Baccouche, M. Marzouk, M. Tarchouna, J. Boukadida (Sousse, TN)

**Introduction:** Although macrolides is not intended in the treatment of *E. coli* infections, because of the frequent contact of this bacterium with macrolides in the digestive tract, it is susceptible to become a real reservoir for macrolide resistance genes and able to transfer them to other target bacteria. All of these genes confer full cross-resistance between erythromycin and azithromycin. We aimed to assess the resistance to macrolides in commensal isolates of *E. coli* and to characterize the mechanisms of resistance.

**Materials and methods:** A total of 70 commensal *E. coli* isolates were collected from feces of hospitalized and non hospitalized patients. Susceptibility to antibiotics was determined as recommended by the French society for microbiology. MICs of erythromycin were determined by E-test (AB-Biodisk). The macrolide resistance genes screened by PCR were *mph* (A), *erm* (A), *erm* (B), *erm* (C), *ere* (A), *ere* (B), *mef* (A), *msr* (A).

**Results:** Resistance to amoxicillin, cefotaxime and cotrimoxazole was detected for 32%, 4% and 11% of isolates respectively. MICs of erythromycin ranged from 4 to 64 mg/L. the majority of strains (47%) had high MICs ( $\geq 32$  mg/L). the *mph* (A) gene was the most common macrolide resistance gene, it was present in 11 isolates obtained essentially from patients receiving antimicrobial drugs. The *erm* (B) gene was detected in seven isolates. The six other genes were not detected.

**Conclusion:** The *mph* (A) gene giving resistance to azithromycin was the most common macrolide resistance gene detected in *E. coli*. Because *E. coli* and other species can exchange plasmids, further dissemination of resistance to macrolides in target bacteria may be predicted.

## Epidemiology of MRSA, VRE and other Gram-positives

#### **P1309** First occurrence of methicillin-resistant *Staphylococcus aureus* with a novel *mecA* homologue in a child in Switzerland

H. Adler\*, U. Heininger, D. Brandenberger, E. Schultheiss, R. Frei (Basel, CH)

**Objectives:** We describe a methicillin-resistant *Staphylococcus aureus* (MRSA) with a novel *mecA* homologue. The isolate attracted our interest because it exhibited phenotypic resistance to methicillin but was *mecA* negative by PCR. MRSA isolates with similar characteristics possessing the novel *mecA* homologue *mecALGA251* have been described recently in the UK, Ireland, Denmark and Germany. An association with dairy cattle has been reported.

**Methods and results:** The MRSA isolate was recovered from the blood of a 10-year-old girl who had undergone orthopaedic surgery and presented with a wound infection. An additional MRSA with the same characteristics was isolated from a wound swab. The patient had not been abroad for a year and had no contact with dairy cattle.

Routine susceptibility testing of the *S. aureus* isolate with the Vitek AST P580 card (bioMérieux) revealed resistance to penicillin, oxacillin, and ceftioxin and susceptibility to all other compounds tested. The isolate grew on a chromogenic selective agar plate (chromID MRSA, bioMérieux). Latex agglutination for PBP2a with MRSA-Screen (Denka Seiken) did not indicate PBP2a expression.

Conventional PCR was positive for *femA* and negative for *mecA*. Rapid real-time PCR with the Xpert MRSA/SA test (Cepheid) identified methicillin-susceptible *S. aureus*. PCR designed for the simultaneous detection of both the *mecA* gene and the *mecA* homologue *mecALGA251* as described by Garcia-Alvarez et al. (*Lancet Infect Dis* 2011; 11: 595–603) resulted in a 356-bp product. Sequencing of the PCR product revealed 100% homology to *mecALGA251*.

The isolate was typed by pulsed-field gel electrophoresis and compared with 621 different MRSA types consecutively isolated from humans since 1994. Analysis of the restriction patterns did not reveal any relationship with other MRSA strains except from one single isolate obtained in 2006.

**Conclusion:** To our knowledge this is the first case of MRSA with the novel *mecA* homologue *mecALGA251* in Switzerland. Molecular typing results suggest that the isolate is not associated with strains circulating in Switzerland. Clinicians and microbiologists have to be aware that MRSA isolates with the novel *mecA* homologue may go undetected by both PCR assays and agglutination tests for PBP2a.

#### **P1310** Molecular epidemiology of methicillin-resistant *Staphylococcus aureus* in Switzerland: diversity from bacteraemia represents only a small part of the diversity found in colonised/infected patients

L. Senn\*, P. Basset, G. Greub, G. Prodhom, R. Frei, R. Zbinden, C. Balmelli, V. Gaia, G. Pfyffer, K. Mühlemann, G. Zanetti, D.S. Blanc (Lausanne, Basel, Zurich, Lugano, Bellinzona, Lucerne, Berne, CH)

**Objective:** To assess the molecular epidemiology of methicillin-resistant *Staphylococcus aureus* (MRSA) strains in Swiss hospitals.

**Methods:** National survey of MRSA cases identified in >500-bed Swiss hospitals from January to June 2011. Participating hospitals were asked to submit the first five successive MRSA isolates from individual patients with MRSA bacteremia and the first ten successive MRSA isolates from individual new cases (colonization or infection other than bacteremia). Molecular analysis of MRSA strains was done by Double Locus Sequence Typing (DLST), *spa*-typing, and SCCmec typing. In addition, the presence of PVL genes was also investigated. Swiss genotypes were compared to a reference database including international MRSA clones.

**Results:** Six out of eight >500-bed Swiss hospitals participated in the survey. A total of 74 MRSA isolates were sent to the reference laboratory: fourteen strains isolated from blood cultures (0–5 per hospital) and the 10 first MRSA isolates of each participating hospital. Depending on the hospitals' MRSA incidence, 9 days to 3 months were needed to obtain the first 10 isolates.

Among the 74 MRSA isolates, 40 different DLST types were observed (4–10 types per hospital). Only nine types were shared by more than one patient (2–8 patients). Seven international clones were found

among the Swiss isolates: Berlin clone (ST 45-IV-PVL neg), South German clone (ST 228-I-PVL neg), UK EMRSA-15 clone (ST 22-IV-PVL neg), New-York/Japan clone (ST 105-II-PVL neg), Lyon clone (ST 8-IV-PVL neg), Brazilian clone (ST 239-IImerc-PVL neg), European CA-MRSA clone (ST 80-IV-PVL pos). Among the 14 MRSA strains isolated from blood cultures, only nine different DLST types were found.

In the hospital with the highest MRSA incidence (18 cases/1000 admissions), 6/10 isolates were of the same type (DLST 4-4-I-neg). In contrast, in two hospitals with a lower incidence (ca one case/1000 admissions), 9/10 and 10/10 isolates were of different types, respectively. However, in the hospital with the lowest incidence (0.3 case/1000 admissions), four patients shared the same strain (DLST 2-2-II-neg).

**Conclusion:** In a country with a low to intermediate MRSA prevalence among invasive *S. aureus* (ca. 10%), strains isolated from blood cultures represent only a small part of the genetic diversity of MRSA encountered in hospitals and does not allow a representative description of the local molecular epidemiology.

**P1311 Studying recombination in the context of the population structure: the case of a recently emerged methicillin-resistant *Staphylococcus aureus* lineage**

S. Castillo-Ramírez\*, P. Martinen, J. Corander, M. Holden, Z. Gulay, H. Westh, E. Feil (Bath, UK; Turku, FI; Hinxton, UK; Izmir, TR; Hvidovre, DK)

**Objectives:** Study the role of recombination within the context of the population structure for the recently emerged methicillin-resistant *S. aureus* (MRSA) clone Sequence Type 239 (ST239).

**Methods:** Previously, 63 isolates of the MRSA ST239 were sequenced through a second-generation sequencing platform to study the global geographic structure and intercontinental transmission of this clone. Recently, this data set was expanded with another 127 isolates, many of which were collected from hospitals in Turkey, but also from hospitals in other parts of the world. This extended data set was analyzed using Bayesian approaches and homemade perl scripts.

**Results:** We find that although recombination has introduced a significant amount of genetic variation that has affected almost 30% of the genome, it has mainly been confined to the so-called mobile genetic elements (MGE). Furthermore, the ratio of the rates at which nucleotides are substituted as a result of recombination and mutation ( $r/m$ ) is 1.2, but drops to 0.6 if the MGE are not considered, implying that recombination has been introducing slightly more than half of the variation introduced by mutation in the core genome. Additionally, we note that much of the population structure of this clone is regional and so is the pattern of recombination between the strains. Interestingly, we observe that for the core genome the older the clade, the more recombination is found. Nonetheless, we find an outsider clade that appears to be less affected by recombination, and this suggests non-constancy in the recombination rate across the clades.

**Conclusions:** Our results suggest that recombination has introduced a good deal of genetic variation, although the level of recombination has varied not only along the genome but also across the clades. In addition, the possibility of recombination between the clones is constrained by the population structure.

**P1312 High prevalence of ST228-MRSA-I blood isolates with the hVISA/VISA phenotype in the northern Italian province of Bolzano**

R. Aschbacher\*, B. Pichon, M. Wootton, M. Ganner, R. Hill, R. Pike, P. Innocenti, L. Moroder, R. Meyer, C. Spitaler, I. Unterkircher, A. Griessmair, E. Pagani, C. Larcher, I. Agreiter, S. Spertini, A. Kearns (Bolzano, IT; London, Cardiff, UK; Merano, Bressanone, Brunico, IT)

**Objectives:** Methicillin resistant *Staphylococcus aureus* (MRSA) causing bloodstream infections is frequently treated with

glycopeptides; reduced vancomycin susceptibility among hVISA and VISA phenotypes is therefore disturbing. We therefore performed a microbiological and molecular survey of 81 first, non-duplicate blood MRSA isolates collected during 2002–2010 in the Province of Bolzano, Northern Italy (population size 500 000).

**Methods:** All MRSA isolates were subjected to staphylococcal cassette chromosome mec (SCCmec), accessory gene regulator (agr) and surface protein A (spa) typing together with PCR-based screening for 14 toxin genes. Representative strains were also analysed by multi-locus-sequence-typing (MLST) and pulsed-field-gel-electrophoresis (PFGE). MICs were determined by agar dilution (British Society for Antimicrobial Chemotherapy), screening for hVISA was by Macro-Etest and Etest GRD and confirmed by PAP-AUC.

**Results:** Two of the 81 MRSA isolates were VISA with vancomycin MICs of 4 mg/L and teicoplanin MICs of 4 and 8, respectively. Two MLST clonal complexes predominated: CC8 (59%) and CC5 (33%); the remainder included representatives of CC1, CC22, CC45 and CC398. All isolates were PVL negative. The major clones identified were ST8-MRSA-IVc, spa t008 (55%), ST228-MRSA-I, spa t041 (16%) and ST225-MRSA-II, spa t003 (6%); all of the ST228-MRSA-I, spa t041 isolates were hVISA or VISA. Twenty-one (26%) of the isolates were positive at the screening tests and at the PAP-AUC confirmation tests for hVISA; the difference in the frequencies of the hVISA/VISA phenotypes between the two major clones was statistically significant ( $p = 0.0001$ ). One ST8-MRSA-IVc, spa t008 isolate had ccrA2B2 together with ccrA4B4. One isolate had the genotype ST398-MRSA-V, spa t011 (CC398) associated to Livestock-Associated MRSA (LA-MRSA).

**Conclusion:** Single major MRSA clones together with sporadic isolates are present in blood isolates in a Province in Northern Italy and the high prevalence and association of a specific genotype with the hVISA/VISA phenotype is of concern clinically. A correlation of this phenotype with minor glycopeptide treatment success has been described; for this reason elaboration of the treatment outcomes for our patients is in progress to study the clinical implication of this genotype.

**P1313 Molecular typing and phenotype characterisation of methicillin-resistant *Staphylococcus aureus* Isolates from blood in Taiwan**

J. Lu\*, W. Wang (Taoyuan, TW)

**Objectives:** *Staphylococcus aureus* causes a variety of severe infections such as bacteremia and sepsis. At present, 60–80% of *S. aureus* isolates from Taiwan are methicillin resistant (MRSA). It has been shown that certain MRSA clones circulate worldwide. The goals of this study were to identify MRSA clones in Taiwan and to correlate the molecular types of isolates with their phenotypes.

**Methods:** A total of 157 MRSA isolates from bacteremic patients were collected from nine medical centers. They were typed based on polymorphisms in agr, SCCmec, MLST, spa, and dru. Phenotypes characterized included Pantone-Valentine leucocidin (pvl), inducible macrolide-lincosamide-streptogramin B resistance (MLS<sub>SB</sub>i), vancomycin (VA) and daptomycin (DAP) minimal inhibitory concentrations (MIC), and superantigenic toxin gene profiles. Difference between two consecutive samples was determined by Mann-Whitney *U*-test, and difference between two categorical variables was determined by Fisher's exact test.

**Results:** Four major MRSA clone complexes CC1, CC5, CC8, and CC59 were found, including four CC1, nine CC5, 111 CC8, and 28 CC59 isolates. These clones had the following molecular types: CC1: SCCmecIV and ST573; CC5: SCCmecII and ST5; CC8: SCCmecIII, ST239, and ST241, and CC59: SCCmecIV, SCCmecVT, ST59, and ST338. The toxin gene profiles of these clones were CC1: sec-seg-(sei)-sell-selm-(seln)-selo; CC5: sec-seg-sei-sell-selm-(seln)-selp-tst1; CC8: sea-selk-selq, and CC59: seb-selk-selq. Most isolates with SCCmecVT, ST59, spat437, and dru11 types were pvl+ (13 isolates), while multidrug resistance (<sup>3</sup> four antimicrobials) were associated with

SCCmecIII, ST239, spa t037, agrI, and dru14 (119 isolates) ( $p < 0.001$ ). One hundred and twenty four isolates with the following molecular types had higher VA MIC: SCCmecII and SCCmecIII; ST5, ST239, and ST241; spa t002, t037, and t421; dru4, dru10, dru12, dru13, and dru14 ( $p < 0.05$ ). No particular molecular types were found to be associated with MLSBi phenotype.

**Conclusion:** Four major MRSA clone complexes were found in Taiwan. Further studies are needed to delineate the evolution of MRSA isolates.

#### **P1314** Methicillin-resistant *Staphylococcus aureus* in four Balkan countries

M.D. Bartels\*, L. Raka, D. Osmalli, G. Mijovic, Z. Cekovska, G. Mulliqi-Osmani, B. Kakaraskoska, G. Bosevska, S.M. Rohde, K. Boye, H. Westh (Hvidovre, DK; Phirstina, XZ; Tirana, AL; Podgorica, ME; Skopje, MK)

**Objectives:** Little is known about Methicillin-resistant *Staphylococcus aureus* (MRSA) in the Balkan countries Albania, Kosovo, Macedonia and Montenegro. The purpose of this study was to characterize hospital acquired (HA) and community onset (CO) MRSA isolated in these four countries.

**Methods:** Fifty-eight MRSA isolates were collected and tested for the presence of the mecA gene, nuc gene, spa gene and Panton Valentine leukocidin (PVL) genes. Typing of the spa region was performed on all spa PCR positive isolates and spa types were assigned using the Ridom StaphTyper. All isolates were from 2010 or 2011. Supposed CO or HA-MRSA was recorded. Multi locus sequence types (ST) and clonal complexes (CC) for each spa type were predicted when available at the Ridom SpaServer.

**Results:** Among 58 isolates we found 16 spa types and six MRSA isolates that were spa PCR negative. spa type t030 (ST239, Brazilian/Hungarian clone) was found in three countries, t041 (ST228, Southern German clone) and t969 (related to t030) in two countries, while the remaining spa types were only found in one country each. Twenty-three isolates were CO-MRSA, while 32 were HA-MRSA, and three were not defined. Seven of the spa types (t002, t005, t015, t026, t030, t041, t062 and t969) belonged to major HA-MRSA clones [1] and 70% of these were considered HA-MRSA. PVL was present in 13 isolates (22%). Five of the PVL positive isolates were CO-MRSA, seven were HA-MRSA, and one was not defined. Based on spa type, 43 of the isolates could be assigned to six CCs and three STs without CC-designation.

**Conclusion:** The finding of a high diversity in spa types and a high number of PVL positive HA-MRSA in the Balkan region was surprising. Although PVL is usually found in CO-MRSA, the same percentage of isolates in the HA-MRSA group was PVL positive (22%). Thirty-one isolates belonged to well-known pandemic HA-MRSA clones, including eight t002 isolates from Macedonia of which five were PVL positive. PVL positive HA-MRSA is not common in Europe, but in the USA the PVL positive clone USA300 has become endemic hospitals. None of the 13 PVL positive isolates belonged to the three most common PVL positive International clones USA300, ST80 (European clone) and ST30 (South West Pacific clone).

**Reference:** 1. Deurenberg RH, Vink C, Kalenic S, Friedrich AW, Bruggeman CA, et al. The molecular evolution of methicillin-resistant *Staphylococcus aureus*. Clin Microbiol Infect 2007; 13: 222–235.

#### **P1315** Characterisation of resistance, virulence, surface and immune evasion genes in Spanish epidemic methicillin-resistant *Staphylococcus aureus* strains

F. Menegotto, S. González Cabrero, A. Cubero Ribas, W. Cuervo, V. de Santiago Montaña, M.P. Gutiérrez Rodríguez, A. Ortega Andrés, M. Simarro, A. Orduña Domingo, M.A. Bratos Pérez\* (Valladolid, ES)

**Objectives:** Methicillin-resistant *Staphylococcus aureus* (MRSA) spa-type t067 strains are currently epidemic in Spain. The aim of

this study was the characterization of resistance, virulence, surface and immune evasion genes profiles in a collection of spa-type t067 MRSA strains.

**Methods:** A total of 91 spa-type t067 MRSA strains were isolated in the Microbiology Laboratory at the Hospital CUV (Spain) in 2005, 2007 and 2008. They were subjected to analysis using spa-typing, multilocus sequence type (MLST) and ADN microarrays to characterise and assign the bacterial isolates.

**Results:** All the strains studied belong to the clonal complex CC5 and present a type II agr locus. The 62% of t067 MRSA strain in addition to carrying the genetic elements characteristic of SCCmec IV (class B mec gene complex and ccrA/B2 genes), presented additional elements such as ccrA/B4 or ccrB4 (SCCmec VI). Using MLST, the ST125 was assigned to spa-type t067; most of spa-type t067 MRSA strains are related to ST125-MRSA-IV/VI. The ST125-MRSA-IV/VI strains were mainly associated with the genotypic resistance profile mpbBM + mrsA, aadD + aphA and sat, which are responsible for erythromycin, tobramycin, and streptothricin resistance respectively, while ST125-MRSA-IV strains were characterized by the only presence of the tobramycin-resistant gene aadD. All the isolates carry the enterotoxin gene cluster egc (seu-positive variant). Correlation between the egc cluster and the sea gene (sea-N315) was also observed in the majority of the cases. This superantigen together with the sak, chp and scn genes it forms the immune evasion cluster (IEC). The IEC type F (sep, sak, chp and scn) were presented by 71% of the isolates, and IEC type B (sak, chp and scn) were detected in 4% of the isolates. The alpha-hemolysin gene and the Leukocidin/hemolysin gamma genes were negative in 15% and 13% of the respectively. The profile of surface genes was homogeneous and the variant alleles are the same ones as those of the Mu50 strain. Seven isolates presented a deletion of the bone sialoprotein-binding protein gene, five isolates were negative for the sdrD gene and another one was negative for the fibronectin-binding protein gene.

**Conclusion:** It was possible to subdivide the epidemic genotype t067 based on the acquisition or loss of resistance or virulence genetic elements. Surface and immune evasion genes profiles were homogeneous.

**Acknowledgement:** Dolores Rico and Julia Panero for their technical support.

#### **P1316** Clonality of methicillin-resistant *Staphylococcus aureus* and methicillin-resistant *Staphylococcus pseudintermedius* isolated from healthy and sick companion animals and humans in Portugal

N. Couto\*, A. Belas, C. Pomba (Lisbon, PT)

**Objectives:** To characterize the clonality, antimicrobial and biocide susceptibility patterns of methicillin-resistant *Staphylococcus aureus* (MRSA) and methicillin-resistant *Staphylococcus pseudintermedius* (MRSP) strains isolated from dogs, cats and humans in close contact.

**Methods:** Sixteen MRSA isolates from five dogs (one nasal colonization isolate, three pyoderma and one urinary tract infection-UTI isolates), two cats (nasal colonization) and nine humans (nasal colonization) were studied. The nine humans included seven veterinarians, one veterinary caretaker and one owner. Twenty MRSP isolates from 16 dogs (nine isolates from nasal colonization, five isolates from pyoderma, one from an otitis externa-OE and one from a surgical infection) and four cats (three isolates from an UTI and one from an OE) were analysed. Antimicrobial susceptibility testing was performed according to CLSI guidelines. MICs of several biocides and dyes were also determined. MRSA and MRSP isolates were subjected to spa typing, SCCmec typing and PFGE.

**Results:** spa typing of the 16 MRSA isolates classified them as: t032 (n = 8), t1865 (n = 3), t020 (n = 1), t910 (n = 1), t2357 (n = 1) and t002 (n = 2). All MRSA isolates except spa type t002 belonged to the MLST clonal complex (CC) 22, harboured an SCCmec IV and had indistinguishable PFGE patterns. The MRSA t002, which corresponds to MLST CC5, clustered differently from the other strains by PFGE.

Both clones, CC5 and CC22, included animal and human isolates. Fifteen MRSP isolates were spa type t02, four were t06 and one was t05. Eighteen MRSP were SCCmec III, while only two strains were SCCmec V. PFGE revealed two main MRSP clusters. All MRSA isolates were co-resistant to ciprofloxacin and three also had elevated MICs to erythromycin. MRSP strains were multidrug resistant, being resistant at least to ciprofloxacin, erythromycin, clindamycin, kanamycin and trimethoprim/sulfamethoxazole. Only the two MRSA CC5 strains had high MICs to ethidium bromide (32 mg/L), benzalkonium chloride (1 mg/L) and chlorhexidine (1 mg/L). The other MRSA and MRSP strains had no elevated MICs towards biocides.

**Conclusions:** This study shows that MRSA clones CC5 and CC22 may be disseminated in both human and companion animal populations. This underlines the importance of the animal-to-human transmission of resistant bacteria and the potential of zoonotic dissemination. MRSP strains although not frequently identified in humans are multidrug resistant but susceptible to biocides. Nevertheless, they can spread and act as reservoirs of important resistance genes.

**P1317** Nationwide survey of methicillin-resistant *Staphylococcus aureus* harbouring mecALGA251 reveals a reservoir in ruminants

A. Larsen\*, M. Stegger, O. Heltberg, J. Christensen, A. Zeuthen, A. Petersen, M. Soerum, R. Skov (Copenhagen, Slagelse, DK)

**Objectives:** In this study the epidemiological impact of isolates harbouring the recently discovered mecALGA251 in a MRSA low prevalence country was investigated.

**Methods:** Retrospective and prospective search for phenotypic positive but genotypic negative MRSA was performed. Collections screened retrospectively included all Dan-ish MRSA cases since 1988 (n = 7200) as well as all Danish bacteremia cases since 1975 (n = 38 000). Isolates previously tested resistant to methicillin, oxacillin or cefoxitin and negative for the mecA gene were further tested for the presence of the recently discovered mecA gene variant, mecALGA251, by PCR. The genetic background of all mecALGA251 positive isolates was determined by spa typing. Pro-spective screening for mecALGA251 was introduced as routine in the Danish Staphylococcus reference laboratory by August 2011. Clinical data was obtained from 22 patients by interviews and review of discharge summaries in the Zealand region. In four cases samples were taken from animals (cow, horse, dog and sheep) with suggestive contact to persons positive for mecALGA251.

**Results:** In total, 104 persons were found to be carrying or infected by mecALGA251 positive MRSA. One case dated back to 1975, one to 1992, then no isolates were found until 2003 where after the annual numbers increased to reach 28 by the 11 November 2011 constituting 2–3% of the total number of MRSA. Isolates could be grouped in two genetic lineages CC130 and CC1943.

Clinical cases from Zealand were further investigated (n = 22). Two patients had postoperative bacteremia. In the other 20 cases a wide spectrum of infections was seen, dominated by skin and soft tissue infection (n = 11), postoperative infections (n = 4) and two bacteriuria. Three individuals were symptom free and MRSA (CC130) was only detected by screening cultures.

In four cases there was a suggestive contact between patient and animals: cows, sheep, butcher (profession). In two cases with cow respectively sheep contact, similar strains by PFGE analysis were isolated from owner and animal (one of these in a patient with bacteremia).

**Conclusions:** Since 2003 the number of isolates has increased and mecALGA251 is now found in 2–3% of all new MRSA cases in Denmark. In two cases screening of livestock animals in vicinity of infected persons resulted in the first direct evidence for bo-vine and ovine reservoirs with transmission to humans.

**P1318** Analysis of the immune evasion cluster genes in clinical and commensal *Staphylococcus aureus* strains of human and animal origins

D. Benito\*, C. Lozano, E. Gómez-Sanz, P. Gómez, M. Zarazaga, C. Torres (Logroño, ES)

**Objectives:** To analyze the genes that form the Immune Evasion Cluster (IEC) in a collection of clinical and commensal *S. aureus* isolates of human and animal origin. The IEC types detected were correlated with the origin and the clonal complexes (CC) of the strains.

**Methods:** One hundred and six methicillin-resistant and methicillin-susceptible *S. aureus* (MRSA and MSSA) isolates were studied: (i) 36 MRSA implicated in human bacteremia (Group 1); (ii) 15 MSSA fecal isolates of healthy humans (Group 2); (iii) 28 MSSA and MRSA of healthy human nasal samples (Group 3); (iv) 27 MRSA of human (n = 16) and animal origin (n = 11) of the clonal complexes CC398 or CC97 or CC1 (Group 4). The presence of the genes scn, sak, chp, sea and/or sep were studied by PCR and sequencing and according to the pattern of genes detected, they were classified into different IEC types.

**Results:** Sixty-four strains harbored genes of the IEC, representing 60% of all strains studied.

The following IEC types were obtained (IEC type/number of strains): Group 1, 72% with some IEC (IEC A/1; IEC B/1; IEC D/1; IEC E/1; IEC F/21; IEC G/1 and non-IEC/10); group 2, 86% with some IEC (IEC A/2; IEC B/4; IEC C/4; IEC E/1; IEC F/1; IEC G/1 and non-IEC/2); group 3, 90% with some IEC (IEC A/2; IEC B/13; IEC C/1; IEC D/1; IEC D/5; IEC F/1; IEC G/2 and non-IEC/3). The genes of IEC were detected in MSSA CC398 but not in MRSA CC398. Clinical MRSA strains from group 1 presented a high frequency of genes encoding the IEC, and were mainly ascribed to IEC type F (these strains belonged to CC5 (ST5, ST125). The IEC type B was highly detected among the strains of group 2 (50% of the positive strains), mainly related to CC15 (ST15), CC45 (ST45), CC509 (ST509), CC8 (ST1498), CC109 (ST1141), CC121 (ST121) and CC398 (ST398). The IEC type B was also found in more than 25% of positive strains of group 3 related to CC9 (ST109), CC30 (ST30) and CC59 (ST59). Strains of human origin CC97 exhibited the IEC type E. All strains of group 4 were negative for the genes of the IEC.

**Conclusions:** There is a relation between certain genetic lineages and the presence and type of IEC, highlighting the high prevalence of IEC type F among clinical isolates (MRSA) and IEC B among community isolates (MSSA). The IEC system was detected among commensal MSSA-CC398 of human origin but not among MRSA-CC398 of animal-human related origin. IEC could be a marker of interest to track *S. aureus* clones and their origin.

**P1319** Clonal transmission of MRSA between horses and staff at a veterinary teaching hospital and successful decolonisation of staff

M.J. Schwaber\*, S. Navon-Venezia, S. Masarwa, S. Tirosh-Levy, I. Chmelnitsky, R. Glick, Y. Carmeli, E. Klement, A. Steinman (Tel Aviv, Rehovot, IL)

**Objectives:** In the context of active surveillance for MRSA among horses at a veterinary teaching hospital, performed while two horses were treated for MRSA wound infections, several horses were found to be nasal carriers. As a result, staff members at the hospital were screened to determine whether cross-transmission of MRSA was occurring.

**Methods:** Nasal swabs were obtained from staff members and community equine veterinarians and plated on CHROMagar MRSA plates. Suspected MRSA colonies were sub-cultured and definitively speciated, and antimicrobial susceptibility testing performed by VITEK2. Molecular characterization was carried out by pulsed-field gel electrophoresis (PFGE), spa typing and multi-locus sequence typing (MLST) on representative horse and human isolates. PCR for the Pantan–Valentine leukocidin (pvl) gene was performed.

**Results:** One hundred thirty-nine individuals were screened. Positive results were obtained in the following distribution: full-time equine staff, 10/20 (50%); part-time equine staff, 3/27 (11%); non-equine staff, 2/70 (3%); community equine veterinarians, 1/22 (5%). The predominant phenotype of MRSA isolates of staff and horses (89%) was non-susceptibility to erythromycin, clindamicin, gentamicin and ciprofloxacin. Horse isolates subjected to molecular testing were of spa type t535 (global frequency 0.08%), MLST type ST5 and identical pulsotype. Spa type t535 predominated among equine staff isolates as well (11 of 12 tested – 92%), and those further characterized were of identical pulsotype and MLST type to those of the horse isolates. All isolates were pvl negative.

All equine staff and other staff carriers were treated with 1 week of daily 4% chlorhexidine soap showers and thrice daily 2% intranasal mupirocin. Infection control procedures were reinforced in the equine department, and horses discharged when possible. Follow-up screening of 27 staff members after treatment yielded 0% positive results. Six-month follow-up screening of 33 staff members and 28 horses yielded 0% positive results.

**Conclusions:** Cross-transmission of a rare MRSA clone with a healthcare-associated phenotype between horses and staff occurred at a veterinary hospital caring for horses with MRSA-infected wounds. Intensity of exposure to hospitalized horses was associated with likelihood of staff carriage. An infection control intervention including decolonization of staff succeeded in eradicating carriage at 6 months post-intervention.

**PI320 High prevalence of PVL-positive *Staphylococcus aureus* skin infections among outpatients in Brussels region, Belgium**

V. Sisteck\*, F. Antoine, A. Dediste, M. Gérard, P. Mols, J. Andrée, E. Maillart, G. Mascart, B. Richert, M. Van Nuffelen, C. Melot, V. Del Marmol, F. Van Bambeke, S. Blumental, A. Vergison, F. Jacobs, O. Denis (Brussels, BE)

**Objectives:** Community-associated methicillin-resistant *Staphylococcus aureus* (CA-MRSA), carrying the Panton-Valentine leukocidin (PVL), is an emerging problem worldwide. In this study, we determined the prevalence of *S. aureus* as a cause of skin and soft-tissue infections (SSTIs) among outpatients in Brussels region and evaluated risk factors for methicillin-sensitive *S. aureus* (MSSA) and methicillin-resistant *S. aureus* (MRSA) infections.

**Methods:** We enrolled patients with acute, purulent SSTIs presenting to emergency or dermatologic departments in four hospitals, during a prospective study from May to September 2011. Data for risk factor analysis (e.g. demographic data and clinical information) were collected through a case report form. *S. aureus* isolates were characterized by antimicrobial-susceptibility testing, detection of toxin and resistance genes, spa typing, and multilocus sequence typing (MLST). On MRSA isolates, we also performed typing of the staphylococcal cassette chromosome mec (SCCmec).

**Results:** *S. aureus* was isolated from 61 of 113 (54%) patients with SSTIs. The prevalence of MRSA was 6% (7/113). The clinical manifestation of MSSA and MRSA infections was similar with a predominance of skin abscess (including furuncle). The median age of patients with MSSA and MRSA was 23 and 34 years, respectively. Among the seven patients with MRSA, three patients had previously received antibiotics in the month before enrolment, and two patients had a history of hospitalization. Among patients with MSSA, 39% of patients had travelled abroad in the 3 months before enrolment. The pvl toxin gene was detected in 57% of MRSA, and 31% of MSSA. Other toxin genes were recovered rarely. The molecular profile of MSSA collected was heterogeneous whereas only three different MRSA clones were isolated (ST8, ST80, and ST45). All ST45-MRSA were isolated from patients with a history of hospitalization.

**Conclusion:** Our study underlines the high prevalence of PVL-positive *S. aureus* (35%) as a major cause of SSTIs among outpatients presenting to emergency or dermatologic departments in Brussels. Our

data also showed the importance of MRSA (6%) as a public health issue in Belgium. Surveillance should be intensified to monitor the incidence of MRSA and control its spread in the community.

**PI321 Lack of emergence of PVL-positive MRSA strains in a university hospital**

A. Strandén\*, R. Frei, A.F. Widmer (Basel, CH)

**Objectives:** The incidence of methicillin-resistant *Staphylococcus aureus* (MRSA) strains is decreasing, while the percentage of Panton-Valentine leukocidin (PVL) positive strains is increasing. The aim of this study was to characterize the PVL-positive MRSA strains in a Swiss university hospital (USB) with a prevalence of MRSA <2%.

**Methods:** Between January 2006 and December 2010, all MRSA first isolates per patient and year isolated at the microbiology laboratory of USB were tested for PVL genes by PCR. All PVL-positive strains were further analyzed by antimicrobial susceptibility testing, molecular typing by determining the SCCmec type and sequence-based spa type, as well as by pulsed-field gel electrophoresis (PFGE). Demographic and clinical data were collected.

**Results:** During the study period, a total of 258 MRSA cases among in- and outpatients were detected. Fifty-seven (22.1%) of these were PVL-positive exhibiting no increase over time. The mean age of PVL-positive patients was  $44.9 \pm 20.6$  years compared to  $58.4 \pm 22.4$  years of PVL-negative patients. Among the PVL-positive patients, 63.2% were outpatients, 50.9% female, and 21.1% had been hospitalized during the last 12 months. Twenty-eight (49.1%) originated from Switzerland, 10 (17.6%) from the European Union (EU), and 19 (33.3%) outside from the EU. Thirty-two (56.1%) of the PVL-positive strains were isolated from infections, most common skin, soft-tissue or wound infections (90.6%). Forty-four (77.2%) of the PVL-positive strains were classified as community-associated MRSA (CA-MRSA), and 13 (22.8%) as hospital-associated MRSA. Forty-five (78.1%) isolates harboured SCCmec type IV, 8 (14.0%) SCCmec type V variant, two new variants, and one SCCmec type II. Seventeen (29.2%) strains belonged to spa-type t008 which includes USA300 (ST8), 10 (17.5%) strains were of spa-type t044, representing clone ST80, which is known to commonly circulate as CA-MRSA in Europe. Half of PVL-positive strains belong to spa type t008 or t044. Overall, 16 different spa types were detected. PVL-positive MRSA strains were non-susceptible to ciprofloxacin in 42.6%, to tobramycin in 24.1%, to clarithromycin in 22.0%, and to fusidic acid in 20.4%. All strains were susceptible to vancomycin, teicoplanin, and doxycycline. There was no evidence for an outbreak during the study period.

**Conclusion:** In contrast to most published reports, we did not observe an increase of PVL-positive MRSA strains, despite the fact that 53.1% of all strains were CA-MRSA.

**PI322 Analysis of gene distribution of *Staphylococcus aureus* strains isolated from healthy volunteers with intermittent or persistent nasal carriage and from infected patients**

P.O. Verhoeven\*, F. Grattard, A. Carricajo, O. Garraud, B. Pozzetto, P. Berthelot (Saint-Etienne, FR)

**Objectives:** The nasal carriage of *Staphylococcus aureus* is a major risk factor for further infection with this bacterium. It has been shown previously that *S. aureus* carriers can be classified into two different states, persistent and intermittent. This study was designed to describe the distribution of 185 genes in *S. aureus* strains isolated from intermittent or persistent carriers and from patients with clinical *S. aureus* infections.

**Methods:** Thirty-three *S. aureus* strains from a cohort of healthy healthcare workers were tested, including 11 nasal intermittent carriers (IC) and 22 nasal persistent carriers (PC); they were compared to *S. aureus* strains isolated at the University Hospital of Saint-Etienne between 2008 and 2010 from 32 patients with community-acquired bloodstream infection in the absence of foreign material (BSI) and 36

patients with prosthetic joint infection without bacteremia (PJI). All these strains (n = 101) were genotyped by using the StaphyType microarray (Alere, Jouy-en-Josas, France).

**Results:** Among the 185 genes analyzed, no difference was found between strains of PC and strains of clinical infection (PJI and BSI) except for the gene coding for enterotoxin H. By contrast, four genes coding for toxins (entB, entK, entQ and lukE), the ssl08 gene coding for a staphylococcal superantigen like protein and two genes coding for serin proteases (splA and splB) were more prevalent in IC strains than in strains of the three others groups. In addition, the cna gene coding for a collagen adhesin was harbored by half of the PC, BSI and PJI strains but in only one IC strain.

**Conclusion:** These results suggest that the strains of *S. aureus* isolated from infected patients are genetically closer to those of PC subjects than those of IC subjects, which is in accordance with previous works showing that PC subjects, by contrast to IC subjects, are at higher risk of *S. aureus* infection.

**P1323** Nasal carriage rate and molecular epidemiology of methicillin-resistant *Staphylococcus aureus* among medical students in a Taiwanese university

C.S. Chen\*, C.Y. Chen, Y.C. Huang (Taoyuan County, TW)

**Background:** Methicillin-resistant *Staphylococcus aureus* (MRSA) is among the important pathogens of nosocomial infections. To investigate whether clinical exposures in the hospital affect nasal MRSA carriage among medical students, we conducted this cross-sectional study.

**Methods:** From June to September 2010, a total of 322 students of Chang Gung University, pre-clinical (n = 167) and clinical (n = 155), were recruited. Specimens from the nares of the subjects were obtained and sent for the detection of *S. aureus*. A questionnaire regarding demographics and potential risk factors for acquisition of *S. aureus* was also completed for each subject. All the MRSA isolates were further molecularly characterized.

**Results:** Overall, the carriage rate of *S. aureus* was 19.3%, with a rate of 16.8% for pre-clinical students and 21.9% for clinical students (p = 0.26); the carriage rate of MRSA was 2.2%, with a rate of 2.4% for pre-clinical students and 1.9% for clinical students (p = 0.54). There was no significant difference between the pre-clinical and clinical students in terms of nasal carriage of *S. aureus* and MRSA. All seven MRSA isolates belonged to sequence type 59, carried staphylococcal chromosome cassette type IV or VT and were categorized as community strains in Taiwan. The risk factors for acquisition of *S. aureus* included male gender, age  $\geq 23$  years, and not taking antibiotics in the past year.

**Conclusions:** A substantial proportion of medical students in northern Taiwan harbored MRSA, categorized as community strains, in their nares. The carriage of MRSA was not affected by the clinical exposure in the hospital for 1–2 years.

**P1324** Methicillin-resistant *Staphylococcus aureus* in community-, healthcare-, and hospital-associated infections: results of a 12-month observational study in a large tertiary-care Italian hospital

E. Graglia, E. Mantengoli\*, F. Bartalesi, A. Cavallo, D. Cecconi, P. Pecile, G.M. Rossolini, A. Bartoloni (Firenze, Siena, IT)

**Objective:** To investigate the role of methicillin-resistant *Staphylococcus aureus* (MRSA) in community-associated (CA) and healthcare-associated MRSA (HCA-MRSA) infections in Florence University hospital, Italy, and to compare it with the role of hospital-acquired MRSA (HA-MRSA) infections in the same setting.

**Methods:** MRSA isolated from patients within 48 hours of hospitalization without risk factors for HA-MRSA were defined CA-MRSA, with risk factors were defined HCA-MRSA. HA-MRSA infections constituted the control group. A data questionnaire was used

to collect patients demographics, clinical history and risk factors. SCCmec cassette type and PVL genes presence were investigated by PCR.

**Results:** Seventy-nine patients were enrolled from April 2009 until March 2010: seven infected by CA-MRSA, 33 by HCA-MRSA and 39 by HA-MRSA. The mean ages were 68, 65 and 51 years and the average length of stay was 6, 5, 26 days, respectively. All CA-MRSA were from skin and soft tissue infections (SSTI). HCA-MRSA were from SSTI (64%), sputum or bronchoalveolar lavage (BAL) (15%), blood (21%). HA-MRSA were from SSTI (32%), sputum or BAL (50%), blood (18%). Two CA-MRSA infected patients had HIV and alcohol as risk factors. Most of HCA- (100%) and HA-MRSA (98%) infected patients had at least one risk factor. Complications (septic shock, sepsis, pneumonia) were observed in none of the patients infected by CA-MRSA but in 8/33 (24%) and in 11/40 (28%) of those infected by HCA- and HA-MRSA, respectively. Four and eight deaths (12% and 20%) were observed in the HCA- and HA-MRSA infected patients and none in those with CA-MRSA. The susceptibility rates for CA-, HCA- and HA-MRSA were, respectively: clindamycin 57%, 33%, 15%; levofloxacin 0%, 9%, 2%; gentamicin 57%, 45%, 17%; rifampicin 100%, 94%, 77%; tetracycline 71%, 97%, 92%; trimethoprim sulfamethoxazole 100%, 94%, 95%; all isolates were susceptible to vancomycin, teicoplanin, linezolid, and tigecycline. Molecular analysis showed heterogeneity of SCCmec cassettes (type I, IV in CA-MRSA, type I, II, III, IV in HCA-MRSA and type I, II, IV in HA-MRSA) and the presence of PVL genes in 3, 3 and 1 of CA-, HCA- and HA-MRSA, respectively.

**Conclusions:** HCA-MRSA infections exhibited an intermediate profile between HA- and CA-MRSA one, showing a worse prognosis than CA-MRSA infections, but a higher antibiotic susceptibility and lower length of stay respect to HA-MRSA infections. HA-, HCA- and CA-MRSA were found to share some molecular features, as recently reported.

**P1325** Nasal carriage of methicillin-resistant *Staphylococcus aureus* among hospitalised patients and healthcare workers in a Belgrade university hospital

I. Cirkovic\*, A. Larsen, M. Svabic Vlahovic, D. Radenkovic, P. Gregoric, S. Stepanovic (Belgrade, RS; Copenhagen, DK)

Methicillin resistant *Staphylococcus aureus* (MRSA) has emerged as a major hospital-acquired pathogen worldwide, but also as an important community acquired pathogen. Many MRSA infections are preceded by a period of carriage. According to our knowledge no data concerning carriage of MRSA in Serbia have been published so far. The aim of the present study was to provide the analysis of carriage of MRSA in hospitalized patients and healthcare workers (HCWs) in the largest healthcare facility in Serbia.

Nasal swab were taken from 195 patients and 105 HCWs at the Clinical Center of Serbia in Belgrade. Nasal swabs were inoculated in Mueller-Hinton broth supplemented with 2.5% NaCl at 35°C for 24 hours. Each broth sample (50 µl) was inoculated onto MRSA-ID agar (bioMérieux, France). Chromogenic media were incubated at 35°C and read after 24 and 48 hours of incubation. Identification of isolates was confirmed by PCR for nuc and mecA genes. Susceptibility to antibiotics was performed by Vitek2 System (bioMérieux, France). Molecular typing of all MRSA strains was performed using spa, SCCmec and agr typing according to previously described protocols. Detection of Pantone Valentine leukocidin (PVL) genes were performed by PCR.

Among 195 hospitalized patients and 105 HCWs, 23 (11.8%) and 8 (7.6%) respectively were colonized with MRSA. All tested MRSA strains were susceptible to fusidic acid, trimethoprim/sulfamethoxazole, vancomycin, linezolid and mupirocin, while 27 (87.1%) were resistant to gentamicin, 27 (87.1%) to tobramycin, 17 (54.8%) to erythromycin, 17 (54.8%) to clindamycin (only two strains showed inducible type of resistance), 25 (80.6%) to ciprofloxacin and 4 (12.9%) to tetracycline. There have been detected seven different spa types (t001, t041, t030, t595, t242, t005 and t044). The spa type t001 (SCCmecI, agrII, resistant to gentamicin, tobramycin, erythromycin and ciprofloxacin) was

dominant (45.2%). PVL genes were detected in 2 (6.4%) MRSA strains (t595-SCCmecV-agrI (two strains) and t044-SCCmecIV-agrIII). Out of eight MRSA strains isolated from HCWs, 4 (50%) were indistinguishable from strains isolated from patients indicating circulation of MRSA strains between patients and HCWs.

Nasal carriage of MRSA among hospitalized patients and HCWs was determined to be high. Carriage was higher in hospitalized patients than in HCWs. The spa type t001 was dominant among tested population in this study. Our study also showed exchange of MRSA between patients and HCWs.

**P1326** **Molecular epidemiology and nasal carriage of *Staphylococcus aureus* and methicillin-resistant *S. aureus* among young children attending day care centres and kindergartens in Hong Kong**

Y.Y.M. Chan\*, P.Y. Chan, S.S. Chiu, Y. Gan, F. Chow, E.L. Lai, Y.L. Lau, P.L. Ho (Hong Kong, HK)

**Objectives:** To investigate the prevalence, molecular epidemiology as well as the risk factors associated with *Staphylococcus aureus* and methicillin-resistant *S. aureus* (MRSA) nasal carriage in Hong Kong children.

**Methods:** Nasal and nasopharyngeal swabs were collected from children who were 2–5 years old attending 79 day care centers (DCCs) and 113 kindergartens (KGs) in all 18 school districts in Hong Kong during September 2009 to April 2010. A standardized questionnaire was also used to obtain information from parents of participating children so as to study the variables associated with MRSA carriage.

**Results:** 27.6% (610/2211, 95% confidence interval [CI] 24.8–28.5%) of the children were found to carry *S. aureus* and the overall nasal carriage rates of MRSA was 1.3% (28/2211, 95% confidence interval [CI] 0.8–1.8%). Univariate analyses of the risk factors showed that only younger age was significantly and negatively associated with *S. aureus* carriage. Molecular typing including staphylococcal cassette chromosome mec (SCCmec), sequence type (ST) and clonal cluster (CC) showed that all the 28 MRSA isolates were belonged to SCCmec IV (n = 13) or V (n = 15). In these 28 isolates, 12 isolates had community-associated-MRSA genotypes (ST59/SCCmec IV/V, ST30/SCCmec IV and ST88/SCCmec V), 10 isolates had healthcare-associated-MRSA genotypes (ST45/SCCmec IV/V, CC5/SCCmec IV and ST630/SCCmec V) and six isolates had novel genotypes (ST10/SCCmec V and CC1/SCCmec IV). Spa typing results also indicated an intra- and inter-school transmission of certain MRSA and methicillin-sensitive *S. aureus* strains.

**Conclusion:** Our findings indicate that DCCs and KGs can act as potential reservoirs for different types of antimicrobial-resistant *S. aureus*. This highlights the importance of enhancing education, infection control measures and hygiene in these crowded environments in order to reduce the transmission of these emerging bacteria in the community.

**Acknowledgement:** The work is supported by a research grant from the Research Fund for the Control of Infectious Diseases (RFCID) of the Health, Welfare and Food Bureau of the Hong Kong SAR Government.

**P1327** **The epidemiology of methicillin-resistant *Staphylococcus aureus* in elderly residents of 65 care homes in a single primary care trust of northern England**

C. Horner\*, A. Kearns, J. Heritage, M. Wilcox (Leeds, London, UK)

**Objectives:** To determine the prevalence and epidemiology of methicillin-resistant *Staphylococcus aureus* (MRSA) colonising elderly residents of care homes registered in the city of Leeds, between November 2006 and February 2009.

**Methods:** Participants from 65 care homes were screened for nasal colonisation with MRSA in four surveys: November 2006–December

2006; October 2007–November 2007; May 2008–June 2008, and January–February 2009. Antibiotic susceptibility, detection of the genes encoding the Panton-Valentine leucocidin (PVL), typing of the accessory gene regulator (agr) and the staphylococcal cassette chromosome mec (SCCmec) were used to characterise isolates. Pulsed-field gel electrophoresis and spa-typing were used to genotype the isolates.

**Results:** MRSA was identified from 888 nasal swabs taken from 2492 residents. MRSA prevalence was 20%, 19%, 22% and 21% in the four sequential surveys. Isolates were commonly resistant to beta-lactam agents and two other classes of antibiotic (39%), most commonly ciprofloxacin and erythromycin (n = 243). Of the isolates examined, 34% isolates were categorised as having multiple antibiotic resistance; isolates in this category were commonly resistant to beta-lactams, ciprofloxacin, erythromycin and trimethoprim. Isolates with resistance to beta-lactam agents and no resistance to the other agents tested had a low prevalence (2.9%). No isolates carried the genes encoding PVL. The majority of isolates (81%) were related to the predominant healthcare-associated MRSA strain in the UK, EMRSA-15 (ST22-IV). The remainder belonged to five MLST clonal complexes (CC), including CC1 (n = 6) and CC5 (n = 1); lineages known to include PVL-negative strains of community-associated MRSA. During the study the prevalence of isolates belonging to the EMRSA-15 lineage decreased (87–71%) with a corresponding increase in isolates belonging to CC59 strains (10–25%). High-level mupirocin resistance (4% overall) and fusidic acid resistance (13% overall) were most commonly associated with isolates belonging to CC59 (25% overall).

**Conclusions:** These data provide a baseline for future surveillance of MRSA in the care home setting. CA-MRSA strains were uncommon; however, there was an increasing subgroup of isolates that historically have not been clearly identified as either healthcare- or community-associated MRSA strains. By tackling MRSA colonisation in both primary and secondary healthcare settings there is a greater chance of permanently reducing levels of MRSA colonisation.

**P1328** **Organisation of genetic diversity and spread of *Staphylococcus aureus* into an intensive care unit**

A.-S. Brunel, A.L. Bañuls, H. Marchandin, D. Morquin\*, F. Chevenet, E. Jumas-Bilak, P. Corne (Montpellier, FR)

**Objectives:** *Staphylococcus aureus* is an important human pathogen characterized by a high genetic diversity in healthy nasal carriers. Here, we compared the genetic diversity and population structure of *S. aureus* isolated from patients, health care workers (HCWs) and environment in an Intensive Care Unit (ICU) of Montpellier University Hospital. The objective is to genetically characterize the isolates and clarify the circulation of *S. aureus*.

**Methods:** One hundred and twenty-five *S. aureus* (110 methicillin-susceptible and 15 methicillin-resistant) were isolated between February and June 2011 from 33 patients, 26 HCWs and 36 environment samples and were divided in five groups: asymptomatic nasal carriage (NCp, n = 32), bronchial colonization (BC, n = 17) and infections (I, n = 12) in patients, nasal carriage in HCWs (NCh, n = 28), and environment (E, n = 36). The genetic diversity and population structure of *S. aureus* were investigated using MultiLocus Sequence Typing (MLST) and Double Locus Sequence Typing (DLST) with clustering of strains by the electronic Based Upon Related Sequence Type algorithm. Genotypic and nucleotide diversity ( $\pi$ ) and mean genetic diversity (H) were calculated within each group based on the 7-MLST loci concatenated sequence.

**Results:** Twenty-eight Sequence Types (STs) of which nine new STs, were found among the 125 isolates, the most prevalent being ST398 (20% of the isolates) and ST12 (11%), grouped in 12 clonal complexes. Five genotypes (ST12, ST15, ST398, ST30, ST45) were shared by patients, HCWs and environment. Nineteen DLST genotypes were detected. Variable genetic characteristics were noted among the five defined groups (Table 1). Highest and lowest genotypic diversities were observed in the groups I (0.83) and E (0.22), respectively while

**Table 1.** Sequence analysis for the seven loci of the MLST scheme in the *S. aureus* population and subpopulations (5 groups)

Group	Number of Isolates	Number of STs	Genotypic diversity	Nucleotide diversity ( $\pi$ )	Mean genetic diversity ( $\mu$ )
<b>Nasal colonization (NC):</b>					
Patients (NCp)	32	15	0.46	0.00693	0.8315
Healthy Care Workers (NCh)	28	17	0.61	0.00752	0.8428
<b>Bronchial colonization (B)</b>					
Infection (I)	12	10	0.83	0.00750	0.8247
Environment (E)	36	8	0.22	0.00707	0.7082
<b>Global population</b>	<b>125</b>	<b>28</b>	<b>0.22</b>	<b>0.00731</b>	<b>0.8564</b>

ST: sequence type

colonizing isolates displayed intermediate characteristics (Table 1). ST398 and ST12 genotypes were significantly associated with group E (Fisher Test, Odds ratio = 5.54 and 8 respectively;  $p < 0.001$ ).

**Conclusion:** High genetic diversity was observed for *S. aureus* in patients and HCWs and a gradient of genetic diversity was noted from environmental to infecting strains, suggesting that: (i) infections in critically ill patients is due to a wide variety of *S. aureus* genotypes (ii) a selection of genotypes may occur in the environment due to differential survival characteristics of the strains and/or cleaning procedures. The environmental reservoir may then favor the persistent spread of some genotypes in both patients and HCWs in the ICU.

**P1329** Incidence of community-acquired methicillin-resistant *Staphylococcus aureus* and level of non-beta-lactam resistance in outpatients with skin and soft tissue infections in Buenos Aires, Argentina

E. Cordova\*, M.I. Lespada, N. Gomez, E. Cassini, W. Cornistene, M. Badia, C. Rodriguez (Buenos Aires, AR)

**Objectives:** Community acquired methicillin resistance *Staphylococcus aureus* (CA-MRSA) is a rapidly emerging public health problem. For empirical coverage of CA-MRSA in outpatients with skin and soft tissue infections (SSTIs) is recommended oral antibiotics including clindamycin, trimethoprim-sulfamethoxazole (TMP-SMX), a tetracycline (doxycycline or minocycline) and linezolid. However, susceptibility to these antibiotics is variable in different geographic regions, especially for clindamycin and macrolides. The aim of this study was to describe the incidence of CA-MRSA and level of non beta-lactam resistance in outpatients with SSTIs in Buenos Aires, Argentina.

**Methods:** Prospective and observational study of CA-MRSA SSTIs in outpatients attended at the Infectious Diseases Department, 'Cosme Argerich' Hospital (March 2010–October 2011). Susceptibility tests were performed by disk diffusion and Vitek 2 system (bioMérieux) according to the CLSI. For clindamycin susceptibility the D-Test method was also performed. A phenotypic rule was applied and CA-MRSA was defined as strains resistant to  $<3$  of the following non-beta-lactams antibiotics: gentamicin, erythromycin, tetracycline, TMP-SMX, rifampin and ciprofloxacin. Only one sample per patient was included.

**Results:** Of a total of 99 isolates of *S. aureus*, 79% (IC95 70–86) corresponded to CA-MRSA. Male sex: 63%. The median age was 31 years (IQR 27–53). HIV-infected patients: 8% (IC95 3–16). Clinical presentation included: cutaneous abscesses 44%, furuncles 35% and cellulitis 21%.

Resistance profile: gentamicin 8% (IC95 3–16), erythromycin 18% (IC95 11–28), clindamycin 18% (IC95 11–28) and TMP-SMX 1% (IC95 1–7). No resistance to minocycline, rifampin, vancomycin, linezolid and ciprofloxacin was observed. However it was observed 5% (IC95 2–13) of intermediate susceptibility strains to ciprofloxacin.

Strains with susceptibility to all non beta-lactam antibiotics: 73% (IC95 62–82). Resistance to clindamycin changed over time in the form of outbreaks raging from 0% to 50% in different periods of the study (Figure 1). No significant differences were seen in CA-MRSA resistance profile between HIV positive and negative patients.

**Conclusion:** A high prevalence of CA-MRSA in outpatients with SSTIs was observed. The level of resistance to clindamycin changed over time. For this reason it is crucial to surveillance the susceptibility profile of non beta lactam antibiotics in CA-MRSA infections.

**P1330** Association of MRSA colonisation and infection in adult patients hospitalised at chest intensive care units

C.-B. Chen\*, H.-C. Chang, Y.-C. Huang, H.-C. Lin, S.-M. Lin (Taipei City, Taoyuan, TW)

Study design A prospective, observational study.

**Objective:** To assess the association between the carriage of methicillin-resistant *Staphylococcus aureus* (MRSA) and the subsequent infections in patients hospitalized at chest intensive care units (ICUs) base on molecular methods

**Methods:** From November 2008 to May 2010, the patients admitted to our chest ICUs were included in this study and specimens from the nares were obtained within 3 days after admission and next week for the detection of MRSA. Genetic relatedness for all colonized and clinical isolates from each study patient with MRSA infection were analyzed and compared. Statistical analyses were performed with the Statistical Package for the Social Sciences (SPSS software for Windows, version 16.0). Appropriate chi-square tests and Yates' correction were used for analysis. Odds ratio (OR) and 95% confidence interval (CIs) were also calculated.

**Results:** A total of 1461 patients were recruited in this study, MRSA colonization was detected in 338 patients (23%) during their chest ICU stay, and MRSA infection was noted in 432 (30%) patients during their hospitalization. Methicillin-resistant *S. aureus* colonization was significantly associated with endotracheal tube insertion, central venous catheter in site, hospitalization within 1 year, current pneumonia and previous MRSA infection, and patients with colonization had a significantly higher rate of MRSA infection, compared with those without colonization (63% vs. 20%; OR: 6.91; 95% CI: 5.25–9.09;  $P < 0.001$ ). Methicillin-resistant *S. aureus* colonization was noted for 212 (49%) of 432 patients with MRSA infections. A total of 65 clinical isolates and 43 colonized isolates from 36 patients with MRSA infection were available for genotyping analysis. Excluding four patients with multiple colonized and/or clinical isolates, colonized and clinical isolates from the same patient were indistinguishable in 24 patients (75%), highly related in six patients (18.8%), and distinct in two patients (6.2%).

**Conclusions:** Around one-fourth of the hospitalized patients were colonized with methicillin-resistant *S. aureus* during their stay in our chest ICUs; this was significantly associated with MRSA infection. Half of the patients with methicillin-resistant *S. aureus* infections had MRSA colonization and mostly an indistinguishable strain.

**P1331** Genotypic and phenotypic characterisation of methicillin-resistant *Staphylococcus aureus* strains recovered from a phase IV clinical trial for linezolid vs. vancomycin for the treatment of nosocomial pneumonia

R. Mendes\*, L. Deshpande, D. Smyth, B. Shopsin, D. Farrell, R. Jones (North Liberty, New York, US)

**Objective:** To characterize methicillin-resistant *S. aureus* (MRSA) strains responsible for nosocomial pneumonia (NP) collected during an international phase IV trial comparing linezolid (LZ) to vancomycin (VA).

**Methods:** Four hundred and thirty-five MRSA baseline isolates were collected from subjects in Latin America (LA; six countries, 45 [10.3%] strains; Table 1), Europe (EU; 10 countries, 55 [12.6%] strains), including Turkey and Russia, Asia (five countries, 67 [15.4%] strains), South Africa (three strains) and the USA (265 [60.9%] strains). Only one isolate per subject was included. PVL genes and SCCmec types were determined by PCR. All strains were subjected to PFGE and spa typing. Selected strains were evaluated by MLST. Clonal complexes (CCs) were assigned based on the spa and/or MLST results. Susceptibility (S) testing and interpretations were performed by CLSI and EUCAST methods. Inducible clindamycin (CL) resistance was assessed by D-test and isolates screened for heterogeneous resistance to VA (hVISA; Etest macromethod).

**Results:** Overall, most strains were CC5 (56.1%), which originated from the USA (CC5-MRSA-SCCmec II/IV; 70.1% [171/244]), Asia (CC5-MRSA-II; 13.9% [34/244]) and LA (CC5-MRSA-I/II; 12.3% [30/244]). The second and third most prevalent clones were CC8-MRSA-II/IV (23.4%) and CC239-MRSA-III (11.3%), respectively. Furthermore, CC5-MRSA-I/II clones predominated in Asia (50.7% within this region) and LA (66.7%), followed by CC239-MRSA-III (32.8% and 28.9%, respectively). EU strains were CC8-MRSA-IV (36.4%) or CC22-MRSA-IV (18.2%) or CC5-MRSA-IV (16.4%), while USA MRSA were CC5-MRSA-II/IV (64.5%) or CC8-MRSA-IV (28.7%). Among USA CC8-MRSA-II/IV, 73.7% (56/76) of strains (21.1% of all USA MRSA) clustered within USA300. Overall, strains were PVL-negative, except for one ST80 strain from Greece, one ST96 from Russia, one ST59 from Taiwan, one ST8 from Puerto Rico and USA300 strains from the USA. All strains were S to LZ and daptomycin, while VA and teicoplanin were active against 96.1–99.8% of strains (EUCAST). S to gatifloxacin, CL and tetracycline varied among CCs and regions. hVISA strains (14.5%) were mostly CC5-MRSA-II (63.5%; 40/63) from Asia.

Clonal complex	Number (%) of strains per region				Total
	USA	Europe	Latin America	Asia	
CC5	171 (64.5)	9 (16.4)	30 (66.7)	34 (50.7)	244 (56.1)
CC8	76 (28.7)	20 (36.4)	1 (2.2)	5 (7.5)	102 (23.4)
CC239	4 (1.5)	7 (12.7)	13 (28.9)	22 (32.8)	49 (11.3)
CC45	7 (2.6)	6 (10.9)	0 (0.0)	1 (1.5)	14 (3.2)
CC22	0 (0.0)	10 (18.2)	0 (0.0)	0 (0.0)	10 (2.3)
Total	265 (60.9)	55 (12.6)	45 (10.3)	67 (15.4)	435

**Conclusions:** Each region had two predominant clones responsible for NP. The rate of USA300 (21.1%) appears high, corroborating previous reports describing increased rates of invasive infections caused by this clone in the USA. The prevalence of hVISA was elevated in Asia and these strains appear to be associated with the CC5 lineage.

**P1332** An overview on staphylococcal linezolid resistance in Italy

D. Bongiorno\*, F. Campanile, G. Mongelli, M. Falcone, F. Menichetti, A. Novelli, M. Pastucci, P. Pecile, M. Sarti, A. Sartor, C. Scarparo, C. Tascini, M. Venditti, F. Zoppi, S. Stefani (Catania, Rome, Pisa, Florence, Perugia, Modena, Udine, IT)

**Objective:** The most common mechanisms of linezolid resistance involve mutations in the central loop of domain V of the 23S rRNA, or

carrying of the cfr gene implicated in the methylation of A2503 in the 23S rRNA of the large ribosomal subunit, which methylation affects the binding of at least three antimicrobial classes (phenicols, lincosamides, and streptogramin A), leading to a multi-drug resistant phenotype.

The aim of our study was to investigate the rapid spread, in Italy, of staphylococci strains sharing high level resistance to linezolid, compared with the molecular mechanisms responsible of this resistance.

**Methods:** The activity of linezolid and other comparator agents was evaluated against 63 clinical *Staphylococcus* spp. isolates (53 *S. epidermidis*, five *S. simulans*, five *S. hominis* and one *S. aureus*) recovered during 2007–2011, from nine Italian hospitals, by broth dilution (MICs) and E-test methods. Mutations in the domain V of the 23S rRNA or cfr-mediated linezolid resistance were confirmed by PCR, PCR digestion with the enzyme NheI and sequencing assays. Molecular analysis was performed by PFGE, SCCmec typing (mec-complex and ccr-complex) and MLST.

**Results:** All the 63 clinical staphylococci strains, were methicillin-resistant, MDR, and showed linezolid MIC values ranging from 16 mg/L to 256 mg/L, related to G2576T mutation of 23S rRNA and presence of cfr gene. Mutational linezolid resistance was detected in 16 *S. epidermidis* strains belonging to two different PFGE types and prevalently associated to the same ST2; while, 37 *S. epidermidis* strains carried cfr gene and belonged to three different PFGE-types, widely correlated to ST 23. All *S. simulans* strains, belonging to similar PFGE subtypes (S1–S2), and all *S. hominis* strains, belonging to a unique PFGE type (H1), carried the G2576T mutation of 23S rRNA. The only strain of *S. aureus*, ST5-HAMRSA-II, carried a partial mutation of the G2576T of 23S rRNA.

**Conclusion:** This study displays a comprehensive overview of linezolid resistance among *Staphylococcus* spp. in Italy. This scenario shows the increase and rapid spread of specific clones, particularly among *S. epidermidis* strains, due to the different molecular mechanisms.

**P1333** Decreasing rates of methicillin-resistant *Staphylococcus aureus* and correlation to antimicrobial consumption pattern in a tertiary level hospital

E. Iosifidis\*, D. Papanikolaou, P. Kadiltzoglou, A. Katragkou, E. Siaka, E. Roilides (Thessaloniki, GR)

**Objectives:** To study prevalence of methicillin-resistant *Staphylococcus aureus* (MRSA) and effect of antimicrobial (ABC) consumption pattern in a general tertiary care hospital with high level of resistance mainly among gram-negative bacteria.

**Methods:** This was a longitudinal study of MRSA prevalence and ABC consumption rates in 15 adult hospital departments (seven internal medicine and subspecialties [MD], seven surgical and subspecialties including solid organ transplant unit [SD] and mixed ICU) from 2001 to 2010. Antibiotic consumption calculator version 3.1 (WHO) was used and annual ABC consumptions were expressed as DDDs/100 bed-days (DDDHBD). Mean annual antibiotic consumption rates were correlated (using appropriate correlation coefficient) to MRSA rates of the next year.

**Results:** MRSA rates in all departments declined from 61% to 37%,  $p < 0.001$ . Among different departments, MRSA significantly decreased in ICU (from 89% to 25%,  $p = 0.001$ ), in SD (from 67% to 41%,  $p = 0.016$ ) and after 2005 in MD (from 43% to 34%,  $p = 0.004$ ). During study period mean ABC consumption of departments increased from 112 to 136 DDDHBD ( $p = 0.004$ ). More specific, ABC consumption increased to 92% in ICU and 7% in both SD and MD. Longitudinal analysis of ABC consumption showed significant increase of penicillins (34–42 DDDHBD), carbapenems (3–10 DDDHBD), fluoroquinolones (9–16 DDDHBD) and colistin (0.2–14 DDDHBD), whereas significant decrease was found in aminoglycoside (11–9 DDDHBD) and cephalosporin (36 to 24 DDDHBD) consumption. Especially in ICU, cephalosporin consumption declined from 65 to 8 DDDHBD ( $p < 0.001$ ). No significant variations were found in consumption of glycopeptides and macrolides. Decline of MRSA rates positively correlated only to consumption of

cephalosporins ( $r = 0.76$ ,  $p = 0.017$ ) and especially of 3rd generation cephalosporins ( $r = 0.8$ ,  $p = 0.006$ ). This correlation remained significant when MRSA rates and consumption of cephalosporins (mainly 3rd generation) was studied separately in MD, SD and ICU ( $r > 0.8$ ,  $p < 0.04$ ). Negative correlations were found between MRSA rates and consumption of combination of penicillins with beta lactamase inhibitors ( $r = -0.7$ ,  $p = 0.037$ ), carbapenems ( $r = -0.8$ ,  $p = 0.007$ ), fluoroquinolones ( $r = -0.7$ ,  $p = 0.03$ ), and colistin ( $r = -0.7$ ,  $p = 0.034$ ). No correlations were found between MRSA rates and consumption of glycopeptides, macrolides or aminoglycosides.

**Conclusion:** During study period a decline of MRSA rates significantly correlated to decreasing cephalosporin consumption mainly of 3rd generation.

**P1334** Vancomycin MIC and clone type are independent predictors of persistent MRSA bacteraemia at a USA hospital

J.A. Otter\*, N.L. Havill, M.D. Virata (London, UK; New Haven, US)

**Objectives:** To investigate associations with persistent MRSA bacteraemias.

**Methods:** Five hundred and eighty-one patients with MRSA bacteraemia were reported at our US hospital from 1999 to 2008 and 61 isolates were selected for molecular analysis based on two factors: (i) isolates with an initial vancomycin minimum inhibitory concentration (MIC)  $\geq 2$  mg/L and/or (ii) persistent bacteraemia. A smaller cohort consisting of 59 isolates not meeting the two criteria was randomly selected from the remaining isolates. MRSA was characterised by spa type, staphylococcal cassette chromosome mec (SCCmec) allotype and MIC to vancomycin (VA), and daptomycin (DP) performed by e-test. SCCmec IV isolates were tested for carriage of the Panton-Valentine leukocidin (PVL). To explore possible associations with MICs, cut-offs of  $\geq 1.5$  and  $\geq 1$  mg/L were chosen for VA and DP respectively. Clones were defined by using Based Upon Repeat Pattern (BURP) clustering with a calculated cost between lineages of four and PVL data. Persistence was defined as bacteraemia lasting 5 days or more. Univariate analysis of contingency tables was performed using Chi-squared tests to identify variables associated with persistent bacteraemia. Multivariate binary logistic regression was used to identify independent predictors of persistent bacteraemia.

**Results:** Persistent bacteraemia occurred in 31 (25.8%) of the 120 cases (Table 1). The univariate analysis indicated that persistent bacteraemia was associated with increasing age, clone type, HIV status, and VA MIC  $\geq 1.5$  mg/L. VA MIC (adjusted odds ratio (AOR) 83.8, 95% confidence interval (CI) 9.9–710.1,  $p \leq 0.001$ ) and one clone, USA500, CC8-IV, PVL-negative (AOR 6.4, 95% CI 1.1–36.1,  $p = 0.036$ ) remained independently associated with persistent bacteraemia in the multivariate analysis. DP MIC  $\geq 1$  mg/L was not associated with persistent bacteraemia.

Table. Associations with persistent bacteraemia at a US hospital.

	No persistent bacteraemia (n=89)	Persistent bacteraemia (n=31)	Univariate P	Multivariate P	Odds ratio (95% confidence interval)
Age / years (mean +/- standard deviation)	67.3 +/- 16.7	75.5 +/- 12.1	0.02	0.445	-
Clone	n (%)	n (%)	0.01	Ref	-
CCS-II	71 (79.8)	18 (58.1)			
CC8-IV (PVL-)	9 (10.1)	10 (32.3)	-	0.036	6.4 (1.1-36.1)
Other	9 (10.1)	3 (9.7)	-	0.769	-
PVL carriage	4 (4.3)	0 (0.0)	0.07	-	-
Pigment $\geq 0.3$	49 (55.1)	17 (54.8)	0.94	-	-
Vancomycin MIC $\geq 1.5$ mg/L	30 (33.7)	30 (96.8)	<0.001	<0.001	83.8 (9.9-710.1)
Daptomycin MIC $\geq 1$ mg/L	19 (21.3)	2 (6.4)	0.06	-	-
HIV positive	16 (18.0)	0 (0.0)	0.01	0.998	-
Patient died	52 (58.4)	14 (45.2)	0.20	-	-

**Conclusion:** In our analysis, patients from a single institution with persistent MRSA bacteraemia were more likely to have a VA MIC  $\geq 1.5$  mg/L and infected with a particular clone. Other studies

have indicated that VA MIC, agr function and other factors are associated with persistent bacteraemia. Increasing age was associated with persistent bacteraemia in univariate but not multivariate analysis, which could be a function of sample size. Additional studies are required to confirm these findings and explore other possible predictors of persistent bacteraemia.

**P1335** Impact of low-level glycopeptide resistance on treatment failure in orthopaedic device-related methicillin-resistant *Staphylococcus aureus* infection

P. Vaudaux\*, T. Ferry, I. Uçkay, P. François, J. Schrenzel, A. Renzoni, S. Harbarth, D.P. Lew (Geneva, CH; Lyon, FR)

**Objectives:** Reduced susceptibility to glycopeptides in clinical methicillin-resistant *Staphylococcus aureus* (MRSA) isolates is considered a risk factor for failure of glycopeptide therapy. We analysed the clinical impact of reduced glycopeptide susceptibility, in particular low-level teicoplanin resistance, on treatment failure of patients with orthopaedic device-related MRSA infections (ODRI).

**Methods:** Clinical and epidemiological characteristics of a retrospective cohort of patients with MRSA ODRI who were treated at the University Hospital of Geneva between 2000 and 2008 were previously reported (Ferry et al., 2010). Fifty-seven individual or multiple isolates were retrieved from 41 ODRI patients for glycopeptide susceptibility and clonality studies, including 20 patients with prosthetic joint (PJ) and 21 with osteosynthesis (OS) MRSA infections. Microbiological criteria for treatment failure were persistent ( $>5$  days) or recurrent (post-therapy) MRSA-positive infectious episodes as described (Ferry et al.). GISA isolates were detected by testing individual or consecutive, clonally-related MRSA isolates from each patient, for elevated teicoplanin or/and vancomycin MICs ( $\geq 4$  mg/L), using a previously described, modified macrodilution assay (Vaudaux et al., 2010).

**Results:** MRSA isolates showing elevated teicoplanin MICs before, during, or/and after glycopeptide therapy, were detected in 20 (49%) of the 41 MRSA-infected patients, namely 10/20 (50%) PJ-infected and 10/21 (48%) OS-infected patients. Only one isolate also showed elevated vancomycin MIC. All GISA isolates belonged to the widely prevalent MRSA clonotype ST228 found in 35/41 (85%) patients. 18/41 (43%) ODRI patients, namely nine PJ and nine OS-infected patients, experienced treatment failure. 13/20 (65%) patients with GISA-associated ODRI, namely 7/10 (70%) with PJ and 6/10 (60%) with OS, experienced treatment failure. In contrast, therapy failed in only 5/21 (24%) non-GISA-infected ODRI patients, including 2/10 (20%) with PJ and 3/11 (27%) with OS, indicating a significantly ( $p < 0.02$ ) lower failure rate in patients with non-GISA vs. GISA-associated ODRI. Emergence of low-level teicoplanin resistance could not be explained by teicoplanin administration, since 40/41 ODRI patients received vancomycin but only 5/41 teicoplanin, for therapy of the initial episode.

**Conclusion:** Low-level teicoplanin resistance in MRSA is a significant risk factor and may be a predictive marker for therapy failure, and seems to be promoted by vancomycin therapy of ODRI patients.

**P1336** A 4-year study of coagulase-negative *Staphylococcus* resistance profile in a Greek tertiary hospital

A. Stylianakis\*, S. Tsiplakou, V. Papaioannou, K. Tsopelas, E. Chatziandreou, D. Argyris, I. Papadakis, K. Mouta (Athens, GR)

**Objectives:** Coagulase negative staphylococci (CoNS) are recognized as one of the major causes of nosocomial infections. In this study we aimed to study the resistance profile of CoNS isolations considered as pathogen during a 4 year period.

**Methods:** From July 2007 till June 2011 we examined  $n = 977$  non duplicated CoNS isolations recovered from blood cultures of patients hospitalized in all wards of a Greek tertiary hospital. The distribution location of the collected isolates was: ICUs  $n1 = 365$  isolates, medical

ward n2 = 187 and surgical ward n3 = 233 isolates. Species identification and susceptibility testing were performed using the automated VITEK II system (Biomérieux). Additionally we used the E-test method (Biomérieux, ABI-Biodisk) in order to estimate the MIC levels of daptomycin, vancomycin, teicoplanin and linezolid when it was judged as necessary, especially to confirm some isolation resistances found by the VITEK II system. The interpretation of results was done according to the CLSI guidelines.

**Results:** Twenty three different *Staphylococcus* species were identified among the 977 CoNS isolates collected. *S. epidermidis*, *S. haemolyticus*, *S. hominis*, *S. cohnii* and *S. lugdunensis*, together, accounted for 74% of the isolates. Methicillin resistance was observed in all of the 23 species identified, with an overall prevalence of ca. 81.3%. The percentage of resistance profile of the examined CoNS isolates is shown in the following table.

All linezolid and teicoplanin resistant isolates were resistant to methicillin, too.

Period	7/2007- 6/2008 (%) (n=240 isolates)	7/2008- 6/2009 (%) (n=236 isolates)	7/2009- 6/2010 (%) (n=284 isolates)	7/2010- 6/2011 (%) (n=217 isolates)
antibiotics				
penicillin	93,2	92,8	92,1	95,4
gentamicin	41	40,2	39,1	46,8
co- trimoxazole	37	46,8	34,3	34,7
clindamycin	61,5	65	63,7	68,4
erythromycin	73,2	79,1	69,4	70,8
oxacillin	79	82,1	76,3	87,9
linezolid	0,9	1,4	3,9	12
vancomycin	-	-	-	-
teicoplanin	1,3	1,8	3,3	4,7
quinupristin/ dalfopristin	0,9	0,9	0,7	-
daptomycin	-	-	-	-

**Conclusion:** CoNS isolates present a remarkable increase of resistance to linezolid and teicoplanin in contrast to daptomycin and vancomycin which could be a very good alternative solution for treating infections caused by CoNS. These data enforced the necessity to take the appropriate measures in the hospital environment and during the clinical practice to avoid the dissemination and the amplification of these resistances.

## Genetics of antimicrobial resistance

### P1337 Role of ISKpn7 and deletions in blaKPC gene expression

T. Naas\*, G. Cuzon, H. Truong, P. Nordman (Le Kremlin Bicêtre, FR)

**Objectives:** The carbapenemase-encoding blaKPC gene, that is rapidly spreading worldwide, is located on a Tn3-based transposon, Tn4401. Five isoforms of Tn4401 (a, b, c, d, e), based on small deletions located immediately upstream of blaKPC gene have been described. Here, we have investigated the functional role of the different upstream located sequences on blaKPC-gene expression in respect to the major deletions observed.

**Methods:** The entire blaKPC gene with its flanking region was amplified by PCR from three clinical isolates of *K. pneumoniae* harboring Tn4401a, Tn4401b and Tn4401c, and cloned into PCR-ScriptTMCam vector resulting in pKPCprom (1, 2, 3), pKPCprom (1, 2) and pKPCprom (2) respectively. Reverse transcription and rapid amplification of cDNA ends were performed with the 5' RACE system aimed to determine the blaKPC-2 transcription initiation sites. Expression level of blaKPC gene was measured by qRT-PCR,

spectrophotometric analysis and imipenem MIC was determined by E-Test for each construct.

**Results:** We have identified three potential promoter sequences (P1, P2, and P3) upstream of blaKPC gene. Only P1 and P2 were shown to be true promoters involved in expression. P1 promoter, which is the promoter initially characterized for blaKPC gene, is absent from isoform c and d. P2 promoter was present in all isoforms, and is a composite promoter made of a -35 region located in the IR of ISKpn7, and a -10 box located in the flanking sequence. Two alternative structures surrounding blaKPC gene have been described in the literature, where both P1 and P2 promoters are absent, but where the immediately located mobile element are likely to be responsible of blaKPC gene expression. Using RT-PCR, the highest level of expression was obtained with isoform a, followed by b and c. These differences in expression led to slight differences for MIC of carbapenems. In silico analysis of DNA sequence of isoform b revealed a stem-loop structures likely responsible of strong stops, decreased expression as compared to isoform a and that could also be at the origin for the deletions observed in isoforms a and c.

**Conclusion:** Our results indicate that P1 and P2 promoters contribute to blaKPC gene expression, and that the construct with the highest expression is the isoform a, which is also the commonly encountered form in clinical isolates.

### P1338 Complete characterisation of In70-harboring plasmid pAX22 from Achromobacter xylosoxydans

V. Di Pilato\*, S. Pollini, G. Mastrogiovanni, G.M. Rossolini (Siena, IT)

**Objectives:** VIM-type enzymes are among the most widespread metallo-B-lactamases, and their diffusion is mediated by mobile gene cassettes inserted into integrons that, in *Pseudomonas aeruginosa*, are generally chromosomally-located. Integron In70 is the most common genetic support of the VIM-1 determinant in Italy in *P. aeruginosa* and was firstly characterized in pAX22, a non-conjugative plasmid from a clinical isolate of *Achromobacter xylosoxydans*. pAX22 is the only In70-harboring plasmid known so far, and was supposed to be a donor in the acquisition and evolution of chromosomally encoded In70 by *P. aeruginosa* epidemic clones. The aim of this study was to obtain the complete nucleotide sequence of pAX22 plasmid in order to characterize the In70 genetic context.

**Methods:** The complete sequence of pAX22 was obtained by pyrosequencing using Roche 454 GS Junior, according to the manufacturer's instructions. Bioinformatic analyses were performed by Roche Newbler software; the draft sequence was finished through a bridge-PCR reaction within the terminal ends of the sequenced fragment and annotated via BASys tool.

**Results:** The complete sequence was 28 466 bp long and revealed the presence of 32 ORFs besides those composing the In70 structure; the plasmid includes genes needed for replication and maintenance functions as well as for transposition and mobilization. In70 is part of a novel transposon characterized by a Tn402-like tni module and a transposase-resolvase module upstream In70. Comparative analyses showed a high similarity with TNCP23 transposon, a mobile element that carries a different integron and is only found as a chromosomal element in *P. aeruginosa* strains; a common evolutionary origin could be hypothesized for these elements that, apart from sharing the same common ancestor, could have subsequently undergone different recombination events.

**Conclusion:** To date, pAX22 represents the unique case of a sequenced In70-harboring plasmid and one of the first characterizations of the genetic platform of VIM-1-harboring integron. The complete characterization of pAX22 structure represents an important finding and could help to get new insights on his potential role as donor source of In70-carrying elements in VIM-1 positive *P. aeruginosa*. Moreover, this study put a good base for a more comprehensive analysis of In70 genetic context in important pathogens, in order to get a better knowledge about transmission dynamics of this successful mobile genetic element.

**P1339** ICESp009, a mega-carrying conjugative genetic element in *Streptococcus pyogenes*

M. Del Grosso\*, R. Camilli, E. Rizzi, A. Pietrelli, G. Barbabella, G. De Bellis, A. Pantosti (Rome, Milan, IT)

**Objective:** In *Streptococcus pyogenes* efflux-mediated resistance to macrolides is mainly associated with the *mef(A)* gene that is carried by well characterized genetic elements. The *mef(E)* gene, carried by mega, has been infrequently found in *S. pyogenes*. Aim of this study was to characterize mega and its genetic context in *S. pyogenes*.

**Methods:** Fifteen *S. pyogenes* isolates showing M phenotype and carrying *mef(E)* were examined. In one isolate, MB56Spyo009, transferability of *mef(E)* was evaluated by conjugation experiments. Genomic DNA was analyzed by PFGE and hybridization assay. Nucleotide sequence of the genetic element carrying *mef(E)* was obtained by 454 technology and by direct sequencing of PCR products. Comparative analysis was performed using BLAST algorithm.

**Results:** All *S. pyogenes* isolates carried *mef(E)* in the mega element. In MB56Spyo009, macrolide resistance was transferable by conjugation both to *S. pyogenes* and to *S. pneumoniae* recipient strains. Analysis of PFGE profiles of transconjugants and hybridization assay with a *mef(E)* probe confirmed the transfer of a fragment of approximately 50 kb. Sequencing of the transferred fragment showed the presence of a 55 kb-genetic element. This element, named ICESp009, was found integrated downstream an ORF corresponding to chromosomal 50S ribosomal protein L7/L12. A free circular form was also detected. By PCR mapping, ICESp009 was also found in the transconjugants obtained and in other *S. pyogenes* isolates. In ICESp009, besides *mef(E)* and *msr(D)* encoding the two components of the macrolide efflux system, sequence analysis showed the presence of ORFs encoding a putative aminoglycoside phosphotransferase, ABC transporters, and proteins homologous to those of functional modules of ICE structures. Comparative analysis showed similarity of ICESp009 to a sequence of *Streptococcus sanguinis* and to regions of putative genetic elements of different streptococcal species, suggesting the presence of similar modules among the ICEs of streptococci.

**Conclusion:** ICESp009 is the first genetic element able to transfer *mef(E)* in *S. pyogenes* and *S. pneumoniae* by conjugation. The presence of functional modules shared among ICESp009 and genetic elements of different streptococci suggested that this element could contribute to the dissemination of antibiotic resistance among different species.

**P1340** Dynamics of digestive carriage of antibiotic-resistant integrons in new-borns during the first weeks of life

M. Peyre, O. Barraud, A. Bedu, F. Garnier, D. Chainier, A. Le Pichoux, C. Bahans, V. Guignonis, M.C. Ploy\* (Limoges, FR)

**Objectives:** At birth, the gut of neonates is sterile but begins to be colonized on the first days of life. Resistant integrons (RI) are bacterial genetic elements able to capture and express antibiotic resistance genes. RI are largely involved in the dissemination of antibiotic resistance in Gram-negative bacteria (GNB). Three main classes of RI were described to be involved in antibiotic resistance. The aim of our study was to evaluate both by culture and by a molecular technique (cultivation-independent) the dynamics of the RI digestive carriage in term and premature new-borns.

**Methods:** One hundred and eighty-seven term and 49 premature new-borns were enrolled between October and November 2010 at the University Hospital Centre of Limoges, France. For term new-borns, meconium and the last stool before leaving the hospital (Day 2 or 3) were sampled; for premature new-borns, meconium and a stool once a week were sampled until they left the hospital. Samples were inoculated onto Drigalski agar plates; total DNA was extracted from samples using the QIAamp® DNA Stool Mini kit (Qiagen®). The three main classes of RI were detected by qPCR both from GNB and directly from samples.

**Results:** We sampled 517 specimens from term babies and 199 from premature new-borns. We isolated GNB (with a majority of *Escherichia*

*coli*) in 39% of term babies' samples and in 46% of premature new-borns' samples. We detected RI from GNB in 5.8% and 18.4% of the patients (term and premature new-borns respectively) and in 10.7% and 22.4% when we used the molecular method. We found class 1 and class 2 RI but no class 3. The proportion of RI in term new-borns was 1% from meconium samples and 9.7% from stools; in premature new-borns, the proportion was 6.1% from meconium samples and 14.8% from stools.

**Conclusion:** RI acquisition occurs rapidly during the first days of life. Few babies were colonized with RI very early, as 1–6% of meconium samples were RI-positive. Further studies are needed to investigate if the RI were acquired from the mother or from the hospital environment.

**P1341** IncFIIK plasmids conferring resistance to cephalosporins and fluoroquinolones among Enterobacteriaceae from patients hospitalised in a children's oncological clinic

M. Dolejska\*, E. Brhelova, H. Dobiasova, J. Jurankova, A. Sevcikova, M. Vavrina, L. Dubska, I. Literak, A. Cizek, J. Sterba (Brno, CZ)

**Objective:** The aim of this study was to investigate the molecular epidemiology of extended-spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae in a children oncological clinic in the Czech Republic.

**Methods:** From June 2009 to January 2010 a total of 51 ESBL-producing isolates were obtained from rectal swab samples of thirty patients. Further characterization with regard to ESBL enzymes, plasmid-mediated quinolone-resistance genes (PMQR), multilocus sequence types (MLST) and plasmids was performed.

**Results:** ESBL-producing strains were identified as *Klebsiella pneumoniae* (36), *Escherichia coli* (7), *K. oxytoca* (3), *Enterobacter cloacae* (3) and *Citrobacter freundii* (2). *K. pneumoniae* isolates belonged to seven MLST: 280, 321, 323, 419 and novel types 626, 627, 628. The multiresistant highly virulent epidemic *E. coli* O25b-ST131 clone was detected in one patient. The gene blaCTX-M-15 was found on large conjugative FIIK plasmids, considered as virulence plasmids specific for *Klebsiella* spp., along with blaTEM-1b, blaOXA-1, qnrB1, aac(6')-Ib-cr, strA, sul2, aac(3)-II and tetA in most isolates including the O25b-ST131 clone. Sequences of copA gene of all FIIK plasmids were identical and showed the allele type 6.

**Conclusion:** Spreading of particular clones among patients and dissemination of FIIK plasmids among bacterial species were considered to be likely involved in the ESBL bacteria infections in the clinic. This is the first study documenting these multiple antibiotic resistance elements on FIIK plasmids in different bacterial species, highlighting the evolution of IncF plasmids into new variants containing novel antibiotic resistance elements and their important role in spreading ESBL-producing bacteria among diseased children. The study was funded by Czech Science Foundation (P502/10/P083); CEITEC – “Central European Institute of Technology” (CZ.1.05/1.1.00/02.0068); Ministry of Education, Youth and Sports of the Czech Republic (MSM6215712402) and RECAMO (CZ.1.05/2.1.00/03.010).

**P1342** Comparative phylogenetics of ICEHin1056 family reveals deep evolutionary relationships of mobile genetic elements

E.R. Robinson\*, X. Didelot, D. Hood, D.W.M. Crook (Oxford, UK)

**Objectives:** Integrating and conjugating elements (ICEs) are self-transmissible mobile genetic elements. ICEs are composed of modules of conserved genes, with accessory genes at hotspots. Antibiotic resistance genes are often encoded on ICEs, leading to rapid intra and inter-specific spread of resistance. Our aim was to study ICEs with homology to ICEHin1056 in *Haemophilus influenzae* using the large number of whole genome sequences now available.

**Methods:** Members of the ICEHin1056 family were identified using tBLASTx searches on the NCBI genome database. The query sequences were concatenated core genes from ICEHin1056. Alignments were performed with the Artemis Comparison Tool

(ACT). Sequences were stored in a BIGS (Bacterial Isolate Genome Sequence) database and homologues of core genes identified. Alignments were performed in ClustalW and phylogenetic trees drawn in MEGA. Ancestral sequences were predicted using GASP (Gapped Ancestral Sequence Prediction). Predicted ancestral sequences were used as BLAST inputs to find further possible members of the ICE family and more distant relatives.

**Results:** We identified over a hundred whole or partial sequences in the ICEHin1056 family in a-, b- and g- proteobacteria. This is the largest comparative phylogenetic study of ICEs performed to date and demonstrates extensive lateral gene transfer across the whole phylum. The three core ICE modules encode: replication, type IV secretion and excision/integration. The conservation of synteny implies a powerful selective advantage of the ICE. GC content of the core modules mirrors that of the host chromosome, suggesting co-existence deep in evolutionary history.

Absence of core genes or modules represent “lifestyle” adaptations of the mobile genetic element. Absence of an integrase and presence of a replicative DNA helicase are markers of a “plasmid lifestyle”.

A variety of accessory genes are found at hotspots; they confer survival advantage in the ecological niche of the organism, which ranges from eukaryotic pathogens to extreme environments.

**Conclusion:** This large comparative phylogenetic study of ICEs allows inference about evolutionary relationships within the ICEHin1056 family. This evolutionary history is so ancient that it may link all mobile genetic elements transferred by conjugation in proteobacteria. This provides important insights into the mobile gene pool and may have implications for prediction of spread of antibiotic resistance and pathogenicity.

#### **P1343** Complete sequencing of a novel IncH plasmid carrying the blaNDM-1, blaCTX-M-15 and qnrB1 genes

L. Villa, L. Poirel, P. Nordmann, C. Carta, A. Carattoli\* (Rome, IT; Le Kremlin-Bicêtre, FR)

**Objective:** The current emergence of the blaNDM-1 gene is not related to the spread of an epidemic plasmid but rather to multiple events of acquisitions on different plasmid types. In several strains isolated from seepage water and public tap water collected from New Delhi, India, the blaNDM-1 was identified on large (>250 kb) and non-typeable plasmids (Walsh et al. 2011). The complete sequence of pNDM-MAR, a non-typeable plasmid of 250 kb identified from a *K. pneumoniae* from Morocco and carrying the genes encoding NDM-1, CTX-M-15 and qnrB1, was determined and analyzed.

**Methods:** Plasmid sequencing was performed by the 454-Genome Sequencer FLX procedure on libraries obtained on total plasmid DNA purified from an *E. coli* J53 transconjugant. Contigs with at least 15-fold coverage obtained by GS-FLX gAssembler software were assembled in continue plasmid sequences by the PCR-based gap closure method.

**Results:** Plasmid pNDM-MAR was 267 242 bp in-size and encoded 177 predicted CDS. BLASTN comparison indicated a completely novel plasmid scaffold, showing only small portions of homology with GenBank data. pNDM-MAR possessed novel replicons and transfer loci, defining a new group within the IncH plasmid family.

Plasmid pNDM-MAR carried the blaNDM-1 gene into a genetic environment that was different from those previously described for other plasmids encoding NDM-1. In addition, it encoded the ESBL CTX-M-15 and the plasmid-mediated quinolone resistance gene qnrB1. That latter was flanked by an IS26 element and the Tn3 transposase which immediately preceded the groEL-groES genes, flanking the blaNDM-1 gene. The blaCTX-M-15 gene was associated to insertion sequence ISEcp1. Plasmid pNDM-MAR carried additional resistance determinants to tellurite, mercury, quinolones, chloramphenicol, and aminoglycosides.

**Conclusion:** pNDM-MAR is the first identified plasmid carrying the blaNDM-1 gene together with an ESBL encoding gene which is the most widespread worldwide (blaCTX-M-15). It did not harbor any 16S

rRNA methylase encoding genes, whereas all the other NDM-1 encoding plasmids did. It is the largest NDM-1-encoding plasmid described so far and interestingly harbors two completely new replicons. The presence of the HIB replicon, and conservation of conjugative pilus proteins, strongly suggest that pNDM-MAR is a novel plasmid type that however derives from the IncHI plasmid family. Our study provides further insights regarding the current successful dissemination of blaNDM-1 gene.

#### **P1344** Complete sequence of an IncT-type plasmid carrying the blaOXA-181 carbapenemase gene from *Citrobacter freundii*

A. Carattoli\*, P. Nordmann, L. Villa, C. Carta, L. Poirel (Rome, IT; Le Kremlin-Bicêtre, FR)

**Objectives:** Multiple plasmids were identified in an extensively drug resistant *Citrobacter freundii* isolate in France from a patient transferred from India. That isolate co-expressed the metallo-beta-lactamases NDM-1 and VIM-1, but was additionally positive for the blaOXA-181 gene, that latter encoding a class D carbapenem-hydrolysing beta-lactamase. OXA-181 that differs from OXA-48 by four amino acid substitutions hydrolyses penicillins, carbapenems at low level, but spares broad-spectrum cephalosporins.

**Methods:** Transconjugants expressing OXA-181 were obtained at very low frequency by mating-out assays from the *C. freundii* strain to *Escherichia coli* recipient. One transconjugant contained three plasmids, two non-typeable and one assigned by PCR-based replicon typing to the IncT group. Complete sequencing of the blaOXA-181-bearing plasmid was performed using the 454-Genome Sequencer FLX procedure on libraries obtained on total plasmid DNA purified. Contigs with at least 15-fold coverage obtained by GS-FLX gAssembler software were assembled in continue plasmid sequences by the PCR-based gap closure method.

**Results:** Sequencing revealed that the blaOXA-181 gene was located onto a 83 557-bp IncT-type plasmid, named pTOXA-181. A fragment of 69 kb of pTOXA-181 derived from the IncT reference Rts1 plasmid (217 182 bp), including the replicon, the origin of transfer and partitioning proteins, but conjugation capability of pTOXA-181 was impaired by the complete loss of the transfer system, with only the TraN and TraG pilus biogenesis proteins remaining. The traG locus was actually truncated through the integration of the blaOXA-181-containing fragment, including a Tn3 transposase similar to a TnpA identified in *Acinetobacter baumannii* AbaR1 resistance island, the PinR site-specific recombinase, and the ISEcp1 insertion sequence that has mobilized the blaOXA-181 gene by a one-ended transposition process. A 34 828-bp helper IncN-like conjugative plasmid was also identified in the transconjugant, encoding a complete transfer locus. We observed that this latter plasmid had mobilized both pTOXA-181 and a small mobilizable plasmid (8969 bp) which was also identified in the transconjugant.

**Conclusion:** This study identified the genetic vehicle of the emerging blaOXA-181 carbapenemase gene. Our study shows that the plasmid at the origin of spread of the blaOXA-181 gene was totally different from that of the blaOXA-48 gene known to be vehiculated by an IncL/M plasmid.

#### **P1345** Analysis of CTX-M plasmids in *E. coli* by antisense silencing

A.R. Edwards\*, R.M. La Ragione, L. Good (London, Weybridge, UK)

**Objectives:** Extended spectrum beta-lactamases, including the CTX-M family, pose serious problems for human and animal health as they substantially reduce the number of effective therapeutic antibiotics. In enteric bacteria, ESBLs are carried on large (>60 kb) promiscuous plasmids, which are of interest because, apart from contributing resistance traits, little is known about how they benefit or burden the host bacteria. Two ESBL *E. coli* outbreak strains were isolated from a

cattle farm for study. The project objectives are: (i) Sequence and annotate the two ESBL plasmids; (ii) Establish RNA silencing of large plasmid encoded genes; (iii) determine the fitness contribution of the plasmid and certain plasmid-borne genes in relation to the host.

**Methods:** Due to difficulty in studying genes on large plasmids by traditional means, Antisense silencing is an attractive alternative for genetic and functional analyses as it can give a clearer picture of gene contribution in comparison to other techniques which may distort whole cell processes. The large ESBL plasmids were sequenced using 454 technology and this information was used to determine several targets for silencing. Peptide nucleic acid (PNA) or expressed antisense silencers or both were designed against plasmid genes of interest and their knockdown effect validated by various phenotypic assays.

**Results:** The sequence data reveals a number of genes of potential benefit to the host in addition to CTX-M. The plasmids isolated from the two strains appears to be highly homologous, but shows different lactamase activities, suggesting that genes at other loci within these large plasmids may affect the CTX-M phenotype. Work silencing the CTX-M resistance gene has shown a significant reduction in lactamase activity; however this does not initially appear to be sufficient to revert the phenotype to CTX susceptibility.

**Conclusion:** These studies show that the silencing of plasmid genes is a viable option for the study of gene function and that these ESBL plasmids do appear to contribute fitness advantages to their hosts in addition to drug resistance. Silencing of other plasmid genes is ongoing and the method validation and phenotypic effects data will be presented.

#### **P1346** CTX-M plasmid sequencing (Part 1): development of a plasmid multi locus sequence typing scheme

*M. AbuOun\*, M. Stokes, H. Preedy, L. Randall, G. Wu, R. La Ragione, N. Coldham, M. Woodward (Surrey, UK)*

**Objectives:** Enteric bacteria carrying the Extended Spectrum Beta-Lactamase (ESBL) blaCTX-M gene on large promiscuous plasmids are increasingly isolated from human and animals worldwide. These bacteria show resistance to third generation cephalosporin antibiotics and can cause both morbidity and mortality in humans. The presence of these bacteria in food producing animals is of particular public health concern as they may pose a risk of infection to humans via the food chain. Accurate identification and epidemiological tools to trace the plasmid mediated spread of blaCTX-M ESBLs within bacterial populations are essential. Current methodologies are limited to certain types of plasmids, thus a typing scheme encapsulating the range of CTX-M plasmids is required.

**Methods:** Fifteen CTX-M plasmids from various veterinary sources, CTX-M types, Inc types and of various sizes were selected for full plasmid sequencing and interrogated using BLAST analysis to identify gene/sequence candidates for the design of a plasmid multi locus sequence typing (pMLST) scheme. Six primer sets were designed to amplify and sequence 6 loci. Computer generated pMLST results from plasmids available on the NCBI database were also incorporated.

**Results:** BLAST analysis of the initial set of 15 CTX-M plasmids identified six loci, four loci allowed sequence based differentiation. The pMLST scheme presented was applied to a panel of 270 ESBL and non-ESBL plasmids. One hundred and forty-five different plasmid types were recognised by the pMLST scheme, with 42 types with more than one plasmid. There are 103 "unique" plasmid pMLST types identified. Six large pMLST types were identified containing 8–21 plasmids each. For several pMLST types, plasmids with different characteristics such as different CTX gene types, sources and incompatibility groups were present within the same pMLST type. Several pMLST types appeared to be restricted to animal source (e.g. swine).

**Conclusion:** Using newly sequenced CTX-M plasmids of animal origin, a generic plasmid typing scheme has been developed. The pMLST scheme has been used to determine the relationships between 270 plasmids from various sources and possessing a range of

characteristics. The scheme identified several groups of plasmids from related sources or CTX group. The development of this generic pMLST typing scheme will contribute much needed information for further epidemiological studies to track the dissemination of ESBL plasmids from farm to fork.

#### **P1347** CTX-M plasmid sequencing (Part 2): development of plasmid biomarkers for epidemiological studies

*M. Stokes\*, M. AbuOun, H. Preedy, L. Randall, G. Wu, I. Freire-Martin, R. La Ragione, M. Fielder, M. Woodward, N. Coldham (Surrey, Kingston, UK)*

**Objectives:** CTX-M genes are the most widely disseminated plasmid mediated Extended Spectrum beta Lactamase (ESBL), and such plasmids can be carried by different Enterobacteriaceae species. *E. coli* containing CTX-M plasmids can cause both morbidity and mortality in animals and humans, and can be difficult to treat due their resistance to 3rd and 4th generation cephalosporins. Plasmids harbouring blaCTX-M vary in size and replicon type and often have similar plasmid backbones and undergo recombination events. Such changes are typically facilitated through mobile genetic elements resulting in a mosaic and recombinant plasmids. The presence of such plasmids in bacteria from food producing animals could lead to transmission of bacteria to humans through the food chain. By developing plasmid biomarkers, it is aimed to identify the epidemiology of ESBL plasmids as well as identifying recombination events.

**Methods:** Eight plasmids ranging in size from 35 to 160 kb with various CTX-M and Inc types were isolated from *E. coli* originating from chickens, turkeys, cattle and pig which were sequenced using a Roche 454 sequencer. BLAST analysis against the NCBI database identified several plasmid specific sequences to eight of the plasmids from which the primers were designed. Primers were screened in silico using computational methods against CTX-M and non CTX-M plasmids from the NCBI database and then tested against a range of field isolates.

**Results:** The analysis of the plasmids sequences identified 39 specific sequences, which have been used to distinguish the eight sequenced plasmids. Of these 39 sequences, 14 were unique among the eight plasmid sequences. All plasmids could be distinguished using a combination of primers, including plasmids which are in the same pMLST group according to a new typing scheme (Poster by AbuOun ECCMID 2012). Plasmids from poultry and pig isolates shared a high proportion of biomarkers suggesting link between plasmids.

**Conclusion:** The sequencing of CTX-M plasmids in *E. coli* of veterinary origin has allowed identification of biomarkers which can be used to distinguish between several different plasmid types. These biomarkers could further be applied to elucidating the evolution of plasmids through recombination events as well as the epidemiology of ESBL plasmids, potentially highlighting routes of transmission and dissemination.

Accompanying abstract: CTX-M plasmid sequencing (Part 1): Development of a plasmid multi locus sequence typing scheme.

## Diagnosis and follow-up of syphilis

#### **P1348** Value of a treponemal test in follow-up of therapy in patients with syphilis

*S. Desmet\*, P. De Munter, K. Lagrou (Leuven, BE)*

**Objectives:** Nowadays follow-up of patients with syphilis is based on non-treponemal tests. Guidelines recommend evaluation of the non-treponemal titer at fixed time points after diagnosis. The applicability of treponemal tests in follow-up is not clear and has not been studied in detail. The aim of this study is to evaluate the value of a treponemal test in follow-up of patients with syphilis.

**Methods:** The Architect Syphilis TP<sup>®</sup> (Abbott) is a chemiluminescence immunoassay for the detection of IgG and IgM antibodies to *Treponema pallidum* (TP) in human serum or plasma. The presence or absence of anti-TP antibodies is determined by comparing the signal (S) of the reaction to a cut-off signal (CO). In this retrospective study, 54 patients with a diagnosis of syphilis and with more than one follow-up sample in a 2 years' time period were included. Diagnosis was based on clinical signs and symptoms, patient history and treponemal and non-treponemal test results. Relapse or reinfection was defined by a fourfold increase in Rapid Plasma Reagin (RPR) titer (Macro-Vue<sup>®</sup> RPR, Beckton Dickinson).

**Results:** Seven out of eight patients diagnosed with a relapse or reinfection had an increase in treponemal signal (mean increase: 6.95 S/CO) at time of relapse or reinfection compared to the signal of a sample before the new diagnosis. The increased treponemal signal corresponded to the increase of the RPR titer. All patients without relapse or reinfection during follow-up showed a minimum fourfold decrease in RPR titer within 24 months. The treponemal result remained positive in all patients in follow-up. However, patients with a follow-up sample 6 months after diagnosis and subsequent treatment, had a significant lower signal of the Architect assay compared with the signal at diagnosis (Wilcoxon;  $p < 0.01$ ) (Figure). Also 12 and 24 months after diagnosis the signal showed a significant decrease (Wilcoxon;  $p < 0.01$ , Wilcoxon;  $p < 0.01$ ) compared with the signal at diagnosis.

**Conclusions:** The findings of this study show a promising correlation between the Syphilis TP<sup>®</sup> signal and treatment response of patients with syphilis. The treponemal signal decreased significantly after successful treatment. Relapse or reinfection cases during follow-up were associated with an increase in treponemal signal in seven out of eight patients. Further studies are needed to evaluate whether treponemal tests can add value to the follow-up of syphilis.

#### P1349 Diagnostic value of the ADVIA Centaur<sup>®</sup> syphilis assay for the screening of antibodies to *Treponema pallidum*

A. Donkers\*, A. Letens van Vliet (Rotterdam, NL)

In this study, the ADVIA Centaur<sup>®</sup> Syphilis was compared to the IMMULITE<sup>®</sup> 2000 Syphilis Screen and the bioelisa SYPHILIS 3.0 assay for the detection of total antibodies specific for *Treponema pallidum*. The ADVIA Centaur<sup>®</sup> Syphilis assay uses Tp15 and Tp17 recombinant antigens, the IMMULITE<sup>®</sup> 2000 Syphilis Screen uses Tp17 rec. antigens. The bioelisa SYPHILIS 3.0 assay uses Tp15, Tp17, and Tp47 rec. antigens. All reactive samples were tested with VDRL and Euroline *Treponema* IgG and IgM Western-blot.

**Objective:** To evaluate the performance of the ADVIA<sup>®</sup> Centaur Syphilis assay.

**Methods:** A total of 1251 patient samples (of which 500 pregnancy specimens) were tested by the ADVIA Centaur<sup>®</sup> syphilis, IMMULITE<sup>®</sup> 2000 Syphilis Screen and bioelisa SYPHILIS 3.0 assay. All reactive samples were tested by Western-blot IgG and IgM, and VDRL. The ADVIA Centaur<sup>®</sup> and IMMULITE 2000<sup>®</sup> Syphilis Screen are fully automated, one-step chemiluminescent immunoassays. The bioelisa SYPHILIS 3.0 assay is a two-step enzyme immunoassay (EIA). The Euroimmun *Treponema* Western-blot is for the separate detection of IgG and IgM antibodies using the pathogen-specific *Treponema* antigens Tp15, Tp17, p22 (unspecific), Tp45, and Tp47.

**Results:** The overall agreement for the Centaur vs. IMMULITE 2000 Syphilis Screen is 100%, the agreement Centaur and IMMULITE vs. the bioelisa SYPHILIS 3.0 assay is 99.92%. The relative sensitivity, specificity, for the Centaur and IMMULITE 2000 is 100%. The Centaur and IMMULITE relative sensitivity, specificity vs. bioelisa Syphilis Screen kit is 99%, and 100% respectively. Out of a total of 100 reactive results, with all three assays, 11 samples were diagnosed as active infections based on a positive IgM blot and a VDRL  $\geq 1:8$ . One bioelisa positive, negative Centaur and IMMULITE sample was negative with the WB IgM, IgG and VDRL. The WB IgM and VDRL test results suggest the presence of reactivity to anti-TP in 0.88% (11/1251) of the tested population.

**Conclusions:** The ADVIA Centaur<sup>®</sup> Syphilis Assay has shown to be a highly specific and sensitive method for syphilis antibody screening. The follow-up of reactive syphilis results with a combination of WB IgM and VDRL is a good method to confirm the active infections and reduce the amount of FP VDRL results.

#### P1350 Evaluation of an automated chemiluminescent microparticle immunoassay for screening of antibodies against syphilis

Z.Y. Li\*, P. Liu, Z. Feng (Beijing, CN)

**Objectives:** To analyze the performance of a newly introduced chemiluminescent microparticle immunoassay (CMIA) for screening of antibodies against syphilis, CMIA was compared to the rapid plasma reagin test (RPR), ELISA for detection of antibodies against syphilis, and the *Treponema pallidum* particle agglutination assay (TP-PA) in the present study.

**Methods:** A total of 4870 samples were detected of antibodies against syphilis by CMIA, ELISA, RPR and TP-PA. When the results were inconsistent using the four methods, dot-immunoblotting test (dot-IBT) was adopted for confirming the test results. Using dot-IBT as gold standard, the sensitivity and total accordance rate of the other four methods were analyzed.

**Results:** There were 160 samples with inconsistent results. Among these, 149 samples were reactive by CMIA, 119 samples by ELISA, 116 samples by TP-PA and 58 samples by RPR. After retesting by dot-IBT, 122 samples were confirming to be reactive, with 13 equivocal results. The sensitivities of CMIA, ELISA, TP-PA and RPR compared with the results of the dot-IBT were 96.7%, 93.4%, 91%, and 46.7%, respectively. CMIA has highest sensitivity, but there were 19 false positive results. The accordance rate of CMIA with the dot-IBT was 77.5%, only slightly below the rate of ELISA and TP-PA (84.4% and 83.1%, respectively). The receiver operating characteristic (ROC) curve showed that the area under the curve of CMIA was higher than that of ELISA (0.920 and 0.901, respectively), but there was no significant difference. The diagnostic optimal cutoff determined by this analysis was  $>1.91$  S/CO for CMIA. The sensitivity and specificity obtained at this cutoff point were 90.9% and 96.0%, respectively.

**Conclusion:** The high sensitivity and specificity of CMIA, together with the fact that it was a simple, objective, and easily automated method, lead us to believe that it could be used as a screening test for syphilis.

**P1351** Comparison of two fully automated serologic tests for Lues antibodies

M. Obermeier\*, S. Müller, H. Klima, R. Bertele, S. Neifer, T. Berg (Berlin, DE; Rotkreuz, CH; Penzberg, DE)

**Background:** Screening for Lues antibodies is still performed with TPPA (Treponema pallidum particle agglutination) or TPHA (Treponema pallidum hemagglutination) in many laboratories. Especially in settings with a high throughput there is an urgent need for automatized testing, which can not be fulfilled by those assays.

**Material and methods:** We compared the Abbott ARCHITECT Syphilis TP (Micro particle enzyme immuno assay) vs. the Roche/Sekisui Cobas Mediace TPLA (Treponema pallidum latex agglutination test), which is a latex enhanced immunoturbidimetric assay. We analyzed 617 fresh serum samples sent to the Medizinisches Labor Dr. Berg for routine diagnostics in which a high prevalence of Lues antibodies was expected and 300 samples from healthy blood donors.

**Results:** In the 617 routine clinical samples 197 (31%) of the samples were tested positive and 397 (64%) were tested negative in both assays, resulting in an overall agreement between the two assays of 96%. In the 300 samples from healthy blood donors all 300 samples were detected negative with the Architect assay, while only 264 samples were detected negative by the Roche/Sekisui assay. As the Roche/Sekisui assay is based on turbidimetric measurement we analysed Serum Indices, especially the basal turbidity of the samples which is represented by the L(=lipemic)-Index. In the 36 samples which showed reactivity in the Roche/Sekisui assay, while negative in the Abbott assay, the L-indices were between 28 and 969 with a median of 347.5. Forty-five samples which were negative for both assays showed L-indices between 14 and 434 with a median of 77. This difference in L-indices between falsely reactive and correctly negative samples was statistically significant ( $p < 0.005$ ).

**Conclusions:** Both assays show excellent performance in terms of sensitivity and specificity in the routine clinical samples. In the samples from healthy blood donors a number of unspecific positive results with the Roche/Sekisui assay were observed. As the Roche/Sekisui Mediace TPLA is a turbidimetric assay we were observing some interference in samples with high turbidity (high L-index). Therefore we recommend testing of serum indices in each sample and careful evaluation of samples with high lipemic indices (L-Index  $>100$ ). We conclude that both assays are valuable tools for syphilis screening. Nevertheless, positive results should be confirmed by further serological testing.

## Diagnosis and prevention of device-associated infection

**P1352** Successful prevention of ventilator-associated pneumonia (VAP) in intensive-care setting by using VAP prevention bundle

M.A. Alhedaihy\* (Riyadh, SA)

**Background:** Ventilator-associated pneumonia is one of the most common health-care associated infection (HAIs) encountered in the intensive care units with an incidence ranging from 6% to 52%. It has the highest mortality rate of any HAI. Many different interventions for preventing VAP in ICUs have been described. In this study we report the results of implementing the VAP prevention bundle suggested by the Institution of Healthcare Improvement in a private hospital, Riyadh, Saudi Arabia.

**Methods:** This study was done as part of quality improvement plan in the 14bed ICU of Dallah Hospital, a 350 bed private, general hospital in Riyadh, Saudi Arabia. VAP was defined according to CDC definition. The surveillance was carried out by trained infection control practitioners. The study period was from January 2009 until 31 December 2010. The VAP bundle consisted of Elevation of the head of the bed to  $>30^\circ$ , Daily "sedation vacations" and assessment for

readiness to extubate, Peptic ulcer prophylaxis and Deep venous thrombosis prophylaxis.

**Statistical analysis:** Data were analyzed using Epi-Info Software. 2010 was compared to 2009 regarding VAP rate and mortality rate in ventilated patients. Relative Risk (RR) and 95% Confidence Intervals (CI) were calculated. Chi square was used to assess linear trends for the 2 year period. p Value was considered significant if  $\leq 0.05$ .

**Results:** The total admission to the ICU in 2009 and 2010 were 497 and 465 with total ICU days of 3327 and 4405, respectively. The number of VAP was 18 and 10 with VAP rate of 15.3/1000 ventilator days and 4.34/1000 ventilator days, respectively ( $p = 0.0006$ ). The mortality in ventilated patients decreased significantly at 65.6/1000 ventilator days in 2009 vs. 32.6/1000 in 2010 ( $p = 0.000$ ).

**Conclusions:** VAP remains one of the leading causes of mortality and morbidity in ventilated patients. Several evidence based interventions have been shown to reduce the VAP rate and mortality in ventilated patients. The Institute for Healthcare Improvement has recommended the implementation of several of these interventions in a bundle format to decrease the VAP rate and mortality in ventilated patients. In Dallah Hospital we started a Quality Improvement Plan for several device-associated infections including VAP in 2008 using the published guidelines and tools. Our findings confirm the previously published results of the effectiveness of bundle implementation.

**P1353** Comparison of bacterial colonisation of central venous haemodialysis catheters with needle free connection device TEGO® and conventional closing cap system

S. Erb\*, P. Grosse, S. Tschudin-Sutter, U. Neff, M. Dickenmann, A.F. Widmer (Basel, CH)

**Introduction:** Catheter related blood stream infection (CRBSI) is a major problem in patients with long-term central venous catheter (CVC) for chronic hemodialysis. The closed needlefree connection device system TEGO® was developed to protect long-term CVC from tip and hub colonization and showed a 50% decrease of CRBSI in children with a hemodialysis catheter in one study (McAfee et al. 2008). The goal of our study was to determine the colonization rate of central venous catheters used for hemodialysis with the TEGO® connection device in comparison to conventional closing cap (CCC) Discofix® in the dialysis centre of the University Hospital in Basel, Switzerland – a university affiliated tertiary care center.

**Methods:** All consecutive patients receiving hemodialysis using a permanent or transient CVC with the TEGO® connection device system and 0.9% sodium chloride as catheter branch lock solution in June 2010 were included. In July 2010, the TEGO® system was replaced by conventional closing caps Discofix® using 46.7% or 30% citrate lock solution respectively. Lock solution from the arterial and the venous branch of the CVC of all patients were cultivated in aerobic blood

culture bottles (BacT/ALERT<sup>®</sup>) at a given time during the study period from 26 June 2010 until 7 June 2011 (Table 1).

**Results:** In the TEGO<sup>®</sup> group, 16 of 33 patients (48.5%) had bacterial growth of at least one microorganism from the 0.9%-sodium chloride lock solution. Bacterial colonization in the CCC-group with citrate lock solution was found in only seven of 56 tested patients (10.8%), thus significantly less frequent than in the TEGO<sup>®</sup>-group ( $p < 0.001$ ).

Coagulase-negative staphylococci were the most common pathogens detected in both groups.

Table 1. Results and baseline characteristics of the TEGO<sup>®</sup> and the CCC-Discofix<sup>®</sup> group

	TEGO <sup>®</sup>	Discofix <sup>®</sup>
Number of patients	33	56
Patients with culture positive lock solution	16 (48,5%)	7 (10,8%)*
Total isolated bacteria	21	9
CNS	16 (76,2%)	5 (55,5%)
<i>Streptococcus sanguinis</i>	1	
<i>Micrococcus sp</i>	1	
<i>Aerococcus viridans</i>	1	
<i>Bacillus non-anthraxis</i>	1	
<i>Enterococcus faecalis</i>		2
<i>Enterobacter cloacae</i>		1
<i>Pseudomonas aeruginosa</i>		1
Gram-pos cocci**	1	
Time connection device in use	15 August 2008 - 5 July 2010	6 July 2010 - on going
Culture date of lock solution	26 June - 5 July 2010	9-10 August 2010 and 6-7 June 2011
Lock solution	0,9% sodium chlorid	46,7% or 30% - citrate
Disinfection of device/tub	Ethanol 80%	Octenidindihydrochlorid (Octenisept <sup>®</sup> ) or Octenidindihydrochlorid-propranolol (Octeniderm <sup>®</sup> )
Exchange of connection device	once weekly	3 times weekly
Mean age in years (range)	67,3 (28,7-86,9)	67,5 (48,5-89,5)
Gender: female patients	23 (69,7%)	38 (67,9%)

\*OR: 6.59 (95% CI 2.08-21.58),  $p=0.00018$

CNS=coagulase-negative staphylococci (*S. epidermidis*, *hominis*, *warneri*, *capris*, *vitulans*, *simulans*). \*\* not more differentiated

**Discussion:** In contrary to other reports, we found a significant higher colonization rate of the TEGO<sup>®</sup>-sodium lock solution compared to conventional closing caps with citrate-lock solution.

The ease of use of closed needlefree connection devices without antimicrobial active lock solutions (as e.g. citrate) in hemodialysis CVC should be balanced with the infectious risk, since colonization proceeds infection.

#### P1354 Impact of multifaceted "bundle" approach in controlling catheter-related bloodstream infections outside the intensive care unit

J.F. García-Rodríguez\*, H. Álvarez-Díaz, L. Vilariño-Maneiro, M.V. Lorenzo-García, A. Cantón-Blanco, P. Ordoñez-Barrosa, A. Mariño-Calleja, P. Sesma-Sánchez (Ferrol, ES)

**Objective:** To determine the impact of a multifaceted "bundle" approach in controlling catheter-related bloodstream infections (CRBSIs) outside the Intensive Care Unit (ICU).

**Methods:** We performed a 1-day prevalence studies, in a 350-bed hospital, from 1991 to 2010, in order to know the proportion of patients with intravascular catheter (IC) and parenteral nutrition (PN), and all positive blood cultures in adults patients were prospectively followed-up. CRBSIs were defined according to CDC criteria. On November 2008 a comprehensive, multifaceted CRBSIs control program was instituted: instruction in insertion and after care of central venous catheter (CVC) and peripheral line, handwashing, appropriate use of gloves and dispensers for alcohol-based handrubs were installed in every room. For each episode of bacteremia, we collected data as: date, admission ward, germ, catheter site, PN and evolution. CRBSIs incidence per 1000 patient-days was calculated. To assess the efficacy

of our interventions, we recorded (before and after the intervention) the epidemiology and clinical features of CRBSIs in non-ICU adults patients. The X2 for trend was used to compare CRBSIs rates.

**Results:** Prevalence of IC use progressively increased until 2010. In 1991: 19.2% of the patients had peripheral IC, 1% CVC, 1.9% PN; in 2010: 67% peripheral IC, 2.1% CVC, 1.6% PN. We followed 556 CRBSIs, 491 (88.3%) of these in non-ICU patients. Out of 491 cases, 270 were confirmed by culture of the catheter tip (73.2% in CVC vs. 26.9% in peripheral IC). CVC associated bacteremia was the most frequent (298), more often related to PN (227/68) and due to coagulase negative *S.* (215/94), and less frequently by *S. aureus* (35/63) than that peripheral device associated,  $p < 0.05$ . CRBSIs attributable mortality was 4.9%, being higher during summer months (8.7%) and for infection by *S. aureus* (11.2%),  $p < 0.05$ . CRBSIs rate progressively increased until a maximum of 0.47/1000 patient-days in 2008 (51 cases). The distribution per months showed higher incidence in summer period. After the intervention, the incidence fell to 0.32/1000 patient-days in 2009 (34 cases) and in 2010 (33 cases), 32% decrease,  $p < 0.05$ . From 2008 to 2009–2010 the prevalence of IC use and the alcohol-based handrubs consumption increased, and there were no differences between other analysed variables.

**Conclusions:** The implementation of multifaceted infection control program decreased the clinical impact of CRBSIs outside the ICU.

#### P1355 Ethanol lock therapy in the prevention of catheter-related bloodstream infections after major heart surgery

M.J. Pérez, J.M. Barrio\*, C. Rincón, J. Hortal, P. Martín-Rabadán, S. Pernia, E. Bouza (Madrid, ES)

**Objective:** E-Lock has been successful in the cure and eradication of pathogens in patients with CR-BSI. Randomized trials with E-Lock as a therapeutic agent, however, are very limited and results are yet inconclusive. Furthermore, the potential value of Ethanol lock therapy (E-locks) in the prevention of catheter-related bloodstream infections (CR-BSI) has not been evaluated. Our work consist in the assessment of the value of E-Locks in the prevention of CR-BSI in the particular setting of patients with non-tunneled, short-term, Central Vascular Catheters (CVCs) in the postoperative period of patients undergoing Major Hear Surgery (MHS).

**Methods:** This is an academic, prospective, randomized, open and controlled clinical trial comparing patients with E-Lock and patients receiving conventional catheter-care (CCC). Patients with CVCs for >48 hours were invited to participate in the study and randomly allocated to one of the two arms. Patients with E-lock had CCC and all their catheters ethanol locked for a period of approximately 2 hours per day and catheter. The control group of patients received CCC according to standard recommendations. All catheters were withdrawn when clinically required and the catheter tips were systematically sent for culture. Definitions of Catheter Colonization and CR-BSI were standard (Mermel et al., CID 2009).

**Results:** The study is scheduled to finish in 31 December 2011. Up to the present time, 138 patients with 208 catheters were included. Overall 115 catheters (74 patients) received E-Locks and 93 catheters (64 patients) received CCC. Both groups were comparable in severity (Euroscore 3.78 vs. 4.31  $p = 0.21$ ). The results for the E-Lock and CCC were respectively as follows: episodes of Catheter Colonization 8.8% vs. 14.34% ( $p = 0.48$ ), colonization of catheter's hubs 4.09 vs. 4.40 ( $p = 0.88$ ), colonization of skin around catheter entrance 22.54 vs. 22.02 ( $p = 0.90$ ), CR-BSI 1 vs. 3 ( $p = 0.24$ ), median days of antibiotic use 7.76 vs. 7.79 ( $p = 0.99$ ), median length of ICU stay, 5 vs. 6 days ( $p = 0.82$ ) and median length of hospital stay, 11 vs. 14.5 days ( $p = 0.40$ ). No severe clinical side effects of E-Locks were observed. The E-Locks were much more time demanding for the nursing staff than CCC.

**Conclusion:** At this interim analysis, Ethanol Catheter Locks do not significantly prevent CR-BSIs nor improve in other surrogate markers of catheter infection. The process is well tolerated by the patients but cumbersome and time-consuming for the Health Care Workers.

**P1356 Validation of a prediction rule for drain-related meningitis complicating external cerebrospinal fluid drainage**

M.S.M. van Mourik\*, A. Troelstra, M.J.M. Bonten (Utrecht, NL)

**Objectives:** Drain-related meningitis (DRM) is a relatively frequent complication of external cerebrospinal fluid drainage using ventricular (EVD) or lumbar (ELD) drains. Manual surveillance of infection rates is time-consuming and prone to subjective interpretation. Therefore, an automated prediction model was previously developed to retrospectively identify patients who developed DRM (*PLoS One* 2011; 6: 8). We now present the results of model validation in an independent patient population within the same medical center.

**Methods:** Model validation was performed on patients receiving an EVD or ELD in the University Medical Center Utrecht between 1 January 2010 and 10 June 2011 (n = 137). Children, patients with multiple simultaneous drains, <1 day of follow-up or meningitis at drain placement were excluded (n = 105 in analysis). The model uses drain characteristics as well as clinical chemistry results, microbial culture results and antibiotic use from a clinical data warehouse as predictors. Model prediction was compared to routine surveillance of DRM by infection control professionals (reference standard). Missing data were imputed using multiple imputation. Recalibration of the model was performed on the derivation and validation dataset combined (time period 2004–2011), to improve prediction in future patients.

**Results:** Of the 105 included patients, 20 developed DRM as determined by the reference standard (17.4/1000 days at risk). The discriminatory power as determined by the area under the ROC curve was 0.951 (95% confidence interval: 0.914–0.988). The sensitivity and specificity of the model were 100% and 88.2% respectively, and predictive values were 58.8% positive and 100% negative. The predicted overall number of infections, as given by the summed predicted probability was 19.52 (observed = 20). Calibration of the model was adequate although the relatively large proportion of culture negative infections gave some distortions. Recalibration of the model (intercept = -0.1792, slope 1.0032) improved the group-level prediction although sensitivity at the patient-level declined slightly (99.0–97.1%)

**Conclusion:** The previously developed prediction model for drain-related meningitis performed well in an independent patient population. Recalibration further improved performance at the group level and more extensive model updating will be done to achieve optimal performance in new populations. This model will then be tested in a multi-center validation.

**P1357 Success revisited: 8-year sustainability of an intervention to prevent urinary tract infections in orthopaedic patients**

Y. Alipour Tehrani, R. Ren\*, A. Agostinho, I. Uçkay, H. Sax (Geneva, CH)

**Background:** Overuse of urinary catheters (UC) is the main modifiable risk factor for healthcare-acquired urinary tract infections (UTI). In 2003, a multimodal intervention in the framework of a prospective controlled trial succeeded in reducing UTI (by >50%) and antibiotic use, whereas the control group sustained UTI rates (Stephan F, et al. *Clin Infect Dis* 2006; 42: 1544–1551). The objective of this study was to evaluate whether the intervention effect was sustained at 8-year follow-up.

**Methods:** Prospective incidence surveillance of all patients undergoing elective orthopedic surgery at the University of Geneva Hospitals (HUG) over 3 months starting November 2009, for UC use and UTI. We compared the results with those of the 2-year follow-up of the original study (N = 300 patients), reapplying the same definitions and methods. In addition, semi-structured staff interviews on indication, training, insertion techniques, and recall of the former intervention were performed.

**Results:** We included 336 study patients (mean age 60 years; 55% female). Among those, 10.1%, 3.6%, 3.9%, 17.6% received an UC in the current study against 15.7%, 1.0% and 3.7%, 18.7% at 2-year follow-up in the operating room, the post-anesthesia care unit (PACU), surgical wards, and overall, respectively. The UTI incidence density amounted to 2.4 per 1000 patient days in this study vs. 2.6 at 2-year follow-up (vs. 6.5 before the intervention). The 17 interviews demonstrated that the collective memory of the intervention and knowledge of guidelines was poor except in the operating room where we identified a champion opinion leader.

**Conclusions:** The intervention effect was sustained concerning the overall UTI rate and the catheterization rates (except that in PACU). Dedicated advocating by an opinion leader seems beneficial to sustainability. Qualitative inquiry was useful in confirming and explaining the quantitative results.

**P1358 Microbiology of cardiac device infections**

A. Leonildi, I. Ciullo, C. Tascini\*, S. Flammini, M.G. Bongiorno, E. Soldati, A. Di Cori, E. Tagliaferri, F. Menichetti (Pisa, IT)

**Objectives:** We aimed at studying the microbiological characteristics of implantable cardiac devices (CDs) infection observed during the 2000–2011 period at the Cardiology Unit of Cisanello Hospital in Pisa (Italy), a national reference centre for transvenous removal of the infected CD.

**Methods:** The tip or other parts of the leads were rolled onto the solid media while the material drawn from the pocket was spread directly on the culture plate. Blood culture system used was BACTEC 9240. For organism identification an automated system (API, Bio-Merieux, Marcy L'Etoile, France) was used. Antimicrobial susceptibility was tested according to the Kirby Bauer method.

**Results:** Electrodes from 1204 patients were analysed. Out of these, 854 (70.9%) tested positive. In 663 (77.6%) cases only one species was isolated, in 175 (20.5%) two species and in 14 (1.8%) more than two species. In 116 cases material from the pocket was also cultured. The result was consistent with that from the electrodes in 69 (59%) cases, including 16 cases in which culture was negative from both samples. In 359 cases a blood sample was also obtained for culture. The result was consistent with that from the electrodes in 124 (35%) cases, including 70 cases in which culture was negative from both samples. A total of 1068 strains was isolated from electrodes (Table 1). Coagulase negative staphylococci (CoNS) were 69% of isolates, *Staphylococcus epidermidis* was the most frequently isolated single agent (67% of CoNS isolates), followed by *S. capitis* (5.8%) and *S. schleiferi* (5.3%). Oxacillin-resistance was 33% among CoNS and 13% among *S. aureus*; strains were generally susceptible to glycopeptides

**Table 1. Isolates from electrodes of CDs  
Pisa, 2000-2011**

	N	%
<b>Total isolates</b>	1,068	100.0%
<b>Gram positive</b>	988	92.5%
CoNS	737	69.0%
<i>Staphylococcus aureus</i>	147	13.8%
<i>Corynebacterium spp</i>	53	5.0%
<i>Propionibacterium spp</i>	27	2.5%
<b>Gram negative</b>	65	6.1%
<i>Enterobacteriaceae</i>	32	3.0%
<i>Pseudomonas spp</i>	16	1.5%
<b>Candida spp</b>	11	1.0%
<i>Candida albicans</i>	4	0.4%
<b>Moulds</b>	4	0.4%

and linezolid. Seventeen percent of Enterobacteriaceae strains had a phenotype compatible with extended spectrum beta-lactamase (ESBL) expression.

**Conclusion:** Culture of the removed electrodes offers the possibility of an etiologic diagnosis of CD infection in the great majority of cases. Culture of material from the pocket is often consistent with that from the electrodes, while species isolated from blood cultures are often different and more likely to be the result of contamination. CD infection is more often monomicrobial, CoNS are most frequently isolated and *S. epidermidis* is largely the main single agent. The pattern of susceptibility to antimicrobials is in general that of community-acquired infections, though oxacillin resistance among CoNS and ESBL-like phenotype among Enterobacteriaceae were relevant.

#### P1359 Atrium blood culture for the diagnosis of cardiovascular implantable electronic device endocarditis

C. Tascini\*, M.G. Bongiorno, G. Zucchelli, I. Ciullo, A. Leonildi, E. Tagliaferri, G. De Socio, E. Soldati, A. Di Cori, F. Menichetti (Pisa, IT)

**Objectives:** Transvenous removal of complete hardware of cardiovascular implantable electronic device (CIED) is indicated for CIED infections. In case of endocarditis, vegetations larger than 2 cm, are at risk of massive pulmonary embolism, therefore percutaneous lead extraction should be postponed or surgical removal might be preferred. The best way to see the diameter of lead or right valve vegetations is intra-cardiac echocardiography (ICE), performed intravenously via femoral vein. Once the echocardiography lead is removed, a blood sample may be taken from the atrium. Our objective was to demonstrate this new method is sensitive and specific.

**Methods:** Once ICE was performed, 20 mL of blood were taken from the atrium and an aerobic and an anaerobic culture bottle were inoculated. Blood culture system used was BACTEC 9240 (Becton-Dickinson, Milano, Italy). The incubation time was prolonged for at least 14 days.

**Results:** In the last 2 years we have performed 21 atrial blood cultures. According to our data, taking as gold standard leads cultures, atrial blood culture has a sensibility of 50% and a specificity of 42%; peripheral vein blood culture has a sensibility of 6% and a specificity of 57% (Table 1). We had to consider as false negative four patients with positive atrial blood cultures and leads cultures negative, patients treated for several months with antibiotics targeted on isolates from atrial blood.

Overall, 18 microorganisms were isolated, 14 coagulase negative staphylococci (CoNS), two *Propionibacterium* spp. and two gram negative.

Table 1. Results of atrial blood culture (ABC), CIED leads culture (LC), and peripheral vein blood culture (PVBC).

	ABC pos	ABC pos	ABC neg	ABC pos	ABC pos	ABC neg
	LC pos	LC pos	LC pos	LC neg	LC neg	LC neg
	PVBC pos	PVBC neg	PVBC neg	PVBC pos	PVBC neg	PVBC neg
Number of patients	1	6	7	3	1	3

**Conclusion:** Our cases suggest atrial blood cultures performed during the procedure for intra-cardiac echocardiography might be an useful option for better targeted antibiotic therapy in difficult to treat CIED endocarditis.

#### P1360 Sonication of explanted devices improves the pathogen detection in cardiac device infections

A. Oliva\*, B.L. Nguyen, M.T. Mascellino, F. Chiarini, F. Mengoni, A. Ciccaglioni, F. Fattorini, A. D'Abramo, M. Iannetta, C.M. Mastroianni, V. Vullo (Rome, IT)

**Objectives:** There is a lack of microbiological gold standard for the diagnosis of cardiac device infections (CDIs). Aim of the study was to analyze the role of sonication before culture in the diagnosis of CDIs and in asymptomatic bacterial colonization.

**Methods:** Over a 6 months period, a total of 80 explanted devices (40 generators, five grafts and 35 lead tips) collected from 20 subjects with CDI and 20 subjects without CDI was analyzed. The removed samples were inoculated in Trypticase soy broth (TSB) for 24 hours and cultured with traditional methods. In addition, they were vortexed for 30 seconds, sonicated for 5 minutes at a frequency >20 kHz and vortexed again for 30 seconds, using the BactoSonic (BANDELIN electronic GmbH and Co. KG). Statistical analysis were performed using STATA 9 software (STATA corp. LP, College Station, TX, USA).

**Results:** Overall sensitivity of sonication fluid culture was higher than standard culture and intra operative pocket swab culture (90% vs. 80% and 33.4%, respectively;  $p = 0.16$ ,  $p < 0.0001$ ). Among all the removed devices, culture after sonication yielded bacteria in 77% of the components compared with 60% of standard culture ( $p = 0.001$ ). Coagulase-negative Staphylococci (CoNS) accounted for 72% of the strains whereas *Staphylococcus aureus* and Gram-negative bacilli were found in 4% and 8% of the total, respectively. No bacterial growth occurred in 8% of CDI. Culture after sonication detected more bacteria than standard method ( $29.91 \times 10^4$  UFC/mL vs.  $21.10 \times 10^4$  UFC/mL,  $p = 0.019$ ), especially when the bacterial amount with TSB was  $<10^4$  UFC/mL ( $p = 0.0002$ ). The difference in the bacterial cell count between the two methods was particularly noticeable for the electrodes ( $19.41 \times 10^4$  UFC/mL vs.  $66.90 \times 10^3$  UFC/mL,  $p = 0.018$ ) rather than for the generators ( $47.77 \times 10^4$  UFC/mL vs.  $46.55 \times 10^4$  UFC/mL,  $p = 0.7$ ). Previous antibiotic therapy had no effect on the diagnostic value of sonication fluid culture ( $p = 0.9$ ). In the control group, standard culture yielded bacteria in 4/20 subjects (20%) compared with 8/20 (40%) of sonication fluid culture. The best cell-count value which discriminated between infected and non-infected devices in sonication fluid culture was  $10^4$  UFC/mL.

**Conclusion:** The sensitivity of culture after sonication is higher than standard culture, both in infected and non-infected cardiac devices. Sonication of explanted devices may represent a useful tool to improve microbiologic diagnosis of CDIs and to detect asymptomatic bacterial colonization.

#### P1361 Sonication cultures improved the microbiological diagnosis of orthopaedic implant infections

M. Yano, C. Silva, M. Murça, S. Nigro, E. Celestino, E. Vicentino, O. Avanzi, E. Honda, M. Salles\* (São Paulo, BR)

Despite the progress on the management of orthopedic-implant infection, there have been difficulties for the microbiologic diagnosis of these infections as the peri-prosthetic tissue cultures can show no microorganisms growth.

**Objectives:** To compare the sensitivity for the pathogen identification obtained by conventional peri-prosthetic tissue culture samples with culture of samples obtained by sonication of explanted implants in the microbiological diagnosis of orthopedic infections.

**Methods:** In a single-center prospective cohort study from August to November 2011, 34 patients with orthopedic implants (osteosynthesis or joint prosthesis) were evaluated, five with hip prosthesis, and 29 with screw-plate and intramedullary nails undergoing partial or total removal due any cause were included. Diagnosis of implant associated infection was based upon standard criteria of infection previously published by Zimmerli et al. (NEJM 2004) and Berbari et al. (CID 1998). Minimal of three samples from the peri-implant tissue were taken and sent under sterile conditions to the laboratory for culture. The removal implants were packed into sterile containers and covered with Ringer's solution, vortexed for 30 seconds and sonicated for 5 minutes (frequency, 40 kHz; power density, 0.22 W per square centimeter). The sonicated fluid is then cultured and the microorganisms isolated were identified

according to standard method. Statistical analysis was performed using two tailed Fisher exact or Chi-square's test.

**Results:** Septic loosening was diagnosed in 16 patients (47.1%) and infection associated with orthopedic implants was diagnosed by either tissue cultures and sonicated fluid in 52.9% of patients. Sensitivity of peri-prosthetic tissue culture and sonication culture was 56.2% and 81.3% respectively ( $p = 0.001$ ). Seventy-six percent of patients with positive sonicated cultures were using antibiotics during at least 14 days. There was only one microorganism growing on tissue culture but not on sonicate culture. The organisms isolated from sets of plate-screw and hip prosthesis were: coagulase-negative *Staphylococcus* (*S. epidermidis*, *S. schleiferi*), *Staphylococcus aureus*, *Enterococcus faecium*, *Streptococcus pyogenes*, *Pseudomonas aeruginosa* and *Enterobacter cloacae*. Of note, one *Candida albicans* infection was also diagnosed by sonication.

**Conclusion:** In our study, sonication technique improved the microbiological diagnosis of orthopedic implant infections.

**P1362 Study of sonication fluid cultures in the microbiologic diagnosis of implant-associated infections. The first Greek experience**

A. Stylianakis\*, K. Tsopelas, D. Argyris, E. Chatziandreou, N. Zalavras, K. Mouta, E. Papafragas, A. Trampuz (Athens, GR; Lausanne, CH)

**Objectives:** Sonication of removed implants using low-frequency ultrasound (35–40 kHz) has been shown to improve the microbiologic diagnosis of implant-associated infections. The purpose of this study was to compare the sonication fluid cultures with the periprosthetic tissue cultures in the microbiology laboratory of a tertiary trauma hospital.

**Methods:** During a 5-month-period, we prospectively included patients undergoing hip or knee prosthesis removal for a suspected infection. The explanted joint components were sonicated for 1 minute at frequency of 40 kHz in sterile Ringer's solution in a sterile plastic box. Aliquots of 0.1 mL sonicate were inoculated each onto aerobic and anaerobic blood agar, chocolate, SDA and McConkey agar, as well as inoculated in thioglycolate broth. The cultures were examined for 10 days and the number and identity of any distinct colony morphology was recorded. In addition, periprosthetic tissue specimens ( $\geq 5$  specimens) were collected and cultured following the usual laboratory practice. The duration of antimicrobial interruption interval before culture sampling was recorded.

**Results:** We included 32 patients undergoing hip ( $n = 28$ ) or knee ( $n = 4$ ) prosthesis removal. In 14 patients (44%), sonication fluid cultures were positive (13 hip and one knee prosthesis): nine coagulase-negative staphylococci (six methicillin-resistant), four *Escherichia coli*, three *Staphylococcus aureus* (one methicillin-resistant), one *Streptococcus mitis/oralis* and one *Pseudomonas stutzeri*; in four of 14 infected implants (29%), two pathogens were found. In periprosthetic tissue cultures, 10 of 32 samples (31%) were considered positive, all revealing same microbial species than in the respective sonication fluid cultures: only one tissue sample showed polymicrobial infection. In 16 of 32 patients (50%) in whom sonication fluid cultures were negative, the drug interruption interval before culture sampling was  $< 7$  days.

**Conclusions:** To our knowledge this is the first Greek study using sonication of removed implants for the microbiologic diagnosis of periprosthetic infections. Staphylococci (especially coagulase-negative staphylococci) were the predominant pathogen, followed by *E. coli*. The sonication fluid culture was more sensitive than the periprosthetic tissue cultures, although not reaching statistical significance (44% vs. 31%). A longer antimicrobial interruption interval ( $> 2$  weeks) before explantation of the prosthesis may further improve the culture sensitivity.

**P1363 Impact of removed prostheses sonication on prosthetic joint infections diagnosis and outcome**

T. Ascione\*, P. Pagliano, M. Iannece, P. Rosario, M. Conte, M. Mariconda, G. Balato, F. Smeraglia, R. Rotondo, R. Pimpinello (Naples, IT)

Sonication of removed implant may improve the rate of microbiologic diagnosis of prosthetic joint infections (PJI) but the value of a sonication-guided therapy is unknown.

**Objectives:** To evaluate the impact of sonication in ameliorating quality of microbiological diagnosis and consequently in improving cure rate of PJI.

**Methods:** PJI undergoing two-stage exchange consecutively observed during a 4-year period were enrolled. PJI were defined by clinical, microbiological and radiologic findings. In each case, we reported demographic, clinical and microbiological data, including the method employed to obtain microbiological cultures such as conventional culture of intraoperative specimens or culture of the fluid obtained by sonication of the removed implant. Cure was defined by disappearance of any evidence of infection during a 6-month follow-up period.

**Results:** Thirty-seven cases with PJI were observed (median age 64 [range 48–82], 16 hip implants and 21 knee implants). Microbiological investigations revealed bacterial growth in 30 (81%). *Staphylococcus aureus* was identified in 12 (40%) cases (eight methicillin resistant), Coagulase Negative staphylococci (CoNS) were identified in 10 (33%), *Pseudomonas aeruginosa* in 3 (10%), and other bacteria in 5 (17%). In 15 PJI the attempt to microbiological diagnosis was made only by conventional methods reporting a 67% success rate. In 22 cases undergoing both culture of the fluid obtained by sonication and culture of conventional intraoperative specimens, bacterial growth was obtained in 20 (90%) by sonication and 15 (68%) by conventional methods. Three cases reported discordant microbiological evidences between sonication and conventional methods and received antimicrobial therapy according to sonication. Overall, cultures were positive in 90% by sonication and 68% by conventional methods (20/22 vs. 25/37; RR 1.35, 95% CI 1.04–1.74;  $p = 0.04$ ) with an increase of CoNS isolated among those diagnosed by sonication. Failure after two-stage replacement was reported in 3 (20%) diagnosed by conventional methods and 1 (5%) diagnosed by sonication.

**Conclusion:** Sonication of the implant improved the accuracy of PJI microbiological diagnosis revealing a higher number of cases sustained by CoNS which are better revealed by sonication since are embedded within biofilm. Sonication resulted in slight better cure rate, probably because of the reduction of cases needing broad spectrum empiric therapy.

**P1364 Clinical utility of differential time to positivity and semi-quantitative culture of catheter segments for diagnosing catheter-related bloodstream infections**

S. Oh, M. Lee\* (Seoul, KR)

**Background:** Catheter-related bloodstream infections (CRBSIs) is one of the leading cause of infections with a significant morbidity and mortality rate. Because CRBSIs are difficult to diagnose, there have been suggested several diagnostic methods to detect CRBSIs. We evaluated the differential time to positivity (DTP) and semi-quantitative culture of catheter segments (SQCC) as a method for diagnosing CRBSI.

**Methods:** During January 2010–August 2011, 158 positive paired blood cultures which had the same organism isolated from blood cultures drawn simultaneously through the central venous catheter (CVC) and the peripheral vein were included. Positive DTP represents a DTP of at least 120 minutes earlier for the time to detection of CVC drawn than that of a peripheral vein drawn. A positive SQCC result

represents 15 or more colony-forming units from culture of catheter segments with the same microorganism isolated from peripheral blood cultures. We evaluated a clinical utility of DTP and SQCC for diagnosing CRBSIs, which were further divided into two groups: confirmed (either by DTP or SQCC) and non-confirmed CRBSIs (neither DTP nor SQCC positive).

**Results:** Sixty-five percent (103/158) of episodes were confirmed to CRBSIs. In CRBSIs, gram-positive cocci were 62.5% (65/103), non-fermenting gram-negative bacilli were 11.5% (12/103), Enterobacteriaceae were 9.7% (10/103), yeasts were 14.4% (15/103), and others were 1.0% (1/103). In non-CRBSIs, gram-positive cocci were 59.3% (32/55), non-fermenting gram-negative bacilli were 18.5% (10/55), Enterobacteriaceae were 21.8% (12/55), and yeasts were 1.9% (1/55). DTP-positive episodes were high in coagulase-negative *staphylococcus* (68%, 32/47) and yeasts (93.8%, 15/16). Among 88 cases, which were done both DTP and SQCC, 22 cases were both positive and 22 cases were both negative in DTP and SQCC, respectively, and 32 cases were positive in DTP only and 12 cases were positive in SQCC only. Among the other 70 cases, which were done DTP only, 37 cases were positive and 33 cases were negative in DTP. The sensitivities of DTP and SQCC techniques were 88.3% (91/103) and 51.5% (34/66), respectively.

**Conclusions:** The differential time to positivity was more sensitive than the semi-quantitative culture of catheter segments to diagnose CRBSIs. DTP is useful for diagnosing CRBSIs without a removal of catheter.

#### **PI365** A 1-year retrospective audit of vascular catheter tip culture – Is the laboratory workload justified?

S. Frost\*, R. McWade, D. Brady, M. Cotter, M. Hannan, M. Lynch (Dublin, IE)

**Introduction:** The value of routinely culturing vascular catheter tips is debatable. According to IDSA guidelines the clinical impact of positive tip culture without accompanying bacteraemia/fungaemia is uncertain. Previous studies have reported low proportions (20–30%) of positive cultures from tips with fewer still being associated with a catheter related blood stream infection (CRBSI). The cost of culturing vascular catheter tips is substantial. A retrospective audit of vascular catheter tip culture practices in our laboratory was performed with a view to assessing the need to continue to provide a routine tip culture service.

**Methods:** A search of the laboratory database for all tips processed over a 1-year period (June 2010–July 2011) was carried out with results analysed for tip culture result, line type, referring ward and corresponding blood culture results. Peripheral line tips were excluded from further analysis.

**Results:** One thousand eight hundred and fifty-one vascular catheter tips from 1096 patients were cultured in our laboratory over 1 year. Non-tunnelled central venous line tips accounted for 73% of all tips cultured. Sixty eight percent of tips were referred for culture by a high dependency clinical unit.

Overall 463 of tip cultures were positive. Of these positive tip cultures 67% grew coagulase negative staphylococci, 8% grew gram negative bacilli, 4% grew *Staphylococcus aureus*, 4% grew *Candida* sp. and 13% were mixed cultures.

Sixty-three percent (293) of culture positive tips had no corresponding blood culture drawn in the 24 hours preceding/post line removal. Twenty-eight percent (128) had either a negative associated blood culture or a positive with a different organism to the tip culture.

**Discussion:** Only 2.3% of all vascular catheter tips sent for culture in our laboratory over the study period were associated with a proven CRBSI. Sixty-three percent of vascular tips sent for culture did not have an accompanying blood culture drawn. On the basis of this finding a comment has been introduced to the electronic ordering system indicating that blood cultures must be sent with all tips for culture. Tips not accompanied by a blood culture have a rejection comment applied and are not processed further until a blood culture is received in the laboratory.

## Molecular bacteriology: into the deep

### **PI366** Identification of carcinoma suppressive factor produced by bacteria of *Enterococcus* genus

A. Szkaradkiewicz, T.M. Karpinski\*, A. Gamian, E. Brzozowska, A. Zeidler (Poznan, Wroclaw, PL)

**Objectives:** Bacteria of *Enterococcus* genus are capable of producing several virulence factors, exerting toxic effects on host cells. The studies aimed at analysis of effects manifested by supernatants of *Enterococcus* strains supernatants on proliferation of carcinoma cells and at pinpointing the potential anti-proliferative factor.

**Materials and methods:** The studies included 23 strains, including 21 strains of *E. faecalis* and two strains of *E. durans*. All the studied strains represented clinical isolates, recovered from urine or wound. The bacteria were grown on D-Coccosel-Agar medium. Subsequently, suspensions of individual strains were prepared, manifesting density of 0.5 McF. The 0.1 of every studied suspension was inoculated to RPMI 1640 medium (Sigma), supplemented with 0.5% glucose and the cultures were incubated for 24 hour at 37°C. The cultures were filtered obtaining supernatants, which were tested against carcinoma cells (AGS, HeLa). The control involved carcinoma cells incubated without the tested supernatants. Proliferation of the cells was studied using TACS MTT Cell Proliferation Assay (Promega). The results were read as an absorbance value, A. In parallel, the supernatants of *Enterococcus* cultures were subjected to ultrafiltration under pressure of nitrogen using Amicon filtration membrane. Molecular mass of the active factor was determined using gel filtration in FPLC column. Moreover, thermal stability of the obtained fraction was tested incubating it at the temperature of 75°C for 0.5 hour.

**Results:** Mean absorbance value (A) of proliferation manifested by carcinoma cells in control experiments amounted to 1.437 ± 0.051 for AGS, for HeLa to 1.419 ± 0.046. Mean absorbance value of proliferation of carcinoma cells incubated with supernatant of *E. faecalis* or *E. durans* cultures amounted to 1.079 ± 0.094 for AGS (decrease in the percent of the proliferating cells against the control by 24.9%), 1.116 ± 0.085 for HeLa cells (decrease against the control: 21.3%). Absorbance values obtained following incubation with *Enterococcus* supernatants differed significantly from the control values (p < 0.0001). In parallel, the anti-proliferative factor produced by *Enterococcus* strains was shown to involve a peptide substance with molecular weight of 1.6 kDa, heat-stable at the temperature of 75°C for 0.5 hour.

**Conclusions:** The newly identified thermostable peptide of 1.6 kDa, produced by clinical strains of *Enterococcus* bacteria manifests anti-proliferative activity toward carcinoma cells.

### **PI367** Whole genome sequencing of *Neisseria meningitidis* serogroup C isolates reveals subtle genetic difference in the capsule locus of an outbreak strain

E. Lavezzo, L. Barzon\*, S. Toppo, D. Peruzzo, F. Finotello, E. Franchin, B. Di Camillo, R. Manganelli, G. Toffolo, C. Cobelli, G. Palù (Padua, IT)

**Objective:** Comparative analysis of the genomes of *N. meningitidis* serogroup C isolates in order to detect cues associated with a highly virulent phenotype.

**Methods:** Whole genome sequencing by using the standard shotgun and the 3-kb paired-end protocols provided by Roche 454 next generation platform.

**Results:** We sequenced the whole genome of two isolates of *N. meningitidis* serogroup C, which were isolated from patients with invasive disease in northern Italy during the 2007–2008 winter and belonged to the same ST-11/ET-37 clonal complex. One of the two strains was responsible of an outbreak with seven cases of meningitis, including three fatal cases, while the other strain was isolated from a sporadic case of meningitis in the same area and period. Whole-genome comparative analysis revealed local and remarkable differences between

the genomes of the two isolates and in comparison with the reference genome of strain FAM18.

Since these differences between the two *N. meningitidis* isolates could be the result of genetic variations of the same *N. meningitidis* strain within the outbreak, the most relevant changes in terms of sequence length and predicted function were selected for further investigation and validation through primer-specific cycle sequencing in the two sequenced *N. meningitidis* strains and in the other seven ST-11/ET-37 isolates collected in 2007–2008 in the same area. This analysis confirmed findings provided by next generation sequencing and bioinformatic comparison and demonstrated that the other five isolates from the same outbreak shared the same sequences of the outbreak index strain, whereas the isolate from sporadic meningitis shared sequence identity with isolates from other sporadic cases of meningitis occurring in Veneto Region both before and after the outbreak, during the same season. All genetic differences among strains occurred in the capsule locus and were compatible with horizontal acquisition of a cluster of genes involved in lipooligosaccharide biosynthesis from commensal meningococci.

**Conclusions:** The results of this study showed that an outbreak strain of *N. meningitidis* serogroup C was characterized by horizontal acquisition of a capsule biosynthesis operon that could contribute to its highly virulent phenotype.

#### **P1368** The significance of PCR in the diagnosis of post surgical meningitis

Y. Maor\*, T. Avnon, Y. Schindler, D. Ben-David, G. Smollan, N. Belasov, N. Keller, G. Rahav (Ramat Gan, IL)

**Background:** Post surgical meningitis is a dreaded complication of CNS surgery. As most patients after CNS surgery experience signs and symptoms of meningitis, the spinal fluid exam is pathological due surgery or recent bleeding, and many patients receive empirical antibiotic treatment the diagnosis of postsurgical meningitis is challenging. We examined whether PCR of the spinal fluid can improve the diagnosis of post surgical meningitis.

**Methods:** A random sample of patients after CNS surgery (n = 86) were enrolled. CSF samples were sent for routine examination (chemistry, gram stain and culture). In addition PCR identifying ribosomal bacterial DNA was performed on all samples. Bacterial DNA was produced and DNA samples were assessed for the presence of 16s rRNA. If positive, sequencing was done and the sequence obtained was compared to sequences available at the world gene bank with BLAST Software to identify bacteria. In addition, patients' files were reviewed and a blinded ID physician decided whether the patients had a clinical picture compatible with post surgical meningitis. PCR results were compared with culture results and the clinical diagnosis.

**Results:** Mean age was 59 years. 52% were males. Common reasons for surgical intervention were bleeding in 38% of patients and resection of a tumor in 37% of patients. 67% of patients had a clinical diagnosis of postsurgical meningitis but only 33% had a positive culture and 20% had a positive PCR result. Concordant results between bacterial growth in culture and PCR were found in only 42% of cases ( $\kappa = 0.24$ ). *Propionibacterium acnes* was the most common pathogen identified by PCR. In four cases it did not grow in culture but patients were considered to have clinical meningitis. In one additional case *P. acnes* grew in culture and was also identified by PCR but this case was not thought to be infected. The most common pathogen depicted by culture was coagulase negative Staphylococci (CONS) (n = 8). Of these, six were considered to have meningitis, one was also depicted by PCR and in two cases PCR was positive but sequencing failed.

**Conclusions:** Concordance between the clinical diagnosis, culture result and PCR remained unacceptably low. PCR did not increase the diagnostic yield except for the identification of *P. acnes*. Further improvement of the use of PCR is warranted prior to its application for routine diagnostics in post surgical meningitis.

#### **P1369** Characterisation of a molecular-based assay system (PLEX-ID) for broad range detection of bacteria, *Candida*, and antibiotic resistance from blood culture bottles

L. Blyn\*, M. Frinder, R. Ranken, H. Matthews, D. Toleno, R. Sampath, G. Schneider, D. Ecker (Carlsbad, Chicago, US)

**Background:** An assay was developed on the Ibis Biosciences PLEX-ID platform to detect diverse pathogenic bacteria and *Candida*. The assay was designed to identify 600+ species through mass spectrometric analysis of unfragmented amplicons and comparison of resulting mass signatures to known signatures in a reference database. The assay is capable of detecting the presence of genes conferring resistance to antimicrobials – methicillin (*mecA*), vancomycin (*vanA/vanB*) and carbapenems (*kpc*). We demonstrate the use of the PLEX-ID Broad Bacteria Assay as an innovative approach for both species identification and antibiotic resistance determination from positive blood culture bottle samples.

**Methods:** The PLEX-ID Broad Bacteria Assay is comprised of 18 primer pairs targeting all bacteria (16S rDNA, 23S rDNA), subsets of bacteria (*rplB*, *tufB*, *valS*, *rpoB*), antibiotic resistance markers (*mecA*, *vanA*, *vanB*, *KPC*), and *Candida* (18S rDNA, 25S rDNA, mitochondrial rDNA). The assay uses a 1.1 mL sample from positive blood culture bottles (BacT/ALERT, BD BACTEC, VersaTREK). The assay was fully characterized for sensitivity, cross reactivity, interference, breadth of coverage, and performance on relevant samples.

**Results:** The PLEX-ID Broad Bacteria Assay demonstrated accurate and sensitive detection of a large breadth of bacterial organisms in a wide variety of blood culture bottle media and in the presence of many different blood components and potential cross reactors. Correct identification was achieved for over 150 organisms derived from spiked blood culture bottle samples. The system was able to correctly identify antibiotic resistance markers (*mecA*, *vanA/B*, and *KPC*) for *Staphylococcus aureus*, *Enterococcus faecium/faecalis*, and *Klebsiella pneumoniae*, respectively. Over 300 positive blood culture bottles derived from clinical specimens were tested and 92.2% of the samples were correctly identified at the Genus level. 88.3% of the samples were identified at both the Genus and Species level.

**Conclusions:** Using the high throughput Plex ID Broad Bacteria Assay, we have demonstrated the ability to quickly and accurately detect and identify a wide variety of clinically relevant bacterial and *Candida* species, as well as antibiotic resistant markers, in blood culture samples using a single molecular assay.

#### **P1370** Airway microbiota in healthy state and chronic obstructive pulmonary disease

T. Zakharkina\*, E. Heinzl, J. Pauling, J. Baumbach, R. Bals (Homburg/Saar, Saarbrücken, DE)

Bacterial infection of lower respiratory tract is characteristic for chronic obstructive pulmonary disease (COPD). Routine clinical diagnostic methods include the detection of about 10 most common pathogens. New molecular-based approaches allow studying pulmonary microbiome more deeply. This paper describes the detailed structure of microbial communities found in bronchoalveolar lavage fluid of nine COPD patients compared with nine healthy individuals. The authors designed the experiments to compare two different methods to analyze species composition. They included terminal restriction fragment length polymorphism and clone library analysis. Both methods are based on the universal eubacterial 16S rRNA gene amplification. We identified 151 bacterial ribotypes. Although all probes showed high diversity, genera *Prevotella*, *Sphingomonas*, *Pseudomonas*, *Acinetobacter*, *Fusobacterium*, *Megasphaera*, *Veillonella*, *Staphylococcus*, and *Streptococcus* made up the core microbiome. Presence of *Mycoplasma* and *Pseudomonas* was characteristic for COPD state. *Pseudomonas* sp. monoinfection led to the reduction of microbial diversity. Atypical bacteria (*Mycoplasma* sp. and *Legionella* sp.) were identified by

restriction analysis, but not clone library analysis. Statistical data assessment (principal component analysis) revealed interspecies dependencies between *Pseudomonas* and *Lactobacillus* in COPD patient group. This finding can contribute to the understanding of species interaction in complex pulmonary microbial communities.

#### P1371 Duplex real-time PCR identification of *Pseudomonas aeruginosa* isolates from cystic fibrosis patients

S.J. Reid\*, D. Yirrell, W.J. Olver (Dundee, UK)

**Objectives:** *Pseudomonas aeruginosa* is the main infective cause of morbidity and mortality in Cystic Fibrosis patients. The CF lung environment favours conversion from motile strains of *P. aeruginosa* to atypical mucoid strains. Issues have been raised with the accuracy of standard methods for identifying atypical *P. aeruginosa* by phenotypic and biochemical testing. PCR-based assays have been shown to be a reliable alternative and are now recommended by Cystic Fibrosis Trust guidelines. This study investigates a duplex PCR assay that targets the *ecfX* and *gyrB* genes to identify *P. aeruginosa* isolates from the sputa of CF patients. The use of a simple heat-shock method of extraction was also investigated as a cost and time saving alternative to the current automated extraction method.

**Methods:** The assay was validated using 103 confirmed *P. aeruginosa* isolates from CF patients. These had been previously identified using 16S rDNA PCR. Fourteen similar organisms (such as other *Pseudomonas* spp.) were used as negative controls. A further 42 clinical isolates from CF sputa that had been previously analysed by standard laboratory methods (Vitek 2 and/or API 20NE) were collected, re-analysed using the PCR assay, and the results compared with the original laboratory findings. The heat-shock method was investigated by analysing a total of 69 known isolates.

**Results:** The assay detected all 103 confirmed positive samples. No cross-reaction was detected with the 14 similar organisms. No inhibition was detected as a result of combining the *ecfX* and *gyrB* targets into a duplex assay. The PCR assay gave results with sensitivity and specificity of 100% for *P. aeruginosa*. The PCR assay correctly identified all 42 clinical isolates as either PCR positive or negative, whilst current laboratory methods were found to have produced two

false-positive and four false-negative results upon comparison. Results from the isolates extracted by heat-shock method matched those extracted using the automated extraction method.

**Conclusion:** The assay was shown to be highly sensitive and specific for detection of *P. aeruginosa*. The heat-shock extraction method was shown to be rapid and cost-effective. The implementation of the PCR assay into the laboratory would have prevented two false-positive and four false-negative results in the 42 clinical specimens tested in this study.

#### P1372 Characterisation of drug-resistant *Mycobacterium tuberculosis* strains from Bulgaria and Georgia by bead-based multiplex ligation-dependent probe amplification

S. Sengstake, I. Bergval\*, N. Brankova, V. Levterova, E. Abadía, M. Akhalaia, K. Tuin, A. Schuitema, S. Panaiatov, E. Bachyiska, R. Aspidzeshvili, P. Klatser, C. Sola, R. Anthony (Amsterdam, NL; Sofia, BG; Orsay, FR; Tbilisi, GE)

**Objective:** In *Mycobacterium tuberculosis* (MTB) different genotypes carry characteristic genetic markers and most forms of drug resistance are encoded by distinctive single nucleotide polymorphisms (SNPs), making SNP-based identification an attractive tool for the full characterization of MTB strains. We have developed an MTB-specific Multiplex Ligation-dependent Probe Amplification (MLPA) assay. This method allows simultaneous detection of multiple dispersed drug resistance and genotype-specific markers in the MTB genome and has proved to be highly specific (Bergval et al. 2008).

**Methods:** We have transferred analysis of MLPA to a more robust and user-friendly bead-based array (Luminex MAGPIX) by modifying current MLPA-probes and protocols (manuscript in preparation). Our current MLPA assay includes 43 functional MTB-specific discriminatory markers, allowing simultaneous detection of the most important first- and second-line drug resistance mutations as well as various genotypes that are of particular epidemiological interest.

Local staff tested the performance and the practical use of the adapted MLPA on 49 multidrug-resistant (MDR) MTB strains in Bulgaria. In addition, a randomly selected panel of 100 MTB strains from Georgia was prospectively tested by MLPA in the Netherlands and France and spoligotyped in France, to predict the applicability of the assay on Georgian MTB strains. Results were compared to data previously obtained by other methods.

**Results:** MLPA results obtained in Bulgaria reveal that the majority of the selected strains carried the resistance-conferring mutations rpoB-S531L and inhA(-) C15T, rather than katG-S315T. Data on second-line drug resistance was lacking, but one XDR-TB strain was identified by MLPA. MLPA furthermore indicated that most strains (75%) belonged to principal genotypic groups 2 and 3, whereas the Georgian strains were predominantly of the Beijing genotype (33%). These results were in good agreement with MLPA and spoligotyping data obtained in France.

In the Georgian panel 12% MDR and no XDR strains were identified, as was reflected by the phenotypic data obtained in Georgia.

**Conclusion:** The overall accuracy of MLPA on the bead-based array is comparable to our original assay, with significant reduction of the turn-around-time. This system allows multi-parameter testing by MLPA and could provide a standard platform for several diagnostic and screening tests, which are traditionally performed by different, TB-specific, methods.

#### P1373 Dysbiosis of the lung bacterial community in patients with stable chronic obstructive pulmonary disease

M.C. Scarpa\*, E. Lavezzo, E. Franchin, V. Militello, G. Costanzi, M. Pacenti, M. Saetta, P. Maestrelli, G. Palù, L. Barzon (Padua, IT)

**Objectives:** There has been considerable controversy about the role of lower respiratory tract bacteria in the pathogenesis and exacerbation of chronic obstructive pulmonary disease (COPD). Aim of this study was

to investigate the lower respiratory tract microbioma of stable COPD patients, smokers, and healthy non-smokers subjects in order to identify microbial pathogens potentially associated with COPD.

**Methods:** Sputum was induced in six COPD patients, four smokers, and three healthy non-smoker controls. An aliquot of each specimen was subjected to microscopic examination and bacteriological culture, while another was used for deep sequencing of the 16S rRNA gene by using the 454 Life Sciences FLX system. About 10 000 good-quality reads per sample were obtained. Sequences were processed using the RDP Multiclassifier for taxonomic classification of bacteria phyla and genera.

**Results:** The composition of the microbioma in sputum samples varied widely among subjects, while it was relatively stable during time in the same subject, and included several genera from 10 bacterial phyla. *Pseudomonas*, *Streptococcus* and *Haemophilus* genera accounted for a large percentage of sequences in some patients with COPD, while *Neisseria* and *Streptococcus* genera were abundant in smokers. These genera were absent or rarely detected in healthy subjects. A "core microbioma" composed of bacteria common to all sputum samples was identified that included *Prevotella*, *Streptococcus*, *Leptotrichia*, *Veilonella*, *Fusobacterium*, *Actinomyces*, *Rothia*, *Porphyromonas*, and *Neisseria* (cutoff >1% of sequences), while some genera were specific to patient groups (e.g. *Gemella* and *Granulicatella*, detected in COPD patients and smokers). Conventional microscopy and culturing analyses did not represent the microbial diversity identified by deep sequencing.

**Conclusions:** *Pseudomonas*, *Streptococcus*, *Haemophilus*, and *Neisseria* genera were the most abundant bacteria in the deep airways microbioma of COPD patients and smokers, but not in healthy subjects, and could contribute to COPD symptoms and severe exacerbations. A "core microbioma" including aerobic and anaerobic bacteria, common to all sputum samples, was identified and considered as normal lung flora. The dysbiosis of the lung bacterial community could provide the constant inflammatory stimulus observed in stable COPD patients.

#### **P1374** Clinical significance of PCR positive, culture negative faeces for *Salmonella*, *Shigella*, *Yersinia* or *Campylobacter*

T. Sprong\*, A. Voss, J. Tilburg, M. Kersten, J. Meis, C. Klaassen (Nijmegen, NL)

**Objective:** Direct molecular detection (PCR) of gastrointestinal pathogens (*Salmonella*, *Shigella*, *Yersinia* and *Campylobacter* [SSYC]) from faeces samples has led to an increased sensitivity of the test and consequently a higher number of "positive" samples. The faeces PCR is used in our hospital as pre-culture screening of the faecal samples; all positive PCRs are followed by cultures on organism-specific agars. In the present study, we evaluated how often a positive PCR is confirmed by culture. In addition, since the clinical relevance of PCR positive, culture negative results is still unclear, we compared the clinical characteristics of PCR-positive patients with and without positive culture, respectively.

**Methods:** Between March 2010 and November 2011, we included all faecal samples (n = 5502) sent in for testing of SSYC by general practitioners (n = 4007), internal medicine outpatient clinics (n = 644) and internal medicine wards (n = 851). Clinical data were retrieved by detailed retrospective chart analysis in the patients seen at the internal medicine outpatient clinic or wards (n = 49).

**Results:** Using PCR, 1.8% of the samples were positive for *Salmonella*, 1.1%, for *Shigella*, 8.3%, for *Campylobacter* and 0.1% for *Yersinia*. A positive PCR was followed by a positive culture in 81% of samples tested positive for *Salmonella*, 33% for *Shigella*, 62% for *Campylobacter* and 50% for *Yersinia*. Percentage of *Salmonella* culture positivity was significantly higher in samples sent from GP (87%) than samples from the internal medicine ward (45%,  $p < 0.01$ ). There were no differences in clinical characteristics (admittance to hospital, overall antibiotic use, fever, bloody diarrhoea or CRP) between PCR-positive patients with a positive or a negative culture. A negative culture was more often seen in samples from patients who had received antibiotic

treatment before culture (29% vs. 12% without antibiotics before culture), although this was not significant ( $p = 0.14$ ).

**Conclusions:** A significant number of PCR-positive faecal samples cannot be confirmed by culture. This is only partly explained by previous antibiotic treatment. Clinical characteristics of PCR-positive patients with negative culture do not differ from patients with a positive culture. This suggests that a positive PCR is sufficient to detect clinically relevant cases of gastro-intestinal infections.

#### **P1375** Growth dynamics revealed inter- and intra-clonal fitness differences among major *Enterococcus faecalis* clonal complexes

A.P. Tedim\*, C.M. Rodríguez, F. Baquero, T.M. Coque (Madrid, ES)

**Objectives:** *Enterococcus faecalis* (Efc) has an epidemic population structure with over-representation of Clonal Complexes (CCs) CC2, CC9, CC16 and CC87, which exhibit enhanced ability to cause infection or colonize under different ecological conditions. This study evaluates growth dynamics of major Efc CCs to understand the diversification and extraordinary adaptability of this species.

**Methods:** Thirty-six Efc of CC2 (7 ST6, 2 ST2), CC9 (5 ST9, 1 ST17, 1 ST42), CC8 (4 ST8, 1 ST64), CC16 (4 ST16, 1 ST179), CC87 (2 ST28, 2 ST87), CC21 (1 ST21, 1 ST22), CC40 (2 ST40) and CC1 (2 ST1) were analysed. Isolates are CCs emblematic representatives for which comprehensive data including their mobilome content were considered. Genome size was determined by PFGE (AscI, SmaI, ICeu-I). Growth dynamics experiments were performed at 37°C and different stress conditions using Bioscreen C apparatus. Optical Density (OD) was determined every 5 minute for 24 hour, plates being agitated 10 seconds before each OD measurement. Fitness was analysed by determining Growth Rates (GR) and Generation Time (GT) using standard procedures.

**Results:** Inter and intra-clonal variations in bacterial fitness were observed (average GR =  $0.7478 \pm 0.0841$ , and average GT =  $56.48 \pm 7.12$  minute). CC8 was the less fit CC (Average GR =  $0.6745 \pm 0.1162$ ) followed by CC1 ( $0.6930 \pm 0.0185$ ), CC87 ( $0.7376 \pm 0.0261$ ), CC9 ( $0.7376 \pm 0.0666$ ), CC2 ( $0.7395 \pm 0.0499$ ), CC16 ( $0.8121 \pm 0.0320$ ), CC40 ( $0.9359 \pm 0.0120$ ), CC21 being the fittest clone ( $0.8995 \pm 0.0026$ ). Remarkable variations in the fitness of isolates within CC8, CC9, CC2 and CC16 contrast with low intra-clonal variation for CC21, CC40, CC1 and CC87. Stress conditions ( $T = 42^\circ\text{C}$ ) proved to be either an advantage or a disadvantage for some CCs, intra-clonal variation being observed. Genome size was highly variable (2–3.5 Mb) although a significant association with fitness variation was not established.

**Conclusions:** CCs associated with colonization (CC21, CC16, CC40) show a better in-vitro fitness than those linked to nosocomial infections (CC2, CC9, CC87) or some infrequent and ancient lineages (CC8, CC1). The successful expansion of CCs causing most of the clinical infections, apparently less fit than other CCs, might be due to the presence of acquired genetic elements encoding specific traits (antibiotic resistance, virulence genes) that are absent or rarely found among other CCs. Fitness variations reflects adaptation of particular lineages to different ecological conditions.

## Molecular diagnosis of bacterial infections

#### **P1376** Development of nucleic acid-based diagnostic tests for the detection of microbial pathogens using novel targets

L. O'Connor\*, S. Lahiff, K. Reddington, E. Minogue, K. McShera, C. Fahy, S. Devany, T. Smith, T. Barry (Galway, IE)

**Objectives:** Infectious diseases cause significant morbidity and mortality world-wide. Nucleic acid based tests provide a rapid, sensitive and specific alternative to traditional diagnostic test methods. The Molecular Diagnostics Research Group (MDRG) at NUI Galway have identified and exemplified novel molecular targets for microorganism identification. A focus of the work has been on the

development of nucleic acid based tests for microorganisms of clinical significance. While numerous assays for organisms from a range of categories have been developed, presented here are real-time PCR tests for clinically significant organisms *Klebsiella pneumoniae*, *Enterobacter aerogenes*, *Mycobacterium intercellulare*, *Bordetella pertussis* and *Staphylococcus aureus*.

**Methods:** The initial step in the process of nucleic acid test development was the identification of suitable nucleic acid targets. Following identification of a suitable target an initial sequencing program was undertaken to ensure target specificity. This involved sequencing of the target DNA from a number of geographically distinct isolates of the species of interest. It was also critical to generate sequence information for closely related species and species which are common to the target sample environment. In silico analysis of all generated sequences was performed revealing areas of sequence variability between target and non-target organisms suitable for assay design. The performance of each assay with respect to specificity and limit of detection (LOD) was evaluated on the LightCycler® 480 using Taqman probes.

**Results:** The real-time PCR assays developed for *Klebsiella pneumoniae*, *Enterobacter aerogenes*, *Mycobacterium intercellulare*, *Bordetella pertussis* and *Staphylococcus aureus* are specific for the target organism and show no cross reactivity with panels of closely related organisms tested. The limit of detection of each of the assays is between 1 and 10 cell equivalents.

**Conclusion:** The potential of a novel nucleic acid target for the development of tests for clinically significant microorganisms has been demonstrated. These real-time PCR assays represent highly specific tests with low limits of detection making them ideal for the detection of low numbers of organisms in clinical samples in a short turnaround time. The high specificity of the tests increases user confidence in determining the presence or absence of the infectious agent.

**P1377** **Detection of *Ehrlichia* and other pathogens from serial clinical specimens by PCR/electrospray ionisation mass spectrometry**

M. Eshoo\*, M. Rounds, J. Friesen, C. Crowder, H. Matthews, C. Quinn, D. Ecker, Y. Tang (Carlsbad, Nashville, US)

**Objectives:** *Ehrlichiosis* presents with non-specific, flu-like symptoms, which makes accurate diagnosis difficult. *Ehrlichia chaffeensis* and *Ehrlichia ewingii* are the two main species relating to different clinical outcomes in humans. Here we use a PCR electrospray ionization mass spectrometry (PCR/ESI-MS)-based assay designed to detect a wide range of vector-borne pathogens for the detection and identification of *Ehrlichia* species from serially collected whole blood, plasma, serum, and cerebrospinal fluid.

**Methods:** Specimens were collected from 266 unique patients from the southeastern United States with suspected tick-associated febrile illness between April 4 to September 30, 2010, many of which included of serial collections from the same patients. Nucleic acids from the initial whole blood draw were extracted for each patient using a combination of mechanical and chemical lysis and magnetic bead purification. The specimens were then tested with a multi-locus assay utilizing 10 multiplexed primers targeting different loci which detect a wide range of vector-borne pathogens, including bacteria, protozoa, and viruses. Electrospray ionization mass spectrometry (ESI-MS) of the PCR amplicons was used to determine their base compositions to identify the organisms in the specimens.

**Results:** Of the 266 patients tested, *Ehrlichia chaffeensis* was detected in 18 (6.77%) of the patients. *Ehrlichia ewingii* was detected in two patients (0.75%). *Rickettsia rickettsii* and *Plasmodium vivax* were detected in one patient each (0.38%). Fourteen patients had positive pathogen *Ehrlichia* detections in more than one serial specimen. We demonstrated pathogen detections from whole blood, serum, plasma, and cerebrospinal fluid specimens. Quantitation of pathogen genomes in the specimens revealed that the concentrations decreased but was still detectable for several days following administration of antibiotic therapy.

**Conclusion:** *Ehrlichia* was detected in whole, serum and plasma at nearly equal levels per milliliter of specimen by PCR/ESI-MS and the organisms is detectable for several days following the start of antibiotic therapy. Results of this analysis suggest that, in infected individuals, the *Ehrlichia* nucleic acids being detected may not be coming from living cells but rather free DNA in the serum/plasma.

**P1378** **Identifying pathogens in culture-negative infections: a case series exploring PCR and electrospray ionisation mass spectrometry for microbial identification**

J. Farrell, R. Sampath\*, R. Bonomo (Peoria, Carlsbad, Cleveland, US)

**Background:** The sensitivity of culture is influenced by many factors, including the site of infection, quantity of specimen, the organism, and prior or concurrent antimicrobial treatment. Timeliness of culture results is also influenced by these variables. We present seven cases suspicious for infection in which conventional culture methods failed to yield a microbiologic diagnosis. When the clinical specimens were analyzed by PCR and electrospray ionization mass spectrometry (PCR/ESI-MS), our findings were consistent with the clinical scenario. These results suggest that PCR/ESI-MS may play a unique role in culture negative infections.

**Methods:** Both conventional culture and PCR/ESI-MS were performed on the following specimens:

1 Cerebrospinal fluid (CSF) obtained by lumbar puncture from a previously healthy 26-year-old HIV-negative man with numerous brain abscesses.

2 Pleural fluid obtained by thoracentesis from a previously healthy 46-year-old woman with a right lung abscess.

3 Vitreous humor from a 53-year-old woman with cirrhosis secondary to chronic hepatitis C infection who developed hemorrhagic retinitis while hospitalized with a small bowel obstruction.

4 Wound drainage from a 38-year-old woman following fasciotomy for right lower extremity compartment syndrome.

5 Bronchioalveolar lavage fluid from a 51-year-old man with community acquired pneumonia and sepsis.

6 CSF and brain tissue from a 50-year-old man with meningoencephalitis.

7 Skin biopsy of a left thigh lesion in a 71-year-old man with acute myelogenous leukemia.

**Results:** Specimen 1: All stains and cultures were negative. PCR/ESI-MS detected *S. intermedius*.

Specimen 2: All stains and cultures were negative. PCR/ESI-MS detected *S. pneumoniae/S. mitis*.

Specimen 3: Viral cultures were negative. PCR/ESI-MS detected HSV-2.

Specimen 4: Gram stain and anaerobic cultures were negative. PCR/ESI-MS detected *Clostridium perfringens*.

Specimen 5: All stains and cultures were negative. PCR/ESI-MS detected *S. pneumoniae*.

Specimen 6: All stains and cultures were negative. PCR/ESI-MS detected *S. pneumoniae*.

Specimen 7: Fungal cultures were negative. PCR/ESI-MS detected *Fusarium solani*.

**Conclusions:** In each case, a pathogen consistent with the clinical presentation was identified. PCR/ESI-MS can assist in the rapid identification of pathogens from a variety of clinical specimens when culture results are likely to be delayed, or viable organisms are not recovered. This sensitivity can help guide antimicrobial therapy.

**P1379** **Evaluating the performance of GeneXpert in screening pregnant women for *Streptococcus agalactiae***

W. Alfouzan\*, R. Dhar (Farwania, KW)

**Objectives:** *Streptococcus agalactiae* or group B streptococcus (GBS) is a common flora of the gastrointestinal and the female genitourinary tract. Babies born to mothers colonized with the organism are at risk of

developing invasive infection. Intrapartum antibiotic prophylaxis is recommended for all pregnant women who test positive for GBS screening especially at or after 35 week of gestation and for women with intrapartum risk factors and unknown GBS colonization status. We aim to assess the diagnostic accuracy of GeneXpert GBS (Xpert® GBS, Cepheid, Sunnyvale, CA, USA) in detecting GBS as compared to culture method.

**Methods:** High vaginal swabs (HVS) collected from women attending obstetrics and gynecology out-patient clinics, in-patients using transport swab (Copan, Italy). For patients in the labour wards swabs (Venturi Transystem transport swab, Copan, Italy), which came in duplicate form were used for GeneXpert and the other for culture on 5% sheep blood agar (BA). The BA plates were incubated at 37°C for 24 hour and examined for growth of GBS which were identified by gram stained smear, catalase and grouping (Streptococcal grouping kit; Oxoid Ltd., UK).

**Results:** During the period of 3 months, a total of 485 HVS were processed in our laboratory. Of these 87 were found to be positive for GBS by culture giving the prevalence rate was 17.9% in the female genital tract. Of 84 HVS received from labour ward 23 (27%) tested positive by culture as well as GeneXpert and 56 were found to be negative by both methods. The sensitivity, specificity, positive and negative predictive values for GeneXpert were 95.8%, 98.2%, 95.8% and 98.2% respectively.

**Conclusion:** GeneXpert is considered a highly accurate point of care test to identify intrapartum GBS carriers. Not only does it helps to identify candidates who require intrapartum antibiotic prophylaxis, but also excludes the non-carriers. Its role in decreasing unnecessary antibiotic consumption in pregnant women is valuable.

**P1380 Evaluation of Xpert® GBS assay for rapid detection of group B Streptococcus in amniotic fluid among pregnant women with premature rupture of membranes after 37 weeks of gestation**

*N. Bourgeois-Nicolaos, F. Casanova, C. Guillet-Caruba, A. Benachi, F. Doucet-Populaire\* (Clamart, FR)*

**Objective:** Group B Streptococcus (GBS) is the leading cause of life-threatening neonatal bacterial infections and maternal chorioamnionitis. Premature rupture of membranes (PROM) is associated with an increased risk of these infections. GBS are present in the vagina of about 10–30% of pregnant women. Intrapartum antibiotic prophylaxis reduces significantly the rate of neonatal GBS colonization and the incidence of early-onset GBS disease. Recently, Xpert® GBS assay (Cepheid) was presented as an accurate and easy-of-use test to detect GBS DNA from vagina/rectal swabs specimens.

The objective of our study was to evaluate the Xpert® GBS test directly on amniotic fluid samples collected from pregnant women with term rupture of membranes before the onset of labor.

**Material and Methods:** Xpert GBS test was performed on 62 amniotic fluid samples from 62 pregnant women with PROM after 37 weeks of gestation. The results of the real-time PCR assay were compared to the results of amniotic fluid bacterial culture and GBS vaginal screening by culture at 35–37 weeks of gestation.

**Results:** The overall molecular GBS test yield was 100%. Out of the 62 amniotic fluid samples, 8 (12.7%) were found positive by Xpert® GBS. Cycle thresholds (C<sub>t</sub>) for positive samples ranged between 27.1 and 39.3. One sample had a positive Xpert GBS result (C<sub>t</sub>: 39.3) but a negative culture on blood agar plate. Another sample had a negative Xpert GBS test but a positive culture with low GBS colony density. Compared to the culture method, the Xpert GBS test for the amniotic fluids demonstrated a sensitivity and a specificity of 87.5% and 98.1% respectively and a positive and negative predictive value of 87.5% and 98.1% respectively.

Out of the eight women with a positive Xpert GBS test in amniotic fluid, five had a negative prenatal GBS culture based screening.

**Conclusion:** Xpert GBS assay is a rapid and accurate method for the detection of intrapartum GBS in amniotic fluid samples. This new tool

could enhance the exact identification of candidates for maternal intrapartum antibiotic prophylaxis. It could be helpful in the management of the delivery of pregnant women with PROM.

**P1381 Development of a high-throughput, rapid and sensitive molecular assay on the Abbott m2000 for detection of group B Streptococcus in antepartum and intrapartum women**

*H. Reiske\*, C. Leslin, R. Kowal, A. Jacobs, R. Del Mastro (Cambridge, Des Plaines, US)*

**Objectives:** Group B streptococci (GBS) are responsible for most cases of neonatal sepsis. Current culture-based screening methods are time consuming and may delay the start of prophylaxis. We have developed a high-throughput, automated assay for rapid and accurate screening or detection of GBS in antepartum and intrapartum women (IMDx GBS for Abbott m2000 assay) in order to address the unmet need for the rapid screening or detection of GBS.

**Methods:** IMDx has developed NGENix™, a proprietary bioinformatics platform for designing multiplexed, real time PCR-based assays. NGENix™ identifies unique regions within sequenced genomes to iteratively design sets of primers and probes, assesses the thermodynamics of the DNA multiplex, and reviews potential cross-reactivity to other genomes. We utilized NGENix™ to design oligonucleotide solutions for a specific region of the GBS genome shown to be essential in the production of virulence factors of GBS, then assessed analytical performance on the Abbott m2000 System.

**Results:** Combined vaginal/rectal swabs or enriched culture broth samples obtained from antepartum and intrapartum women were tested with the IMDx GBS for Abbott m2000 assay to establish performance characteristics. Testing a panel of 235 samples (221 bactiswabs and 14 eSwabs), the assay resulted in 90% diagnostic sensitivity and 100% diagnostic specificity compared to standard culture methods. All eSwabs were correctly identified. The IMDx GBS for Abbott m2000 assay is highly specific for GBS, reacting with serotypes Ib, Ic, II and IV at or below the calculated LoD for the most common serotypes III and V (Table 1). No cross reactivity was observed when the assay was tested against 29 microorganisms. No interference was observed in the presence of potentially interfering substances, such as over the counter medications and prescription medications used at or around the sampling site. A total of 105 tests were performed in precision studies and demonstrated <2% CV of FCN for all variables.

**Table 1. IMDx GBS Assay Performance Characteristics**

<b>Limit of Detection</b>	722.4 CFU/swab for a serotype III isolate (95% CI: 722.27 – 722.60)
	370.12 CFU/swab for a serotype V isolate (95% CI: 370.06 – 370.16)

**Conclusions:** The IMDx GBS Assay for Abbott m2000 provides a rapid alternative to current culture methods for screening or detecting GBS in pregnant women. This assay will provide physicians an accurate and faster method to detect the presence of GBS in antepartum and intrapartum women to allow administration of preventative treatment and reduce occurrence of newborn infection.

**P1382 Development of a new diagnostic tool for the detection of Chlamydia pneumoniae and Mycoplasma pneumoniae in a duplex real-time PCR**

*M. Bertrand\*, M. Vignoles, J. Bes, S. Magro, C. Barranger, M. Joannes (Verniolle, FR)*

**Objectives:** *Chlamydia pneumoniae* and *Mycoplasma pneumoniae*, two atypical respiratory pathogens, are common causes of community-acquired pneumonia. Both bacteria are implicated in upper and lower respiratory tract infections among children and adults

and share clinical features, including symptoms, with many other bacterial and viral infections. A sensitive and effective identification of these agents is necessary and important in order to ensure an appropriate antibiotic therapy. Currently, culture and serological confirmation of the diagnosis of *C. pneumoniae* and *M. pneumoniae* are difficult and time-consuming. Real time PCR, sensitive, specific and rapid technology, is an effective alternative. We offer a new real-time PCR based diagnostic tool for *C. pneumoniae* and *M. pneumoniae* diagnosis.

**Methods:** Nucleic acids were extracted from nasopharyngeal specimens by using easyMag™ NucliSENS (bioMérieux). A Proteinase K (Novagen) pre-treatment was performed. Ten microlitre of purified nucleic acids were added to 15 µL of ready-to-use Chla/Myco pneumo r-gene™ amplification premix. *C. pneumoniae* and *M. pneumoniae* were distinguished in a duplex reaction. Amplification was performed on ABI7500 Fast (Applied Biosystems), Dx Real Time System (Bio-Rad), Versant kPCR System AD (Siemens) or LC480 (Roche) platforms.

**Results:** On the QCMD European Proficiency Panel 2011, 11 positive/negative samples were correctly identified with Chla/Myco pneumo r-gene™. Four positives *C. pneumoniae* and five positives *M. pneumoniae* were detected, including weak positives (0.049 IFU/100 µL for *C. pneumoniae* and 5 CCU/100 µL for *M. pneumoniae*). Analytical sensitivities study on *C. pneumoniae* and *M. pneumoniae* samples were performed in respiratory specimens. The limit of detection at 95% is 0.16 IFU/mL and 180 CCU/mL respectively for *C. pneumoniae* and *M. pneumoniae*. Specificity study performed on 80 pathogens showed no cross reaction with other respiratory bacteria or viruses. Technical studies are in progress and can also be presented.

**Conclusion:** The high quality of Chla/Myco pneumo r-gene™ kit, associated with its compatibility with the major extraction and real time PCR platforms allows immediate integration into most routine diagnostic laboratories. This tool is part of the Respiratory MWS r-gene™ brand range which represents an innovative solution to the challenges of respiratory infections.

**P1383** Evaluation of a novel high multiplexing real-time PCR array for the identification and characterisation of bacteria causative of ventilator-associated pneumonia on clinical specimens

S. Roisin\*, C. Plennevaux, R. de Mendonça, C. Nonhoff, T.D. Huang, P. Bogaerts, M. Hallin, F. de Longueville, W. Plüster, Y. Glupczynski, O. Denis (Brussels, Namur, Yvoir, BE)

**Objectives:** The VAPChip is a molecular tool aiming to identify directly from clinical samples the major nosocomial pneumonia causative bacteria and beta-lactam resistance genes. We evaluated the analytical performances of the VAPChip on respiratory samples.

**Methods:** The VAPChip uses the RAP-ID technology (Real-time Array PCR for Infectious Diseases; Eppendorf Array Technologies, Belgium). It combines multiplex PCR with real-time microarray-based detection of amplification products. The VAPChip targets 13 bacterial species and 28 resistance genes or variants.

Respiratory samples (n = 45) were tested by the VAPChip and by the following reference methods: quantitative culture with identification by Vitek2 or biochemical tests and antimicrobial resistance profiles by Vitek2 or by disk diffusion. The presence of resistance genes was detected by PCR. Discrepancies were resolved by Maldi-tof and by CT103 array (Check-Points, the Netherlands).

**Results:** The comparison of the VAPChip vs. reference methods showed a sensitivity of 97.4% and 100% and a specificity of 71.4% and 94.1% for identification and detection of resistance mechanisms respectively. The culture of 30 out of the 45 samples yielded growth of 38 significant isolates targeted by the VAPChip. Species recovered by culture were distributed as follow: *E. coli* (n = 3), *K. pneumoniae* (n = 5), *E. aerogenes* (n = 1), *E. cloacae* (n = 1), *S. marcescens* (n = 1), *H. influenzae* (n = 7), *P. aeruginosa* (n = 8), *S. maltophilia* (n = 2), *A. baumannii* (n = 1), *S. aureus* (n = 6), *S. pneumoniae*

(n = 3). The VAPChip missed 1 *S. aureus* but detected two *H. influenzae* and two *K. pneumoniae* not recovered by culture. In addition, two *C. koseri* were misidentified as *K. oxytoca* by the VAPChip. Resistance genes detected by reference methods were: mecA (n = 1), blaTEM non-ESBL (n = 3), blaSHV ESBL (n = 1), blaSHV non-ESBL (n = 1), blaCTX (n = 1) and oxacillinase-23 (n = 1). All these mechanisms were detected by the VAPChip. The VAPChip detected one blaSHV- and one blaTEM-non ESBL genes that were not detected by the reference methods. One methicillin-susceptible *S. aureus* isolate was misidentified as methicillin-resistant by the VAPChip.

**Conclusion:** The VAPChip is a rapid diagnostic tool able to identify resistant bacteria directly on clinical samples. Some discrepancies could be explained by high sensitivity of VAPChip. This hypothesis should be confirmed by further analysis. In addition, clinical trials are needed to evaluate the clinical impact and cost-effectiveness of the new promising tool.

**P1384** "Direct PCR" on sputa is faster and as sensitive as PCR with extracted nucleic acids

T. Barkham\*, M. Inoue, W.Y. Leong, W.Y. Tang (Singapore, SG)

**Objectives:** To assess the performance of reagents that enable direct PCR without traditional extraction of nucleic acids.

**Methods:** The direct PCR reagents were developed and donated by Shimadzu as a prototype for a qualitative end-point PCR assay. We used 50 stored sputa, frozen at -80°C, previously shown by PCR to contain Influenza A (34 samples) or B (16 samples). The samples were thawed and a 5 µL aliquot of raw material was used for direct PCR; the raw material was heated to 90°C for 1 minute with 5 µL of direct PCR reagent before the mastermix was added. Further 200 µL aliquots of the same raw sputa were re-extracted into 60 µL eluates by two commercial methods, an EasyMag (Biomérieux) and an RNA viral mini kit (Qiagen). The extracted RNA and the raw samples were subjected to an influenza PCR with the same primers and detection system, a bead based array on a Luminex instrument, but different mastermixes. The Qiagen one step RT-PCR reagent was used with RNA extracted with the EasyMag and the RNA viral mini kit but, as stipulated by the manufacturer, the Invitrogen SuperScript III Platinum one-step End Point PCR reagent was used for the direct PCR. The work was performed in one day by two people.

**Results:** Influenza was detected in 44 (88%) samples by direct PCR, 43 (86%) samples extracted with the Qiagen kit and 38 (76%) samples extracted with the EasyMag instrument.

A further 50 positive and 29 negative samples were tested in a similar exercise using half the volumes, 2.5 µL of raw sample, with a real time PCR protocol. The direct PCR failed to detect any cases. When the direct method was applied to the same samples with gel based detection, it detected influenza in 47 of the 50 positive samples but none of the 29 negatives.

**Conclusion:** Direct PCR was easy and fast. It delivered a similar performance to PCR with nucleic acids extracted with commercial systems that used much larger volumes: these results demonstrate the inefficiency of methods for extracting RNA and point to sample preparation as an area of potential for further refinement. The direct PCR reagents did not work with our real time assay, reminding us that reagents cannot be assumed to work across all platforms. Direct PCR opens up an avenue for significantly reducing the total time to a result by about an hour. Automation of direct PCR methods would allow real competition with existing extraction platforms.

**P1385** Molecular identification of pathogens in pleural infection

J. Wray\*, J. Wrightson, N. Rahman, D. Crook (Oxford, UK)

**Objectives:** The detection of bacteria in pleural fluid culture, using routine microbiological techniques, typically occurs in only 40% of

cases. Nucleic acid amplification testing (NAAT) is emerging as a new tool for diagnosing infection. This study aimed to improve the poor diagnostic yields in this disease, using these molecular techniques.

**Methods:** Three hundred and seventy-seven pleural fluid samples from the Oxford Pleural Infection collection underwent standard microbiological culture. DNA from these samples was also extracted (FastPrep, MP Biomedical) and subjected to two molecular diagnostic strategies: A 625 bp fragment of the ribosomal 16S RNA gene (present in all bacteria) was amplified, using primers targeting flanking conserved regions, and then capillary sequenced (Seq); alongside a nested multiplex PCR (mPCR), initially targeting a 1070 bp fragment of the ribosomal 16S RNA gene, and then amplifying genus-specific sequences of this gene in several multiplex reactions. The mPCR panel comprised of bacterial genera previously identified in pleural infection. Negative samples were depleted of human DNA by human-specific digestion and subtraction, followed by repeat molecular testing.

**Results:** Standard culture detected a pathogen in 41.9% (Fig. 1) of pleural fluid samples. When combined with the molecular testing, this positive rate increased to 89.4%. When samples were positive by all three tests, concordance was 84.4%, compared to 90.0% for mPCR and Culture positive, and 98.9% for mPCR and Seq positive. Superiority of a test was defined as detecting the taxonomic classification to the highest precision, and/or the ability to detect multiple pathogens. Overall, Seq was the most superior test (36.9% of concordant results), followed by mPCR and Seq together (15.6%). Culture was only superior in 9.1% of cases, whereas no overall superiority was determined for 16.8% of concordant results.

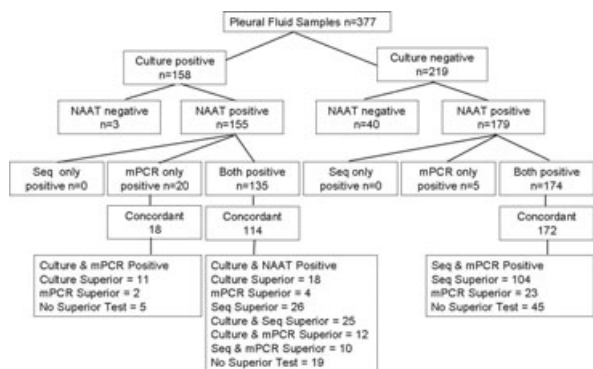

Figure 1. Diagnosis of Pleural Infection. Pleural fluid samples were subjected to standard culture methods to determine infection. Samples were then tested by two nucleic acid amplification techniques (NAAT), Seq and mPCR. When samples were positive by more than one method, only concordant samples were analysed for superiority of testing. Superiority of a test was defined as detecting the taxonomic classification to the highest precision, and/or the ability to detect multiple pathogens.

**Conclusions:** To our knowledge, this is the highest diagnostic yield of any study of this type conducted to date. In our study, NAAT was substantially superior to standard diagnostic methods. Sensitivity and specificity values for combined NAAT are 98.1% (confidence interval 94.6–99.4%) and 18.3% (confidence interval 13.7–23.9%) respectively, using culture as a “gold standard”. However, this poor result was due to NAAT identifying 47.5% more positive samples compared to culture, which leads us to question whether it should still be considered the “Gold Standard” for diagnostic techniques.

#### P1386 Spectrum of pathogens identified by molecular methods in patients with acute bacterial meningitis

E. Némecová\*, B. Malisová, M. Stechová, M. Freibergerová, R. Parížková, J. Juranková, T. Freiberger (Brno, CZ)

**Objectives:** Acute bacterial meningitis is a progressive illness with high morbidity and mortality. Fast diagnosis and early treatment are therefore crucial. The aim of this study was to characterise a spectrum of pathogens in Czech patients with acute bacterial meningitis.

**Methods:** Two hundred and sixty-eight samples of cerebrospinal fluid or brain abscess collected from adult patients with acute meningitis from 19 April 2004 to 14 November 2011 were included into this study. DNA was extracted using enzymatic pretreatment and QIAamp DNA Blood Mini Kit (Qiagen) and analysed by 16S rRNA broad-range PCR and direct sequencing. The results were available within 24 hour in a routine clinical setting.

**Results:** Bacterial DNA was detected in 104 (38.8%) cases, remaining 164 materials were negative. Out of positive samples, 80 (76.9%) belonged to aerobic or facultative anaerobic pathogens, 7 (6.7%) to anaerobic pathogens and causative agent was not specified due to poor PCR signal in 17 (16.3%) cases. *Streptococcus* spp., *Staphylococcus* spp., and *Neisseria meningitidis* were responsible for the vast majority of cases (67.3%). *Haemophilus influenzae* and *Listeria monocytogenes* were identified sporadically. Out of anaerobic bacteria, *Fusobacterium* spp. was detected in four and *Peptostreptococcus* spp. in three samples.

**Conclusion:** Broad-range 16S rRNA PCR followed by direct sequencing was shown to be a rapid and useful tool in detection of a wide range of acute bacterial meningitis causative agents. In addition, pathogens were detected even in cases of previous antibiotic application or presence of atypical or fastidious pathogens. Results should be interpreted carefully with respect to clinical and other laboratory signs of infection and possible contamination, mainly in cases of poor quality PCR signal and/or coagulase-negative staphylococci.

#### P1387 The nasopharyngeal microbiota in infants with acute otitis media

M. Hilty\*, W. Qi, S. Brugger, L. Frei, P. Agyeman, P. Frey, S. Aebi, K. Mühlemann (Berne, Zurich, CH)

**Objective:** Interspecies interactions of the nasopharyngeal microbiota are likely involved in the pathogenesis of acute otitis media (AOM). Capturing the breadth of microbial interactions requires a detailed description of the microbiota during health and AOM.

**Methods:** The nasopharyngeal microbiota of 163 infants with (n = 153) or without (n = 10) AOM was characterized using nasopharyngeal swabs (NPS) and multiplexed pyrosequencing of 16S rRNA. NPS were collected during four winter seasons between 2004 and 2010 for infants with AOM and during 2010 for controls.

**Results:** Fifty-eight bacterial families were identified of which Moraxellaceae, Streptococcaceae and Pasteurellaceae were the most frequent. Commensal families were less prevalent in infants with AOM compared to controls. In infants with AOM, prior exposure to antimicrobials and administration of the heptavalent conjugated pneumococcal polysaccharide vaccine (PCV7) were also associated with reduced prevalence of distinct commensal families (Streptococcaceae and Corynebacteriaceae). In addition, antimicrobial exposure increased the prevalence of Enterobacteriaceae and the abundance of Pasteurellaceae. Other factors, such as age, sex, day care and a history of recurrent AOM did not influence the microbiota.

**Conclusion:** The infant’s nasopharyngeal microbiota undergoes significant changes during AOM, and after exposure to antimicrobials and PCV7, which is mainly due to reduced prevalence of commensal bacterial families.

#### P1388 Detection and typing of *Streptococcus pneumoniae* by RT-PCR in clinical samples from children with acute otitis media

N. Alyabyeva\*, N. Mayanskiy, O. Ponomarenko, L. Katosova, T. Kulichenko, L. Namazova-Baranova (Moscow, RU)

**Objectives:** Isolation and typing of *Streptococcus pneumoniae* is routinely based on the classical microbiological methods, such as culturing and serological reactions, that require viable bacteria. The wide use of antibiotics and delay in microbiological analysis may preclude detection of *S. pneumoniae* in clinical samples justifying utilization of molecular methods for this purpose.

**Methods:** Nasopharyngeal swabs, tympanocentesis material or ear discharge in case of tympanum perforation were taken from children (age <5 years) with acute otitis media (AOM) by an eSwab collection and preservation kit (Copan). After swab inoculation for culture, DNA was extracted from the liquid preservation medium and used for RT-PCR with primers targeting specific *S. pneumoniae* *lytA* alleles. In the *lytA*-positive samples, separate RT-PCRs were done with primers for selected serotypes 19F, 6A/B, 23F and 14 that are the most prevalent serotypes in Russia. Serotyping of isolated *S. pneumoniae* was performed by Neufeld reaction.

**Results:** In total, we examined 67 samples from 31 patients with AOM. In 30 samples (45%) growth of relevant bacteria was found: *S. pneumoniae* – 8 (27%), *S. aureus*, *H. influenzae*, *M. catarrhalis* – 7 each (23% each), *S. pyogenes* – 1. In 15 samples, no growth was observed, in the remainder 22 samples physiological flora was present. Pneumococcal *lytA* RT-PCR was positive in 42 out of 67 samples (63%) including all eight samples where *S. pneumoniae* was isolated by culture. In 34 *S. pneumoniae* culture-negative/*lytA*-positive samples, no growth of relevant flora was observed. Serotype-specific RT-PCR with the selected serotype primers was positive in 26 samples (63%): 19F (n = 11, 26%), 23F (n = 5, 12%), 6A/B and 14 (n = 4, 10% each), 9V (n = 2, 5%). In each sample, only one serotype-specific RT-PCR was positive. RT-PCR results were in accordance to Neufeld serotyping in isolated *S. pneumoniae* strains (19F, n = 2; 9V, n = 2; 6A, n = 1; 23F, n = 1). Two isolates were typed only by Neufeld reaction (serotypes 19A and 38), specific RT-PCR for these serotypes was not used.

**Conclusion:** Our study demonstrates that PCR-based detection and typing of *S. pneumoniae* may be directly applied to clinical samples. Higher yield of RT-PCR-positive samples in comparison to culture is unlikely to reflect the presence of etiologically irrelevant bacterial debris because the *lytA*-positive samples were negative for other pathogens and RT-PCR gave similar to serological methods serotype distribution pattern.

**P1389** **Detection of *C. burnetii* DNA from patients with acute Q fever using a fluorescent nucleic acid dye (SYTO9) in a real-time PCR assay**

P.N.A. Harris\*, A. Cooper, G. Vincent, R.E. Norton, S. Graves (Newcastle, Townsville, Geelong, AU)

**Objectives:** This study aimed to assess whether a real-time polymerase chain reaction (PCR), using a novel fluorescent nucleic acid dye (SYTO9) and primers targeting the *com 1* gene, was able to reliably detect *C. burnetii* from acute phase sera in patients from an area with a high incidence of Q fever.

**Methods:** Serial 10-fold dilutions of *C. burnetii* DNA at known concentrations, extracted from the avirulent Nine Mile phase 2 (clone 4) strain, were tested by real-time PCR to obtain a standard curve and to ascertain the reportable linear range. The analytical sensitivity (limit of detection) was determined by Probit analysis for 60 samples with low copy numbers. Primer specificity was determined by testing DNA extracts from a selection of non-Coxiella bacteria. The assay was then tested on stored acute phase sera from patients with acute Q fever (confirmed by serological criteria) as well as clinical samples without serological evidence of Q fever to determine sensitivity and specificity. Performance of the assay was further compared with a reference real-time PCR method on a selection of blinded samples.

**Results:** The assay was found to have a reportable linear range of between  $10^1$  and  $10^5$  copies/ $\mu$ L. The lower limit of detection for 95% of samples was 4 copies/ $\mu$ L. No positive results were found when tested against non-Coxiella bacterial extracts. There was 88% agreement between the assay and a routine reference PCR when tested on 84 samples = 0.74 [0.59–0.88];  $p < 0.0001$ . In clinical specimens (37 with confirmed acute Q fever and 24 with no Q fever), the assay had a sensitivity of only 40.5% (24.8–57.9%), but a specificity of 100% (85.8–100%). However, when a subset of Phase 2 IgM non-reactive samples were analysed the sensitivity increased to 66.7% (34.9–90.1%).

**Conclusions:** The SYTO9-based real time PCR assay was able to detect *C. burnetii* from acute phase human sera. While the assay was very specific, the sensitivity was modest but improved when tested on Phase 2 IgM non-reactive samples. The assay was less sensitive than a reference PCR using oligonucleotide probes and two primer targets. Incorporation of PCR into routine testing algorithms for acute Q fever, especially if the Phase 2 IgM is non-reactive, would improve the early detection of *C. burnetii*. Although this SYTO9-based assay has some advantages in relative low cost and improved specificity by melt-curve analysis, its lesser sensitivity may limit its utility

**P1390** **Identity and quantity of micro-organisms in necrotising fasciitis determined by culture based and molecular methods**

V.B. Rudkjøbing\*, T.R. Thomsen, P.H. Nielsen, R. Melton-Kreft, A. Ahmed, G.D. Ehrlich, C. Moser (Aalborg, DK; Pittsburgh, US; Copenhagen, DK)

**Objectives:** Necrotising fasciitis (NF), commonly known as flesh eating disease is a fast progressing, potentially lethal infection of the subcutaneous tissue/fascia. Treatment includes high doses of intravenous antibiotics and aggressive surgical debridement. Accurate identification of the microorganisms may add to the knowledge of NF pathogenesis and influence the administration of antibiotics, and thereby potentially improve the outcome for the patients. Here we investigate the applicability of different molecular methods compared to standard culture-based methods.

**Methods:** Twenty one samples were obtained during debridement of NF patients (n = 8). Samples were investigated by standard bacteriological examination (culture and microscopy) at Copenhagen University Hospital, Denmark, and a range of molecular methods. The best DNA extraction protocol was chosen based on tests of five protocols performed on five NF samples. Molecular methods included full-length 16S rRNA gene analysis, real-time PCR, the Ibis T5000 Biosensor System, and 454 pyrosequencing of partial 16S rRNA genes.

**Results:** No growth of bacteria was observed in nine samples (43%); of these microscopy revealed Gram-positive cocci in chains in two samples. Molecular methods were positive for all samples. Culture identified *Streptococcus* sp. in most cases (48%). By molecular methods the incidence was increased (90%) and identification to species level was possible, with *S. pyogenes* being dominant (85% of samples with *Streptococcus*). Real-time PCR showed dominance of *Streptococcus* sp. in the samples, however some additional bacteria were found. The remaining samples were found to contain yeast by culture and a mixture of *Mycoplasma* sp., *Fusobacterium necrophorum* and *Candida albicans* by molecular methods. Overall polymicrobial findings were more common by molecular- than culture-based methods.

**Conclusion:** Correspondence between findings by culture-based and molecular methods indicates that the latter may be an appropriate method. The advantages of using molecular methods are: (i) identification of the pathogen(s) even when antibiotics have been administered and (ii) less time-consumption than conventional culture. The challenge is the interpretation of the significance of the findings by molecular methods. The use of the molecular methods will potentially enable a more rapid adjustment from empiric antibiotic treatment to defined treatment directed at identified microorganisms.

**P1391** **Flow cytometry assay of adenylate cyclase toxin of *Bordetella pertussis* CyaA preparations on phagocytosis**

A. Khosravani\*, A. Sharifi, H.R. Mohammadi, B. Sharifi, A.R. Rezaee (Yasouj, Mashhad, IR)

**Introduction:** Using flow cytometry, the phagocytic ingestion of *E. coli* by human peripheral blood cells from healthy donors, J774.2 mouse macrophages and U937 human monoblastic cells was determined after exposure to different concentrations of CyaA .

**Material and Methods:** This technique was developed for the evaluation of phagocytosis activity in human peripheral blood (neutrophils and monocytes) and other cells. Ingestion activity was measured as the mean fluorescence intensity (MFI) produced after 20 minutes of incubation with FITC-conjugated *E. coli*. All tubes were read by flow cytometry at a wavelength of 488 nm after quenching and DNA staining.

**Results:** Exposure of granulocytes or J774.2 cells to different concentration of CyaA and CyaA\* (0.05, 0.1, 0.2 mg/mL final concentrations) resulted in significantly lower mean neutrophil ingestion in the presence of CyaA. The results also showed that phagocytosis was significantly impaired by increases in CyaA concentrations for granulocytes and J774.2 cells compared to cells treated with PBS. With 0.2 mg protein/mL of CyaA there was almost complete (92%) inhibition of phagocytosis by J774.2 cells and 63% inhibition of phagocytosis by human granulocyte cells.

**Conclusions:** The flow cytometry histograms that represents the amount of ingested *E. coli*, also indicated the dose-dependent inhibitory effect of CyaA on J774.2 and granulocytes.

Overall the results of this assay would imply that inhibition of phagocytosis by CyaA was due mainly to the AC enzymic activity of the protein.

**P1392** *Bordetella* PCR methods in Europe. A EUVAC.NET/ ECDC supported study

T. Dalby\*, K. Krogfelt, N. Fry, Q. He (Copenhagen, DK; London, UK; Turku, FI)

**Objectives:** The study was performed in order to evaluate the differences and the quality of PCR methods for diagnosis of *Bordetella pertussis* infections around Europe. The study was initiated by the EUVAC.NET organization on an ECDC grant.

**Methods:** Twenty four laboratories from 19 European countries participated in the study. Eight coded samples were sent to the laboratories for analysis by their respective in-house PCR methods in use for laboratory diagnosis of *B. pertussis* infections. Five samples contained *B. pertussis* DNA in varying concentrations, one sample contained *B. parapertussis* DNA, one contained *B. holmesii* DNA and the last sample was a negative control.

**Results:** The PCR methods in use around Europe were very different. None of the laboratories were able to identify all eight samples in detail and only one laboratory was able to correctly identify the *B. holmesii* DNA. Ten (42%) laboratories tested only for the presence of *B. pertussis* DNA and were thus not able to diagnose infections by *B. parapertussis* or by other bordetellae; three of these laboratories identified the *B. parapertussis* DNA as a *B. pertussis* sample. Fourteen (58%) of the laboratories identified the *B. holmesii* DNA as *B. pertussis*. As expected, real-time PCR was generally capable of detecting lower concentrations of DNA than block-based PCR. However, in two instances real-time PCR identified the negative control as a weak positive. All laboratories correctly identified the high concentrations of *B. pertussis* DNA.

**Conclusions:** When laboratory-surveillance data around Europe are to be compared there is a need for standardized methods. This study underlines the need for standardization of PCR methods for diagnosis of *B. pertussis* as large differences were observed in the ability to identify DNA from different species of *Bordetella*. Infection by *B. parapertussis* is not uncommon, and the laboratories need to be able to discriminate between this and *B. pertussis*. Infection by *B. holmesii* is less common, but it is however important that laboratories are aware of the possible false-positive *B. pertussis* results caused by *B. holmesii* DNA.

**P1393** Phage mini-antibodies and their use for detection of microbial cells by using electro-acoustic sensor

O. Guliy\*, B. Zaitsev, I. Kuznetsov, A. Shikhabudinov, O. Karavaeva, L. Dykman, S. Staroverov, O. Ignatov (Saratov, RU)

Nowadays, cell detection in molecular biology is performed with the help of genetic engineering technologies for cloning recognizing

fragments (hypervariable immunoglobulin domains). These technologies are cheaper and can be competitive in selectivity with hybridoma technologies. One such method is antibody phage-display.

**Objectives:** Obtaining the phage-displayed mini-antibodies to *Azospirillum brasilense* Sp245 as example, and their use for detection of microbial cells by using electro-acoustic sensor.

**Methods:** All experiments were conducted by specially manufactured sensor based on a resonator with a transverse electric field in the frequency range 6–7 MHz.

**Results:** The first preparation of phage mini-antibodies to *Azospirillum brasilense* Sp245 surface antigens was made by using a combinatorial phage library of sheep antibodies. The prepared phage mini-antibodies were used for cell detection by dot assay, electro-acoustic analysis of cell suspensions, and transmission electron microscopy. It has been found that the frequency dependencies of the real and imaginary parts of the electrical impedance of the resonator loaded by the cell suspension *A. brasilense* Sp245 with the phage mini-antibodies, significantly differs from ones of the resonator with the control cell suspension without phage mini-antibodies. The electro-acoustic results were in good agreement with the electron microscopic data. We have shown that the concentration limit of a possible determination of the microbial cells in their interaction with the phage mini-antibodies is equal  $10^3$  cells/mL. It has been also found that the detection of cell *A. brasilense* Sp245 using the phage mini-antibodies is possible even in the presence of other cultures.

**Conclusion:** These results demonstrate the promise of analysis of microbial suspensions using a lateral electric field excited piezoelectric resonator and show the possibility of developing a biological sensor for the quantitative detection of microbial cells. This is the first reported possibility of employing phage mini-antibodies in bacterial detection aided by electro-acoustic analysis of cell suspensions.

**P1394** Bacterial and fungal infections of the cystic fibrosis lung: what can we learn from combining culture, RFLP and pyrosequencing approaches?

F. Botterel\*, O. Cabaret, F. Stressmann, D. Rivett, F. Wallet, B. Wallaert, K. Bruce, L. Delhaes (Creteil, FR; London, UK; Lille, FR)

**Objectives:** Given the polymicrobial nature of pulmonary infections in patients with cystic fibrosis (CF), it is essential to enhance our knowledge on the composition of the microbial community to improve CF management. Our aim was to identify bacterial and fungal communities present in CF sputa by combining culture-based and independent approaches, including a new pyrosequencing approach.

**Methods:** Results from conventional microbiological culture for fungi and bacteria in four sputum samples from adult CF patients (followed at Lille Hospital, France) were compared with those from molecular methods.

Terminal Restriction Fragment Length Polymorphism (T-RFLP) analysis was used to examine the dominant bacterial community members by resolving ribosomal RNA (rRNA) gene fragments. Fungal populations were characterized by performing an ITS-RFLP method followed by cloning and sequencing of gene products. A pyrosequencing method targeting the 16S rRNA gene and ITS2 locus was also applied. Results of deep-sequencing, RFLP and conventional methods were compared.

**Results:** Using RFLP methods, we identified 6.5 bacterial species (range 2–15), and 2 (range 1–4) micromycetes. This was confirmed by cloning. A comparable mean number of microbial species per sputum was obtained using the pyrosequencing method. In addition, a detailed phylogenetic analysis showed high molecular diversity at the sub-species level for the main fungal and bacterial taxa identified in the present study.

Culture-based findings were compared to the culture-independent data and species richness as well as evenness of fungi and bacteria is discussed in relation to clinical data on the CF patients followed.

**Conclusion:** The present pyrosequencing approach evaluates more extensively the diversity of fungi and bacteria compare to culture-based

methods. Further work is required to explore the clinical pertinence of pyrosequencing for informing therapy.

Grants: This work was supported in part by PFIZER and by APHP.

**P1395 Variants in the colony-stimulating-factor 1 region and risk of childhood meningococcal meningitis: a Danish genome-wide association study**

M. Nørgaard\*, F. Skjøth, T.L. Benfield, M.V. Hollegaard, D.M. Hougaard, Z.B. Harboe, T.L. Lash, K.L. Lunetta, H.T. Sørensen (Aarhus, Aalborg, Hvidovre, Copenhagen, DK; Boston, US)

**Objectives:** To identify host genetic susceptibility variants in cases of childhood meningococcal disease and controls and to validate potential single-nucleotide polymorphism (SNP) variations in a separate case control analysis.

**Methods:** Through the registries at the Danish National Neisseria and *Streptococcus* Reference Center, Statens Serum Institut, we identified children below age of 5 years who had invasive meningococcal disease in the period 1982–2006. For each case we selected a control matched on age and place of birth.

We identified neonatal dried bloodspots on potential cases and controls in the Danish Neonatal Screening Biobank and extracted DNA. We used the Illumina Infinium HD HumanOmni1-Quad chip array for the initial genome-wide association study (GWAS). We required call rates >95%, a minor allelic frequency >0.1, and a significance level for Hardy Weinberg >0.001 (Fisher's exact test). Following the GWAS we selected SNPs based on either biological function or strength of the association. We validated selected SNPs using the KASPar technique.

**Results:** We identified 841 children who presented with meningococcal meningitis before age 5. For the initial GWAS we obtained DNA from 376 of these children and 440 controls without any episodes of meningococcal disease. For validation we additionally obtained DNA from 274 children who presented with meningococcal bacteraemia and 274 controls.

In the GWAS analysis two SNPs encoding colony stimulating factor 1 (CSF-1) were found among the 500 SNPs with strongest association to disease status. For rs333949 the minor allele frequency among cases was 0.18 and among controls it was 0.25 corresponding to an odds ratio (OR) for meningococcal disease of 0.68 ( $p = 0.003$ ). For rs333951 the minor allele frequency among cases was 0.22 and among controls it was 0.30 corresponding to an OR for meningococcal disease of 0.68 ( $p = 0.002$ ).

In the validation study the minor allele frequency for rs333949 was 0.19 among 270 cases and 0.27 among 268 controls, the corresponding OR was 0.61 (95% confidence interval [CI], 0.45–0.81). For rs333951 the minor allele frequency was 0.23 among 263 cases and among 268 controls it was 0.33, OR 0.60 (95% CI, 0.45–0.79).

**Conclusion:** In this study including more than 600 Danish children who had an episode of meningococcal meningitis or meningococcal bacteraemia before age 5 we found that variation in the CSF-1 region may be associated with host susceptibility to meningococcal disease.

**P1396 MALDI-TOF mass spectrometry based methods for the characterisation of enterococci**

T. Parfenova\*, A. Philimonova, L. Borisova, T. Chermenkaya, E. Ilina, M. Kostrzewa, V. Govorum (Moscow, RU)

**Objective:** Vancomycin-resistant enterococci have a leading position among the pathogens causing nosocomial infections. Their rapid identification to species as well as differentiation in accordance with their drug sensitivity is very important to choose the correct treatment strategy. In our work we applied a mass spectrometry based approach for identification and differentiation of enterococci.

**Methods:** In total 162 enterococci isolates were collected. Susceptibility testing to glycopeptides (vancomycin, and teicoplanin) was done for each strain. Identification to species level was performed by MALDI Biotyper technique (Bruker Daltonics, Germany). The

correctness of identification was confirmed by 16S rRNA gene sequencing and PCR using species-specific primers of the *ddl* gene encoding Ddl-ligase enzymes. Also the presence of genes conferring the resistance to glycopeptides (*vanA*, *vanB*, *vanC-1*, *vanC-2/3*, *vanD*, *vanE*, *vanG*, *vanL*, *vanM*) was estimated by PCR. Cluster analysis of mass spectra collected from enterococci with different resistant profiles was carried out using software package MALDI Biotyper 3.0.

**Results:** The 95 *E. faecalis*, 56 *E. faecium*, 1 *E. raffinosus*, 6 *E. gallinarum*, 2 *E. avium*, 1 *E. casseliflavus*, 1 *E. hirae* were correctly identified at the species level. All *E. faecalis* appeared to be susceptible to vancomycin and teicoplanin and did not carry any of the drug resistance markers. Among *E. faecium* there were 21 drug susceptible isolates without any of the *van* genes present. All 35 drug resistant isolates carried *vanA* ( $n = 20$ ), *vanB* ( $n = 10$ ), *vanC-1* ( $n = 1$ ) or both *vanA* and *vanB* ( $n = 4$ ) genes.

Preliminarily a small group from *E. faecium* was selected for thoughtful cluster analysis of mass spectra. There were four isolates of a sensitive profile, and eight resistant isolates – four of a *VanA* genotype, and four of a *VanB* genotype. Composition analysis as well as dendrograms undoubtedly divided collected mass spectra into two groups in accordance with phenotype characterization without any differences between isolates carrying *vanA* or *vanB* genes.

**Conclusion:** Novel reproducible and efficient approach based on the MALDI ToF MS is reliable of species identification and characterization of enterococci. The differentiation of vancomycin-resistant from susceptible *E. faecium* has to be confirmed with further isolates from different regions.

**P1397 Evaluation of the QuickFISH BC test, a rapid method to distinguish *Staphylococcus aureus* from coagulase-negative staphylococci in positive blood cultures**

E. Carretto\*, M. Mirra, M. Bardaro, S. Ferretti, C. Zuelli (Reggio Emilia, IT)

**Objective:** the reduction of turn around time (TAT) for blood cultures is a major goal in clinical microbiology. Recently, a ‘‘peptide nucleic acid fluorescence in situ hybridisation test’’ (PNA-FISH, AdvanDX) has become available in clinical practice, allowing the identification of some microorganisms directly from positive blood culture bottles in 90 minutes. A modification of this technique (Staphylococcus QuickFISH BC, AdvanDX) is currently under evaluation: it allows the distinction between *Staphylococcus aureus* (SA) and coagulase negative staphylococci (CNS) with a 20 minutes procedure. Aim of this study was to evaluate the performance of this test on different sets of blood cultures positive for Gram-positive cocci in clusters.

**Methods:** the blood cultures were analyzed using the Bactec system (Becton Dickinson, USA). The samples showing Gram positive cocci in clusters were examined using the Staphylococcus QuickFISH BC, performed according to the manufacturer procedure, and the coagulase tube test. Quick-FISH BC slides were read independently by different test operators and blinded to the final results with traditional techniques. The identification of the microorganisms grown from cultures were performed using Vitek2 (BioMerieux, France).

**Results:** Fifty-nine blood cultures of 44 different patients were analyzed. Sixty staphylococcal isolates were identified (one bottle yielded two different strains). In particular 23 *S. epidermidis*, 21 *S. aureus*, 7 *S. hominis*, 4 *S. capitis*, 3 *S. haemolyticus*, 1 *S. warneri* were identified by Vitek2; one coagulase negative strain was not identified at species level. The direct coagulase tube test was negative, after incubation at 36°C, both after 4 hour and after 24 hour for all the CNS. Among the 21 *S. aureus*, 18 were positive after 4 hour incubation, two were negative after 4 hour but positive after 24 hour, one strain was still negative after 24 hour. There was no discrepancies between the QuickFISH test results and the phenotypic identification.

**Conclusion:** This study demonstrates the excellent agreement between QuickFISH test and standard laboratory techniques in identifying staphylococcal strains from positive blood cultures. Although the direct coagulase tube test is cheaper, QuickFISH BC appears quick, reliable

and easy to perform. For its reduced time of analysis, this test can be performed also in the late afternoon, when direct coagulase tube test is useless. This is very important for patient with *Staphylococcus aureus* bacteremias.

## Molecular epidemiology of bacterial infections

### P1398 Characterisation and typing of *Staphylococcus aureus* isolates from deep neck space infections in India

B.K. Pati\*, S. KrishnaPrakash, A.K. Agarwal, B. Uppal, A. Gulati (Lucknow, New Delhi, IN)

**Aims and objectives:** To screen for methicillin resistance (MRSA) and to determine the antimicrobial susceptibility pattern of all the isolates of *Staphylococcus aureus* from deep neck space infections (DNSIs). To characterize all the *Staphylococcus aureus* isolates by phage typing; and the MRSA isolates by biotyping and typing by antibiogram, in addition.

**Materials and methods:** A total of 56 cases of DNSIs from a 1600-bedded tertiary care teaching hospital of New Delhi were recruited. Aspirated pus from the patients were cultured and the *Staphylococcus aureus* isolates were identified by conventional techniques. The antimicrobial susceptibility against a wide range of antimicrobial agents was performed by the disc diffusion method employing the modified Stokes' technique. The MICs of vancomycin, teicoplanin, amikacin, ciprofloxacin, mupirocin, fusidic acid were determined by the E test. Screening for methicillin resistance was performed both by cefoxitin disc method as well as oxacillin agar screening method. All the isolates were subjected to bacteriophage typing by the 23 conventional (basic) set of phages (Blair et al). All the MRSA isolates were further subjected to biotyping (Coia et al.) and a novel typing method using the antibiogram.

**Observations:** *Staphylococcus aureus* was isolated in 46.4% of cases (n = 56). Of the 26 isolates of *Staphylococcus aureus* obtained, 3(11.5%) were identified as MRSA. Penicillin resistance was found to be 100% among *S. aureus* isolates. Cotrimoxazole resistance was seen in 100% of MRSA and 69.6% of methicillin Sensitive *S. aureus* (MSSA) isolates, while ciprofloxacin resistance in 66.6% and 56.8% respectively. However, all the *S. aureus* isolates were uniformly sensitive to vancomycin and teicoplanin at MIC90 value of 2 µg/mL for both. An overall phage typeability of 53.9% was observed for the isolates with maximum in the mixed group of phages (39.1%). Biotyping of MRSA isolates showed that all the three MRSA isolates belonged to biotype A. Based on the antibiogram pattern, the three different isolates of MRSA showed three distinct resistant phenotypes.

**Conclusions:** All the MRSA isolates were found to be non multi resistant oxacillin resistant *Staphylococcus aureus* (NORSA).

### P1399 Correlation between molecular types and minimal inhibitory concentration to vancomycin among methicillin-resistant *Staphylococcus aureus* isolates from sterile sites: TIST study, 2006–2010

W. Wang\*, T. Chiueh, J. Lu, P. Hsueh, S. Tsao (Taichung, Taipei, Tao-Yuan, TW)

**Objectives:** This goal of this study was to illustrate the molecular and phenotypic characters of methicillin-resistant *Staphylococcus aureus* (MRSA) strains from sterile sites and delineate the correlation between them.

**Materials and methods:** MRSA isolates from sterile sites of patients with invasive MRSA infections were collected from 22 teaching hospitals in Taiwan during a 5-year study period (Tigecycline In-vitro Surveillance in Taiwan – TIST, 2006–2010). MRSA were confirmed with resistance to cefoxitin disc and presence of *mecA* gene. All isolates were analyzed with molecular typing methods including staphylococcal chromosome cassette *mecA* (SCCmec), gene encoding accessory gene regulator (*agr*), and direct repeat unit (*dru*) and phenotyping method

with minimal inhibitory concentration (MIC) to vancomycin by agar dilution.

**Results:** Totally 688 isolates labeled as MRSA were collected from sterile sites of patients with invasive infections. Among these, 670 MRSA isolates (mostly from blood, 93.7%) were confirmed with cefoxitin resistance and *mecA* existence. The median and mean of vancomycin MIC of these isolates were 1 and 1.31 mg/L, respectively (range: 1–3 mg/L). The highest mean MIC occurred in 2007 (1.57 mg/L) and gradually decreased to the lowest value (1.10 mg/L) in 2010 significantly ( $p < 0.001$ ). SCCmecIII (256, 38.2%), IV (144, 21.5%), II (131, 20%) and VT (77, 11.5%); *agr* group I (495, 73.9%) and II (139, 20.7%); and *dru*14 (216, 32.2%), 9 (140, 20.9%), 4 (116, 17.3%), and 11 (77, 11.5%) accounted the majority of MRSA isolates. Strains with SCCmec II and III were found to have higher MICs than those with SCCmec IV, V, and VT. The decrease in mean MIC to vancomycin in the 5-year study period was associated with the increase in strains with SCCmecIV, V, and VT and the subsequent decrease in strains with SCCmecII and III ( $p < 0.001$ ).

Figure 1. Distribution of minimal inhibitory concentration (MIC) of 670 MRSA isolates from sterile sites and the trend of mean MIC from 2006 to 2010

**Conclusion:** No vancomycin creep was observed in the 5-year period. The trend with decreased MIC to vancomycin was associated with the changing molecular epidemiology of MRSA isolates, which reflected the increasing numbers and proportion of molecularly community-associated MRSA (CA-MRSA) strains in clinical settings.

### P1400 Molecular characterisation of Panton-Valentine leukocidin-positive *Staphylococcus aureus* in southwestern England

A. Hidalgo-Arroyo\*, E. Woodward, J. Leeming, A. Kearns, J. Sunderland, J. Steer, A. Lovering (Bristol, London, Plymouth, UK)

**Objectives:** In the last decade there has been an increase in PVL toxin-producing (PVL+) methicillin sensitive *S. aureus* (SA) community-acquired infections in one city in South West England. The objective of this study was to assess whether this was linked to higher nasal carriage rates compared to other cities and to determine whether molecular typing could identify clonal relationships among PVL+ nasal and clinical strains circulating in this region.

**Methods:** In 2009–2010, swabs were sent to a representative sample of adults in three cities of SW England. Self-taken nasal swabs were returned and cultured for SA. These strains, plus SA isolated from community-acquired infections in each location, were screened for *pvl* and *mecA* by PCR. All PVL+ SAs, MRSAs and 181 randomly selected MSSAs were genotyped by *spa* typing. The multilocus sequence type clonal complex (CC) was then inferred from *spa* types where possible.

**Results:** SA was recovered from 553 of 1952 nasal swabs (28.3%). Six isolates (1.0%) were PVL+ with no statistically significant association with geographic locality (Chi square test  $p > 0.05$ ). In contrast, 28 of 578 (4.8%) clinical isolates were PVL+; 4.3% in city A, 0.6% in city B and 7.8% in city C ( $p < 0.05$ ). Only two PVL+ MRSA were detected;

one (a nasal isolate from city C) corresponded to the CA-MRSA USA 300 clone, the other (a clinical isolate from city B) corresponded to the emerging multi-resistant CA-MRSA Bengal Bay clone. PVL+ isolates comprised 18 spa types and nine CCs. All PVL+ nasal isolates had different spa types and CCs. Spa types t008 (CC8) and t355 (CC152) were common in both nasal and clinical PVL+ isolates. In contrast, spa type t417 (CC22) was the most common among clinical PVL+ isolates (10/28, 35.7%), but was not found among any nasal or PVL negative isolates. Other CC22 spa types were common among both clinical and nasal isolates.

**Conclusions:** Community-acquired infection with PVL+ SA is uncommon in SW England but rates vary geographically. However carriage rates in the nares does not reflect this variation, indicating that community-based nasal screening poorly predicts pvl rates among isolates causing infection. This is consistent with the failure to identify the spa type (t417) accounting for over a third of PVL+ SA clinical isolates among nasal isolates. This clone was not geographically restricted, and the typing data did not suggest any explanation for the high incidence of PVL associated infection in city C.

**P1401** Community-acquired methicillin-resistant *Staphylococcus aureus* encoding the Pantone Valentine leukocidin genes are rarely detected in Istanbul and belong to ST22 and USA300 clones

L. Oksuz\*, A. Tristan, M. Bes, J. Etienne, N. Gurler (Istanbul, TR; Lyon, FR)

**Introduction:** Community-acquired methicillin resistant *Staphylococcus aureus* (CA-MRSA) containing the genes encoding Pantone Valentine leukocidin (PVL) have spread all over the world with various incidences and in different genetic backgrounds. For instance, the ST8 USA300 clone is more frequently detected in North and South America and Spain, whereas the ST80 clone is the major European clone, but is also frequently detected in Algeria; the PVL+ ST30 clone being more frequently detected in Oceania and Asia. Multiple other PVL+ CA-MRSA clones have been reported worldwide but few information are known about the epidemiology of PVL+ MRSA in Istanbul, Turkey.

**Methods:** From 2007 to 2011 we have collected all the MRSA isolates at the Istanbul Medical Faculty hospital in Istanbul. The resistance to methicillin was detected with cefoxitin disc, MRSA-agar and MRSA detection kit. The presence of the PVL genes was detected by PCR. The strains were also characterized using DNA microarrays obtained from Clonediag® and covering 334 target sequences corresponding to 185 distinct genes and their allelic variants. Sequence types were assigned by the microarray results analysis.

**Results:** On a total 88 MRSA, PVL positive MRSA were detected in four isolates only (4.5%), with the following characteristics:

**1** Two PVL positive MRSA isolates were assigned to the ST22 clone. One isolate was resistant to penicillin, gentamycin, tobramycin, kanamycin, erythromycin and the another one to penicillin, tobramycin, kanamycin, erythromycin, levofloxacin. Both of them carried the Staphylococcal Cassette Chromosome (SCC) mec type IV gene and were ermC-positive.

**2** Two PVL positive MRSA isolates were assigned to the ST8-USA300 clone. One of them carried the SCCmec type IV and arginine catabolic mobile element (ACME) genes and was resistant to penicillin, kanamycin, erythromycin. The other one carried only SCCmec type IV gene and was resistant to penicillin, kanamycin, erythromycin, levofloxacin.

These four PVL positive MRSA strains were isolated from outpatients with skin-soft tissue infections and considered to belong to community-acquired infections. The PVL positive ST80 European clone was not detected in Istanbul, whereas this clone is frequently detected in Greece that has common boarder with Turkey).

**Conclusion:** This first report described the characteristics of PVL positive CA-MRSA clones detected in Istanbul, Turkey: their rate of detection was low and they belonged to the ST22 and USA300 clones.

**P1402** Prevalence and significance of in vivo *mecA* gene deletions from the chromosome of *Staphylococcus aureus*

G. Barker\*, S. Bamber (Chester, UK)

Infection due to Methicillin Resistant *Staphylococcus aureus* (MRSA) causes a range of health-care associated infections (HCAIs). MRSA infection is associated with high morbidity and mortality, prolonged hospitalisation and increased health-care costs. As an aid to infection control, rapid screening for MRSA by molecular techniques has been introduced into many NHS hospitals. There are, however, problems with the specificity and sensitivity of the molecular techniques currently available.

Staphylococcal resistance for broad spectrum beta-lactams including methicillin, is encoded by the *mecA* gene. In *Staphylococcus aureus*, this is carried within a mobile genetic element termed SCCmec, which is inserted into the *S. aureus* genome at the *orfX* junction. As a result of selective pressures the *mecA* gene can be deleted from the SCCmec resulting in Methicillin Sensitive *Staphylococcus aureus* (MSSA). At present many molecular methods for the detection of MRSA use primers that specifically target the SCCmec. Therefore, methods detecting SCCmec only could lead to a false MRSA positive interpretation.

**Objectives:** The aim of this research is to enumerate the prevalence and identify the significance of *SCCmecA* gene deletions in the patient populations screened by the Microbiology Department, Countess of Chester NHS Foundation trust.

**Method:** The study population included 503 *S. aureus* isolates from the hospital and community and 50 clinical samples from the Countess of Chester Hospital.

Nucleic acid sequenced based amplification (NASBA) was performed on all the 503 Clinical isolates and the 50 clinical samples using NuclisensEasyQ (bioMerieux®). The Nuclisens EasyQ MRSA detection kit has primers for both the *mecA* gene and the SCCmec cassette *orfX* junction.

**Results:** 11.3% (57/503) of the clinical *S. aureus* isolates tested contained *mecA* gene deleted *S. aureus*.

Of the 50 clinical samples tested, MRSA was not detected, however 4% (2/50) of the clinical samples tested contained *mecA* gene deleted *S. aureus* which would have resulted in a false positive result by other methods.

**Conclusion:** The percentage of *mecA* gene deleted *S. aureus* present in the sample population would cause a significant false positive rate, therefore the need for a method which contains primers for the SCCmec cassette *orfX* junction and the *mecA* gene is essential.

**P1403** *Streptococcus agalactiae* serotype Ia ST23/ST24 are dominant among invasive infections in Portugal

E.R. Martins\*, J. Melo-Cristino, M. Ramirez (Lisbon, PT)

**Objectives:** We have characterized 225 group B streptococci (GBS) isolates recovered from invasive infections in non-pregnant adults in Portugal. Our aim was to document the prevalence of serotypes, antimicrobial resistance patterns and genetic lineages in this population as compared to the previously characterized neonatal population.

**Methods:** The GBS isolates were serotyped and assigned to clones according to their pulsed-field gel electrophoresis (PFGE) profiles and MLST-based sequence types. Susceptibility to penicillin, chloramphenicol, tetracycline, levofloxacin, erythromycin and clindamycin was tested by disk diffusion according to the CLSI guidelines. Macrolide-resistant phenotypes were determined by PCR by detection of the *erm* and *mef* genes. The presence of the surface protein genes *bca*, *alp2*, *alp3*, *alp4*, *eps* and *rib* genes was also tested by PCR.

**Results:** Our analysis revealed a GBS population showing a more diverse clonal composition when compared to that of neonates, consistent with the broader spectrum of disease presentation in these patients. Invasive disease in this population increased with age and was more frequent among men.

Whereas serotype V is dominant among invasive isolates recovered from non-pregnant adults elsewhere, serotype Ia was the most frequent in Portugal. Serotype Ia was represented mainly by a single PFGE cluster defined by ST23 and surface protein gene *eps*, and ST24 and *bca*, as previously seen in neonatal invasive infections in Portugal. This indicates that the same genetic lineages can be responsible for invasive disease in all age groups. Serotype V isolates were distributed into two genetic lineages, one defined by ST1, *alp3* and macrolide resistance, and another presenting with ST2, *eps* and fully susceptible to all antimicrobials tested. The *erm(TR)* gene was more frequent among erythromycin resistant isolates and the *tet(M)* gene was nearly ubiquitous.

**Conclusions:** The dominance of serotype Ia highlights the importance of this serotype in GBS pathogenesis as a leading cause of invasive infections in adults, regardless of age, contrasts to that found elsewhere but was already noted among neonatal infections in the Iberian Peninsula. Furthermore, the high prevalence of ST24, as opposed to rare descriptions elsewhere, suggests that this lineage has enhanced invasiveness and is probably expanding as a regionally successful clone that may disseminate more globally.

**P1404** First NDM-1-producing *Acinetobacter baumannii* in Belgium

R. Rezende de Castro\*, P. Bogaerts, S. Roisin, A. Deplano, T. Huang, M. Hallin, O. Denis, Y. Glupczynski (Yvoir, Brussels, BE)

**Objectives:** To characterize the genetic environment of a NDM-1-producing *Acinetobacter baumannii* (Ab) isolated from a patient who was repatriated to Belgium from Algeria in 2011.

**Methods:** Antimicrobial susceptibility testing was performed by microdilution method according to CLSI guidelines. Resistance genes were characterized by PCR, DNA microarray (Check-points CT102) and sequencing. The genetic background of blaNDM-1 was analysed by PCR mapping. Transferability of beta-lactam resistance was tested by broth mating-out assays and transformation of plasmids. Typing of the Ab strain was performed by multilocus sequence typing (MLST).

**Results:** A multidrug and carbapenem-resistant Ab isolate 11314 was recovered from a rectal swab specimen of a 20-year old patient in vegetative state transferred from Algeria to Belgium after severe traffic injury. The isolate was highly resistant to all beta-lactams including meropenem and imipenem (MIC  $\geq$  32 mg/L), aminoglycosides (gentamicin, tobramycin and amikacin), and quinolone (ciprofloxacin) but it remained susceptible to colistin (MIC = 0.5 mg/L), and tigecycline (MIC < 0.25 mg/L). PCR/sequencing and Check-points micro-array revealed the presence of blaNDM-1 only. A single non-typeable plasmid of 174 kb was detected but transfer experiments failed to demonstrate the presence of any carbapenem-resistant trait, suggesting that the blaNDM-1 was located on the chromosome. PCR-mapping revealed that blaNDM-1 was located between two direct repeat of ISAbA125 element in a transposon similar to the one reported in Ab 161/07 isolated in Germany (Pfeifer et al. JAC 2011; Accession Nr HQ857107). By MLST, Ab 11314 presented an allele profile 1-3-3-2-2-7-3 corresponding to sequence type (ST) 92 (Bartual et al., JCM 2005), a ST already described in many different regions of the world (mostly in association with OXA-23-producing Ab strains). Sequencing analysis of the intrinsic blaOXA-51-like and blaADC genes showed that this strain harboured the blaOXA-64 and the blaADC-26, neither of which were preceded by ISAbA1 nor ISAbA125.

**Conclusions:** Here, we report for the first time an *A. baumannii*-producing NDM-1 isolated in Belgium belonging to ST92. The blaNDM-1 gene was located in a composite transposon structure composed of two copies of the insertion sequence ISAbA125, very similar to the structure described for another *A. baumannii* strain (Ab 161/07) from Germany.

**P1405** Identification of IS1006 interrupting an ISAbA3 upstream of blaOXA-58 in *Acinetobacter baumannii* from a cancer patient in Egypt

L. Al-Hassan\*, H. El Mehallawy, B. Lopes, S. Amyes (Edinburgh, UK; Cairo, EG)

**Objectives:** *A. baumannii* is an important opportunistic infection that is commonly found in hospitals, particularly intensive care units. Class D carbapenemase blaOXA-58 is increasingly identified in *A. baumannii* as plasmid-mediated and is believed to confer carbapenem resistance when associated with insertion sequences (IS) upstream. We hereby report a carbapenem-sensitive *A. baumannii* strain isolated from a paediatric cancer patient in Egypt, harbouring blaOXA-58 with IS1006 interrupting an ISAbA3 upstream.

**Materials and methods:** The isolate was obtained from a catheter tip culture of a paediatric cancer patient in Cairo, identified by 16s-23s rRNA restriction analysis as well as by amplification and sequencing of the blaOXA-51-like gene. The presence of Class D Carbapenemases was performed by Multiplex PCR, and the upstream region of blaOXA-58 was amplified and sequenced accordingly. Minimum inhibitory concentrations (MICs) were determined according to BSAC guidelines

**Results:** The isolate possessed the chromosomal blaOXA-64 gene, now commonly found in the Middle East. In addition, it was also positive for blaOXA-58. Sequencing directly upstream of blaOXA-58 revealed the presence of ISAbA3, which would normally provide a suitable promoter and be associated with carbapenem resistance. However, the MICs of Imipenem and Meropenem were 4 and 1 mg/L, respectively. Sequencing also revealed that the ISAbA3 was interrupted by the incorporation of another insertion sequence, IS1006, 176 bp upstream of the start codon of blaOXA-58, which is interfering with the promoter of ISAbA3.

**Conclusion:** ISAbA3 has been previously reported upstream of blaOXA-58 conferring carbapenem resistance in *A. baumannii*. Our results suggest that the insertion of IS1006 in the ISAbA3 serves to switch off the resistance promoter, hereby rendering the isolate susceptible to carbapenems.

**P1406** Characterisation of invasive non-type B *Haemophilus influenzae* disease in children in England and Wales, 2003–2010

A.A. Vickers\*, D. Litt, S. Ladhani, M. Slack (London, UK)

**Objectives:** Characterisation of all non-serotype b invasive *Haemophilus influenzae* (Hi) isolates from children 1 month to 10 year of age in England and Wales (2003–2010).

**Methods:** The UK Health Protection Agency (HPA) routinely collects all invasive Hi isolates from hospitals in England and Wales as part of prospective, enhanced national surveillance of Hi disease. All non-type b encapsulated (serotypes a [Hia], c [Hic], d [Hid], e [Hie] and f [Hif]) and non-capsulated (NTHi) isolates of Hi from children aged 1 month–10 year received by the HPA between January 2003 and December 2010 were characterised by multilocus sequence typing (MLST), antibiotic susceptibility testing (BSAC agar dilution) and biotyping. 390 Hi isolates were examined (316 NTHi [81%], 58 Hif [15%], 13 Hie [3%], 2 Hic [ $<$ 1%] and 1 Hia [ $<$ 1%]).

**Results:** A small but steady increase in incidence of invasive non-b Hi disease was observed during the study period. MLST showed that capsulated isolates were highly clonal, clustering around a dominant ST within each serotype (Hie around ST18, ST124 Hif). Conversely, NTHi isolates exhibited a high degree of diversity, with 57 STs among 316 isolates. 59 novel STs were identified. No ST was found in isolates of different serotype. 93% (69/74) of capsulated strains were biotype I. By contrast, NTHi were diverse in biotype (42% biotype II, 22% biotype III, 16% biotype I, 16% biotype V and  $<$ 5% biotypes IV, VI, VII and VIII). 38% of strains were resistant to trimethoprim, 11% to ampicillin,

5% to amoxicillin-clavulanate, 2% to ceftriaxone and <1% to chloramphenicol, erythromycin, levofloxacin, rifampicin and tetracycline. 98% (42/43) of ampicillin-resistant strains were beta-lactamase positive. 21% (4/9) strains with intermediate susceptibility to ampicillin (MIC = 1 mg/L) carried known beta-lactamase-negative ampicillin-resistant (BLNAR) amino acid substitutions in *ftsI* (encoding PBP3). All BLNARs identified were NTHi.

**Conclusions:** The incidence of invasive non-type b Hi disease in children aged 1 month–10 year increased over the study period. Capsulated strains exhibited less genotypic and phenotypic diversity than NTHi strains. Rates of resistance to ampicillin, chloramphenicol and tetracycline were consistent with those observed in a study of invasive Hi disease in England and Wales between 1985 and 2004; trimethoprim resistance rates were substantially higher (38% c.f. 11%) than reported previously.

This study was funded by a grant from GlaxoSmithKline.

#### **P1407** Clonal structure of *Vibrio cholerae* El Tor strains isolated at the cholera outbreak in Yuzhno-Sakhalinsk, 1999

L. Mironova, M. Afanas'ev\*, S. Balakhonov, L. Urbanovich, E. Basov, E. Goldapel (Irkutsk, RU)

Epidemiological complications of cholera in Siberia and the Far East during 7-th pandemic were associated with introducing infection from other part of the world. Here we consider a largest outbreak of cholera in this region at last decade and a half. For retrospective outbreak analysis we used classical microbiological and epidemiological methods and modern molecular genetics techniques. The main aim of study was to identify of genetics features and clonal structure of outbreak *V. cholerae* strains. A total of 21 *V. cholerae* eltor strains isolated during cholera outbreak in Yuzhno-Sakhalinsk in 1999 were studied. Six of them were isolated from patients and six – from vibriocarriers. Demographic, social, epidemiological and clinical data were collected for each patient. Nine analyzed strains were isolated from environments at the same period. Standard microbiological procedures were used for strains identification. Complex genetics analysis was carried out by PCR-based biovar-specific and pathogenicity-associated genes detection (*ctxB*, *rstR*, *rstC*, *TLC*, *ctxAB*-promoter domain), *ctxB* and *ctxAB*-promoter sequencing analysis, MLST-typing (nine “housekeeping” genes – *dnaE*, *lap*, *recA*, *pgm*, *gyrB*, *cat*, *gmd*, *chi*, *rstA*) and PFGE-typing (with *CciNI* restriction enzyme).

During August–September, 1999, in Y.-Sakhalinsk 11 patients and 11 vibriocarriers were detected. Fourteen *V. cholerae* strains isolated from environment samples. Pending the epidemiological investigation probable ways and factors of infection's spread were revealed. All tested in present study strains (*n* = 21) belonged to *V. cholerae* serogroup O1 biovar eltor by its phenotypic features. Genetics structure of *ctxB* corresponded to classical biovar (*ctxB1* variant). All strains had identical biovar-specific and pathogenicity-associated genes profiles (*ctxB1* + *rstREI* + *rstRCl* + *rstC* + *TLC*- *tr4*) and sequence type and belonged to one genotype. Analysis of PFGE-patterns revealed seven genotypes (two cluster formed and five unique). We observed significant association between PFGE genotypes and individual foci within outbreak. Obtained DNA sequences have been deposited in GenBank under accession numbers HM366179, HM590455-56 (*ctxB*) and JN571738, JN579649-54 (*dnaE*).

PFGE-profiles polymorphism shows that clonal structure of *V. cholerae* eltor strains is heterogeneous. It may be associated with multiple importations of pathogen and forming unlinked foci of infection.

#### **P1408** Characterisation of invasive *Listeria monocytogenes* isolates in Poland, 1996–2010

A. Kuch, K. Wasiak, I. Wasko, A. Golebiewska, P. Ronkiewicz, M. Markowska, W. Hryniewicz\*, A. Skoczynska (Warsaw, PL)

**Objectives:** *Listeria monocytogenes* is the causative agent of invasive listeriosis that affects mainly newborns/neonates, pregnant women, the

elderly and immunocompromised patients. The aim of the study was to obtain the antimicrobial susceptibility data and serological profile of invasive isolates causing infections in Poland.

**Methods:** The study was performed on 196 invasive *Listeria monocytogenes* isolates (one isolate per patient) from 68 medical centres located in different parts of Poland, collected in the National Reference Centre for Bacterial Meningitis (NRCBM) between 1996 and 2010. All clinical isolates were identified according to standard procedures. PCR reactions were run to confirm species identification, serotype determination, and affiliation to epidemic clones (ECI, ECII or ECIII) according to protocol described by Chen et al. (2007) and Borucki et al. (2003). MICs were determined for 10 antimicrobials (ampicillin, penicillin, gentamicin, meropenem, co-trimoxazole, erythromycin, tetracycline, levofloxacin, vancomycin and rifampin) by the broth microdilution method and interpreted according to the EUCAST, BSAC and SFM guidelines.

**Results:** All but one isolates were grouped into three serotypes: 4b (59.2%), 1/2a (32.0%) and 1/2b (8.2%). The EC markers were found in 106 (54.0%) isolates tested. The most common represented was ECII (36.0%), followed by ECI (16.5%) and ECIII (1.5%). All the isolates were susceptible to ampicillin, penicillin, gentamicin, meropenem, erythromycin, levofloxacin, vancomycin and rifampin. Only one isolate (0.5%) showed resistance to tetracycline (MIC = 64 mg/L) and according to new co-trimoxazole breakpoints proposed by the EUCAST, 15 isolates (7.7%) with MIC values of 0.06 mg/L were resistant to this antibiotic.

**Conclusions:** Most of the invasive *Listeria monocytogenes* isolates in Poland belonged to the epidemic clones responsible for food-borne outbreaks worldwide. Almost 60% of isolates represented the serotype 4 b. Proposed by the EUCAST new breakpoints for *L. monocytogenes* reinforce the need for microbiological surveillance to determine adequate treatment of invasive listeriosis.

#### **P1409** Characterisation of six clinical isolates representing a novel *Actinomyces funkei*-variant

V. Hinic\*, C. Straub, P. Kaempfer, R. Frei, D. Goldenberger (Basel, CH; Giessen, DE)

**Objectives:** The genus *Actinomyces* comprises 37 described species but clinical significance of some recently described species still has to be documented. We isolated Gram-positive, non-sporeforming branched rods from six clinical specimens. On the basis of partial 16S rRNA gene sequence analysis, the strains were presumptively identified as *Actinomyces funkei*. However, further analysis of the entire 16S rRNA gene revealed significant differences between all six investigated strains and the *A. funkei* type strain indicating that the strains represent either a variant of *A. funkei* or a novel *Actinomyces* species.

**Methods:** The strains were isolated from hospitalized patients from Basel, Switzerland, between 2007 to 2010. They were characterized phenotypically and with routine biochemical methods. Partial and complete 16S rRNA gene sequences of the six isolates were determined and compared with each other and to the sequences deposited in MicroSeq and GenBank databases.

**Results:** Three strains were isolated from abscesses (gluteal, liver and vulva), two from deep wound swabs (epididymis and navel), and for one strain no clinical data were available. All isolates were facultatively anaerobic and catalase-negative. The identification by means of API Coryne kit gave the identification result *Arcanobacterium haemolyticum* for two strains and no identification for the remaining four strains. Species identification on the basis of partial 16S rRNA gene sequence comparison allocated the strains to *A. funkei*. However, sequencing of the whole 16S rRNA gene (HQ906497) showed 12 mutations/gaps compared to the *A. funkei* type strain AJ404889 which is consistent with 99.2% identity. Full 16S rRNA gene sequences from our six isolates were 100% identical to each other. Three strains have been deposited at CCUG Culture Collection in Göteborg, Sweden.

**Conclusion:** All strains were isolated from deep materials and involved in suppurative processes including abscess formation. The isolates could not be identified with routine biochemical methods. The entire 16S rRNA sequence differences between our investigated strains and the type strain of *A. funkei* indicate a variant of *A. funkei* which may represent a novel *Actinomyces* species. This has to be clarified with further taxonomic tools such as DNA-DNA hybridization analysis.

**P1410 Evaluation of a monitoring system for nosocomial pathogens in a burn centre by three molecular typing methods**

W.A. van der Reijden\*, S.A. Boers, I.F. van Ess-Visser, B.M.W. Diederer, R. Jansen (Haarlem, Beverwijk, NL)

**Introduction:** Burn wound patients are continuously at increased risk of developing infection by endogenous and exogenous pathogens. Early recognition of colonization and concomitantly typing of the colonizing strain may provide early infection prevention.

**Objective:** To determine a suitable monitoring program for infection prevention purposes of *Staphylococcus aureus* (SA) and *Pseudomonas aeruginosa* (PA) strains in a burn centre using molecular typing methods.

**Methods:** During a six-months period all SA and PA strains from 136 patients admitted at the Burn Centre, were isolated from the nose, throat, and perineum on admission and from wounds and infection sites on admission and thereafter twice a week. All strains were typed using High Throughput MLST (HiMLST) using NGS, AFLP and Raman spectrometry (RS) (SA only). Clustering of patients was defined as a group of at least two patients carrying an identical SA or PA strain.

**Results:** Using HiMLST, 12 clusters of patients carrying SA with unique sequence types (ST) could be defined. These ST-clusters comprising 2–8 patients can be subdivided into one to five AFLP types per cluster. This results in an average of 2.6 AFLP types per ST-cluster. If AFLP is used to cluster patients, these clusters can be subdivided into one to three ST per cluster. The number of ST per AFLP cluster is, however, lower than the opposite: 1.5. This implies a significantly higher discriminatory power of AFLP in contrast to HiMLST ( $p = 0.0185$ ). Comparable results were found using RS instead of AFLP although its discriminatory power is even higher.

Only three ST-clusters of patients with PA were found in which only one comprised two AFLP types. Conversely, both AFLP-clusters contained only one ST.

**Conclusions:** A high diversity of SA infections with a notable number of possible transmissions based on both HiMLST and, to lower extend, on AFLP and RS respectively, was found. Since AFLP and RS clusters can contain more than one ST, use of them in a monitoring system can result in a lower positive-predicted value to trace an outbreak. Moreover, AFLP data are prone to day-to-day variation and RS require strict standardized culture methods. HiMLST data however, can be stored easily without loss of quality and can be compared to custom-made and international databases.

In our view, the combination of HiMLST for continuously monitoring transmission and AFLP for occasional outbreak management is a feasible and reliable system for infection prevention.

**P1411 The ex-unibus plurum evolutionary concept applied to understand the dynamic of epidemics**

M.-C. Turrientes\*, F. Baquero, A. Ripoll, M.-R. Baquero, R. Cantón, J.-C. Galán (Madrid, ES)

**Objective:** We investigate the adaptive changes in metabolic functions that occur when a homogeneous population (clonal expansion in epidemics) begins to diversify.

**Methods:** A clone from an *Escherichia coli* clinical strain (homogeneous population) was submitted to serial passages during 200 days in unstructured environment. Every day, the culture was diluted 1:100 in fresh medium giving rise to evolved population during

1500 generations. After 1000 generations six evolved clones were chosen and biochemical profiles analyzed. Genomic DNA from these evolved clones was extracted, XbaI-digested and DNA fragment separated in CHEF-DRIII system. In addition, genomic RNA was obtained in order to determine global gene expression profiles in the evolved clones respect to ancestral clone using the AffymetrixGenechip technology. We analyzed the gene expression in only two metabolic pathways (tricarboxylic acid cycle, TCA, and glycolysis/gluconeogenesis) and repair pathways involved in the generation of adaptive mutations.

**Results:** PFGE and biochemical profiles of all the isolates were exactly the same suggesting that the evolved clones were identical to ancestral clone and the original population remained homogeneous. However, the global gene expression profiles yielded unexpected results. The differences in the number of genes with altered expression respect to ancestral clone ranged between 8.9% and 36.6%, suggesting different evolutionary trajectories in the adaptive process. The gene expression in TCA showed two different patterns suggesting two different subpopulations. Four clones showing the same TCA-pattern could be discriminate in two glycolysis/gluconeogenesis-patterns and each of these patterns could be differentiate in two patterns when the profile of repair pathways were compared. Therefore transcriptomic analysis of six clones with identical PFGE and biochemical profile allowed us to identify, at least, five different subpopulations derived of single ancestral clone coexisting in the same environment.

**Conclusion:** During the clonal expansion process of a winner clone in an epidemic, the initial homogeneous population explores all adaptive possibilities, increasing its survival probabilities and decreasing the possibility to be eradicated. When the population is homogeneous at the beginning of epidemics (ex-pluribus unum), the winner clone must be easier eliminated than when the same clone is diversified in multiples subpopulations (ex-unibus plurum).

**P1412 Relation of clinical and histological finding with prevalence of *cagA* gene of *H. pylori* in Iranian population**

H. Rezaee\*, H. Goudarzi, M. Rafizadeh, A. Taghavi (Tehran, IR)

**Background/Objective:** the aim of this study was to determine the relation among the cytotoxin associated gene (*cagA*) status of *Helicobacter pylori* isolates, the associated clinical diseases, and histopathological features of gastric disease in Iranian populations.

**Methods:** DNA was extracted from paraffin embedded gastric biopsies obtained from dyspeptic patients, and the *cagA* status determined by the PCR. The prevalence of *cagA* gene in three clinical groups, gastritis, gastric ulcer, and gastric malignancies was compared. The histological features in sections from antral and corpus biopsies were graded according to Sydney classification system criteria. The grades were compared with *cagA* gene status, and with clinical outcomes.

**Results:** Isolates from 86 patients were included. Forty-six (63.9%) were *cagA* positive. The prevalence of *cagA*+ strains in peptic ulcer

patients (43.5%) was rather greater than in those with gastritis (30%). Chronic inflammation, activity of gastritis, *H. pylori* density were all significantly more severe in the cagA+ than in the cagA- group (chart1).

**Conclusions:** *Helicobacter pylori* strains showing cagA positivity genotype are associated with infiltration of inflammatory cells in to gastric mucosa and accumulation of bacteria in infected area. but this virulence factor do not appear to determine the overall pattern. The pattern is closely linked to clinical disease. Therefore, the nature of the disease is determined by host, environmental factors, and bacterial factors determine the risk of developing such disease.

## Good to know: drug potency, purity, prescribing, errors and toxicity

### PI413 More potency assay results for EX-USA generic piperacillin/tazobactam lots and initial meropenem generic lots marketed in the USA

R. Jones\*, H. Sader, A. Watters, G. Moet, R. Flamm, D. Farrell (North Liberty, US)

**Objective:** To further assess piperacillin/tazobactam (P/T) generic lots in EX-USA nations and to initiate screening of meropenem (MER) generic lots recently (2011) marketed in the USA. P/T potency results expand prior experience reported in 2008 and 2009, performed by a precise, incremental MIC assay as published by Jones et al. (2008).

**Methods:** An additional 15 P/T generic lots (eight manufacturers; marketed in India, Chile, United Kingdom, and Sweden) were analyzed as part of an ongoing worldwide (EX-USA) screen that now includes results from 61 generic product lots (through 12/2010). Each lot was directly compared to a reference branded (Zosyn; Pfizer) lot or RBL using a previously described and validated assay method. MER lots (Hospira and Sandoz) from the USA were also tested and compared to a Merrem reference branded lot (TM0052; expirations of lots ranged from 06/2012–02/2013).

**Results:** The results (in 2010) of 15 P/T generic lots supplement reports of 46 other lots tested from EX-USA nations published in 2008 and 2009. Vials ranged from 2.25 to 4.5 g each and all were tested within labeled expiration dates. Orchid (three lots), Aurobindo (one lot), Libra (one lot), Wockhardt (two lots), Hospira (two lots), Sandoz (two lots), Fresenius-Kabi (two lots) and Stragen (two lots) generic products were assayed. Variations compared to P/T RBL were -23% to +3% (average, -10%; prior 46 lot experience was -16%). USA MER generic lots (Hospira [four lots], Sandoz [two lots]) exhibited potencies equal to Merrem RBL, without any significant variation, see Table.

Table Meropenem assay (MIC) results using branded (Merrem®) and five generic lots marketed in the USA.\*

Meropenem sample (exp. date)	Replicate MIC (µg/ml) for			
	<i>P. aeruginosa</i> ATCC 27853	<i>P. aeruginosa</i> 4-48716A	<i>E. cloacae</i> 106-49157A	<i>S. aureus</i> 104-37827A
Merrem TM0052 (06/2012)	0.313	0.156	0.045/0.038	0.045
Hospira 609A029 (06/2012)	0.313	0.156	0.045	0.045
Hospira 609B013 (12/2012)	0.313	0.156	0.038	0.045
Hospira 609B020 (12/2012)	0.313	0.156	0.038	0.045
Sandoz CA0710027A (04/2012)	0.313	0.156	0.038	0.045
Sandoz BN1589 (02/2013)	0.313	0.156	0.038	0.045
Variation (%)	(0.0)	(0.0)	(0.0)	(0.0)

a. Triplicate testing of four selected assay strains (3 wildtype [WT] by methods described earlier [Jones et al. 2008, Moet et al., 2010 and Sutter et al., 2011]. Vial strength was 0.5 or 1.0 gram for each product.

**Conclusions:** P/T generic lots marketed outside of the USA continue to demonstrate sub-optimal activity averaging 10–16% less activity when compared to the RBLs. Some lots, however, show comparable or acceptable activity. MER lots, FDA-approved for use in USA, exhibited equal activity compared to Merrem via this validated in-vitro assay

method. Hospital formulary practices should consider these documented differences between lots as well as between generic and branded products when making therapeutic choices.

### PI414 Particulate matter in combined intravenous antibiotics

J. Konsil\*, S. Supattanapong, O. Apirakkan (KhonKaen, TH)

**Introduction:** The manufacturing processes to combine antibiotics are typically more complicated than those of a single one. Variation in particulate contamination was reported earlier in multi-source IV antibiotics.

**Objectives:** To study the powder characterization and particulate matter in combined IV antibiotics, collected from the Southeast Asia region including products of ampicillin/sulbactam (A/S), amoxicillin/clavulanate (A/C), cefoperazone/sulbactam (C/S), and piperacillin/tazobactam (P/T).

**Method:** This was a double blinding study. Powder characterization was investigated using scanning electron microscope (SEM). Two laboratory methods were applied to investigate the contamination of particulate matter after reconstitution/storage, that is, microscopic (SEM) and electrical sensing zone methods. The samples of A/S, A/C and C/S were freshly reconstituted with particle-free water before testing. Only P/Z samples were dissolved in acidic particle free water with spike zinc concentration and stored for 24 hour at room temperature before analysis, based on the previous US pharmacopoeial recommendation.

**Results:** There were 16 commercially available products, collected during 2010–2011, that is, A/S (n = 3), A/C (n = 6), C/S (n = 3) and P/Z (n = 3). Most of combined antibiotics were manufactured by dry-fill sterile blend, except for one of the P/Z products that was made by lyophilization in primary vials. Difference in particle burden was found among samples, esp. for A/S, A/C and P/Z. The microscopic method revealed heavy load of the subvisible particles with sizes smaller than the routine quality control limit, that is, <10 µm for some samples of A/C and P/Z. The finding supported the necessary application of buffer and chelating agent in P/Z formulation. However, the sizes and shapes of the particles found in A/C samples revealed that they were unlikely to be the incomplete dissolving drugs. Most of the samples were complied with pharmacopoeial standard, that is, the numbers of particles with sizes ≥25 and ≥10 µm were not more than 600 and 6000 particles, respectively.

**Conclusion:** The commercially available products of combined antibiotics A/C and P/Z from Southeast Asia region were different in particulate matter, esp. with sizes <10 µm. The serious load of these small particles could possibly lead to inferior clinical safety/efficacy when used in critically ill patients with microvascular compromise.

### PI415 Error analysis in prescribing and administration of intravenous anti-infective therapy with standard infusion pump technology

K. Seeber\*, R. Pang, T. Markl, S. Lam, M. Hoeningl (Graz, AT; Melbourne, AU)

**Objectives:** The study was conducted to gain a better understanding of the nature of errors that happen during the prescribing and administration of continuous/intermittent intravenous (IV) anti-infective therapy with standard infusion pump technology. The aim was to characterize the different types of errors and find out the level of adherence to the hospital IV anti-infectives prescribing and administration protocols, The Society of Australian Hospital Pharmacists of Australia (the SHPA) Australian Injectable Drugs Handbook as well as international prescribing guidelines. Further we assessed preventability with smart pump technology.

**Methods:** Within a 3-months-period data was collected at the University Hospital of Frankston, Australia. Three data sources were reviewed: the doctor's handwritten prescription, the IV medication

additive label on the infusion bag and the displayed rate and volume on the infusion pump. Errors in terms of deviations (i.e. non-adherence) to protocols/guidelines and administration as well as formal prescribing errors (e.g. incomplete order/missing instructions) were defined. Each observed IV medication could contain one or more errors; each error was documented and evaluated independently. Data collection and evaluation were conducted by two different persons to ensure objective decisions. Preventability using the smart pump technology was determined based on a retrospective evaluation.

**Results:** IV medication errors occurred frequently and were widespread: almost half (42 of 100) anti-infectives prescribed with standard infusion pump technology were associated with errors. Errors happened with nearly all anti-infectives used. Non-adherence to protocols in prescribing or administration was identified as the most common source for errors (n = 35) followed by administration errors (n = 12). Thirty-two out of 47 (68%) non-adherence to protocols or administration errors were considered to be preventable if smart pump technology had been implemented. Details are outlined in Table 1.

Anti-infective Agents	No. Infusions	No. Infusions with Error(s)	Error Details			
			No. Non-Adherence to Protocol	No. Administration Error(s)	No. Prescribing Error(s)	No. Preventable with Smart Pump Technology
Aciclovir	7	2		2		
Amikacin	5	2	2		1	3
Benzylpenicillin	1					
Cefepime	2					
Ceftriaxone	4	1	1			1
Cefuroxime	7	4	3	1		2
Ceftazidime	2	2	4			2
Fluconazole	4	2	2			2
Flucanazole	4	2		2		
Miconazole	1					
Miconazole	5	2	1	1		1
Penicillin	2	1	1			1
Piperacillin-Tazobactam	1					
Ticarcillin-Clavulanic acid	13	10	9	2		9
Vancomycin	42	14	12	4	2	11
Total No.	100	42	35	12	3	32

TABLE 1. Anti-infective Agents Administered with Standard Infusion Pump Technology and Associated Errors

NOTE: \* More than one error type possible

**Conclusion:** Errors happened frequently with the use of standard infusion devices. Overall, non-adherence to the protocols was shown to be a major issue with rate deviations occurring most commonly. Administration was identified as the stage in the medication-use process that is most susceptible to errors. The most severe errors were those likely to be reduced by the implementation of smart pump technology.

#### P1416 Fluoroquinolones and QTc prolongation in the hospitalised population: first results from a case-series ongoing study

M.P. Zorzou\*, G. Giannikopoulos, A. Koulai, M. Psallas, E. Papadopoulou, M. Bouki, A. Kosti, C. Zotika, G. Panagi, I. Stamoulis, G. Dounias (Chios, Athens, GR)

**Objectives:** Although the effect of fluoroquinolones in QTc has long been described in either animal models, healthy volunteers or case reports, there are only sparse data regarding the clinical significance of such an effect in the hospitalized population. This prospective clinical study was designed in order to compare this effect in a hospitalized population, to identify the risk factors that potentially influence it and to clarify its clinical significance.

**Methods:** One hundred and seven patients receiving moxifloxacin, levofloxacin and ciprofloxacin were included in the study. QTc interval was recorded upon admission and at 72 hour of fluoroquinolones' initiation. The difference between the two prices was calculated. Patients' clinical characteristics, baseline renal and liver function, fluoroquinolone dosage and site of infection were registered. Renal function was reevaluated at 72 hour. Any cardiac events during hospitalization were recorded. Data analysis was performed with SPSS 17.

**Results:** Median age was 69 years. There were 56 men (52.3%). Nineteen Patients suffered from chronic kidney disease (17.8%). Twenty three patients (21.5%) already received medications known to interfere with QTc. Fifty-two patients were treated with levofloxacin, 35 with ciprofloxacin and 15 patients with moxifloxacin. QTc difference at 0 and 72-hour was estimated at 15.5 ms, which is statistically significant ( $p < 0.001$ ). QTc difference at 0 and 72-hour was estimated at 12.61 ms for the levofloxacin group, 16.93 for moxifloxacin and 19.34 for ciprofloxacin. Despite a tendency towards a longer prolongation for ciprofloxacin, no statistical significance was reached ( $p = 0.08$ ). Interestingly, patients with chronic kidney disease showed a shorter QTc prolongation (10.93 ms) than those with normal renal function (18.56 ms). Only two patients experienced supraventricular arrhythmia. No other serious adverse event was recorded.

**Conclusion:** Our data show that QTc was significantly prolonged in all patients under fluoroquinolones. However, only a trend toward a longer prolongation for ciprofloxacin was implied. Gender, age and preexisting cardiac disease did not influence this effect. In patients with normal renal function this phenomenon was more pronounced. QTc prolongation was not translated in adverse cardiac events, rendering fluoroquinolones a safe option for these predisposed, at-risk patients. As these are the first results from an ongoing study, caution is warranted before safer data can be extracted.

#### P1417 Effect of a suprathreshold dose of ceftazidime avibactam on the QTc interval in a thorough QT study

T. Edeki\*, S. Das, J. Armstrong, D. Mathews (Wilmington, US; Macclesfield, UK; Overland Park, US)

**Objectives:** Avibactam is a non-beta-lactam beta-lactamase inhibitor that has been shown to restore the in vitro activity of ceftazidime against extended-spectrum beta-lactamase-producing pathogens. A key aim of this study was to assess the potential effects of a suprathreshold dose of ceftazidime avibactam (CAZ-AVI) on cardiac repolarisation in a thorough QT (TQT) study.

**Methods:** This was a double-blind, randomised, placebo-controlled, 4-way crossover study in healthy males (n = 51; age 18–45 year; BMI 19.4–30.0 kg/m<sup>2</sup>). Each subject received, in randomised order: CAZ-AVI 3000 mg/2000 mg infused over 30 minute (following a 30-minute placebo [saline] infusion for blinding); ceftaroline fosamil avibactam 1500 mg/2000 mg infused over 60 minute (split into two infusion bags administered sequentially for 30 minute each); placebo (administered as for ceftaroline fosamil avibactam); and a single open-label oral dose of moxifloxacin 400 mg as a positive control for assay sensitivity. All treatments were separated by ≥3 days washout. Electrocardiogram (ECG) readings and safety were assessed. This abstract focuses on the CAZ-AVI ECG data. The least square mean differences vs. placebo in change in the Fridericia-corrected QT interval (QTcF) from baseline for CAZ-AVI at 10 time points over 24 hour were calculated with two-sided 90% confidence intervals (CIs). In order to conclude that there was no observed effect on the QTcF interval, all upper confidence bounds were required to be <10 ms. To determine assay sensitivity, the difference between moxifloxacin and placebo for the mean change from baseline in QTcF over the 1 to 4-hour post-dose interval was estimated, and the lower bound of the 90% CI was evaluated against a 5 ms threshold.

**Results:** In total, 43 subjects completed the study. Assay sensitivity was confirmed as the lower bound of the 90% CI for the difference between moxifloxacin and placebo for the mean change from baseline in QTcF over 1–4 hour was >5 ms (7.3 ms). In addition, the upper bound of the 90% CI for the difference between CAZ-AVI and placebo in the mean change from baseline in QTcF did not exceed 10 ms at any time point (Table). No QTcF interval was >450 ms nor were any QTcF interval changes from baseline >30 ms. There were no differences in change in heart rate, RR, PR, QT and QRS intervals for CAZ-AVI vs. placebo.

Time point (h)	Least square mean difference (90% CI) in change-from-baseline QTcF for CAZ-AVI vs placebo										
	0.5	1.0	1.5	2.0	3.0	4.0	6.0	8.0	12.0	24.0	
LS mean difference (90% CI) (ms)	0.7 (-1.1, 2.5)	4.1 (2.3, 5.9)	1.0 (-0.8, 2.8)	0.9 (-0.9, 2.7)	0.1 (-1.8, 1.9)	-0.5 (-2.3, 1.3)	1.1 (-0.8, 2.9)	1.2 (-0.6, 3.0)	-0.6 (-2.4, 1.3)	1.1 (-0.7, 2.9)	

**Conclusions:** This TQT study showed no observed effect on the QT interval for a supratherapeutic dose of CAZ-AVI.

**P1418** Characterisation of the mechanism of nicotinic acetylcholine receptor inhibition that is likely linked to the off-target activity by telithromycin

D. Bertrand, S. Bertrand, D. Pereira, K. Keedy, P. Fernandes\* (Geneva, CH; Chapel Hill, US)

**Objectives:** Previous studies carried out with telithromycin at the nicotinic acetylcholine receptors have clearly illustrated that the pyridine moiety in the side-chain of telithromycin inhibits the alpha 7 and alpha3beta4 receptors. Similarly, the visual effects of voriconazole led us to the characterization of the inhibition of alpha3beta4 nAChRs by its heterocyclic N in the pyrimidine side chain. The aim of this study was to examine the mode of action of telithromycin at the human alpha7 and alpha3beta4 nAChRs.

**Methods:** Electrophysiological studies were conducted using expression of human nAChRs in *Xenopus* oocytes. ACh dose-response curves were obtained in the absence or presence of a fixed concentration of telithromycin to determine the mode of action of telithromycin. Competitive antagonists are characterized by the fact that blockade caused by the antagonist can be surmounted by the appropriate increase in the agonist concentration. On the contrary, non-competitive antagonists are characterized by the fact that blockade is insurmountable.

**Results:** Data obtained for alpha3beta4 with 2 μM telithromycin suggests that telithromycin might have a dual action with competitive and non-competitive inhibition. The dual mode of action of telithromycin was confirmed by examining the time course of the ACh response measured at a low ACh concentration (10 μM) and at a high ACh concentration (1280 μM). Inhibition caused by telithromycin is not accompanied by a modification of the response time course at 10 μM ACh, whereas a profound modification of the decay time was observed at the high ACh-concentration. The difference in the response time course, with a faster decay time observed at ACh concentrations >160 μM, indicates that inhibition is not caused by competition only, but that telithromycin probably enters the channel pore and blocks ionic conduction by steric hindrance. Exposure of cells expressing the human alpha7 to telithromycin (20 μM) causes a shift in the concentration activation curve towards higher ACh concentrations indicative of a competitive inhibition of alpha7. Similarly to alpha3beta4 at high ACh concentrations (>600 μM), telithromycin causes an additional inhibition probably due to open channel blockade.

**Conclusions:** Mechanistic characterization of the side effects of drugs helps to optimize the side-effect profiles of drugs in development. These studies can mechanistically differentiate new macrolides/ketolides from telithromycin.

## New antibacterial agents under investigation

**P1419** GSK2251052, a novel, leucyl tRNA synthetase inhibitor, is present in the epithelial lining fluid and alveolar macrophages following intravenous dosing to healthy adult volunteers

D. Tenero, G. Bowers, A. Patel, M. Kurtinecz, S. Croy, E. Dumont, J. Tomayko, S. Piscitelli, K. Rodvold, P. Patel\* (King of Prussia, Research Triangle Park, Collegeville, Chicago, US)

**Objectives:** To evaluate in healthy volunteers, the plasma and intrapulmonary pharmacokinetics (PK) of intravenous GSK2251052,

a novel, boron-containing antimicrobial in clinical development for treatment of serious Gram-negative bacterial infections.

**Methods:** In an open-label study, 30 healthy adult subjects underwent bronchoscopy and timed bronchoalveolar lavage (BAL) following either a single intravenous dose of GSK2251052 1500 mg (Cohort 1) or on the morning of days 3 after 5 intravenous doses of 1500 mg twice daily (Cohort 2). Serial PK samples and safety assessments were obtained throughout the study. Bronchoscopy was performed at a single time in each subject at 2, 6, or 12 hour after the start of the 60 minute infusion. Non-compartmental PK analysis was performed for calculation of PK parameters.

**Results:** Thirty subjects completed the study. The mean CL, V<sub>ss</sub>, and t<sub>1/2</sub> values were ~22 L/hour, 231 L, and 10.7 hour, respectively. Approximately 30% of the 1500 mg GSK2251052 dose was excreted unchanged in urine after single dose administration. GSK2251052 concentrations in epithelial lining fluid (ELF) and alveolar macrophage (AM) were ~50%, and 500–600%, respectively, compared to plasma. The most frequently reported drug-related AE was mild to moderate infusion site reactions (ISR, seven subjects) occurring primarily in the repeat dose cohort. No serious drug-related AEs occurred and no clinically significant trends in laboratory values, vital signs, or ECGs were observed.

**Conclusion:** GSK2251052 given as a 1500 mg infusion was generally tolerated following single or repeat dose administration. GSK2251052 distributes into both the ELF and AM of healthy volunteers, which supports further study in patients with pneumonia.

**P1420** A phase 1, open-label, multicentre, single-dose, pharmacokinetic, safety and tolerance study of oral tedizolid phosphate in 12–17 year old patients

J. Bradley, A. Arrieta, E. Capparelli, R. Jacobs, E. Fang\*, K.A. Munoz, S. Flanagan, P. Prokocimer (San Diego, Orange, Little Rock, US)

**Objective:** Community-associated methicillin-resistant *Staphylococcus aureus* (CA-MRSA) causes significant morbidity in children. Tedizolid phosphate (TR-701 FA) is a second-generation oxazolidinone antimicrobial agent, with enhanced in-vitro activity against CA-MRSA, and preliminary evidence suggesting decreased hematopoietic toxicity. Phase 2 studies of tedizolid phosphate in adults with acute bacterial skin and skin structure infection (ABSSSI) have established a favorable antimicrobial exposure associated with efficacy and safety. Investigation of single-dose tedizolid phosphate in adolescents was designed to establish the dose that provides an exposure equivalent to that currently used in adults.

**Methods:** Medically stable adolescent patients aged 12 through 17 years, receiving concurrent systemic antibiotic treatment, were eligible for participation. A single dose of 200 mg tedizolid phosphate was administered by mouth; plasma was obtained predose (0 hour) and 1, 2, 4, 6, 8, 12, and 24 hour postdose to assess concentrations of tedizolid phosphate and its active metabolite, tedizolid (TR-700), by tandem mass spectrometry. PK parameters of tedizolid were determined by WinNonlin.

Clinical and laboratory (hematology, serum chemistry, urinalysis) safety was assessed pre- and postdose.

**Results:** The population was 90% male with a mean age of 14.8 years and mean BMI of 22.9 kg/m<sup>2</sup>. Pharmacokinetic evaluation of drug disposition in adolescents in this study (n = 10) documented similar tedizolid PK results with those seen in adults receiving 200 mg of tedizolid phosphate in a previous study. Mean (SD) AUC<sub>0-inf</sub> values of 25.2 (9.2) and 26.7 (6.0) µg hour/mL and mean C<sub>max</sub> values of 2.2 (0.5) and 1.9 (0.4) µg/mL were observed in adolescents and adults, respectively.

No drug-attributable clinical or laboratory adverse events were noted on our small cohort of adolescents.

**Conclusions:** Two hundred milligram of oral tedizolid phosphate provided an antimicrobial exposure equivalent to adults given the same dose, with no safety issues noted in these 10 adolescents. For clinical investigation of ABSSSI in adolescents, 200 mg of oral tedizolid phosphate should provide an exposure that has been linked to clinical efficacy in adults.

**P1421 Phase I (multiple ascending dose) study with the novel *Pseudomonas aeruginosa* antibiotic POL7080 in healthy volunteers**

K. Dembowski\*, D. Wilbraham, A. Ograbek, J. Argen, A. Wach, G.E. Dale (Allschwil, CH; London, UK)

**Objectives:** POL7080 is a novel PEM (Protein Epitope Mimetics) antibiotic selectively targeting *Pseudomonas* species with demonstrated potent in vitro activity and in vivo efficacy in murine infection models. A multiple ascending dose (MAD) study was conducted to evaluate safety, tolerability, plasma pharmacokinetics (PK) and urinary excretion.
