# Nur77-mediated TRAF6 signalling protects against LPS-induced sepsis in mice

Xiu-Ming Li<sup>1</sup>, Shen Zhang<sup>1</sup>, Xiao-Shun He<sup>2</sup>, Peng-Da Guo<sup>1</sup>, Xing-Xing Lu<sup>1</sup>, Jing-Ru Wang<sup>1</sup>, Jian-Ming Li<sup>1</sup> and Hua Wu<sup>1\*</sup>

## Abstract

**Background:** Nur77, a key member of the NR4A receptor subfamily, is involved in the regulation of inflammation and immunity. However, the *in vivo* regulatory roles of Nur77 in sepsis and the mechanisms involved remains largely elusive. In this study, we used Nur77-deficient (Nur77<sup>-/-</sup>) mice and investigated the function of Nur77 in sepsis.

**Findings:** Compared to wild-type (Nur77<sup>+/+</sup>) mice, Nur77<sup>-/-</sup> mice are more susceptible to LPS-induced sepsis and acute liver inflammation. Mechanistically, we observed that Nur77 can interact with TRAF6, a crucial adaptor molecule in the Toll-like receptor-interleukin 1 receptor (TLR-IL-1R) signalling pathway, in *in vivo* mouse model of sepsis. The interaction may affect TRAF6 auto-ubiquitination, thereby inhibiting NF- $\kappa$ B activation and pro-inflammatory cytokines production.

**Conclusions:** These *in vivo* observations reveals an important protective role for Nur77 in LPS-induced sepsis through its regulation to TRAF6 signalling, and highlights the potential clinical application of Nur77 as a molecular target in prevention and/or treatment of sepsis.

**Keywords:** Nur77, Inflammation, Sepsis, LPS, Animal study

## Introduction

Orphan nuclear receptor Nur77 (also called TR3, NGFI-B, or NR4A1) is a member of the NR4A family of nuclear receptors. Similar to other nuclear receptors, Nur77 consists of an N-terminal transactivation domain, a central DNA binding domain and a C-terminal ligand binding domain, and can act in the nucleus as a ligand-independent and constitutively active transcription factor by binding to its DNA response elements as monomers [1], homodimers [2] or heterodimers with retinoid X receptor [2]. Unlike other nuclear receptors, Nur77 and other members of the subfamily are classified as early response genes whose expression is induced by a diverse range of extracellular stimuli including a wide array of cytokines and growth factors [3]. Consistently, accumulating studies indicate that Nur77 is implicated in the control of inflammatory diseases including atherosclerosis [4], arthritis [5], inflammatory bowel disease (IBD) [6] and cancer

[7]. Nur77 is aberrantly expressed in atherosclerotic lesions [8], and cancer [7]. Nur77 may act to mediate pro-inflammatory signalling by increasing the expression of NF- $\kappa$ B-activating kinase, IKKi [9] to attenuate cytokine signalling. However, recent *in vivo* studies have shown that Nur77 is protective against the development of atherosclerosis by regulating the polarization of macrophages and subsequently inhibits inflammatory responses [10], indicating Nur77 may mediate anti-inflammatory signalling. Despite all of these efforts, however, the *in vivo* roles and underlying mechanism of Nur77 in sepsis are unclear.

Tumor necrosis factor receptor associated factor 6 (TRAF6), a member of TRAF family, is a common signalling mediator for the TLR-IL-1R superfamily [11]. TRAF6-deficient mice have defects in TLR-IL-1R-initiated inflammatory signalling [12]. TRAF6 is reported to possess an E3 ubiquitin ligase and undergoes lysine 63 (K63)-linked auto-ubiquitination [13]. The modification, in contrast to K48-linked polyubiquitin conjugation, is not associated with proteasomal degradation but instead facilitates signal transduction and protein trafficking [14, 15]. The regulatory involvement of various molecules in TRAF6-mediated TLR-IL-1R signalling has

Full list of author information is available at the end of the article

been confirmed.  $\beta$ -arrestin act as negative regulators to prevent ubiquitination of TRAF6 through direct interaction, which effectively blocks excessive inflammatory responses [16]. In contrast, the formation of TRAF6-HSP27 complex promotes TRAF6 ubiquitination and enhances activation of NF- $\kappa$ B signalling triggered by IL-1 $\beta$  [17].

Here, we investigate the in vivo function of Nur77 in sepsis and sepsis-associated liver injury. Our work indicates that Nur77 deficiency in mice increased their susceptibility to LPS-induced sepsis and acute liver injury, and reveal a critical mechanism wherein Nur77 interacts with TRAF6 and regulate its auto-ubiquitination in in vivo mouse model of sepsis.

## Materials and methods

### Mice

Nur77-knockout mice were purchased from Jackson Laboratory (Bar Harbor, ME). Mice were maintained in a pathogen-free environment as recently described [6]. All animal experiments were performed in accordance with the regulations and guidelines of the Animal Care and Use Committee of Soochow University.

### Sepsis model

The age- and sex-matched Nur77<sup>+/+</sup> versus Nur77<sup>-/-</sup> mice were injected with LPS (20 mg/kg, ip). Then, 2 h later, hepatic *Tnf*, *Il6*, and *Il12b* mRNA was measured by RT-PCR and Real-time PCR. TNF $\alpha$  and IL-6 in blood were measured with ELISA. To induce endotoxic shock, mice were injected with LPS (20 mg/kg, ip) and were monitored for survival for the ensuing 72 h.

### Acute liver injury model

Nur77<sup>+/+</sup> and Nur77<sup>-/-</sup> mice used for the model were 8–10 weeks of age and were matched for age and sex. Mice were co-injected with LPS (5  $\mu$ g/kg, ip) and D-GalN (400 mg/kg). 5 h later, mice were anesthetized with ether and retro-orbitally bled. ALT, AST, TNF $\alpha$ , and IL-6 were measured with ELISA. Also, RNA was extracted from liver tissue and relative mRNA of *Tnf*, *Il6*, and *Il12b* were measured by RT-PCR and Real-time PCR. Mice were monitored for 24 h to assess survival.

### Tissue samples collection and evaluation

Pathological analysis of lung, liver and kidney from Nur77<sup>+/+</sup> and Nur77<sup>-/-</sup> mice was conducted and tissue samples were fixed in 10 % buffered formalin and then embedded in paraffin. Tissue was sectioned and stained with hematoxylin and eosin (H&E) according to standard histological procedures.

### Real-time PCR assays

Real-time PCR assays were performed as published [7, 18]. The abundance of each mRNA was normalized relative to

PCR with the housekeeping gene  $\beta$ -actin. The primers for PCR reactions are listed in Table 1.

### ELISA

ALT, AST, TNF $\alpha$ , and IL-6 in serum were measured with commercially available kits according to the manufacturer's instructions.

### Western blot

Western blot analyses were performed as described in the literature [7].

### Immunoprecipitation and ubiquitination Assay

Cells were lysed in lysis buffer (2 mmol/L Tris-HCl (pH 7.4), 10 mmol/L EDTA, 100 mmol/L NaCl and 1 % IGEPAL). Cell lysates were incubated with indicated antibodies in protein A/G beads (Santa Cruz Biotechnology) for 3 h. Then, the protein-antibody complexes on the beads were analyzed with Western blot. To measure TRAF6 ubiquitination, 10 mM N-ethylmaleimide (Sigma) was included in the lysis buffer.

### Statistical analysis

Data are expressed as means  $\pm$  SD, and Student's *t* test (unpaired, two-tailed) was used to compare two groups of independent samples ( $p < 0.05$  were considered statistically significant).

## Results and discussion

Research suggests that orphan nuclear receptor Nur77 is implicated in inflammation and immunity. Mice lacking all Nr4a receptors including Nur77 did not generate T<sub>reg</sub> cells and resulted in systemic autoimmune disease [19]. Nur77 deficiency in mice lead to acceleration of atherosclerosis [10] and inflammatory bowel disease [6]. We recently reported that loss of Nur77 in older mice contributes to systemic inflammation [20]. Sepsis, the major complication of severe infection, usually causes multisystem organ failure and even death of many patients in hospital

[21]. Therefore, it is of great importance to find the new potential targets for sepsis treatment. Here we investigate *in vivo* functions of Nur77 in sepsis and sepsis-associated liver injury. We first challenged Nur77<sup>-/-</sup> mice with LPS to ascertain the role of Nur77 in LPS-induced sepsis *in vivo*. After treatment with LPS, lungs of Nur77<sup>-/-</sup> mice had severe inflammatory hyperemia, as evidenced by increased mononuclear cells and erythrocyte infiltration (Fig. 1a). RT-PCR and Real-time PCR assays, in liver tissues from Nur77<sup>-/-</sup> mice, showed substantial induction of *Tnf* and *Il6* expression (Fig. 1b). Consistent with these results, levels of TNF $\alpha$  and IL-6 in serum were significantly higher in LPS-treated Nur77<sup>-/-</sup> mice than in LPS-treated Nur77<sup>+/+</sup> mice (Fig. 1c), suggesting that the host response in Nur77<sup>-/-</sup> mice is altered. After lethal challenge with

LPS, Nur77<sup>-/-</sup> mouse survival was reduced (Fig. 1d). These results are consistent with a recent report that mice lacking Nur77 had exacerbated inflammatory and immune responses, and survival was decreased after lethal endotoxemic challenge [22]. Thus, Nur77 is important for modulation of inflammatory responses during sepsis.

To further ascertain the role of Nur77 in sepsis, we treated mice with LPS/D-GalN known to induce acute liver injury. At 5 h after LPS/D-GalN challenge, Nur77<sup>-/-</sup> mice had severe hepatocyte destruction compared to wild-type mice (Fig. 2a). LPS/D-GalN injection also promoted hepatocyte cell death in Nur77<sup>-/-</sup> mice revealed by PARP cleavage (Fig. 2b). ALT and AST, liver function markers, were also significantly greater in serum from LPS/D-GalN-treated Nur77<sup>-/-</sup> mice (Fig. 2c), indicating increased

liver necrosis. We also measured TNFα and IL-6 expression as these are known to be involved in this model of acute liver inflammation [23, 24] in liver tissues from wild-type and Nur77<sup>-/-</sup> mice. RT-PCR and real-time PCR assays confirmed that expression of these pro-inflammatory cytokines mRNA was greater in LPS/D-GalN-treated Nur77<sup>-/-</sup> mice than in wild-type mice (Fig. 2d). Similarly, generation of inflammatory cytokines including TNFα and IL-6 were markedly enhanced in serum from Nur77<sup>-/-</sup> mice (Fig. 2e). Thus, Nur77 is protective against LPS-induced acute liver injury.

The molecular mechanism by which Nur77 deficiency promotes sepsis remains obscure. Nur77 has been shown to inhibit LPS-induced inflammation by inhibiting p65 binding to DNA, thereby reducing pro-inflammatory cytokine production [25]. We observed enhanced phosphorylation and degradation of IκBα was in liver and spleen tissues from Nur77<sup>-/-</sup> mice challenged with LPS (Fig. 3a), indicating Nur77 could suppress LPS-induced NF-κB activity in vivo. Also Nur77 contributes to regulation of TRAF6 signalling through its interaction with TRAF6. As shown in

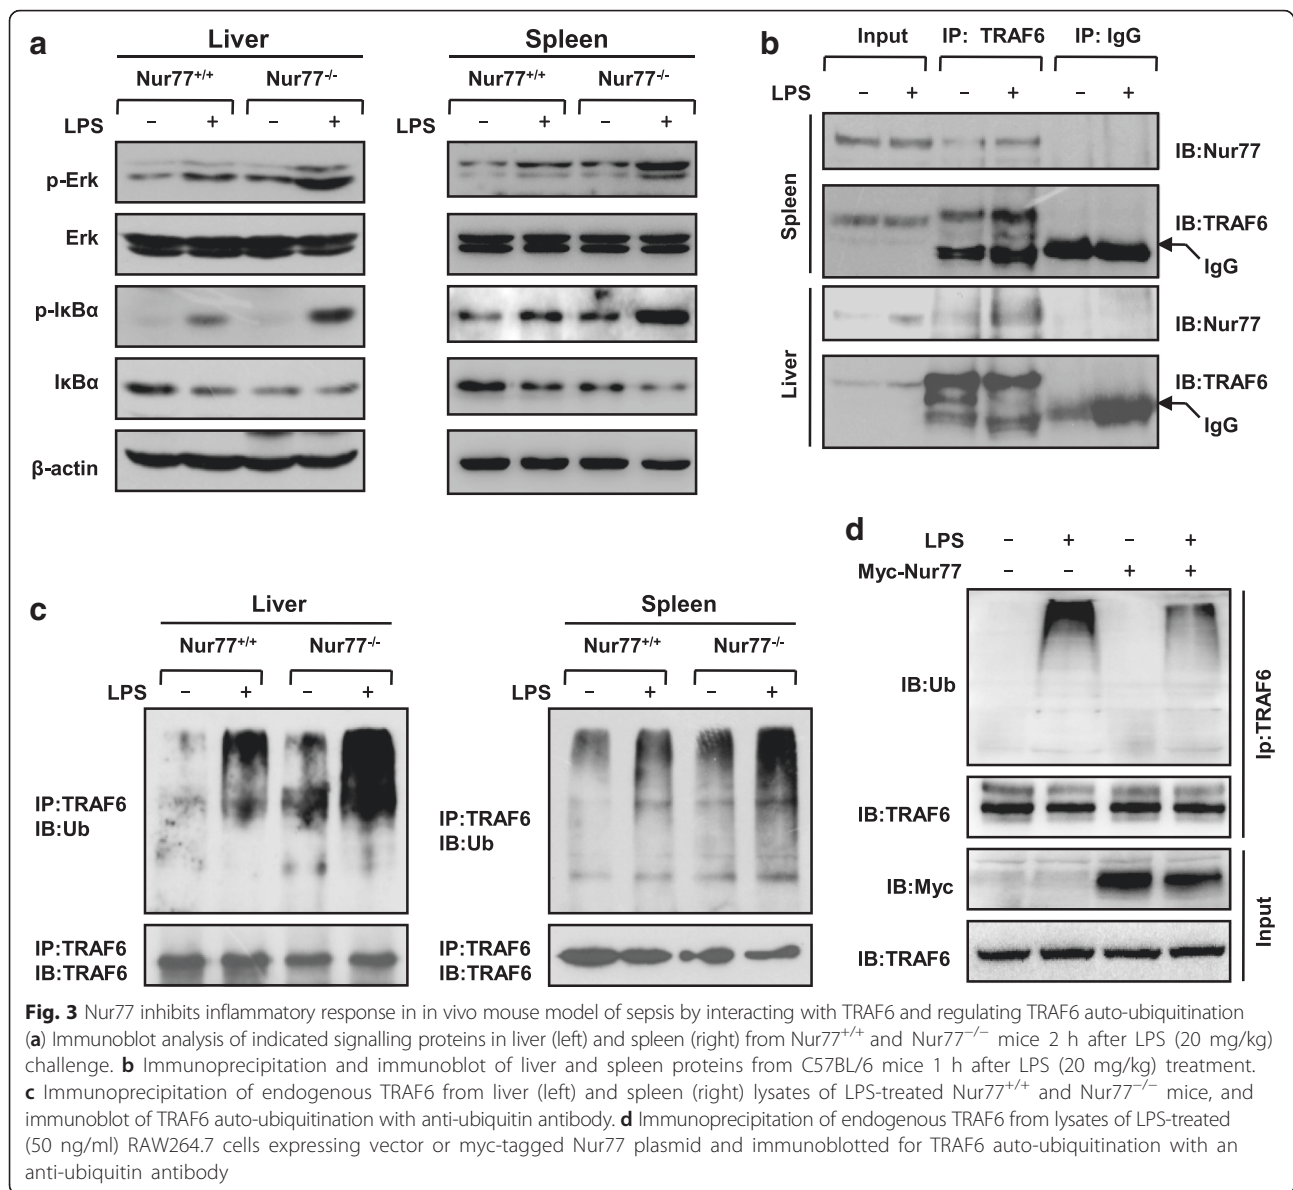

Fig. 3b, mice challenged with LPS for 1 h had enhanced Nur77-TRAF6 interaction in the liver and spleen compared to control PBS-treated mice. These results are consistent with our recent observation that disruption of Nur77-TRAF6 interaction in Nur77<sup>-/-</sup> mice accelerated the development of IBD [6]. Collectively, these data suggest that Nur77 physically interacts with TRAF6 in in vivo mouse model of sepsis, revealing a pathophysiological significance of Nur77-TRAF6 interaction in sepsis. Auto-ubiquitination of TRAF6 is required for NF-κB signal transduction [16]. Here, our results showed that Nur77 deficiency significantly enhanced auto-ubiquitination of TRAF6 in liver and spleen tissues prepared from Nur77<sup>-/-</sup> but not wild-type mice (Fig. 3c). At the same time,

overexpression of Nur77 significantly impaired LPS-induced TRAF6 auto-ubiquitination (Fig. 3d). Also we investigated whether Nur77 can affect auto-ubiquitination of TRAF3, another member of the TRAF family but we observed no significant change. Additional file 1: Figure S1 indicates that overexpression of Nur77 did not affect TRAF3 auto-ubiquitination induced by LPS, suggesting that Nur77 is important in regulating LPS-induced inflammation by targeting TRAF6.

In summary, our in vivo study confirmed a critical protective role for the orphan nuclear receptor Nur77 in sepsis and identify a key mechanism for Nur77 in the regulation of TRAF6 signalling through its interaction with TRAF6 in in vivo mouse model of sepsis.
