**Figure S1: Location of HERITAGE study centres and baseline co-morbidities and COVID-19 symptoms.** A) Location of HERITAGE study centres within the Greater Accra Region in Ghana. B-C) Frequency of co-morbidities (B) and COVID-19 symptoms (C) among study participants (n = 301)

**A**

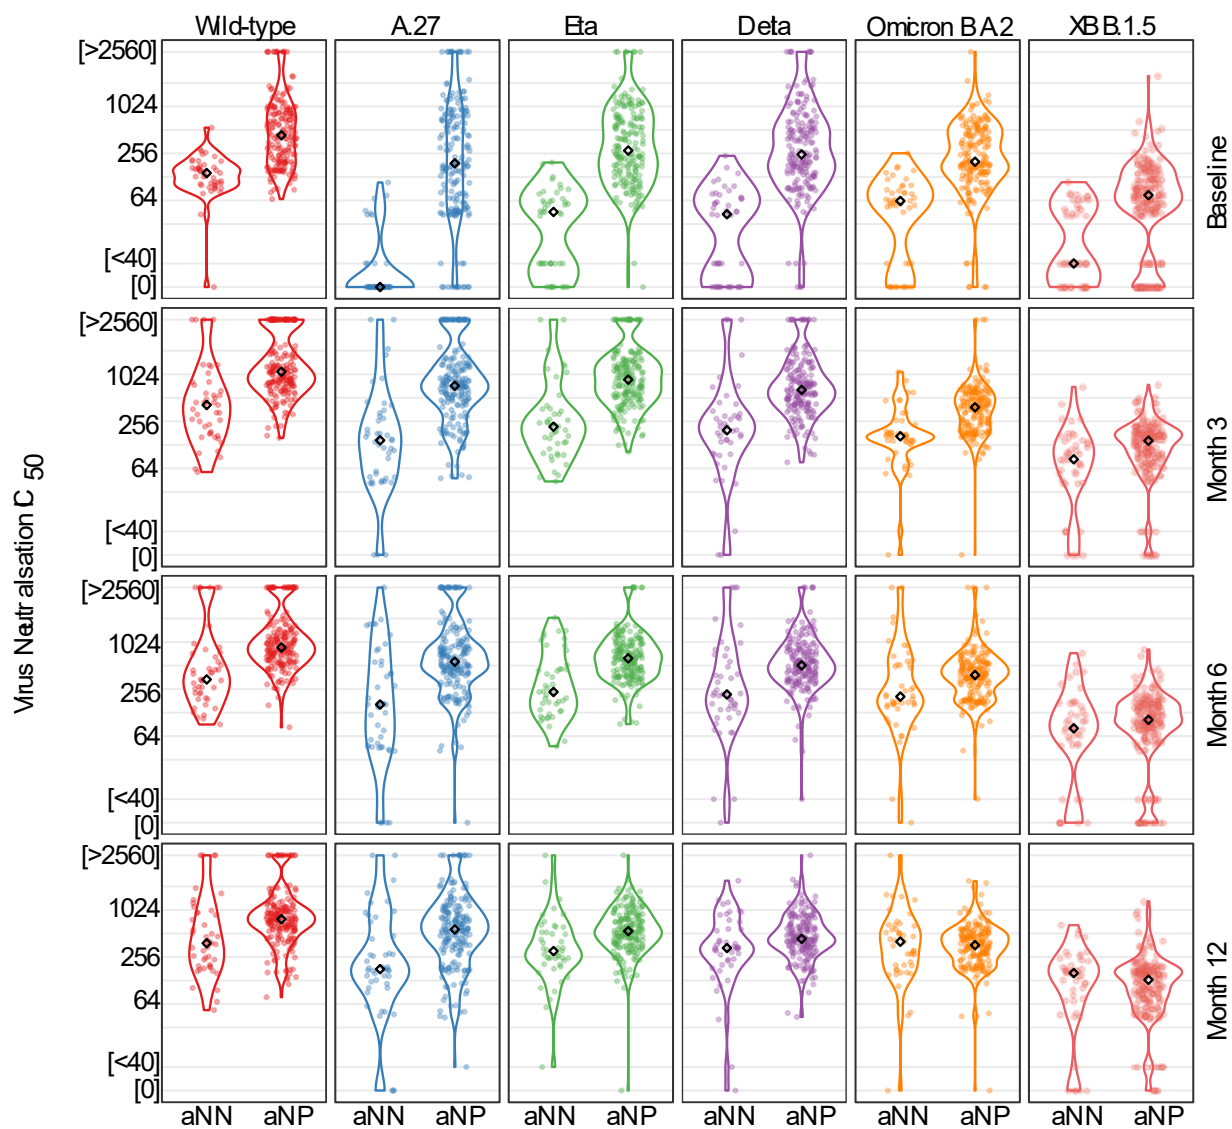

**B**

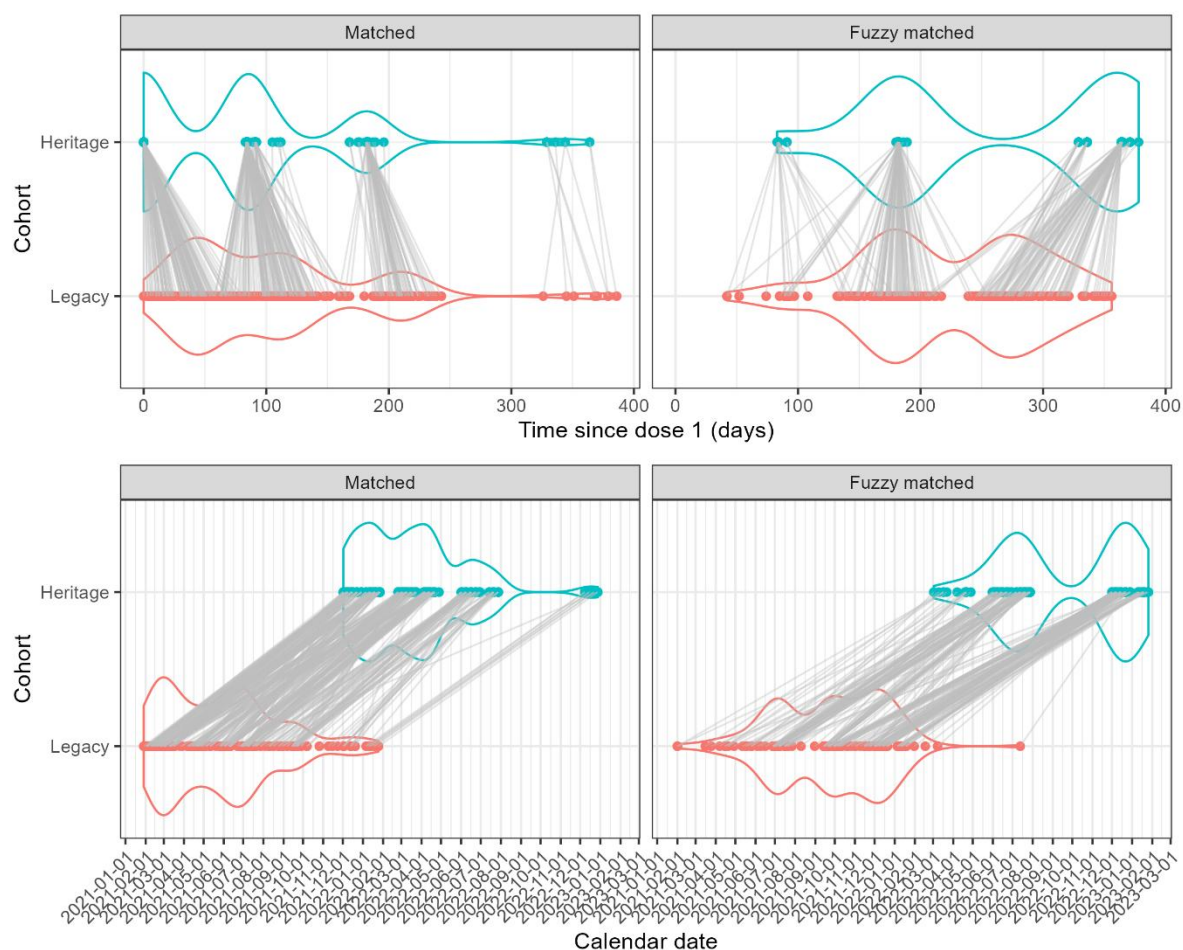

**C**

**Figure S2: PCR positivity and neutralising antibody titres in HERITAGE.** A) COVID-19 positivity, confirmed by qRT-PCR, in the aNP and aNN subgroups at all time points. B) Neutralising antibody titres against SARS-CoV-2 strains in HERITAGE (n=231 for each time point). C) Neutralising antibody titres against SARS-CoV-2 strains in participants vaccinated with AZD1222 and BNT126b2 for all timepoints combined (AZD1222: n = 432 for all strains, BNT162b2: n = 489 (Wild-type) n = 490 (Delta and XBB.1.5) and n = 491 (A.27, Eta and Omicron BA.2)).

**Figure S3: Neutralising antibody titres in SARS-CoV-2 exposed and naïve HERITAGE participants.** Neutralising antibody titres against six SARS-CoV-2 strains for previously exposed (anti-Nucleocapsid IgG positive at baseline, aNP) and SARS-CoV-2 naïve participants (anti-Nucleocapsid IgG negative at baseline, aNN).

**Figure S4: Comparison of matched samples between HERITAGE and LEGACY for time since dose 1 and calendar date.** HERITAGE samples are depicted in blue and connected to their matched LEGACY samples (in pink). One HERITAGE sample is matched with one LEGACY sample that is the most similar based on age, sex, vaccine type, the number of vaccine doses, and the time elapsed since the second dose, this resulted in 357 pairs of matched samples (left). The matching process was repeated with the remaining samples, but with a less strict criterion (fuzzy matched) resulting in an additional 204 pairs of samples (right).

**Table S1**

Socio-demographic characteristics of study participants with auto-immune disease,

<b>Overall</b>	<b>39 (100.0)</b>
<b>Vaccination Site</b>	
Korle-Bu	39 (100.0)
<b>Age, Median (IQR)</b>	35 (31-43)
<b>Age group</b>	
18-19	1 (2.6)
20-29	7 (17.9)
30-39	17 (43.6)
40-49	8 (20.5)
50+	6 (15.4)
<b>Sex</b>

## Supplementary materials and methods

### HERITAGE study sites

Vaccine-seeking participants were recruited at four health facilities, including the Adabraka Polyclinic (Korle Klottey Municipal), the Greater Accra Regional Hospital (Osu-Klottey Sub-Metro of Accra Metropolitan Area), the Korle Bu Teaching Hospital (Ablekuma South Metropolitan District), and the University of Ghana Hospital, Legon (Ayawaso West Municipal District) (appendix p 2). All four health facilities are NHIS-accredited government/public hospitals with certification from the Ghana Health Service for the deployment of COVID-19 vaccines. A special subcohort, consisting of participants with clinically confirmed rheumatologic and autoimmune conditions, was recruited from the Rheumatology Unit of the Korle Bu Teaching Hospital.

### The LEGACY clinical cohort

The Legacy study (NCT04750356) is a prospective observational cohort, established in January 2021 of adults undergoing PCR-based surveillance for SARS-CoV-2 across four institutions in northwest London. Extensive descriptions of the cohort can be found in our prior interim reports [21–24][1–4]. In the UK, from December 2020, healthcare workers, adults over 65 years, and those with either immunocompromise or caring responsibilities were offered a dose of COVID-19 vaccine. Participants were recruited to Legacy from January 2021, inclusion criteria were broad (adults employed by an institution using the Crick-COVID PCR testing pipeline and had undergone testing for SARS-CoV-2), exclusion criteria were limited to ability to provide written informed consent and willingness for longitudinal follow up and ongoing serological surveillance. Participants are followed up every six months. At each study visit, individuals gave details on any recent infection episodes, vaccination doses, and had blood drawn for serum for live-virus microneutralisation assays and anti-N IgG detection. Additional visits are conducted pre/post vaccination where possible and following a reported infection episode.

### SARS-CoV-2 testing by RT-PCR for the HERITAGE study

the novel coronavirus (2019-nCoV) Nucleic Acid Diagnostic Kit (PCR-Fluorescence Probing) (Sansure Biotech Inc., Hunan Province, China) detects the *ORF1ab* gene and *N* gene of SARS-CoV-2 and the *RNase P* gene as an internal control. Oropharyngeal swab specimens were homogenised by vortexing, pulse spun, heat-inactivated at 65 °C for 10 min, and pulse spun to settle any debris. Subsequently, 10 µl of swab suspension was incubated with 10 µl of Sample Release Reagent (Sansure Biotech Inc., Hunan Province, China) for 10 min after gentle vortexing. For each reaction, 10 µl of swab suspension-release reagent mixture of extracted RNA (or negative control-release reagent mixture/positive control) was transported into a 0.2 ml PCR tube prefilled with 15 µl of master mix (13 µl of 2019-nCoV-PCR mix and 2 µl of 2019-nCoV-Enzyme mix). Negative and positive controls (provided in the kit) and blank controls (viral transport medium and nuclease-free water) were processed in each batch. The RT-PCR was run on a Molarray MA-6000 real-time quantitative PCR machine (Sansure Biotech Inc., Hunan Province, China). The thermocycler settings used for amplification include reverse transcription at 50 °C for 30 mins to produce cDNA; cDNA pre-denaturation at 95 °C for 1 min; denaturation at 95 °C for 15 sec; and 45 cycles of annealing, extension, and fluorescence detection at 60 °C for 30 sec. The thermocycler was left to cool at 25 °C for 10 sec. RT-PCR runs with a negative control with no Ct or Ct > 38 for all target channels and a positive control with characteristic sigmoidal amplification curves (S-shape) detected with Ct ≤ 35 for all three channels, were considered valid. Samples with sigmoidal curves for *RNase P* with a Ct value ≤ 38 were considered valid. Samples with sigmoidal curves for *ORF1ab* and/or *N* with Ct ≤ 38 were considered positive for SARS-CoV-2.

### COVID-19 infection surveillance in the LEGACY study

The Crick-COVID PCR testing pipeline provided asymptomatic occupational health PCR based screening for employees of the Francis Crick Institute and a number of NHS hospitals, community trusts and care homes in the northwest London sector [25]. Legacy participants underwent weekly PCR surveillance (employer-mandated for Crick employees) from April 2020-Mary 2022. Subsequently infection surveillance in the Legacy cohort has been through participant reports of either a symptomatic episode or positive lateral-flow test. Following each report, same/next-day home based PCR confirmatory testing is conducted with subsequent sequencing to identify the infecting variant [26].

### Analyses of live virus neutralisation titres

The median neutralisation level was compared across characteristics of the study participants using the Wilcoxon rank sum test for comparison between two groups and the Kruskal Wallis test for comparison between three or more groups. The Wilcoxon rank sum test is a non-parametric test used to compare the median of a non-normally distributed continuous variable between two different groups. The Kruskal Wallis test is also a non-parametric test and a higher level of the Wilcoxon rank sum test which is used to compare median of a non-normally distributed continuous variable between three or more groups [27].

Further analysis was performed to compare the neutralisation level at month 3, month 6, and month 12 to the neutralisation level at baseline using the fold median approach. Fold median was defined as the ratio of the median in one group to the ratio of the median in the comparative groups. The bootstrapping sampling approach was used to estimate the 95% confidence interval of the fold median.

For each of the six COVID-19 variants, the neutralisation was dichotomized to; neutralisation levels below 256, against neutralisation levels of 256 and above. The Pearson's chi-square test was used to assess the factors associated with neutralisation level above 256 over time. A binary logistic regression model, treating the type of vaccine as the major confounding variable, was used to assess the odds of neutralisation level above 256. Variables that were found significant from bivariate analysis were also considered as potential confounding variables in the final analysis. All statistical significance were considered at an alpha of 0.05 level.

To compare neutralisation data between the HERITAGE study and the LEGACY study samples were matched using Coarsened Exact Matching (CEM) to balance the two cohorts based on age, sex, vaccine type, the number of vaccine doses, and the time elapsed since the second dose [28]. Matching was performed with the R package ‘MatchIt’. Each HERITAGE subject was matched to the most similar LEGACY subject and the rest was discarded (1-to-1 matching) [29]. For discrete variables like sex, vaccine type, and the number of doses, the samples were matched exactly. Age was grouped into 15-year intervals, and the time elapsed since the second dose was grouped into 35-day intervals. This process resulted in 357 matched pairs of samples. The matching process was then repeated for the remaining unmatched samples, but with a less strict criterion, grouping the time elapsed since the second dose into 180-day intervals. This produced an additional 204 “fuzzy-matched” pairs of samples.

### **Data analysis and statistics**

Data used in the LEGACY study were collected and managed using REDCap electronic data capture tools hosted at University College London [28]. Data were imported to R from REDCap prior to analysis and integrated using R Chronogram as previously described [29]. Data were manipulated, analysed and visualised using *tidyverse* R packages including *dplyr* and *ggplot2*. Summary descriptions of the cohort were generated using *gtsummary*. Continuous data were reported as the median value and interquartile range (IQR) or the first and third quartiles (Q1; Q3). Statistical tests were conducted with the *rstatix* R package. The Quantum Geographic Information System (QGIS) version 3.28.2 was used to describe the location of the health facilities involved in this study.
