We present a case of Wellens' syndrome together with upright T wave in lead V₁ in a man presenting with atypical chest pain, and we discuss the significance of its prompt recognition by the emergency physicians who are involved in the evaluation of patients with coronary artery disease in emergency departments. [West J Emerg Med. 2012;13(2):160–162.]

INTRODUCTION

As the electrocardiography (ECG) is a simple, noninvasive tool in the diagnosis and management of coronary artery disease (CAD), emergency physicians (EP) must be proficient in the interpretation of ECGs during evaluation of patients in the emergency department (ED). Sometimes specific T-wave changes for coronary artery disease in precordial ECG derivations may be interpreted as nonspecific T-wave changes by EPs. Failure to diagnose these conditions with subsequent inappropriate management may have fatal consequences.

CASE REPORT

A 67-year-old man presented to the ED with anterior chest pain that did not radiate to the neck and left arm. The pain was localized, tight in nature, and had no association with exertion. The patient came from home where the chest pain initiated and was pain free on admission to the ED. His positive cardiac risk factors were smoking and hypertension. The examination was unremarkable. A 12-lead ECG was performed when the patient was free of discomfort and showed normal sinus rhythm with positive T wave in V₁, which was greater than T waves in V₆ (Figure 1, upper trace). Serum troponin I concentration was 0.03 ng/ml (normal values <0.04 ng/ml). The patient was admitted to the cardiology service for ECG and cardiac marker follow up. Approximately 4 h later, repeated ECG (Figure 1,

lower trace) showed obvious positive T waves in V₁ and biphasic T waves in leads V₂₋₃ and negative T waves in V₄₋₅ without chest pain. There were also inverted T waves in lateral leads. Repeated serum troponin I concentration was within the normal range. The electrocardiograph pattern raised the possibility of left anterior descending (LAD) coronary T-wave syndrome. The patient was transferred to another center for cardiac catheterization, which revealed a 95% proximal LAD artery occlusion (Figure 2). The patient underwent emergent percutaneous coronary intervention following coronary angiography with successful outcome.

DISCUSSION

Chest pain is one of the chief presenting complaints among patients attending EDs. Emergency physicians must be able to evaluate these patients and identify those with an underlying life-threatening cause. The ECG is a better predictor of adverse events than history and presenting symptoms in patients with probable acute coronary syndrome (ACS), and it plays a large role in the EP's disposition decision.¹

T-wave abnormalities are the most common ECG abnormality seen in ED patients, occurring in up to 30% of patients with a potential ACS, and their significance has been less clearly defined.² Studies conducted on cardiac care unit patient populations have shown that, in patients with isolated

Figure 1. ECG of the patient at presentation showing tall, positive T wave in lead V₁ (upper trace). ECG of the patient 4 h later showing biphasic T-wave inversions in right precordial leads and deep negative T-wave inversions in left precordial leads. There is no significant ST segment elevation or R progression loss (lower trace).

precordial T-wave inversions, up to 87% have LAD artery stenosis documented at angiography.³ In patients with known CAD, T-wave flattening or inversions raise concern for an ACS; and in patients without known CAD, T-wave abnormalities should still be considered to raise a patient's 30-day risk. Presence of isolated T-wave abnormalities at the time of ED presentation predict 30-day cardiovascular events, even in patients without a prior history of CAD.⁴

It has been shown that there is a close association between precordial T-wave inversions and LAD disease in the setting of unstable angina, and 47% of patients presenting with acute myocardial infarction with upright T-waves in V₁–V₃ had significant LAD disease in coronary angiography.^{3,5} Studies have shown that development of new T-wave changes in the precordial leads (which need not be isolated in midprecordial leads) in patients with unstable angina is a predictor of significant stenosis of the LAD artery and can identify a subgroup of patients with angina with a poor response to medical treatment.^{3,6–8}

In 1982, De Zwann et al⁹ described a characteristic ECG pattern associated with a critical stenosis of the LAD coronary artery and impending myocardial infarction. Tilkian¹⁰ was the first to use the term Wellens' syndrome defined as a group of ECG signs that occur during the pain-free period in a patient with unstable angina. These ECG changes in the absence of pathologic Q waves are predictive of a critical proximal LAD stenosis.⁹ They consist of an isoelectric or minimally elevated ST segment followed by a concave or straight ST segment and symmetrically inverted (or biphasic) T waves in the precordial

leads, frequently in V₂–V₃, but sometimes involving V₄, V₅, or V₆.⁹ This was the case for our patient, who showed biphasic T waves in V_{2–3} and negative T waves in V_{4–5} during pain-free period. Other than Wellens' syndrome, there was a subtle ECG change, which was an upright T wave in V₁.

Wellens' syndrome and positive T waves in lead V₁ in patients with chest pain are preinfarction stages of coronary artery disease. Patients with this syndrome present with characteristic ECG findings in the precordial leads. Sometimes more subtle changes precede the development of the Wellens' syndrome, such as isolated T-wave changes in precordial leads, which are also predictors of advanced LAD lesion and can be easily misinterpreted. While evaluating the ECG on ED settings, one should not forget these red flags for emergency patients. Once these changes have been recognized, cardiology consultation for possible coronary angiography is likely necessary to further evaluate the patient. Stress imaging is strongly discouraged in the presence of suspected left main or left main equivalent lesions and may result in fatal outcome in patients with Wellens' syndrome.^{11,12}

Without prompt diagnosis and aggressive intervention, patients with Wellens' syndrome may go on to develop extensive anterior wall myocardial infarction, the majority occurring within a matter of days.⁹
