Abstract. High-motility group box protein 1 (HMGB1) has an important role in autophagy; however, its exact role in acute necrotizing pancreatitis (ANP) remains unknown. The present study aimed to investigate the expression pattern of HMGB1 in ANP, and to determine its association with autophagy. Sprague Dawley rats (weight, 350±30 g, n=48) were randomly divided into control (n=12) and experimental (n=36) groups. Experimental rats were retrogradely injected with 5% sodium taurocholate into the biliopancreatic duct to induce ANP. Control rats received an equal amount of saline. Serum amylase levels were used to determine whether the model had been successfully generated. Autophagosomes in pancreatic acinar cells were observed under electron microscopy. The expression levels of HMGB1 and Beclin 1 were detected in pancreatic tissues by western blotting, quantitative polymerase chain reaction and immunohistochemistry. HMGB1 levels were also determined in the serum and in isolated nuclei. The results demonstrated that autophagy was detected at 3 h post-ANP induction; however, HMGB1 expression remained unaltered during the early stage (0-6 h; P>0.05). HMGB1 expression was significantly increased at 12 h, and was still increasing at 24 h (P<0.05). Notably, HMGB1 was increased in the nuclei compared with in the cytoplasm at 3-6 h. Furthermore, serum HMGB1 levels began to increase at 3 h, and reached the highest levels at 24 h in the ANP group. In conclusion, in an ANP model, HMGB1 was initially increased in the nuclei to initiate autophagy. Subsequently, it moved into the cytoplasm, where it interacted with Beclin 1 to enhance autophagy, and HMGB1 was released into the blood, leading to the deterioration of ANP.

Introduction

Acute pancreatitis (AP) is an acute, reversible inflammatory disease of the pancreas, which may affect several organs (1). Necrotizing pancreatitis is characterized by the presence of necrosis in pancreatic and/or peripancreatic tissues (2). The incidence of AP varies from 17.5 to 109 per 100,000 admissions to emergency departments (3,4). The risk factors for AP remain unknown; however, smoking, gallstones, alcohol and drugs are likely to increase the risk of AP and chronic pancreatitis (5). AP leads to local and systemic complications, with an overall mortality rate of 4%. In addition, the mortality rate for acute necrotizing pancreatitis (ANP) is 10-25% (1,6). Ultrastructural alterations to the pancreatic tissues of patients with ANP were observed >30 years ago, including morphological changes in zymogen granules and increased autophagy in the pancreatic acinar cells (7). Watanabe *et al* (8) described the morphological features of autophagy in cerulein-induced AP, leading to the understanding of the association between autophagy and AP. In the pathogenesis of pancreatitis, intracellular trypsinogen activation has an important role in its development (9). Morphological changes in zymogen granules and activation of plasminogen are associated with the formation of cytoplasmic vacuoles, which have an important role in autophagy (10).

In cell nuclei, high-motility group box protein 1 (HMGB1) has a role in the transcription of numerous genes, which are crucial to the autophagy process (11-14). In the cytoplasm, HMGB1 binds to Beclin 1, thus sustaining the Beclin 1-PtdIns3KC3 complex during the activation of autophagy (15). Extracellular HMGB1 is involved in the inflammatory response of ANP by triggering secretion of cytokines, including tumor necrosis factor (TNF)- α and interleukin (IL)-1 β (16,17). Furthermore, as a late inflammatory factor, HMGB1 has been reported to have a key role in the development of AP (18).

The exact expression pattern of HMGB1 during ANP development remains unknown. Therefore, the present study aimed to investigate the involvement of HMGB1 in the development of ANP, in order to explore the role of HMGB1 and the autophagy signal Beclin 1 in the development of ANP. The results of the present study may provide evidence regarding the treatment of ANP.

Materials and methods

Materials and reagents. A total of 48 healthy male Sprague Dawley rats (weight, 350±30 g; age, 12-14 weeks), were provided by the Experimental Animal Center of the Third Xiangya Hospital (Changsha, China). Sodium taurocholate was purchased from Sigma-Aldrich (Merck Millipore, Darmstadt, Germany). Amylase polyclonal antibody (cat. no. YT5164) and enzyme-linked immunosorbent assay (ELISA) kit for HMGB1 (Total HMG-1 Cell-Based Colorimetric ELISA kit) were obtained from ImmunoWay Biotechnology Company (Plano, TX, USA). Rabbit anti-HMGB1 (cat. no. ab79823) and anti-Beclin 1 (cat. no. ab55878) primary antibodies were from Abcam (Cambridge, MA, USA). Goat anti-rabbit secondary antibodies were purchased from Jackson ImmunoResearch (West Grove, PA, USA; cat. no. 111-005-144). The color pre-stained protein marker was purchased from Fermentas (Thermo Fisher Scientific, Inc., Waltham, MA, USA). The Bradford protein concentration assay kit was obtained from Beyotime Institute of Biotechnology (Haimen, China). TRIzol[®] reagent was purchased from Invitrogen (Thermo Fisher Scientific, Inc.). The SYBR Green quantitative polymerase chain reaction (qPCR) Mix was purchased from Toyobo Co., Ltd. (Osaka, Japan).

Establishment of animal models and experimental groups. The present study was approved by the ethics committee of the Experimental Animal Center of the Third Xiangya Hospital. The rats were housed at a constant temperature of 22°C under a 12-h light/dark cycle. The rats had access to standard food and water *ad libitum*. The ANP rat model was created according to the method described by Aho *et al* (19). The rats were fasted for 24 h, with *ad libitum* access to water. Subsequently, the rats were anesthetized by intraperitoneal injection with 10% chloral hydrate (0.3 ml/100 g). An incision was made into the ventral midline for entry into the abdominal cavity, in order to expose the common bile duct and the pancreatic duct. The biliopancreatic duct was occluded at the distal duodenum using a vascular clip. For the experimental group, the canal was infused slowly with 5% sodium taurocholate (0.1 ml/100 g) using a 1-ml syringe at the proximal end. For the control group, the canal was infused with an equal quantity of normal saline. After injection, the needle remained motionless for 10 min to prevent drug reflux. After modeling, the skin was disinfected, the peritoneum was closed with a continuous single-layer suture, and the skin was sutured with a full-layer simple-interval suture. After the abdomen had been closed, the rats were injected with 5 ml saline at the inside position of the lower limb muscle to supplement water lost during the operation.

Experimental (ANP) rats were grouped according to the following time points after modeling: 0 h (n=4), 3 h (n=8), 6 h (n=8), 12 h (n=8) and 24 h (n=8). The control rats were grouped according to the following time points: 3 h (n=3), 6 h (n=3), 12 h (n=3) and 24 h (n=3). Rats were sacrificed, at the aforementioned time points, by cardiac puncture following anesthetization by intraperitoneal injection with 10% chloral hydrate (0.3 ml/100 g body weight).

Specimen collection and preservation. Rats were anesthetized and sacrificed. Blood samples (~5 ml) were collected from the heart, which were maintained at 4°C for 30 min and centrifuged

at 1,000 x g for 15 min at normal temperature. The supernatant was then collected and preserved at -80°C, avoiding repeated freezing and thawing. For electron microscopy, pancreatic specimens were maintained in 4% paraformaldehyde for 24 h at 4°C, and were then transferred to tissue preservation solution (0.2% sodium azide) for preservation. Other pancreatic tissues were collected, placed in cryogenic tubes and maintained in liquid nitrogen.

Detection of serum amylase and HMGB1 levels by ELISA assay. Serum amylase and HMGB1 levels were used to determine if ANP modeling was successful. Serum amylase and HMGB1 levels were assessed using ELISA, according to the manufacturer's protocol with the amylase antibody used at a dilution of 1:20,000.

Electron microscopy. The pancreatic tissues were trimmed to 1x1x1 mm³, fixed with 2.5% pentanediol for 24 h, and post-fixed with 2% osmium tetroxide for 2 h; dehydrated with a gradient of 50%, 70%, 90%, and 100% dehydrated acetone, in each solution three times with each time 10 min. The samples were then placed in an epoxy resin and pure acetone mixture (1:1) at 37°C for 24 h, prior to embedding in a mixture of Epon812 resin, methyl nadic anhydride, dodecenylsuccinic anhydride, and dimethylaminomethyl phenol, at 60°C for 24 h. The blocks were trimmed with semi-thin glasscutter, stained with toluidine blue, and observed under light microscopy to select areas with pancreatic acinar structure. Ultrathin sections with a thickness of 500 Å were obtained with an ultrathin microtome and stained with uranyl acetate and lead nitrate. The sections were observed under transmission electron microscopy (Nissan HT7700; Nissan Corporation, Tokyo, Japan) to examine changes of the pancreatic acinar autophagosomes.

Immunohistochemistry of HMGB1 and Beclin 1 in pancreatic tissue. Sections (4 µm) of paraffin-embedded pancreatic tissues were dewaxed and hydrated, and were washed three times with phosphate-buffered saline (PBS; pH 7.4; 5 min/wash). Subsequently, the samples were boiled under high-pressure in 10 mM citric acid buffer (pH 6.0) for 30 min for antigen retrieval, cooled to room temperature, and washed with distilled water and PBS (2x5 min). Sections were incubated with 3% hydrogen peroxide at room temperature for 1 min, and were washed three times with PBS (5 min/wash). Sections were then blocked with goat antiserum (Abcam) for 7 min at 37°C, and were washed with PBS (5 min). Subsequently, the samples were incubated with the following primary antibodies at 4°C overnight: Anti-HMGB1 or anti-Beclin 1 (1:200). Sections were then rinsed three times with PBS (5 min/wash), and a biotinylated secondary antibody (1:100) was then added to the sections, which were incubated at room temperature for 1 h and rinsed in a humidified chamber. Subsequently, enzyme-labeled streptavidin (50 µl; Wuhan Boster Biological Technology, Co., Ltd., Wuhan, China) was added, incubated at room temperature for 30 min and rinsed in a humidified chamber. Sections were stained with DAB (Sigma-Aldrich; Merck Millipore), observed under a BX53 microscope (Olympus Corporation, Tokyo, Japan), and when the color was suitable, the staining reaction was terminated by rinsing. Sections were then counterstained with hematoxylin, rinsed with water, dehydrated in

gradient alcohol, cleared with xylene, and finally sealed with neutral resin. Images were captured using a camera system (Motic B5; Motic, Xiamen, China). Yellow-brown staining of the nuclei or cytoplasm was recognized as positive staining. Densitometric quantitative analysis of the expression levels was carried out using the Image-Pro Plus 6.0 image system (Media Cybernetics, Inc., Rockville, MD, USA).

Nuclear extraction. Tissue samples were washed with saline to remove blood. Subsequently, 400 μ l solution A [200 μ l KCl (10 mM), 2 ml HEPES (10 mM, pH 7.9), 20 μ l EDTA (0.1 mM), 1.2 ml MgCl₂ (1.5 mM), 200 μ l DTT (1 mM), 100 μ l PMSF (0.5 mM) and 16.28 ml of dH₂O] was added. Tissue samples were homogenized and placed on ice for 15 min. Samples were then centrifuged at 15,000 \times g for 1 min at 4°C. The supernatants (cytoplasmic proteins) were transferred to a new tube, and the pellet (nuclei) was resuspended in 400 μ l solution B [5 ml glycerol (25%), 4 ml HEPES (20 mM; pH 7.9), 4 ml NaCl (400 mM), 200 μ l EDTA (1 mM), 200 μ l DTT (1 mM), 200 μ l PMSF (1 mM) and 6.4 ml dH₂O). Samples were placed on ice for 20 min, and were then centrifuged at 15,000 \times g for 10 min at 4°C. The supernatants (nuclear proteins) were transferred to new tubes and were stored at -80°C until further use.

Western blot analysis for HMGB1 and Beclin 1. Following extraction of the cytoplasmic and nuclear proteins, 5% SDS-polyacrylamide gel electrophoresis was used to separate the proteins (10 μ g samples), which were then transferred to polyvinylidene fluoride (PVDF) membranes. After blocking with 5% skim milk at room temperature for 2 h, the PVDF membranes were agitated overnight at 4°C with anti-HMGB1 or anti-Beclin 1 (1:1,000). Subsequently, the membranes were agitated with horseradish peroxidase-labeled goat anti-rabbit secondary antibody (1:1,000) at room temperature for 1 h. The blots were visualized following treatment with enhanced chemiluminescence solution in a dark room for light exposure. The PVDF membrane was then cleaned with eluent to remove antibodies, and was hybridized with rabbit polyclonal anti- β -actin antibodies (1:1,000; Abcam; cat. no. ab8227) or rabbit anti-histone H3 (1:1,000; RayBiotech, Inc., Norcross, GA, USA; cat. no. 168-10463) and a goat anti-rabbit horseradish-peroxidase secondary antibody (1:1,000; Abcam; cat. no. ab6721). The films were scanned, the optical density values of HMGB1, Beclin 1 and β -actin (internal control) bands were measured using an image analysis system (Quantity One software version 4.62; Bio-Rad Laboratories, Inc., Hercules, CA, USA), and the ratios were obtained for semi-quantitative analysis.

qPCR for HMGB1 and Beclin 1. Total RNA was extracted from the pancreatic tissues using TRIzol[®] at various time points (0, 3, 6, 12 and 24 h) following ANP modeling. For each sample, 2.0 μ g total RNA was reverse transcribed to cDNA using 1 μ l oligo (dT) (0.5 μ g/ μ l) primer according to the protocol of the First Strand cDNA Synthesis kit (Thermo Fisher Scientific, Inc.). PCR primers were designed according to the gene sequences downloaded from National Center for Biotechnology Information (<http://www.ncbi.nlm.nih.gov/genbank/>) using Primer 5.0 software (Premier Biosoft, Palo Alto, CA, USA). The PCR primer sequences were sequenced by Sangon Biotech., Co., Ltd. (Shanghai, China) as follows: HMGB1, sense 5'-GCTCAGAGAGGTGGAAGAC-3', antisense 5'-CCAATGGATAAGCCAGGAT-3'; Beclin 1, sense 5'-TGTGGAATGGAATGAAATCAA-3', antisense 5'-CCCCAGAACAGTACAACGGC-3'; and β -actin (internal reference), sense 5'-CCCATCTATGAGGGTTACGC-3' and antisense 5'-TTTAATGTCACGCACGATTC-3'. The PCR cycling conditions were as follows: Pre-denaturation at 95°C for 3 min; denaturation at 95°C for 10 sec, and annealing and extension at 58°C (HMGB1 and β -actin) or 60°C (Beclin 1) for 30 sec, for a total of 35 cycles. The PCR reaction was performed in a total of 20 μ l, including 10 μ l 2X SYBR Green qPCR mix, 1 μ l primers (10 μ M), 1 μ l cDNA and 8 μ l DEPC-water, the reaction was conducted in an Eppendorf MasterCycler Realplex qPCR machine. Fluorescence was read at each extension phase. The C_q values were obtained and calculated by 2^{- $\Delta\Delta$ C_q} formula (20) relative to the mean of 0 h values, to get the relative expression values.

Statistical analysis. Data are presented as the mean ± standard deviation, and were analyzed using Student's t-test and one-way analysis of variance followed by the Student-Newman-Keuls post-hoc test. SPSS 13.0 (SPSS Inc., Chicago, IL, USA) was used for statistical analysis. P<0.05 was considered to indicate a statistically significant difference.

Results

Successful model generation. As presented in Table I, amylase levels were increased 3 h after modeling. No rats succumbed within the 24 h experimental period. This is consistent with our previous modeling approach (21).

TEM. As presented in Fig. 1, phagocytic vesicles appeared in some pancreatic cells at 3 h. The number of phagocytic vesicles increased in a time-dependent manner. These vesicles exhibited typical autophagy-like morphology (Fig. 1A-E).

Figure 1. Autophagy observed under transmission electron microscopy. (A) Pancreatic acinar cells in the acute necrotizing pancreatitis (ANP)-0 h group exhibited normal acinar nucleolus, mitochondria and rough endoplasmic reticulum. Occasionally, visible phagosomes and lysosomes were generated due to the normal stress of starvation. (B) In the ANP-3 h group, the number of phagocytic vesicles was increased, indicating enhanced autophagy. (C) In the ANP-6 h group, the pancreatic acinar cells exhibited cystic expansion of the endoplasmic reticulum, mitochondrial swelling, and margination of nuclear chromatin. (D) In the ANP-12 h group, phagosomes continued to increase, and the fusion of phagocytic vesicles with lysosomes increased, resulting in a large number of double membrane-like structures. (E) In the ANP-24 h group, the large number of double membrane-like structures increased, providing membrane sources for phagosome formation. Magnification, x10,000.

Figure 2. (A) Protein expression, as detected by western blotting. (B) Comparison of high-motility group box protein 1 (HMGB1) expression among the acute necrotizing pancreatitis (ANP)-0, ANP-3 and ANP-6 h groups exhibited no significant difference ($P>0.05$). HMGB1 expression in the ANP-12 h group was significantly increased, and was maintained at high levels at 24 h ($P<0.05$). (C) Beclin 1 protein expression in pancreatic tissues of the ANP group. Expression at each time point was significantly increased compared with the preceding time point ($P<0.05$).

HMGB1 and Beclin 1 expression in pancreatic tissue. The protein expression levels of HMGB1 and Beclin 1 were detected

Figure 3. High-motility group box protein 1 (HMGB1) and Beclin 1 mRNA expression in pancreatic tissues of the acute necrotizing pancreatitis (ANP) group at various time points, as determined by quantitative polymerase chain reaction. (A) Comparison of HMGB1 between the ANP-0, ANP-3 and ANP-6 h groups exhibited no significant difference ($P>0.05$). HMGB1 expression in the ANP-12 h group was significantly increased, and was maintained at high levels at 24 h ($P<0.05$). (B) Beclin 1 mRNA expression in the pancreatic tissues of the ANP group. by western blotting (Fig. 2). As presented in Fig. 2A and B, the protein expression levels of HMGB1 began to increase at 12 h; this finding was supported by the results of a qPCR (Fig. 3A). However, unlike HMGB1, the translation (Fig. 2A and C) and transcription levels (Fig. 3B) of Beclin 1 began to increase

at 3 h. Similar expression patterns of HMGB1 and Beclin 1 were observed using immunohistochemistry (Figs. 4 and 5, Table II).

Nuclear protein levels of HMGB1 in pancreatic cells in the early stage of ANP. Based on the TEM results, autophagy appeared at 3 h, which corresponded with the increase in amylase levels at 3 h. However, HMGB1 levels did not increase until 12 h. Since HMGB1 is a nuclear factor, it may promote autophagy from the nucleus (22). Therefore, the nuclei were isolated in the present study. Notably, HMGB1 was shown to be accumulated in the nuclei at the early stage of ANP (Fig. 6).

HMGB1 may be secreted and induce systemic lesions as an inflammatory factor. It has previously been reported that HMGB1 may be secreted outside of cells, where it has a role as an inflammatory cytokine (23). ELISA was used to evaluate

Figure 6. Expression of high-motility group box protein 1 (HMGB1) in the cytoplasm and nuclei of pancreatitis tissues at 0, 3 and 6 h after induction of acute necrotizing pancreatitis. *P<0.05 vs. HMGB1 at 3 and 6 h.

the presence of HMGB1 in the serum at various time points after ANP modeling. As presented in Fig. 7, compared with the control group, HMGB1 levels in the serum began to increase at 3 h, and were highest at 24 h after modeling.

Discussion

In eukaryotes, autophagy is involved in cell physiological and pathological processes. Autophagy has a dual role, and can either protect cells against damage, or promote

pathological processes associated with changes to the cell environment (24-28). In AP, autophagy is involved in all pathological processes; it protects the pancreas in the early stages, but promotes disease progression in the late stages (10). HMGB1 is involved in ANP-associated autophagy (18,23,29); however, the exact involvement of HMGB1 in ANP remains unknown.

The aim of the present study was to determine the expression pattern of HMGB1 in ANP, and to investigate its association with autophagy. The results of the present study demonstrated that autophagy was detected 3 h after generation of an ANP model; however, HMGB1 expression remained unaltered during the early stage (0-6 h). HMGB1 was significantly increased at 12 h, and was shown to be still rising at 24 h. Notably, HMGB1 expression was significantly increased in the nuclei, rather than in the cytoplasm, at 3-6 h. In addition, in the serum, HMGB1 levels began to increase at 3 h, and reached the highest levels at 24 h in the ANP group.

In the present study, a rat model of ANP was successfully established by retrogradely injecting sodium taurocholate into the biliopancreatic duct. Beclin 1, which is a critical factor in autophagy, continuously increased with the development of ANP. Furthermore, HMGB1 expression in the pancreatic tissue was not significantly altered 3 and 6 h after modeling, but was significantly increased at 12 and 24 h. A previous study demonstrated time differences in the expression of early inflammatory factors, including HMGB1, TNF- α , IL-1 and IL-6 in pancreatic tissue (29). HMGB1 may act as a key signaling molecule in activating or promoting autophagy when early inflammatory factors begin to decrease; therefore, the results of the present study lay a theoretical foundation to further explore the role of HMGB1 as a key factor in the development of AP. The results of the present study are supported by the results of a previous study, which detected increased serum and pancreatic levels of HMGB1 in humans with pancreatitis and animal models of pancreatitis (30).

Activation of trypsinogen particles and nuclear factor (NF)- κ B by autophagy is the initiating event of pancreatitis development, and has been recognized as the main pathological mechanism underlying the occurrence and development of AP (9). It has previously been demonstrated that early inflammatory factors, such as NF- κ B, are downregulated ~12 h after the onset of AP (18); however, AP-induced inflammation continues, and other inflammatory cytokines act to increase inflammation. In autophagy, factors such as vacuole membrane protein 1, microtubule-associated protein light chain 3 II and Beclin 1 are involved in the non-caspase-dependent signaling pathway and have an important role in autophagy (31). However, the exact role of HMGB1 in ANP-associated autophagy is ill known. In cell nuclei, HMGB1 has a role in the transcription of numerous genes that are crucial to the autophagy process (11-14). Indeed, the present study detected increased nuclear localization of HMGB1 post-ANP induction, which may be associated with the increased autophagy features observed using TEM; these results are supported by a previous study (20). In addition, in AP, inhibition of Beclin 1 activity can inhibit autophagy and significantly reduce tissue damage (32). In the cytoplasm, HMGB1 binds to Beclin 1, sustaining

the Beclin 1-PtdIns3KC3 complex during the activation of autophagy (15).

Inhibiting HMGB1 action has been shown to suppress the development of pancreatitis (29). In addition, vitamin K3 is able to inhibit cerulein-induced AP via the inhibition of autophagy, and may reduce tissue damage (33). Therefore, inhibiting autophagy is possible to prevent the development of AP, whereas inducing autophagy may aggravate the condition. However, more studies are required to determine if Beclin 1 or HMGB1 could be considered as possible therapeutic targets in ANP.

The present study is not without its limitations. Firstly, it was performed in animals, and the exact involvement of HMGB1 in ANP may be subtly different in humans. In addition, the present study very superficially explored the involvement of HMGB1 in the mechanisms underlying ANP. Further studies are required to explore these mechanisms in detail. For example, Toll-like receptors and receptor for advanced glycation end products have been reported to be activated by HMGB1 and mediate the extracellular effects of HMGB1 (34,35).

In conclusion, in the ANP model generated in the present study, HMGB1 was initially increased in the nuclei, which may result in the initiation of autophagy. Subsequently, it was translocated into the cytoplasm, where it may interact with Beclin 1 to enhance autophagy, and HMGB1 was released into the blood, leading to deterioration of ANP.
