Background and purpose: Colorectal cancer (CRC) frequently metastasizes to the liver, which involves the participation of multiple cytokines. Tumor microenvironment (TME) composed of cancer-associated fibroblasts (CAFs) and tumor cells acts as an essential factor in cancer metastasis. Transforming growth factor β1 (TGFβ1) is a vital cytokine involved in migration and invasion of cancer cells. However, the underlying mechanisms remain unclear. In the present study, we aimed to investigate the role and molecular mechanisms of TGFβ1 in TME.

Methods: The conditioned medium prepared from colorectal cancer HCT116 and HT29 cells was used to culture mesenchymal stem cells (MSCs). The differentiation of MSCs to CAFs was detected by flow cytometry. The role of TGFβ1 in colorectal cancer cells metastasis was examined by wound-healing assay and transwell assay. And the activation of the Janus kinase/signal transducer and activator of transcription 3 (JAK/STAT3) signaling pathway was measured by Western blot assay.

Results: TGFβ1 induced the differentiation of MSCs to CAFs and improved HCT116 and HT29 cells migration and invasion. Meanwhile, TGFβ1 also upregulated the phosphorylation of STAT3 and enhanced the nuclear localization of p-STAT3, which activated JAK/STAT3 signaling pathway.

Conclusion: TGFβ1 induced the differentiation of MSCs into CAFs and promoted the migration and invasion of HCT116 and HT29 cells, which depended on the activation of JAK/STAT3 signaling pathway.

Keywords: TGFβ1, JAK/STAT3, MSCs-CAFs differentiation, migration and invasion

Introduction

Colorectal cancer (CRC) is one of the most common malignant tumor in the world.¹ By the year 2030, 2.2 million patients will be diagnosed as colorectal cancer and the global burden of this disease will increase by 60%.¹ The clinical data showed that about 14–18% of colorectal cancer patients suffered postoperative metastasis, and more than half of these metastases developed in liver, which had been considered as the main cause of death.² Therefore, a better understanding of the underlying molecular mechanism involved in the metastasis of colorectal cancer is essential for preventing the progression and developing the more efficient therapies.

The “seed and soil theory” has revealed that the metastasis of malignant tumors is dependent on specific tumor microenvironment (TME), which has received more attention recently.³ The complex TME was composed of tumor cells, fibroblasts,

immune and inflammatory cells, bone-marrow-derived inflammatory cells, as well as the extracellular matrix, microvessels and biomolecules.⁴ Studies have found that circulating tumor cells are dormant after reaching the corresponding target organs and require the corresponding TME to form metastases.⁵ Mesenchymal stem cells (MSCs) were involved in the formation of CRC primary lesion. And the differentiation of MSCs to cancer-associated fibroblast (CAFs) promoted the proliferation of cancer cells and the formation of tumor blood vessels.^{6,7} CAFs were heterogenous fibroblasts, and unlike the normal fibroblasts, CAFs could promote cancer stem cell renewal and atmosphere forming capacity and contribute to tumor genesis.⁸ Unfortunately, the mechanism of corresponding TME formation is still unclear.

The evidences showed multiple cytokines might be necessary in the differentiation of MSCs into CAFs. One of the key cytokines plays an important biological role in mediating tumor metastasis is TGF β 1.⁹ Studies have shown that TGF β 1 compels hematopoietic stem cell to differentiate toward myofibroblast via JAK/STAT3 signal pathway.¹⁰ TGF β 1 has also been reported to be secreted by tumor cells in a form of paracrine to stimulate the fibroblasts activation and MSCs differentiation.^{11,12} In addition, the exosome and cytokines secreted by tumor cells and CAFs may induce MSCs to synthesize α -SMA and tumor-promoting factors, which may promote the proliferation, migration and invasion of colorectal cancer cells.¹³ These evidences suggested that TGF β 1 might be involved as a significant active factor in the progression and development of CRC.

Thus, we hypothesize that the growth factor TGF β 1 induces differentiation of MSCs into CAFs and promotes the migration and invasion of HCT116 and HT29 cells via activating JAK/STAT3 signaling pathway, which ultimately accelerates the formation of TME for liver metastasis.

Materials and methods

Cell culture

The human colorectal carcinoma cell lines (HCT116, HT29) and bone-marrow-derived MSCs were obtained from ATCC. HCT116 and HT29 cells were cultured in McCoy's 5a Medium (Gibco), supplemented with 2 mmol/L glutamine (Sigma, Spain) and 10% of FBS (fetal bovine serum, Gibco), at 37°C, 95% of air and 5% of carbon dioxide (CO₂). MSCs were cultured in colorectal cancer

cells' conditioned medium (CM) at 37°C, 95% of air and 5% of CO₂. colorectal cancer cells' CM: HCT116 or HT29 cells were first cultured in general medium. When the cells were in the logarithmic growth phase, general medium was replaced with serum-free medium. The supernatant was collected as conditioned medium after 48 hrs. The TGF β 1-block peptide P17 were synthesized (AnaSpec, USA). P17 (100 mg/mL) was pre-treated with cells for blocking TGF β 1 effects. AG490 (10 μ M), purchased from MedChemExpress, was subjected to block JAK/STAT3 signaling pathway.

ELISA assay

The supernatants of HCT116 and HT29 cells were collected after 48 hrs. The concentration of TGF β 1, TNF α , HGF and PDGF in the supernatants was determined by ELISA kit, purchased from R&D. The OD (optical density) value was detected by a microplate reader (Thermofisher, USA) at 450 nm.

Cell proliferation assay

Cell counting kit-8 (CCK8, Univbio, China) was utilized for cell proliferation assay. MSCs were planted in a 96-well plate (2.5×10^3 cells for each well), and cultured in colorectal cancer cells' CM (HCT116-CM or HT29-CM group) or pre-treated with P17 conditioned medium (HCT116-CM+P17 or HT29-CM+P17 group). Serum-free medium were set as blank control group (Control-CM group). At the 24th/48th/72th hour after seeding, 100 μ L of CCK-8 solution were added for staining. The absorbance at 450 nm was measured via a microplate reader (Thermofisher, USA) after a 2 hrs incubation at room temperature. Triplicates were performed for each condition.

Sphere formation assay

MSCs were seeded in 6-well Corning plates (2.5×10^3 cells for each well) with serum-free medium (Control-CM group), colorectal cancer cells' CM (HCT116-CM or HT29-CM group) or pre-treated with P17 conditioned medium (HCT116-CM+P17 or HT29-CM+P17 group). The spheres in each well were numbered and photographed via an inverted microscope (Zeiss, Japan) after 15 days.¹⁴

Flow cytometry of CAFs biomarkers

CAFs biomarkers were recognized by a flow cytometer (BD Biosciences, USA). MSCs from various culture conditions were gathered. After resuspended with PBS in a

1.5 mL eppendorf tube, primary antibodies for CAFs specific protein: α -SMA, Vimentin or FSP1 (Mouse Anti-Human, Bioss, China) were added in eppendorf tubes, respectively (1:100). After a 1 hr incubation at room temperature, the supernatant was disposed. Cells were washed with PBS for 3 times. The FITC labeled secondary antibodies (Goat Anti-Mouse, Bioss, China) were added in each eppendorf tube (1:200) and incubated in dark for 1 hr at room temperature. The cells were washed for 3 times with PBS and then analyzed with BD FACS Calibur System (BD Biosciences, USA).

Quantitative real-time PCR

The qRT-PCR was performed according to the general protocol: RNA was extracted via TRIzol (Thermo Fisher, USA) and cDNA was synthesized via Prime Script RT Reagent kit (Takara, Japan). RT-PCR was performed using ABI 7500 (Life Tech, USA). The relative expression levels of mRNA were determined using a SYBR-Green PCR master mix kit (Thermo Fisher, USA). Gene expression was evaluated using the $2^{-\Delta\Delta C_q}$ method. GAPDH was used as control.

Wound-healing assay

The wound-healing assay was performed as common protocol: 3×10^5 of HCT116 or HT29 cells were seeded in each well of a 6-well plate (Corning, USA) in McCoy's 5a Medium with 10% FBS, and cultured at 37°C, 5% of CO₂ for 24 hrs to form a monolayer.¹⁵ The middle of the monolayer was scratched using a Cell Scraper (Sigma-Aldrich, USA). PBS was used to wash the well. Subsequently, serum-free medium (Control-CM group), serum-free medium with 10 μ M TGF β 1 (Control-CM group + TGF β 1), colorectal cancer cells' CM (HCT116-CM or HT29-CM group) or pre-treated with P17 conditioned medium (HCT116-CM+P17 or HT29-CM+P17 group) were added to the wells, respectively. The scratched monolayer was incubated at 37°C in an atmosphere of 5% CO₂ for 48 hrs. Wound closure was measured in 3 random fields in each well using an inverted microscope (DMi1, Leica, Germany). Triplicates were performed for each group.

Transwell assay

The transwell assay for the ability of invasion was performed as the following protocol.¹⁵ The polycarbonate membranes with 8- μ m pore (Corning, USA) were placed on 24-well Transwell plates (Corning, USA). Subsequently, the membranes were coated with matrigel (20 μ g per well) and dried in air for 1 hr at 37°C. The other side of the membranes was coated with fibronectin (5 μ g per well). 2×10^5 of HCT116

cells were placed on the Matrigel side of membranes. Serum-free medium (Control-CM group), serum-free medium with 10 μ M TGF β 1 (Control-CM group + TGF β 1), colorectal cancer cell's CM (HCT116-CM or HT29-CM group) or pre-treated with P17 conditioned medium (HCT116-CM+P17 or HT29-CM+P17 group) were added in the upper chamber. The concentration of FBS in upper chamber was 2.5% and the FBS in the lower chamber was 10%. The transwell plate was incubated for 8 hrs at 37°C and 5% CO₂. The cells on the matrigel side of the membrane were scrubbed off with a cotton pad. The membranes were fixed in 95% ethanol and 5% acetic acid for 30 mins and stained with crystal violet. The number of cells in 3 random visual fields were calculated using an inverted microscope (DMi8, Leica, Germany). Triplicates were performed for each group.

Nuclear and cytoplasmic extraction and Western blot analysis

The Western blot assay was performed as the classic protocol.¹⁶ Cells cultured in different conditioned medium were collected and proteins were extracted by using RIPA buffer (Beotime Institute of Biotechnology, China). The NE-PERTM Nuclear and Cytoplasmic Extraction Reagents Kit (Thermo Fisher, USA) was performed to measure p-STAT3 expression in cytoplasm or nuclei. The concentration of protein was measured using a Commassie Blue Staining Kit (Beyotime, China). Subsequently, 150 μ L of lysate protein were mixed with 50 μ L of 4 \times loading buffer and boiled for 5 mins. Equal amounts of total protein were separated by 10% SDS gel (sodium dodecyl sulphate-polyacrylamide) electrophoresis and transferred onto polyvinylidene difluoride membranes (Beyotime, China). The membranes were immunoblotted, respectively, with following primary antibodies: p-JAK1 (1:500), JAK1 (1:500), p-STAT3 (1:1000), STAT3 (1:1000), E-cadherin (1:500), N-cadherin (1:500) and vimentin (1:500), GAPDH (1:5000) and Lamin A (1:2000). All of the antibodies were obtained from Cell Signaling Technology, USA. After incubation overnight at 4°C, the antibodies were blocked with 0.5% of bovine serum albumin. The horseradish peroxidase linked secondary antibodies (Beyotime Institute of Biotechnology) were applied and DAB (3,3-diaminobenzidine tetrahydrochloride) (Beijing Liuyi Biotechnology Co., Ltd., Beijing, China) was used to visualize blot. The amount of total protein was semiquantified as ratio to GAPDH on each gel. Lamin A and GAPDH served as the normalized controls for nuclear and cytoplasmic fractions, respectively.

Statistical analysis

The data of this study were performed using SPSS 19.0 software (SPSS, USA) and GraphPad Prism 5.0 software (GraphPad, USA). Analysis of variance was calculated by the Student's test (*t*-test) or one-way ANOVA analysis. The data were presented as mean \pm standard deviation (SD). $P < 0.05$ was considered to indicate a statistically significant result. All experiments were repeated at least three times.

Results

Colorectal cancer cells' CM promotes the proliferation and differentiation of MSCs to CAFs

We first measured the expression level of growth factors in the conditioned medium of colorectal cancer cells (HCT116-CM and HT29-CM). In the conditioned medium, growth factors such as TGF β 1, TNF α , HGF and PDGF were examined via ELISA kit assay. The result showed that the concentration of TGF β 1, TNF α , HGF and PDGF were significantly upregulated both in HCT116-CM and HT29-CM (Figure 1A). Moreover, the number of MSCs cultured in serum-free medium (control-CM) was significantly less than that in colorectal cancer cells' CM, and the cells were in poor condition with some cells floating in the medium (Figure 1B). The adherent cells in colorectal cancer cells' CM group were spindle-like, which were different from the globoid cells in control-CM group. It indicated that these cells had differentiated to CAFs. The proliferation of MSCs was significantly increased after treated with colorectal cancer cells' CM via CCK-8 assay (Figure 1C). And we found that the ability of sphere formation of colorectal cancer cells' CM cultured MSCs was distinctly strengthened (Figure 1D). To ensure whether colorectal cancer cells' CM could induce the differentiation of MSCs to CAFs, the CAFs-related biomarkers such as α -SMA, vimentin, FSP1 was detected by flow cytometry (Figure 1E). The results showed that colorectal cancer cells' CM promoted the sphere formation of MSCs and increased the level of CAFs-related biomarkers, which suggested that colorectal cancer cells' CM promoted the generation of CAFs.

TGF β 1 induces the proliferation and differentiation of MSCs to CAFs

To further verify our hypothesis that TGF β 1 is the key factor to mediate the metastasis, we applied TGF β 1

blocking peptide P17 for pre-treating with colorectal cancer cells. As shown in Figure 2A, the number of MSCs in the control-CM group and the HCT116-CM+P17 or HT29-CM+P17 group was significantly less than that in the HCT116-CM or HT29-CM group, with some cells floating in the medium. And the result of CCK-8 assay also showed that the increasing proliferation of MSCs incubated with HCT116-CM or HT29-CM group was inhibited by exposure to P17 treatment (Figure 2B). In addition, the sphere formation analysis was similar to CCK-8 assay (Figure 2C). Moreover, flow cytometry revealed that the CAFs-related biomarkers such as α -SMA, vimentin, FSP1 were downregulated in HCT116-CM+P17 or HT29-CM+P17 group and control-CM group compared to those in HCT116-CM or HT29-CM group (Figure 2D), which suggested that the differentiation of MSCs cells was prohibited with TGF β 1-blocking peptide P17. These findings suggested that TGF β 1 acted as a key factor modulating the differentiation of MSCs to CAFs.

TGF β 1 enhances the migration and invasion of HCT116 and HT29 cells

To determine the role of TGF β 1 on metastasis, the migration and invasion of HCT116 and HT29 cells were assessed by wound-healing assay and transwell assay at indicated times. As shown in Figure 3A and B, HCT116 and HT29 cells migration and invasion significantly increased in the control-CM+TGF β 1 group and HCT116-CM or HT29-CM group, while this effect was abolished by TGF β 1-blocking peptide P17. Epithelial-mesenchymal transition (EMT) is a vital mechanism of cancer metastasis. To further investigate, the relative expression of E-cadherin, N-cadherin and vimentin were measured by qRT-PCR and Western blot assay. As shown in Figure 3C and D, the expression of N-cadherin and vimentin were upregulated, whereas the expression of E-cadherin was downregulated after TGF β 1 treatment. These molecules showed an opposite expression following exposure to P17. Therefore, these results demonstrated that TGF β 1 enhances the migration and invasion of HCT116 and HT29 cells.

JAK/STAT3 signaling is involved in TGF β 1-induced migration and invasion of HCT116 and HT29 cells

STAT3 is a key transcription factor, which is involved in cell proliferation, survival and stress. It was reported that

the activation of JAK/STAT3 induced by TGF β 1 promoted the tumorigenesis of lung carcinoma cells. To verify our hypothesis, the STAT3 inhibitor AG490 was pre-treated with HCT116 cells. First, the JAK/STAT3 protein expression was measured by Western blot. The result showed

that TGF β 1 activated the phosphorylation of JAK1 and STAT3 (Figure 4A). And then, in order to further determine JAK/STAT3 signaling may be involved in regulating TGF β 1-induced EMT, the agent AG490, a STAT3 inhibitor, was used. As shown in Figure 4B and C, the TGF β 1

increased the level of N-cadherin and vimentin expression and decreased the level of E-cadherin expression, whereas this effect were reversed by AG490. Meanwhile, the invasive and migratory cells number was also markedly

decreased while adding AG490 (Figure 5A–D), which is similar to the effect of P17. To further explore the correlation of TGFβ1 and JAK/STAT pathway, we detected the expression of p-STAT3 in cytoplasm and nucleus. We

Figure 5 TGFβ1 induces HCT116 and HT29 cells migration and invasion via activating JAK/STAT signaling. (A–D) The migration and invasion of HCT116 cells was determined by wound-healing and transwell assays. *P<0.05 and **P<0.01 vs Con-CM, *P<0.05 and **P<0.01 vs Con-CM+TGFβ1, **P<0.01 vs HCT116-CM or HT29-CM. found a considerable increase in p-STAT3 expression in nucleus versus the cytosol (Figure 5E). GAPDH was used as a cytosol marker and Lamin A was used as a nucleus marker. Thus, the results confirmed that TGF β 1 enhanced p-STAT3 expression and nuclear location, while this effect was blocked by AG490 or P17, which verified that the function of TGF β 1 in metastasis was in a STAT3-dependent manner.

Discussion

It was realized that the TME played a key part in tumor progression.^{17–19} One of the fundamental part of TME is CAFs.^{20,21} CAFs were involved in tumor-associated inflammation through NF- κ B pathway.^{22,23} The activated NF- κ B induced the overexpression of chemokine CCL2 and pro-inflammatory cytokine, cyclooxygenase 2 (COX-2), which produced in CAFs.²⁴ The chemokine CCL2 could recruit the blood mononuclear cells to tumor site, which is helpful for the generation of tumor-related macrophages.²⁴ Meanwhile, COX-2 induces the expression of prostaglandin E2, which promotes the proliferation of malignant colonic epithelial cells.^{25,26} On the other hand, the CAFs secreted ECM (extracellular matrix), collagen and lysyl oxidase (LOX).^{27,28} ECM usually served as a pool of tumor growth factors, and LOX cross-linked to type I collagen to form a scaffold for tumorigenesis.²⁸ Interestingly, the mechanical stress from the firm collagen scaffold induced CAFs to express MMPs (matrix metalloproteinase).²⁷ The CAFs-induced MMPs could mediate the degradation of ECM, which caused cancer cell invasion.²⁹ The origin of CAFs was complexed. Stellate cell, smooth muscle cell, endothelial cell, epithelial cell or resident fibroblast could be transformed into CAFs via different mechanisms.²⁴ It is difficult to identify the source of CAFs and conduct the appropriate treatment of colorectal cancer. Here we found that MSCs, as the essential part of TME, differentiated into CAFs within specific microenvironment, which participated in the cancer metastasis.

The evidences showed that the TGF β 1 participated in tumorigenesis, development and metastasis.³⁰ The high level of TGF β 1 was associated with poor postoperative metastasis in colorectal cancer.³¹ In the present study, we observed that TGF β 1 promoted the differentiation of MSCs into CAFs via upregulating the expression of α -SMA, vimentin and FSP1, which were considered as the CAFs biomarkers. The α -SMA (α -smooth muscle actin) was the fibrotic specific protein which played an important

role in fibrogenesis. It had been widely used in the evaluation of CRC progression in recent years.^{26,32,33} Vimentin was an intermediate filament protein, usually expressed in mesenchymal cells. Vimentin composed the cytoskeleton with microtubules and microfilaments; thus, it was known as the biomarker of mesenchymal-derived cells. The level of vimentin might indicate the progress of CAFs.^{34–37} FSP1, also known as CXCL1 (C-X-C motif chemokine ligand 1), was a growth factor combining with G-protein coupled receptor. FSP1 could be secreted by CAFs and enhanced the progress of cancers.^{38,39} In this study, we found the aberrant expression of these CAFs-related biomarkers. One possible mechanism might be: TGF β 1 bound to TGF β 1 receptors on MSCs and activated Smad2/3 and P38,⁴⁰ mediate the activation of CXCR4 (C-X-C chemokine receptor type 4)/SDF1 (stromal cell-derived factor-1) pathway, and upregulated the expression of fibroblast-specific proteins such as α -SMA, promoted the differentiation of MSCs into CAFs.⁴¹ We used the synthetic peptide P17 to block TGF β 1 signal pathway, and found the levels of α -SMA, vimentin and FSP1 were downregulated. It demonstrated that TGF β 1 played a critical role in the differentiation of MSCs into CAFs.

On the other hand, we found TGF β 1 could activate JAK/STAT3 pathway. The activation of the STAT3 signaling pathway has been proved to associate with cancer cell invasion and metastasis.⁴² And the aberrantly activation STAT3 was found in various tumor tissues.^{43,44} After JAK was phosphorylated, it recruited STAT3 monomers to produce homologous or heterogenous dimers.^{45,46} Subsequently, STAT3 enters the nucleus and binds to DNA to mediate the synthesis of downstream protein, which involved in cell proliferation, differentiation, apoptosis, angiogenesis, immune response and metastasis.^{45,46} The previous study also showed the important role of TGF β 1 in the TME. TGF- β 1 could directly regulate the expression of MMP9, VEGF and SDF-1. In the TME, tumor cells could remodel the surrounding tissues by MMP to achieve invasion and metastasis; VEGF and SDF-1 secreted by cancer cells could promote endothelial cell proliferation. These chemokines in TME and promotes cell proliferation, migration and mediates metastasis and/or homing to the secondary site.^{47–49} In the present study, the invasion and migration of colorectal cancer cells were suppressed after STAT3 signaling pathway was blocked by AG490. Combining the results above, we deduced TGF β 1 activated the JAK/STAT3 pathway, thereby promoting the migration and invasion of colorectal cancer cells.

Conclusions

In conclusion, the findings of the present study verified the biological functions of TGFβ1 in the differentiation of MSCs into CAFs, and provided evidence that the TGFβ1 promoted the invasion and metastasis of HCT116 and HT29 cells. In conclusion, TGFβ1 is an essential growth factor to advance the formation of TME through the activation of JAK/STAT3 signaling pathway, which promotes the tumor metastasis (Figure 5F). This mechanism represents potential molecular targets for the treatment of this disease. However, due to multiple growth factors secreted by cancer cells, we need to further explore the effects of other growth factors such as PDGF, HGF on cancer metastasis and the present study of TGFβ1 in TME is desired to confirm in vivo.

OncoTargets and Therapy

Dovepress

Publish your work in this journal

OncoTargets and Therapy is an international, peer-reviewed, open access journal focusing on the pathological basis of all cancers, potential targets for therapy and treatment protocols employed to improve the management of cancer patients. The journal also focuses on the impact of management programs and new therapeutic

agents and protocols on patient perspectives such as quality of life, adherence and satisfaction. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
