ABSTRACT

Background. Galanthamine, one kind of Amaryllidaceae alkaloid extracted from the *Lycoris* species, is used in the treatment of Alzheimer's disease. In regards to medical and economic importance, the biosynthesis and regulatory mechanism of the secondary metabolites in *Lycoris* remain uninvestigated.

Methods. BLAST was used to identify the sequence of tyrosine decarboxylase in the transcriptome of *Lycoris aurea* (L'Hér) Herb. The enzyme activity of this TYDC was determined by using heterologous expressed protein in the *Escherichia coli* cells. The related productive contents of tyramine were detected using High Performance Liquid Chromatography (HPLC). According to the available micro RNA sequencing profiles and degradome database of *L. aurea*, microRNA396 were isolated, which targets to *LaTYDC1* and RNA Ligase-Mediated-Rapid Amplification of cDNA Ends (RLM-RACE) were used to confirm the cleavage. The expression levels of miR396 and *LaTYDC1* were measured using a quantitative real-time polymerase chain reaction (qRT-PCR).

Results. *LaTYDC1* was mainly expressed in root, bulb, leaf and flower fitting the models for galanthamine accumulation. This decarboxylase efficiently catalyzes tyrosine to tyramine conversion. Under methyl jasmonate (MeJA) treatment, the expression of *LaTYDC1* and the content of tyramine sharply increase. The use of RLM-RACE confirms that miR396 promotes the degradation of *LaTYDC1* mRNA. Under MeJA treatment, the expression of miR396 was suppressed while the expression level of *LaTYDC1* sharply increased. Following the increase of the miR396 transcriptional level, *LaTYDC1* was significantly repressed.

Conclusion. *LaTYDC1* participates in the biosynthesis of galanthamine, and is regulated by miR396. This finding also provides genetic strategy for improving the yield of galanthamine in the future.

Keywords Tyrosine decarboxylase, Amaryllidaceae alkaloids, *Lycoris aurea*, Galanthamine

INTRODUCTION

Plants generate and accumulate secondary metabolites in response to a wide variety of biotic and abiotic stresses, particularly in defense against herbivores or pathogens (Kabera *et al.*, 2014; Yu & De Luca, 2013). These secondary metabolites have developed as resources of natural drugs because of their biological activities. Many others have become commercially important and notably beneficial in the treatment of human diseases (Yu & De Luca, 2013). For example, galanthamine, which is extracted from the *Lycoris* plant, is one type of Amaryllidaceae alkaloid. As an inhibitor of cholinesterase, galanthamine can increase acetylcholine sensitivity and has a positive effect when treating Alzheimer's disease (Dal-Bianco *et al.*, 1991). Other Amaryllidaceae alkaloids, such as lycorine and haemanthamine, have anti-cancer, anti-viral, and anti-bacterial properties. Lycorine might be a good candidate for therapeutic agent against leukemia and severe acute respiratory syndrome (SARS) (Li *et al.*, 2015; Doskočil *et al.*, 2015; Havelek *et al.*, 2014). The officinal and economic values of *Lycoris* species remain uninvestigated.

Since the biosynthetic pathways of Amaryllidaceae were first proposed by Barton, Kirby & Thomas (1963), a few enzymes taking part in the galanthamine synthesis pathway have been identified and characterized (Eichhorn *et al.*, 1998; Kilgore *et al.*, 2014; Kilgore *et al.*, 2016). At the upstream of the galanthamine biosynthesis pathway, tyrosine, which is the origin beginning of isoquinoline alkaloid biosynthesis is converted into tyramine by an undefined tyrosine decarboxylase (TYDC), which is the first committed step in isoquinoline alkaloid biosynthesis. TYDC is a common enzyme in plant kingdom (Lehmann & Pollmann, 2009), and also is implicated in the defense response (Facchini & De Luca, 1994). Then, tyramine and norbelladine 3,4-dihydroxybenzaldehyde are condensed to a Schiff-base (Eichhorn *et al.*, 1998; Kilgore *et al.*, 2014, Fig. 1), which is documented to be the basic bone of all Amaryllidaceae alkaloids (Barton *et al.*, 1961). Norbelladine is then methylated by 4'-O-methyltransferase (*Np* N4OMT) to 4'-O-methylnorbelladine (Kilgore *et al.*, 2014). One key phenol-coupling enzyme cytochrome P450, CYP96T1 from *Narcissus* sp. aff. *Pseudonarcissus* was identified to have C-C phenol coupling capacity to catalyze 4'-O-methylnorbelladine to noroxomaritidine (Kilgore *et al.*, 2016).

Jasmonate (JA) signal regulates plant response to many biotic and abiotic stresses by coordinating the production of abundant of defense-related protein and secondary metabolites (Turner, Ellis & Devoto, 2002; Wasternack, 2015). Methyl jasmonate (MeJA) can induce three major classes of plant secondary metabolites (Wasternack, 2007; Wasternack & Hause, 2013). In our observation, under MeJA treatment, the accumulation of galanthamine is induced distinctly in other *Lycoris* plants (Mu *et al.*, 2009); moreover, some specific genes correlated with secondary metabolism respond to MeJA signaling (Farmer & Ryan, 1992). MicroRNAs (miRNA) are commonly found in both plants and animals, these small regulatory RNAs with 20–24 nucleotides have been recognized for their participation in regulation mechanisms in plant growth, development and defense (Chen, 2009). As a post-transcriptional regulator, miRNAs in complex with Argonaute (AGO) effector protein, they cause target mRNA degradation through complementary region binding, while negatively modulating the expression of a wide

Figure 1 TYDC is involved in the proposed biosynthetic pathway for galanthamine. The enzymes and compounds involved in the galanthamine biosynthetic pathway. range of genes. The plant miRNAs regulate their target mRNA by perfectly or near-perfectly complementary-matching (Axtell & Bowman, 2008; Chen, 2009); therefore, based on sequence complementarity, the target of the plant miRNAs can usually be successfully predicted (Sunkar & Zhu, 2004). It is predicted that miRNAs elicited by MeJA correlate with galanthamine biosynthesis via a possible post-transcriptional regulation (Xu et al., 2016). When investigating the role of miRNAs in the regulation of galanthamine biosynthesis in our earlier study, we observed and profiled *L. aurea* miRNA in response to treatment with MeJA. 154 miRNAs expressing differently in comparison to the vehicle-treated ones were identified (Xu et al., 2016). By using degradome sequencing analysis, 32 genes from different plant processes were validated, and were then targeted by 49 miRNAs. Among these miRNAs and targets, we found that LaTYDC1 was targeted by miR396. Of the conserved miRNAs in plants, miR396 regulates the expression level of transcriptional factors, such as GROWTH-REGULATING FACTOR (GRF) and bHLH74, thereby affecting plant growth and development (Debernardi et al., 2014; Liang et al., 2014; Rodriguez et al., 2015).

In this study, we have identified an enzyme called LaTYDC1, which play role in tyrosine to tyramine conversion step of galanthamine biosynthetic pathway in *L. aurea*. Additionally, the expression level of LaTYDC1 and the content of tyramine were regulated by MeJA. Our results also showed that miR396 may act as a negative regulator that promotes the degradation of *LaTYDC1* to repress the yield of tyramine.

MATERIALS AND METHODS

Plant materials and growth conditions

L. aurea were planted in a nursery at the Institute of Botany, Jiangsu Province and Chinese Academy of Sciences, Nanjing, China. The flowers and scapes of *L. aurea* were collected in August while bulbs, roots, seeds, and leaves of *L. aurea* were collected in October. For the treatment experiments, the seeds of *L. aurea* were planted in an incubator with 16/8 h (22/18 °C) day/night regimes at 100 $\mu\text{mol m}^{-2}\text{s}^{-1}$ irradiation. Eight month-old seedlings

were imposed for 0, 6, 12 and 24 h with 100 μ M MeJA in 0.02% DMSO, or with 0.02% Dimethyl sulfoxide (DMSO) as the vehicle control, respectively, as previously described by [Ma et al. \(2016\)](#). Then each treated sample was collected for further analyses.

Isolation and cloning of *LaTYDC1* cDNA

By BLAST against the transcriptome database of *L. aurea* ([Wang et al., 2013](#); [Wang et al., 2017](#)), using the relevant primers *LaTYDC-F* and *LaTYDC-R* ([Table S1](#)) for running PCR, the full length sequence of *LaTYDC1* was identified. The accession number of *LaTYDC1* is [MG932082.2](#).

Total RNA extraction, cDNA first-strand synthesis and qRT-PCR

100 mg of fresh tissue were fully ground in liquid nitrogen and 1 ml RNAiso was added following the RNA extraction protocol described in the instructions (Takara, Dalian, China). After the extracted RNA was measured using a UV spectrophotometer and 1% (w/v) agarose gel electrophoresis, they were used as templates to create the cDNA transcribed in reverse as previously described by [Xu et al. \(2016\)](#). For the qRT-PCR tests, the DNA sequence of primers of *LaTYDC1* and *LaTIP41* are listed in [Table S1](#). The qRT-PCR program started at 95 °C for 5 min, then took place in a condition of 95 °C for 15 s, 56 °C for 15 s, 72 °C for 20 s, for 40 cycles. The *L. aurea* *TIP41* gene was applied as a reference gene ([Ma et al., 2016](#), the sequence of *TIP41* is shown in [Supplemental Information 1](#)).

miRNA first-strand synthesis and qRT-PCR for microRNA

Reverse transcription was carried out with Mir-XTM miRNA First-Strand Synthesis kit based on a SYBR qRT-PCR user manual for cDNA synthesis (Takara, Dalian, China). Real-time fluorescence quantitative PCR was performed using qTPWER (Analytik Jena, Jena, Germany). The *L. aurea* *U6* gene was used for normalization. The qRT-PCR protocol was as follows: 95 °C for 30 s, 40 cycles of 95 °C for 5 s, 56 °C for 15 s, 72 °C for 20 s. In order to verify the specificity of the primers, a melting-curve was also analyzed. Each qPCR was repeated three times.

Analysis of RNA ligase-mediated-rapid amplification of cDNA ends (RLM-RACE)

Total RNA was extracted and purified from the leaves of *L. aurea* as previously described, followed with further purification with the TRIzolTM Plus RNA Purification Kit (Invitrogen, Carlsbad, CA, USA). The purified RNA was amplified for the RLM-RACE experiment using a First ChoiceTM RLM-RACE Kit (Invitrogen, Carlsbad, CA, USA), following the method described by [Shen et al. \(2014\)](#). The ligation of 5' RACE adapter and oligo RNA were performed following the manual of the kit. By using the gene specific primers listed in [Table S1](#) with the 5' RACE outer or inner primer, nested PCR was performed. The PCR products were agarose gel purified and cloned into pGEM-T vector (Promega, Madison, WI, USA) for sequencing.

Subcellular localization

The complete open reading frame fragment of *LaTYDC1* was cloned into the expression vector pAN580 and followed by green fluorescent protein (GFP). The construct was transformed into *Arabidopsis* protoplasts as previously described (Zhang *et al.*, 2014). After incubation for 16 h, the expressing cells were observed under an LSM 780 confocal laser scanning microscope (Zeiss, Oberkochen, Germany) with the 488 nm excitation and 505–530 nm band-pass emission filter (Xu *et al.*, 2017).

Expression and purification of recombinant LaTYDC1

Heterologous expression and protein purification of recombinant LaTYDC1 were carried out as described by Zhang *et al.* (2011) with some modification. The full length of *LaTYDC1* without the termination codon was cloned into the expression vector pGEX4T-1, followed by GST tag. This recombinant expression plasmid was confirmed by sequencing before being introduced into *E. coli* BL21 (DE3). The transformed bacteria were grown at 37 °C with shaking (180 rpm) in 500 mL of Luria-Bertani medium (Kawalleck *et al.*, 1993) containing ampicillin (50 µg mL⁻¹). When the OD600 of the bacteria reached 0.6~0.8, isopropyl thio-b-D-galactopyranoside (IPTG) at a final concentration of 0.5 mM was added and the incubation conditions were adjusted to 16 °C, 100 rpm. After incubation for 20 h, cells were harvested by centrifugation (4,000 rpm) for 10 min, suspended in 10 ml of 50 mM Tris-HCl (pH 8.0), and then sonicated on ice for 30 min. The homogenate was centrifuged at 12,000 rpm for 20 min at 4 °C, and then the supernatant was passed through a column of high affinity GST purification medium (GenScript, Nanjing, China). The column was washed with 50 mM potassium phosphate buffer (pH 8.0), then the fusion protein was eluted by elution buffer, which contains 50 mM Tris-HCl (pH 8.0) and 0.01 M reduced glutathione.

Enzyme activity and substrate-specificity analyses

The catalytic activity of the purified GST-LaTYCD1 protein were analyzed followed the method of Lehmann & Pollmann (2009) with some modification. 150 µL mixture containing 15 µg fusion protein, 10 mM pyridoxal-5-phosphate, 15 µL of 20 mM L-tyrosine or L-Dopa and 50 mM Tris-HCl (pH 8.0), and was incubated at 37 °C for 40 min. The reaction was stopped by adding 300 µL of methanol or boiling. Then the mixture of reaction was clarified by passing it through a 0.22 µm pore size nylon membrane filter.

Tyramine and dopamine were analyzed by High Performance Liquid Chromatography (HPLC, Shimadzu LC-20AT, Tokyo, Japan) on a reverse phase column (InertSustain C18, 5 µm, 4.6 mm × 250 mm). To measure tyramine, the solvent composition was: mobile phase A, water with 0.1% phosphoric acid; mobile phase B, 100% acetonitrile. The eluent gradient was: 10% B to 15% B in 25 min, from 15% B to 100% B in 1 min, kept for 10 min, from 100% B to 10% B in 1 min, kept for 15 min, 0.6 mL/min flow rate. The injection volume was 10 µL, and tyramine was detected at 275 nm. To measure dopamine, the solvent composition was: mobile phase A, water with 0.1% formic acid; mobile phase B, 100% acetonitrile. The eluent gradient was: 10% B to 15% B in 15 min, from 15% B to 100% B in 5 min, kept for 5 min, from 100% B to 10% B in 5 min, kept for 10 min, 0.6

mL/min flow rate. The injection volume was 10 μ L, and dopamine was detected at 275 nm. Quantification of the target compound was performed using the calibration curves. Varying substrate concentration was used to determine the K_m and V_{max} values (Kang et al., 2007).

Determination of tyramine in plants by HPLC

Fresh plant materials were weighted and totally ground. 1 g of the ground sample was extracted with 25 mL of methanol in a glass tube, and all of these tubes were placed in an ultrasonic bath for 8 h (Zhou & Su, 2008). The supernatants were clarified by passing through a 0.22 μ m pore size NC filter and tyramine was detected by HPLC.

To analyze the tyramine of the extracts by HPLC, the solvent composition was: mobile phase A, water with 0.3% phosphoric acid; mobile phase B, 100% acetonitrile. The eluent gradient was: 5% B for 15 min, then the eluent from 5% B to 100% B in 5 min, kept for 10 min, then from 100% B to 5% B in 5 min, kept for 10 min, 0.8 mL/min flow rate. The injection volume was 10 μ L, and tyramine was detected at 275 nm. Quantification of tyramine was performed using the calibration curves.

Phylogenetic analysis

Phylogenetic tree analysis of LaTYDC1 and TYDCs proteins from different species by using Maximum likelihood method. The phylogenetic tree constructed using MEGA5.5 software comparison of amino acid sequences of plant EgTYDC1 (*Erythranthe guttata*, XP_012827457.1); NnTYDC2 (*Nelumbo nucifera*, XP_010245171.1); DcTYDC2 (*Dendrobium catenatum*, PKU83762.1); QsTYDC1 (*Quercus suber*, SXP_023871760.1); AcTYDC (*Aristolochia contorta*, DQ986331.1); AsTYDC2 (*Apostasia shenzhenica*, PKA66030.1); AcTYDC2 (*Ananas comosus*, OAY76026.1); RcTYDC1 (*Rosa chinensis*, XP_024161133.1); JrTYDC1 (*Juglans regia tyrosine*, XP_018819733.1); LaTYDC1 (*Lycoris aurea*, MG932082.1); NpTYDC1 (*Narcissus pseudonarcissus*, AUG71932.1); PbTYDC1 (*Pyrus bretschneideri*, XP_009377476.1); NpTYDC2 (*Narcissus pseudonarcissus*, AUG71933.1); RsTYDC (*Rhodiola sachalinensis*, ABF06560.1); OsTYDC (*Oryza sativa*, XP_015644906.1); PcTYDC (*Petroselinum crispum*, AAA33862.1); PaTYDC1 (*Prunus avium*, XP_021812417.1); PsTYDC7 (*Papaver somniferum*, AF025434.1); AmTYDC (*Argemone mexicana*, ACJ76782.1); AtTYDC (*Arabidopsis thaliana*, NP_001190862.1); TcTYDC (*Theobroma cacao*, EOX96928.1).

Statistical analysis

Statistical analysis was performed using SPSS 13.0, and differences were analyzed with one-way ANOVA test or t -test. Statistical significance was assumed at $P < 0.05$.

RESULTS

MeJA treatment resulted in more tyramine accumulation in *L. aurea* plants

Secondary metabolite accumulation is tightly controlled by Jasmonate (JA) signaling (Wasternack, 2007), and our previous results show that MeJA induces the accumulation of galanthamine in *Lycoris chinensis* Traub (Mu et al., 2009). In this study, 100 μ M MeJA were

Figure 2 The content of tyramine in root under MeJA treatment. *L. aurea* seedlings showed an increased tyramine under MeJA treatment. The seedlings were treated with 100 μM MeJA for 6, 12 and 24 h (black), Dimethyl sulfoxide (DMSO) was used as vehicle control (gray). Error bars represent SE ($n = 3$). Statistical difference were estimated using independent *t*-test compared with the respective controls. Differences are significant with p value < 0.05 (*) (p -value = 0.027 at 6 h, p -value = 0.014 at 12 h and p -value = 0.039 at 24 h, degree of freedom = 3).

Full-size DOI: 10.7717/peerj.6729/fig-2

used to treat the *L. aurea* seedlings for 24 h, then the contents of tyramine in the roots were measured by HPLC. As the results show in Fig. 2, the seedlings accumulated 31.59 $\mu\text{mol g}^{-1}$ tyramine in the roots after 6 h of MeJA treatment, when the control sample accumulate 19.32 $\mu\text{mol g}^{-1}$ tyramine. After 12 h of MeJA treatment, tyramine content of the treated sample was 30.31 $\mu\text{mol g}^{-1}$, almost two-folds the amount in the control samples. After 24 h, the content of tyramine in experimental seedlings decreased to 7.7 $\mu\text{mol g}^{-1}$, almost one half of the control samples.

Characterization of *LaTYDC1*

LaTYDC1 covers an open reading frame representing 511 amino acids with a predicted molecular weight of 56.7 kDa. Phylogenetic analysis of *LaTYDC* along with *TYDCs* from other species was carried out using maximum likelihood method. We conferred this gene of interest as *LaTYDC1*, which is placed near *NpTYDC1* and another *TYDC* from *L. aurea*, and shares a high similarity with *NpTYDC2* (Fig. 3A). In addition, the sequence alignment of these *TYDCs* indicated that *LaTYDC1* obviously shared the conserved domain with other *TYDC* proteins, and the deduced amino acid sequence of *LaTYDC1* showed 47–89.67% shared identity with those from other plant origins (Fig. S1). *LaTYDC1* expression in root, leaf and flower were 40, 10, and 15-fold greater, respectively, than that in bulb (Fig. 3B). At the beginning, six hours after 100 μM MeJA treatment, the accumulation of *LaTYDC1* significantly increased almost 200 folds when compared with the vehicle control samples, and sharply decreased when compared with the expression level of samples 6 h after MeJA treatment. The similar results were observed after 24 h treatment (Fig. 3C).

To further explore the function of *LaTYDC1*, we transiently expressed the *LaTYDC1*-GFP (green fluorescent protein) fusion protein in the *Arabidopsis* protoplast. As the green

Error bars represent SE ($n = 3$). (C), Time course expression analysis of LaTYDC1 in response to MeJA (100 μ M) treatment. The expression in plants without MeJA was used as a reference of basal expression level. Error bars represent SE ($n = 3$). Statistical difference was estimated using Least Significant Difference test compared with the 0 h controls. Differences are significant with p value < 0.01 (**) (p -value = 0.000 at 6 h, p -value = 0.007 at 12 h and p -value = 0.005 at 24 h, degree of freedom = 8). Full-size DOI: 10.7717/peerj.6729/fig-3

fluorescence signal was observed at the cytoplasm, it showed that LaTYDC1 localizes at the cytoplasm (Fig. 3D).

Enzymatic characterization of LaTYDC1

To examine the enzymatic function of LaTYDC1, we expressed the LaTYDC1 protein fused with a 26.8 kDa GST tag in *E. coli* BL21. As shown in Fig. 4, after purification using a high affinity GST purification column, the LaTYDC1-GST fusion protein was checked by SDS-PAGE, and the fusion protein showed a predictable molecular weight (MW) of 83.5 kDa (Fig. 4A).

Assuming that LaTYDC1 has reductase activity, we were interested in testing whether the fusion protein could catalyze tyrosine into tyramine conversion. HPLC analysis was then carried out with the samples for the enzyme assay, in which the purified LaTYDC1 fusion protein uses tyrosine as substrate. The result shown in Fig. 4B demonstrated that the fusion LaTYDC1 was able to specifically catalyze the synthesis of tyramine, since the product with an identical peak in regards to retention time was the same as the corresponding tyramine standard (Fig. 4B). In addition, this product was determined by

Full-size [DOI: 10.7717/peerj.6729/fig-4](https://doi.org/10.7717/peerj.6729/fig-4)

Table 1 Substrate specificity tests for LaTYDC1. The substrate affinity was determined by calculating the K_m , tyrosine and 3,4-dihydroxy-L-phenylalanine (Dopa) were used as the substrate for LaTYDC1.

Substrate	K_m (μM)	V_{max} (nkat mg^{-1})
Tyramine	602.34 ± 0.12	3.19 ± 0.51
Dopa	966.35 ± 79	1.24 ± 0.09

GC-MS analysis, and it was confirmed that the product is tyramine (Fig. 4C). Moreover, the optimal temperature for LaTYDC1 enzyme activity is 50 °C; when the temperature is below 30 °C or above 55 °C, enzyme activity rapidly declines (Fig. S2A). The optimum pH of LaTYDC1 is 8.5; when the pH value is above 9, enzyme activity sharply declines (Fig. S2B). Furthermore, the substrate affinity was determined by calculating the K_m we used tyrosine and 3,4-dihydroxy-L-phenylalanine (Dopa) as the substrate for LaTYDC1. The K_m for tyrosine is $602.34 \pm 38 \mu\text{M}$, and the K_m for dopa is $966.35 \pm 79 \mu\text{M}$. The V_{max} is 3.19 ± 0.51 (nkat mg^{-1}) and 1.24 ± 0.095 (nkat mg^{-1}), respectively (Table 1).

Identification of LaTYDC1-related miRNA in *L. aurea*

The sudden change of *LaTYDC1* expression under MeJA attracted our attention. MiRNAs play post-transcriptional regulatory roles in plants, and are involved in the regulation of secondary metabolite biosynthesis in many plants (Zhao *et al.*, 2012). To identify the genes and miRNA that participate in the JA signal transduction pathway and are involved

in galanthamine biosynthesis, we searched the response miRNA sequencing database of *L. aurea* (Xu et al., 2016). We identified that miR396 is responsive to MeJA treatment, and the predicted target is *LaTYDC1*. The cleavage site was confirmed by degradome data and is shown in Fig. 5A. qRT-PCR were used to determine the expression level of miR396 in different tissues. The results showed that the expression of miR396 was the lowest in roots, and was mainly expressed in leaves. The expression of miR396 in root, leaf and flower were respectively 2, 17, and 4-fold greater than that in the bulb (Fig. 5B). This co-expression analysis also showed that miR396 was negatively correlated with the target *LaTYDC1*. As miRNA paired with *LaTYDC1* mRNA to direct transcriptional suppression, we did qRT-PCR to determine miR396 expression under MeJA treatment, and the expression of miR396 was repressed about one half of the vehicle sample. Twelve hours after MeJA treatment, the expression of miR396 increased ~3 folds (Fig. 5C). Combined with the repressed expression of *LaTYDC1*, the reversely correlated expression relationship suggests that miR396 may target *LaTYDC1*. RLM-RACE experiments were carried out to confirm the cleavage, and the cleavage sites were mapped in flanking sequence of the complementary region (Fig. 5D), the DNA sequences in the RLM-RACE experiments were listed in Supplemental Information 2).

DISCUSSION

It is known that the secondary metabolites of some medical plants are beneficial for human health. Amaryllidaceae alkaloids that come from plants in the Amaryllidaceae family have anti-cancer, anti-virus and acetylcholine esterase inhibitor properties (Bores et al., 1996). These secondary metabolites have been used clinically, but their product yield has been limited since these alkaloids are extracted from plant tissues. The biosynthetic pathway of the Amaryllidaceae alkaloids has been partly investigated (Kilgore et al., 2014; Kilgore et al., 2016). So far, there are two key enzymes that have been found, but the majority of its mechanism has remained unexplored.

TYDC enzymes take part in primary and secondary plant metabolism. In fact, TYDC catalyzes the initial reaction of many secondary metabolites, such as salidroside in *Rhodiola chalinensis* (Zhang et al., 2011), verbascoside in *Syringa vulgaris* (Ellis, 1983) and hordenine in *Hordeum vulgare* (Leete & Marion, 2011). In *Lycoris* plants, the aromatic amino acid tyrosine is converted to tyramine by TYDC and provides the basic bone for Amaryllidaceae alkaloids including galanthamine (Kilgore et al., 2014). Tyramine and many secondary metabolites play important anti-stress roles, and the accumulation of them could help the plant get over stress (Lehmann & Pollmann, 2009; Kabera et al., 2014). JAs are the key signals in stress response and trigger secondary metabolite production (De Geyter et al., 2012). Under JA signaling, the increase of galanthamine is significant (Colque et al., 2004; Mu et al., 2009; Ptak et al., 2010; Jiang et al., 2013). Meanwhile the content of tyramine in *L. aurea* seedlings was almost two fold when compared with the control (Fig. 2), and the expression of *LaTYDC1* was activated (Fig. 3C). In addition, the expression pattern of *LaTYDC1* was in line with the accumulation pattern of galanthamine (Fig. 3B; Fig. S3). All of these results indicated that under MeJA treatment, the accumulation of galanthamine is associated with the increase of tyramine content.

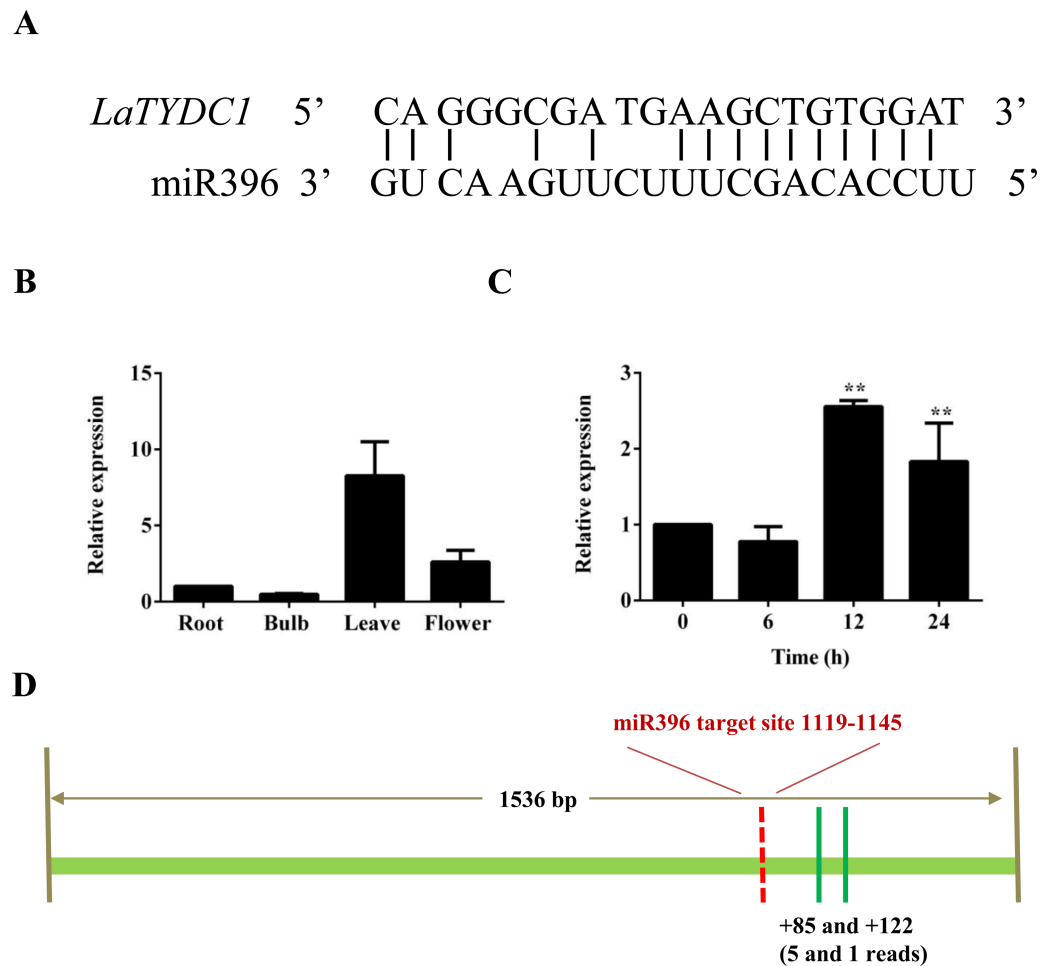

Figure 5 *LaTYDC1* is the proposed target of miR396. (A) The alignments of miR396 with the *LaTYDC1* target sequence. (B) The expression pattern of miR396 analyzed by qRT-PCR. Error bars represent SE ($n = 3$). (C) Time course expression analysis of miR396 in response to MeJA ($100 \mu\text{M}$) treatment. The expression in plants without MeJA was used as a reference of basal expression level. Error bars represent SE ($n = 3$). Statistical difference was estimated using the Least Significant Difference test compared with the 0 h control. Differences are significant with p value < 0.01 (**) (p -value = 0.000 at 12 h and p -value = 0.006 at 24 h, degree of freedom = 8). (D) The validation of miR396-mediated cleavage of *LaTYDC1* by RLM-RACE. The targeting site was indicated with red line and the mapped targeting site was indicated with green lines. Distances relative to the predicted cleavage site and the number of each clone were shown at the bottom.

Several TYDC genes from different plants have been isolated and characterized (Kawalleck *et al.*, 1993; Facchini & De Luca, 1994; Lehmann & Pollmann, 2009; Zhang *et al.*, 2011). TYDCs use tyrosine and dopa as substrates, but are not able to catalyze L-phenylalanine (Compant, Clément & Sessitsch, 2010; Facchini & De Luca, 1994; Facchini, Huber-Allanach & Tari, 2000). To determine the enzymatic function and substrate specificity of *LaTYDC1*, we chose tyrosine and dopa as substrates. The results showed that *LaTYDC1* could convert tyrosine to tyramine (Fig. 4B), and have a higher substrate specificity for tyrosine over dopa (Table 1).

In previous reports, when the gene *RsTYDC* in *Rhodiola chalinensis* was overexpressed, the content of tyramine and salidroside in transgenic seedlings was higher than in the wild type. This showed that final product yield is associated with the expression level of the initial enzyme in the biosynthetic pathway (Zhang et al., 2011). In this study, under MeJA treatment, the content of tyramine was just double fold when compared with the untreated seedlings (Fig. 2), but the transcription of *LaTYDC1* enormously increased (Fig. 3C). The enzyme activity was not correctly in line with the transcriptional level of *LaTYDC1*, most likely due to post-transcriptional modification. The stability of mRNA (Parker & Song, 2004; Wilusz, Wormington & Peltz, 2001), the half-life of mRNA, the regulation of the translation (Preiss & Hentze, 2003), and so on, create a varied and complex mechanism of post-transcriptional regulation that controls gene expression (Mata & Al, 2005; Roundtree & He, 2016).

MiRNAs negatively modulate the expression of targeted genes through direct cleavage (Li et al., 2014). In our results, miR396 was identified from the *L. aurea* miRNA profile, which is responsive to MeJA treatment. By analyzing the degradome sequencing data, miR396 targets *LaTYDC1* (Fig. 5A). At the beginning of the MeJA treatment, the expression of *LaTYDC1* greatly increased (Fig. 3C); meanwhile miR396 was still at the lower level as the control (Fig. 5C). However, with the treatment alone, the expression of miR396 was elevated to a higher level, and the expression of *LaTYDC1* was decreased to only one half of the 6-h treatment samples. Based on our previous miRNA sequencing work (Xu et al., 2016), along with the expressional relationship between miR396, *LaTYDC1*, and the degradome sequencing data together, it is reflected that miR396 negatively regulates *LaTYDC1*.

In Arabidopsis, seven of the GRFs contain the cleavage sites recognized by miR396. These miR396-GRFs target interaction, control the proliferation of cells in leaves, pistil development and the switch between stem cell and transit-amplifying cells in roots (Debernardi et al., 2014; Liang et al., 2014; Rodriguez et al., 2015). Also, miR396 regulate other transcription factors as bHLH74, which is necessary for normal development of Arabidopsis (Debernardi et al., 2012). In this work, we reported the regulation of an additional target of miR396, the enzyme *LaTYDC1*. According to the degradome data, in *LaTYDC1* gene there is one binding site of miR396, and the cleavage site is shown in Fig. 5A. However, the RLM-RACE experiment failed to confirm this cleavage site, although we repeated the experiment several times with different primers. After sequencing the DNA fragments, the cleavage site was not positioned in the predicted target region. Two out of five reads were mapped at the 85th, and the other three reads were at the 122nd nucleotide downstream of the predicted cleavage sites (Fig. 5D). Although we cannot explain the possibility that we failed to get the right cleavage products, the phenomenon that RLM-RACE mapped the cleavage sites beyond the predicted target region was also observed for other miRNAs (Li et al., 2015; Shen et al., 2014). It is likely that these fragments that resulted from miRNA cleavage are very susceptible to degradation induced by RNA decay proteins (Li et al., 2015).

CONCLUSION

This study identified LaTYDC1, which is involved in the biosynthesis pathway of galanthamine. It catalyzes tyrosine to tyramine conversion to provide the base bone of Amaryllidaceae alkaloids. Additionally, we found that miR396 may negatively regulate the expression of *LaTYDC1* to participate in galanthamine biosynthesis. In the future, this finding may also have implications for genetic strategy in increasing the yield of galanthamine.

ACKNOWLEDGEMENTS

We are grateful to Dr. Weikang Chen for his critical reviews during the manuscript preparation.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This work was supported by the National Natural Science Foundation of China (31770387; 31700271), the Natural Science Foundation of the Jiangsu Province (BK20170617), and the Jiangsu Provincial Public Institutions Program for Research Conditions and Building Capacity (BM2015019), Natural Science Foundation of Shanghai (16ZR1431100). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:

National Natural Science Foundation of China: 31770387, 31700271.

Natural Science Foundation of the Jiangsu Province: BK20170617.

Jiangsu Provincial Public Institutions Program for Research Conditions and Building Capacity: BM2015019.

Natural Science Foundation of Shanghai: 16ZR1431100.

Competing Interests

The authors declare there are no competing interests.

Author Contributions

- Rong Wang performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft.
- Xiaokang Han performed the experiments, prepared figures and/or tables.
- Sheng Xu contributed reagents/materials/analysis tools, approved the final draft.
- Bing Xia and Yong Xue conceived and designed the experiments.
- Yumei Jiang analyzed the data.
- Ren Wang conceived and designed the experiments, authored or reviewed drafts of the paper, approved the final draft.

DNA Deposition

The following information was supplied regarding the deposition of DNA sequences:

The LaTYDC1 gene sequences described here are accessible via GenBank accession numbers [MG932082.1](#).

Data Availability

The following information was supplied regarding data availability:

The DNA sequence of LaTYDC1, LaTYDC2 and TIP4 is available in [Supplemental Information 1](#). The DNA sequences in the RLM-RACE experiments is available in [Supplemental Information 2](#). These DNA sequences were used to determine the cleavage site targeted by miR396 in LaTYDC1 gene. The raw data are available in [Dataset S1](#). These data provide the data source of all the figures listed in the manuscript, including the supplemental figures.

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.6729#supplemental-information>.
