Keywords: Radioactivity Cement based materials Supplementary cementitious materials Chemical composition NORM wastes

ABSTRACT

Cement based materials may contain varying levels of radionuclides, mainly ²²⁶Ra (from the ²³⁸U series), ²³²Th and ⁴⁰K, which are used to determine the Activity Concentration Index ("ACI"). According to the European directive Euratom 2013/59 in these materials, the "ACI" must be < 1 to be suitable for their use in construction. In this paper, data on the activity concentration of natural radionuclides in cementbased materials (i.e. cements, additions, pigments and aggregates) as well as their chemical composition are presented. Radioactivity measurements have been determined by using gamma spectroscopy the chemical compositions have been determined by X-Ray Fluorescence. Data for cements measured shown that white cements present a lower concentration of activity than conventional CEM I. In addition, the CAC (Calcium aluminate cements) present high activity concentration in the ²³²Th series. Regarding additions, FA (Fly Ash) are those that present the highest concentration of activity in the ²³⁸U and ²³²Th series, while olive biomass ashes are those supplementary cementitious materials that show the highest concentration of activity for ⁴⁰K. Some pigments used in mortar and concrete technology were also characterized.

Granitic and volcanic rocks, potentially used as aggregates present much higher activity concentration than the siliceous aggregate.

The efficiency calibration of the gamma-ray detectors was computed by using the mathematical code LabSOCS (InSitu Object Calibration Software). The samples were measured for 80,000 s to minimize the measurement uncertainty and achieve the required detection limits. The spectra were analysed using an Excel spreadsheet and Genie 2000 software. Samples were measured in duplicate, except in cases where not enough sample was available.Data source locationThe samples are from different sources, mainly from Spain and other European countries. The samples were collected by both the IETcc-CSIC and the UPCT. All the samples were registered and centralized in the IETcc-CSIC where they were chemically characterized. An aliquot of the samples was sent to CIEMAT for the determination of the gamma emitters by means of high resolution gamma spectrometry (HPGe).Data accessibilityWith the article		photopeak at 1460 keV.

Value of the Data

- The data presented herein can be used as an on-line database of the natural radioactivity of cement-based materials
- The data can be used for radiological studies, as well as for dose rate calculations and the Activity Concentration Index of each of the cement based materials.

LoI: Loss on Ignition

• The results can be the basis for the calculation of the activity concentration or excess effective dose rates described in the European Union Directive 2013/59 [2] for final cement based materials.

1. Data Description

1.1. Chemical composition of cement based materials

This section presents the chemical composition of all materials along with their loss on ignition. A brief description of the materials accompanies these data.

1.1.1. Cements

Chemical composition of 16 different cements (Portland and other types of cements) is shown in Table 1.

1.1.2. Supplementary Cementitious Materials (SCMs)

Table 2 presents the chemical composition data of three different types of SCMs a): FA (Fly <u>A</u>sh); b): S (<u>S</u>lags- where S1 to S3 are blast furnace slags and S4-S5 are steel slags) and c): other SCMs (SF- <u>S</u>ilica <u>Fume</u>, G-Waste <u>G</u>lass, L-<u>L</u>imestone, MK-<u>M</u>eta<u>k</u>aolin, PZ- <u>Poz</u>zolans, OBBAM-<u>O</u>live <u>B</u>iomass <u>B</u>ottom <u>A</u>shes <u>M</u>ixed and OBFAM- <u>O</u>live <u>B</u>iomass <u>Fly A</u>shes <u>M</u>ixed

1.1.3. Pigments used in mortar and concrete technology

Chemical composition of seven mineral pigments used in building materials is shown in Table 3.

1.1.4. Aggregates used in mortar and concretes preparation

Finally, six aggregates with particle size between 0–2 mm (one siliceous- A1, three granitic ones A2, A3, A4 and two volcanic ones A5 and A6) used in the preparation of mortars and concretes have been chemically characterised. Results are shown in Table 4.

LoI: Loss on Ignition

1.2. Activity concentrations of series ²³⁸U, ²³⁵U, ²³²Th and ⁴⁰K in cement based materials

The activity concentrations of ²³⁸U, ²³⁵U and ²³²Th series as well as and ⁴⁰K given in Bq kg⁻¹ in all measured cement based materials are shown below. The uncertainties of the activity concentrations shown in Tables 5, 6, 7 and 8 were calculated from the measurement uncertainties (peak area and counting efficiency). The uncertainty associated with the weight of the samples was considered negligible.

1.2.1. Cements

Activity concentrations of ²³⁸U, ²³⁵U and ²³²Th series, and ⁴⁰K in commercial cements are shown in Table 5.

Aggregates	SiO ₂	CaO	Al_2O_3	Fe_2O_3	MgO	MnO	Na_2O	K_2O	TiO ₂	P_2O_5	Others	LoI	Total

LoI: Loss on Ignition

Table 4

1.2.2. Supplementary Cementitious Materials (SCM)

Results obtained from gamma spectroscopy in ²³⁸U, ²³⁵U and ²³²Th series and ⁴⁰K series for 37 *Supplementary Cementitious Materials (SCM)* are presented in Table 6.

1.2.3. Pigments used in mortar and concrete technology

Activity concentrations of ²³⁸U, ²³⁵U and ²³²Th series and ⁴⁰K in seven different pigments are shown in Table 7.

1.2.4. Aggregates used in mortar and concretes preparation

Activity concentrations of 238 U, 235 U and 232 Th series and 40 K for aggregates are shown in Table 8.

2. Materials and Methods

2.1. Materials

In this work, a total of 56 samples of components used in cement-based materials have been studied.

Commercial Cements: 16 cements with different chemical and mineralogical composition.

- a Six Type I cements (CEM I 42.5R y CEM I 52.5R) from different cement factories (samples C1-C6). according to European Standard EN-197-1-2011 [3]
- b Three blended cements: One CEM II/A-L with a maximum of 20% of limestone (sample C7), one CEM II/B-V with coal fly ash (FA) content around 21–35% (sample C8) and one CEM III/B with high content (around 66–80%) of blast furnace slag (sample C9). All of them according to European Standard EN-197-1-2011 [3].
- c One CEM I 52,5 S/R, sulphate-resistant, which therefore has a lower proportion of tricalcium aluminate (C_3A) (sample C10) [3]
- d Two white cements (samples C11 and C12) with a very low Fe_2O_3 content and without TiO₂. as per standard UNE 80305:2012 [4]
- e Three calcium aluminate cements (CAC) from different factories, with very different chemical and mineralogical composition compared to a Portland cement, whose main component is monocalcium aluminate (CA) (samples C13-C15). This type of cement complies with European standard EN 14647-2006 [5]
- f One calcium sulfoaluminate cement with a very different chemical composition and with a very low SiO₂ content while higher sulphate proportion.

Supplementary Cementitious Materials: 27 SCMs from very different sources, some of them commonly used in the preparation of cement-based materials.

a Fly ash (FA): Eleven coal fly ashes from seven different thermoelectric power plants, with different composition and proportion of unburned material (samples FA1-FA11)

Activity concentration for the main gamma emitters in the naturally occurring ²³⁸U, ²³⁵U, ²³²Th and ⁴⁰K series in cements.

Uncertainties are quoted for a coverage factor k=2 and are due to measurement uncertainties.

- b Slags: Three vitreous blast furnace slags with different origins (samples S1-S3) and two steel slags (samples S4 and S5). Slags are by-products of iron and steel-making production.
- c One silica fume (sample SF1) which is a by-product originated in the reduction of quartz with coal, in electric arc furnaces for the production of silicon and ferrosilicon.
- d One waste glass (sample WG1) from urban glass recycling waste.
- e One limestone (sample L1)
- f One red mud (sample RM1) that is a solid waste with high iron content, generated in the industrial process to produce alumina from bauxite.
- g Two samples of metacaolin (sample MK1 and MK2) resulting from the calcination of kaolinitic clays.
- h Three pozzolans, with different origin and chemical composition (samples PZ1-PZ3)
- i Two olive biomass samples prepared from the mixture of various biomass bottom ashes (sample OBBAM1) or biomass fly ashes (OBFAM1).

Pigments: Seven pigments (samples P1-P7) commonly used in construction, with different colour and chemical composition. One of them (P6) has a high organic matter content. Aggregates: Six aggregates with maximum particle size of 2 mm.

- a One standardized siliceous aggregate according to EN 196-1 (sample A1).
- b Three granitic aggregates of different geographical origin (samples A2-A4).
- c Two volcanic aggregates (samples A5 and A6).

2.2. Methods

2.2.1. Chemical characterization

The chemical characterization of all the materials was determined on a S8 Tiger Bruker Xray fluorescence (XRF) spectrometer. Loss on ignition calculated as per UNE-EN196-2:2014 [1], was also determined. All samples were dried in an oven at 105 °C for 24 h and then, they were milled to ensure a particle size below 63 microns. The oxide composition of the samples, determined by XRF, was carried out on pressed pellets. For this, 2 g of sample were used with 0.2 g of Hoechst wax C on a boric acid support, in an aluminum capsule. For the preparation of fuse beads, 1 g of sample was mixed with 10 g of melting agent (66% Lithium Tetraborate/34% Lithium Metaborate) and LiBr stripper.

2.2.2. Gamma spectroscopy analysis

Radiological measurements of the samples were performed by gamma spectrometry with a counting time of 80,000 s, using three High-purity Germanium detectors (one of them is coaxial Type p, and the others are BEGe Type -Broad Energy Germanium detectors).

The detectors have an active surface from 26 to 38 cm 2 and 2 keV resolution for ⁶⁰Co and intrinsic efficiencies from 30% to 100%. They are protected with 15 cm iron shield. Main characteristics of both types of Ge detectors are shown in Table 9.

The gamma detectors are connected to two electronic chains consisting of: two amplifiers, two Analog-to-Digital Converters (ADCs), 2 High Voltage Power Supplies and 2 AIM modules all from Canberra Industries. The AIMs modules have the function of communicating the electronic chain with the PC allowing it to: (1) control the parameters of the detector and electronic chain and (2) acquire the spectra. Once the spectra were acquired they were analysed with Genie 2000 software [6] and a MS Excel spreadsheet [7]. The efficiency as a function of energy was computed by using the mathematical code based on Monte Carlo LabSOCs. The parameters required for this calibration were (1) dimensions and composition of the detector components, (2) dimensions of the sample container and (3) chemical composition and density of the sample matrix [8].

All samples were measured in specific polypropylene sample container (cylinders 75.4 mm of diameter, 31 mm height) sealed to avoid ²²²Rn loses. Each container was totally filled with the

Table 9

Characteristics of GXGe and BEGe high purity detectors used in gamma measurements.

Parameter	Detector 07	Detector 90
Model	GX10022	BE50360
Туре	Extended Range Coaxial	Broad Energy
Resolution at 1.33 MeV (KeV)	2.04	1.84
Relative efficiency at 1.33 MeV (KeV)	115.7	48.0
Crystal diameter (mm)	84	80
Crystal length (mm)	72	30
Outer shielding (cm)	15	15
Inner shielding 1 st layer (Cu) (mm)	3.0	2.5
Inner shielding 2ndf layer (Zn) (mm)	-	1.5
Inner space shielding (dm ²)	25	25
Shielding composition	Fe	Pb

sample and the measurements were carried out after 21 days to ensure secular equilibrium between radionuclides and their progeny [9-12]. The samples were measured in duplicate, except in cases where a sufficient quantity of sample was not available.

Radionuclides occurring in natural decay chains headed by 238 U (226 Ra), 232 Th and 40 K were determined in the samples.

²³⁸U serie measurements were based on the detection of emissions of their daughter nuclides, ²³⁴Th (63 keV), ²²⁶Ra (186.1 keV), ²¹⁴Pb (351 keV) and ²¹⁴Bi (609, 1120 and 1765 keV).

²³²Th determination was determined on emissions of their daughter nuclides, ²²⁸Ac (911 and 969 keV), ²¹²Pb (238 keV) and ²⁰⁸Tl (583 keV) respectively, since their own gamma emitting lines are not of sufficient intense (²³²Th at 63.8 keV) or present significant interferences with other naturally occurring radionuclides.

 ^{235}U (144 and 163 KeV) and ^{40}K (1460.8 keV) were directly measured by their emissions lines.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships which have, or could be perceived to have, influenced the work reported in this article.

Acknowledgements

This study was funded by the Spanish Ministry of the Economy, Industry and Competitiveness under project BIA2016-77252-P. Dr. M.M. Alonso also wishes to thank CSIC for funding the project PIE 2018 60I 054 (Proyecto Intramural de Incorporación).
