

High expression of AFAP1-AS1 is associated with poor prognosis of digestive system cancers

A meta-analysis

Abstract

Background: Actin filament-associated protein 1 antisense RNA 1 (AFAP1-AS1) is associated with prognosis in many cancers. The aim of this study was to systematically evaluate the potential correlation between AFAP1-AS1 and the prognosis of digestive system cancers (DSC).

Methods: EMBASE, Web of Science, Cochrane Library, PubMed, Wanfang Data (Chinese), and CNKI (Chinese) were comprehensively searched for literature published from the establishment of the database to September 2021. All case-control studies that met the inclusion criteria were retrieved; additionally manual retrieval and literature tracing was performed. After extracting the relevant data, Revman 5.3.5 software was used for meta-analysis.

Results: Eighteen studies were included in analyses, high expression of AFAP1-AS1 was significantly correlated with poor prognosis in DSC, including overall survival (HR = 1.93, 95% CI: 1.72–2.17, $P < .001$) and disease-free survival/progression-free survival (HR = 1.87, 95% CI: 1.56–2.26, $P < .001$). In addition, the expression of AFAP1-AS1 was significantly correlated with tumor size, tumor stage, and lymph node metastasis.

Conclusion: High expression of AFAP1-AS1 was associated with poor prognosis in DSC. Therefore, it could be used as a potential marker for evaluating prognosis in DSC

Abbreviations: 95%CI = 95% confidence interval, AFAP1-AS1 = actin filament-associated protein 1 antisense RNA 1, CNKI = China national knowledge infrastructure, DFS/PFS = disease-free survival/progression-free survival, DSC = digestive system cancers, EMBASE = Excerpta Medica database, ESCC = esophageal squamous cell carcinoma, GBC = gallbladder carcinoma, GEP = gene expression profiles, HCC = hepatocellular carcinoma, HR = hazard ratio, IARC = International Agency for Research on Cancer, lncRNA = long non-coding RNA, MOOSE = Meta-analysis of Observational Studies in Epidemiology, NOS = Newcastle–Ottawa Scale, OS = overall survival, PAAD = pancreatic adenocarcinoma, PRISMA = Preferred Reporting Items for Systematic Reviews and Meta-Analyses, qRT-PCR = real-time fluorescent quantitative polymerase chain reaction, QUIPS = quality in progress studies, RFS = recurrence free survival, TNBC = 3 negative breast cancers.

Keywords: AFAP1-AS1, DSC, expression, long non-coding RNA, meta-analysis, prognosis

1. Introduction

Digestive system cancers (DSC) are among the most common cancers worldwide.^[1] The 2020 data released by the International Agency for Research on Cancer (IARC)^[2] showed that new cases and deaths of major DSC (esophageal, gastric, hepatic, colorectal,

pancreatic, and gallbladder cancers) accounted for 26.65% and 36.44% of all cancers, respectively, and showed an increasing trend.^[3] Many cases of DSC are occult,^[4] and most of them develop to the middle and late stages. DSC prognosis is poor, and there are no known early diagnostic markers. Researchers have been actively investigating potential markers of DSC.^[5]

This research was supported by the National Natural Science Foundation of China (No.14207450) and Henan Province young and middle-aged health science and technology innovation excellent young talent training project (YXKC2022044).

The authors have no conflicts of interest to declare.

All data generated or analyzed during this study are included in this published article [and its supplementary information files].

This study was reported by the Preferred Reporting Items for Systematic reviews and Meta-Analyses. It was based on previous publications and therefore did not require ethical approval or informed consent.

Actin filament-associated protein 1 antisense RNA 1 (AFAP1-AS1) (6810 nucleotides) is located on chromosome 4 of human genes. It is involved in a variety of physiological functions and cancer behaviors, such as migration, invasion, metastasis, and angiogenesis.^[6-9] In recent years, AFAP1-AS1 has been found to be abnormally expressed in many cancers, including cholangiocarcinoma, pancreatic adenocarcinoma, hepatocellular carcinoma,^[6-8] colorectal cancer, gastric cancer, and esophageal cancer.^[10-12]

At present, many studies on AFAP1-AS1 and cancers are ongoing; however, the number of cases reported in each is limited. The specific target of long non-coding RNA (lncRNA) AFAP1-AS1 and its role in the occurrence or prognosis of DSC are still unclear, and further research is needed. Thus, we conducted a meta-analysis to determine the prognostic significance of AFAP1-AS1 expression in DSC.

2. Materials and Methods

The present study was performed according to Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement and the Meta-analysis of Observational Studies in Epidemiology (MOOSE). Owing to its design, the study did not require ethical approval or informed consent.

3. Search strategy

The system retrieved literature published from the establishment of the database to September 15, 2021. The databases include Embase, Web of Science, Cochrane Library, PubMed, Wanfang Data (Chinese), and CNKI (Chinese). The search terms were “cancer,” “long non-coding RNA AFAP1-AS1/LncRNA AFAP1-AS1,” and “survival/prognosis.” In addition, the relevant reference articles not identified through database retrieval were manually searched to avoid potential omissions.

3.1. Inclusion and exclusion criteria

The inclusion criteria were as follows: the expression level of AFAP1-AS1 detected in DSC; correlation analysis between AFAP1-AS1 expression and overall survival (OS), disease-free survival/progression-free survival (DFS/PFS), or other survival indicators; patients with cancer divided into high expression group and low expression group; hazard ratio (HR) and 95% confidence interval (95% CI) provided or calculated indirectly from the survival curve; and the research object included tissue.

Exclusion criteria were as follows: the type of article was a review, meta-analysis, letter, case report, or expert opinion;

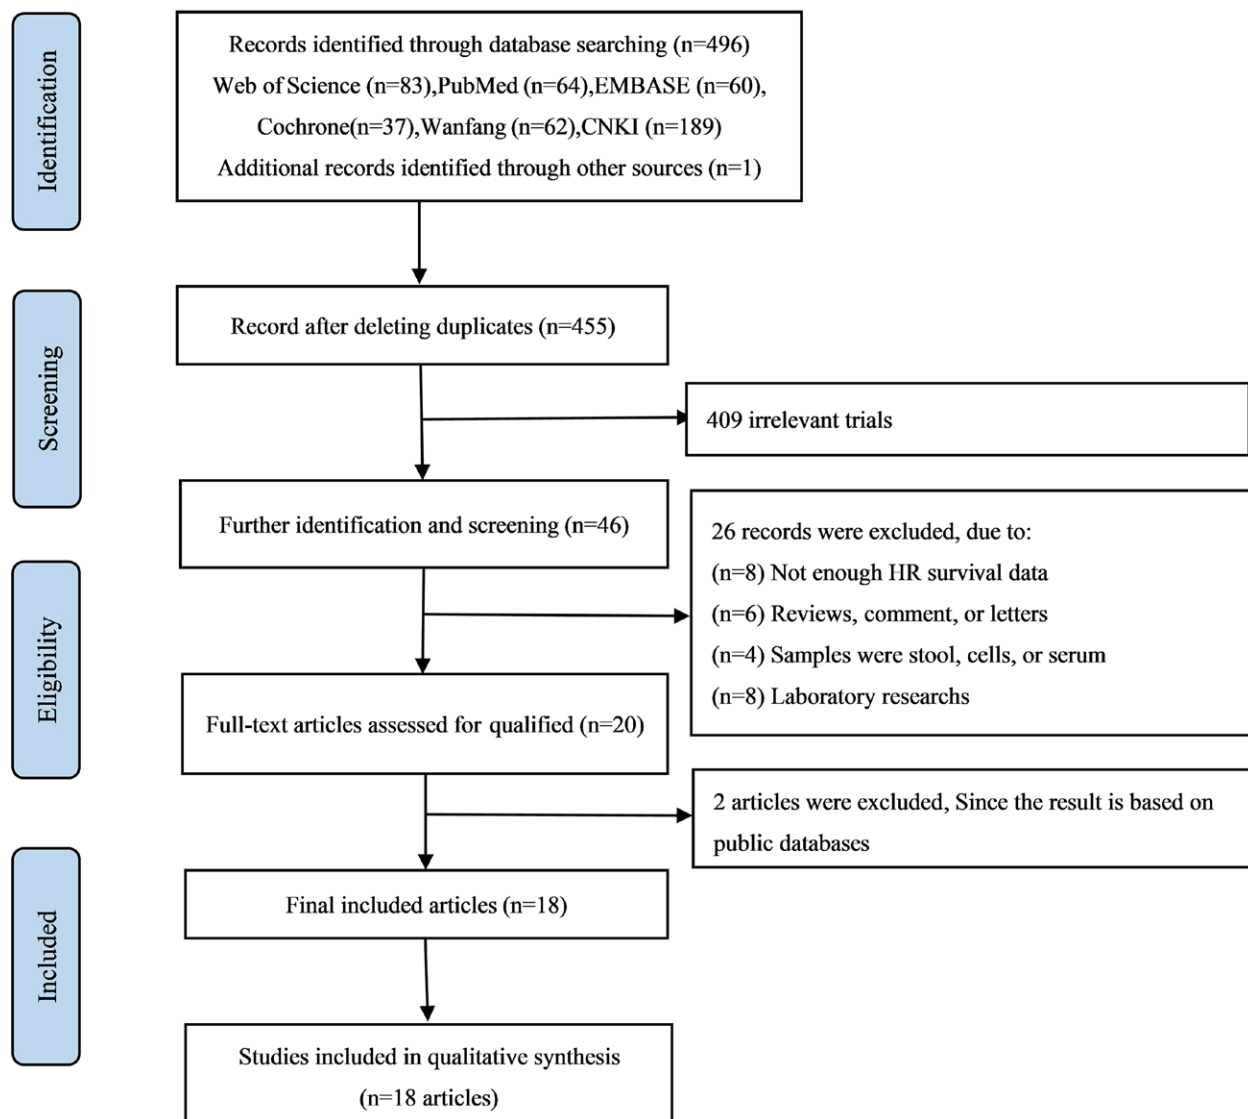

Figure 1. Flow chart of literature retrieval and research selection.

CR = Cox regression, DFS = disease-free survival, ESCC = esophageal squamous cell carcinoma, GBC = gallbladder carcinoma, HCC = hepatocellular carcinoma, HR = hazard ratio, KM = Kaplan–Meier, OS = overall survival, PAAD = pancreatic adenocarcinoma, PFS = progression-free survival, qRT-PCR = quantitative real-time PCR, SC = survival curve, TNM = tumor-node-metastasis.

95% CI and HR could not be obtained; the samples collected from subjects were cells, stool, or serum; and duplicate literature.

3.2. Data extraction

The identified articles were independently evaluated by 2 authors (X.X. and X.W.), and disagreements were resolved by the third author (F.D.). The following information was extracted from the articles: first author, year of publication, country, follow-up time, sample size, cancer type and survival analysis results (univariate and/or multivariate analysis), HR, and 95% CI. All data were analyzed as independent datasets.

If HRs and 95% CIs were not provided in the original text, Kaplan–Meier (KM) curves were extracted and estimated using methods published by Parmar et al^[13] and Tierney et al.^[14]

3.3. Quality assessment

The Newcastle–Ottawa Scale (NOS) was used to evaluate the quality of the literature included in the study, which included 3 categories (selection, comparability, and exposure), a total of 8 items, with a full score of 9. Studies with a score ≥ 7 were considered to be of high quality. The quality of prognostic studies was evaluated according to the method by Hayden et al^[15] for

QUIPS = Quality in Progress Studies.

*Quality assessment of included studies based on the Newcastle–Ottawa Scale.

†The level of evidence was estimated for all included studies with the Oxford Centre for Evidence Based Medicine criteria. QUIPS = Quality in Progress Studies.

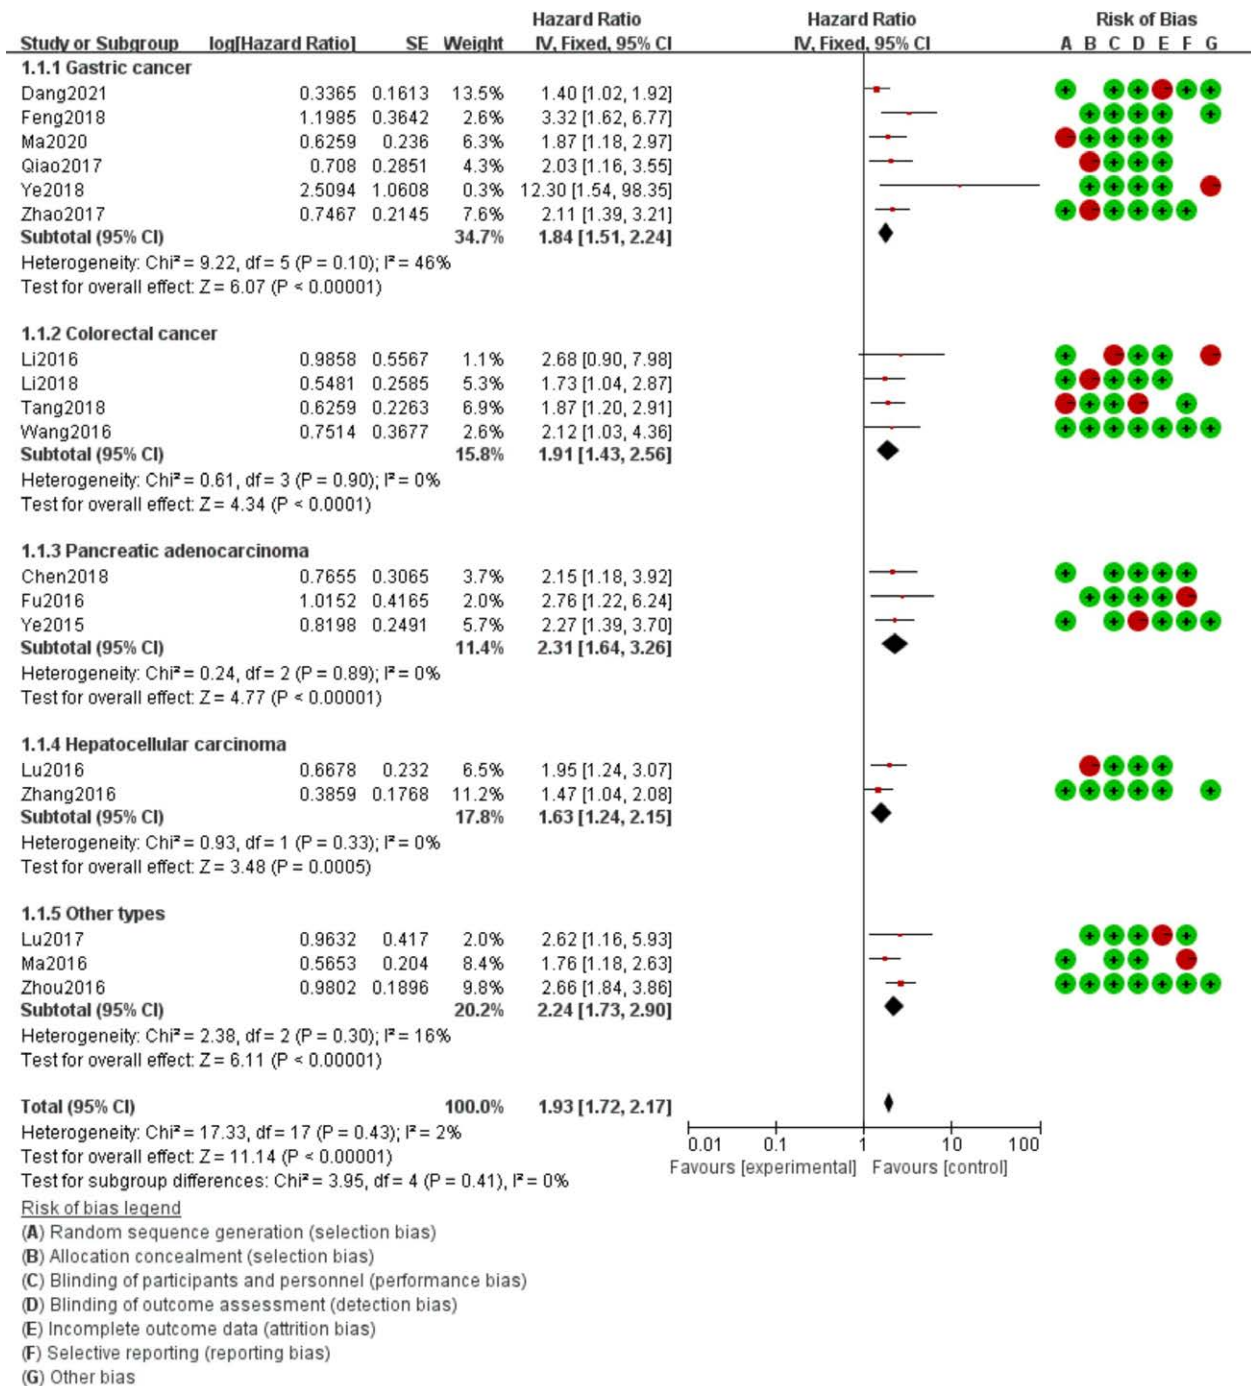

Figure 2. Forest diagram of the relationship between AFAP1-AS1 expression and overall survival (OS). AFAP1-AS1 = Actin filament-associated protein 1 anti-sense RNA 1.

assessing potential biases, which included study participation, study attrition, prognostic factor measurement, outcome measurement, study confounding, statistical analysis, and reporting.

3.4. Statistical analysis

The combined HRs with 95% CIs were conducted using Review Manager 5.3.5 (Cochrane Collaboration, Oxford, UK) to evaluate the relationship between AFAP1-AS1 expression level and prognosis. Inter-study heterogeneity index was tested using Q tests and I².^[16] According to the results of heterogeneity analysis, when the P heterogeneity value was ≥0.1 or I² ≤ 50%, the fixed effects model (Mantel–Haenszel method)^[17] was applied

to calculate the combined effect size, otherwise (P < .1 or I² > 50%), the random effects model (DerSimonian and Laird method) was used.^[18]

For articles that did not provide HR, 95% CI, or P values, the Engauge Digitizer 10.0 (<https://sourceforge.net/projects/digitizer/>) was used to extract the original survival data from the KM curve. Subgroup analysis was performed for different types of cancer, and publication bias was detected using Begg^[19] and Egger^[20] tests.

If the 95% CI did not contain the value 1 and the combined HR > 1, the finding was considered to be statistically significant. All P values were 2-sided, and statistical significance was set at P < .05. A sensitivity analysis was performed to determine the reliability of the combined results. The combined HRs of

Table 3
Relationship between expression of AFAP1-AS1 in DSC and clinicopathological factors.

| Factors | Number of studies | Number of patients | Pooled HR (95% CI) | P value | Heterogeneity | | Model |
|---|-------------------|--------------------|--------------------|---------|--------------------|---------|--------|
| | | | | | I ² (%) | P value | |
| Age (old vs young) | 14 | 1107 | 1.15 (0.88–1.51) | .31 | 3.0 | .41 | Fixed |
| Gender (male vs female) | 14 | 1107 | 1.28 (0.97–1.68) | .08 | 0.0 | .97 | Fixed |
| Tumor size (≥5 vs <5 cm) | 7 | 635 | 2.23 (1.57–3.16) | <.001 | 14.0 | .32 | Fixed |
| Tumor grade (PD vs MD WD) | 10 | 787 | 1.42 (1.05–1.92) | .02 | 11.0 | .34 | Fixed |
| Tumor stage (III vs I/II) | 13 | 1017 | 2.88 (2.18–3.80) | <.001 | 9.0 | .35 | Fixed |
| Lymph node metastasis (present vs absent) | 7 | 617 | 3.08 (2.18–4.34) | <.001 | 0.0 | .44 | Fixed |
| TNM stage (high vs low) | 7 | 613 | 2.11 (1.18–3.77) | .01 | 55.0 | .04 | Random |

CI = confidence interval, DSC = digestive system cancers, MD = moderately-differentiated, OR = odds ratio, PD = poorly-differentiated, TNM = tumor-node-metastasis, WD = well-differentiated.

95% CIs were calculated to evaluate the correlation between AFAP1-AS1 expression and clinicopathological factors. Statistical significance was set at *P* < .05.

4. Results

4.1. Literature search and characteristics of eligible studies

Figure 1 shows a flowchart of the retrieval process. A total of 496 studies were retrieved. First, 41 duplicate articles were excluded, and then 409 non-DSC articles were excluded. Due to incomplete data, article type (conference papers, reviews), non-tissue samples, mechanism research, and other reasons, 20 articles were excluded; another 2 articles based on database search were excluded. Finally, 18 eligible studies were included.^[16,21–37]

4.2. Baseline characteristics of the included studies

Table 1 shows the characteristics of the included studies. The studies were published between 2015 and 2021 and included 1440 patients with OS data and 572 patients with DFS/PFS data. The studies covered gastric cancer, colorectal cancer, cholangiocarcinoma, pancreatic adenocarcinoma (PAAD), hepatocellular carcinoma (HCC), esophageal squamous cell carcinoma (ESCC), and gallbladder carcinoma (GBC), and all used real-time fluorescent quantitative polymerase chain reaction (qRT-PCR) to detect of AFAP1-AS1. The specimens were frozen tissues, and the critical value of AFAP1-AS1 expression was median or normal.

4.3. Quality assessment

The quality assessment according to the Quality in Progress Studies (QUIPS) tool is summarized in Table 2. The NOS scores of eligible articles ranged from 5 to 9 (Table S1, Supplemental Digital Content, <http://links.lww.com/MD/H407>), with an average of 6.78, and 83.3% (15/18) were considered high-quality studies.

4.4. Expression of AFAP1-AS1 in DSC tissue

There was no heterogeneity between AFAP1-AS1 and OS (*P* heterogeneity = 0.43 and *I*² = 2%). Based on these preconditions, the combined HR of AFAP1-AS1 was calculated using the fixed effect. The summary analysis of 18 studies showed that the expression of AFAP1-AS1 was related to OS (HR = 1.93, 95% CI: 1.72–2.17, *P* < .001; Figure 2) and DFS/PFS (HR = 1.87, 95% CI: 1.56–2.26, *P* < .001; Figure 3).

We performed a subgroup analysis by cancer type. The results showed a significant correlation between the high expression of AFAP1-AS1 and OS in gastric cancer (HR = 1.84, 95% CI: 1.51–2.24, *P* < .001), colorectal cancer (HR = 1.91, 95% CI: 1.43–2.56, *P* < .001), PAAD (HR = 2.31, 95% CI: 1.64–3.26, *P* < .001), HCC (HR = 1.63, 95% CI: 1.24–2.15, *P* < .001), and other types of DSC (HR = 2.24, 95% CI: 1.73–2.90, *P* < .001; Figure 2).

4.5. Relationship between high expression of AFAP1-AS1 and clinicopathological factors

High expression of AFAP1-AS1 was related to size (>5 cm; HR = 2.23, 95% CI: 1.57–3.16, *P* < .001), degree of

Figure 4. Sensitivity analysis of the association between AFAP1-AS1 expression and overall survival (OS). AFAP1-AS1 = Actin filament-associated protein 1 antisense RNA 1.

differentiation (poor; HR = 1.42, 95% CI: 1.05–1.92, $P = .02$), stage (III, IV; HR = 2.88, 95% CI: 2.18–3.80, $P < .001$), lymph node metastasis (HR = 3.08, 95% CI: 2.18–4.34, $P < .001$), and high tumor-node-metastasis (TNM) stage (HR = 2.11, 95% CI: 1.18–3.77, $P = .01$). There was no correlation with age and sex (Table 3).

4.6. Sensitivity analysis

To verify the stability of the results, a sensitivity analysis was performed by removing 1 study at a time and recalculating the combined HR. There was no significant change in the results, indicating that our results were reliable (Fig. 4).

74.. Publication bias

Begg and Egger tests did not show a significant publication bias (Table S2, Supplemental Digital Content, <http://links.lww.com/MD/H408>). Concurrently, the shape of the funnel diagram was symmetrical (Fig. 5).

5. Discussion

lncRNAs are non-coding RNAs with a length of >200 nucleotides, which play an important role in cell proliferation, differentiation, apoptosis, invasion, and immune response.^[38–42] Studies have confirmed that lncRNAs participate in oncogenesis^[43,44] through epigenetic, transcriptional, and post-transcriptional regulation. Existing diagnostic techniques, such as gastrointestinal endoscopy, can only detect early precancerous lesions and cancers.^[45] In recent years, the discovery of the prognostic value of biomolecules has greatly promoted research on lncRNAs. Some of these (such as lncRNA MALAT1) can be used to predict therapeutic effects.^[46]

In this study, we used multiple online databases to search for studies related to DSC and conduct a quantitative systematic review. The results indicated that AFAP1-AS1 expression was significantly associated with OS. Additionally, we explored the relationship between lncRNA AFAP1-AS1 expression and cancer type and clinicopathological factors in subgroup

analysis. These findings indicated that AFAP1-AS1 may be a potential diagnostic and prognostic indicator for DSC. Han et al^[47] reported that the combination of AFAP1-AS1 and AUF1 activated the expression of ERBB2 and promoted trastuzumab resistance. Bi et al^[48] found that AFAP1-AS1 induced radiation-resistance in 3 negative breast cancers (TNBC) by activating the Wnt/ β -catenin signaling pathway. Liu et al^[49] reported that AFAP1-AS1 acted on the PI3K/AKT pathway to promote cisplatin resistance in non-small cell lung cancer. It is worth noting that in DSC, AFAP1-AS1 plays multiple roles and affects cancer progression.

AFAP1-AS1, formerly known as afap-110, is an antisense lncRNA, an actin cross-linked protein, and can bind to CSRC. It belongs to the AFAP1, AFAP1 class-1, and AFAP1 like-2/xb-130 family.^[50,51] Wu et al^[52] was first to report that AFAP1-AS1 was overexpressed in Barrett esophagus and esophageal adenocarcinoma owing to its gene site hypomethylation. After that, Zeng et al^[53] analyzed 5 groups of previously published lung cancer gene expression profiles (GEP) in the high-throughput microarray expression profile database. The results showed that AFAP1-AS1 was most significantly expressed in lung cancer, which was related to poor prognosis. Liu et al^[54] conducted a meta-analysis pooled from 8 studies. The results indicated that patients with cancer with high expression of AFAP1-AS1 had a higher risk of lymph node metastasis and distant metastasis, and the OS rate, PFS rate, and recurrence free survival (RFS) rate of patients with high expression of AFAP1-AS1 were lower than those with low expression. High expression of AFAP1-AS1 was associated with poor clinical prognosis. Therefore, AFAP1-AS1 may become a potential new biomarker, which could be used to predict the clinical prognosis in cancer. In addition, Luo et al^[55] showed that AFAP1-AS1 could up regulate the expression in esophageal squamous cell carcinoma, promote the proliferation of cancer cells, and inhibit their apoptosis. To ensure the reliability and homogeneity of our results, this study was limited to detecting the expression of AFAP1-AS1 in tissues by qRT-PCR. The results revealed that high expression of AFAP1-AS1 may have been an independent adverse prognostic factor. Our study is the first meta-analysis of the relationship between prognosis and AFAP1-AS1 expression in

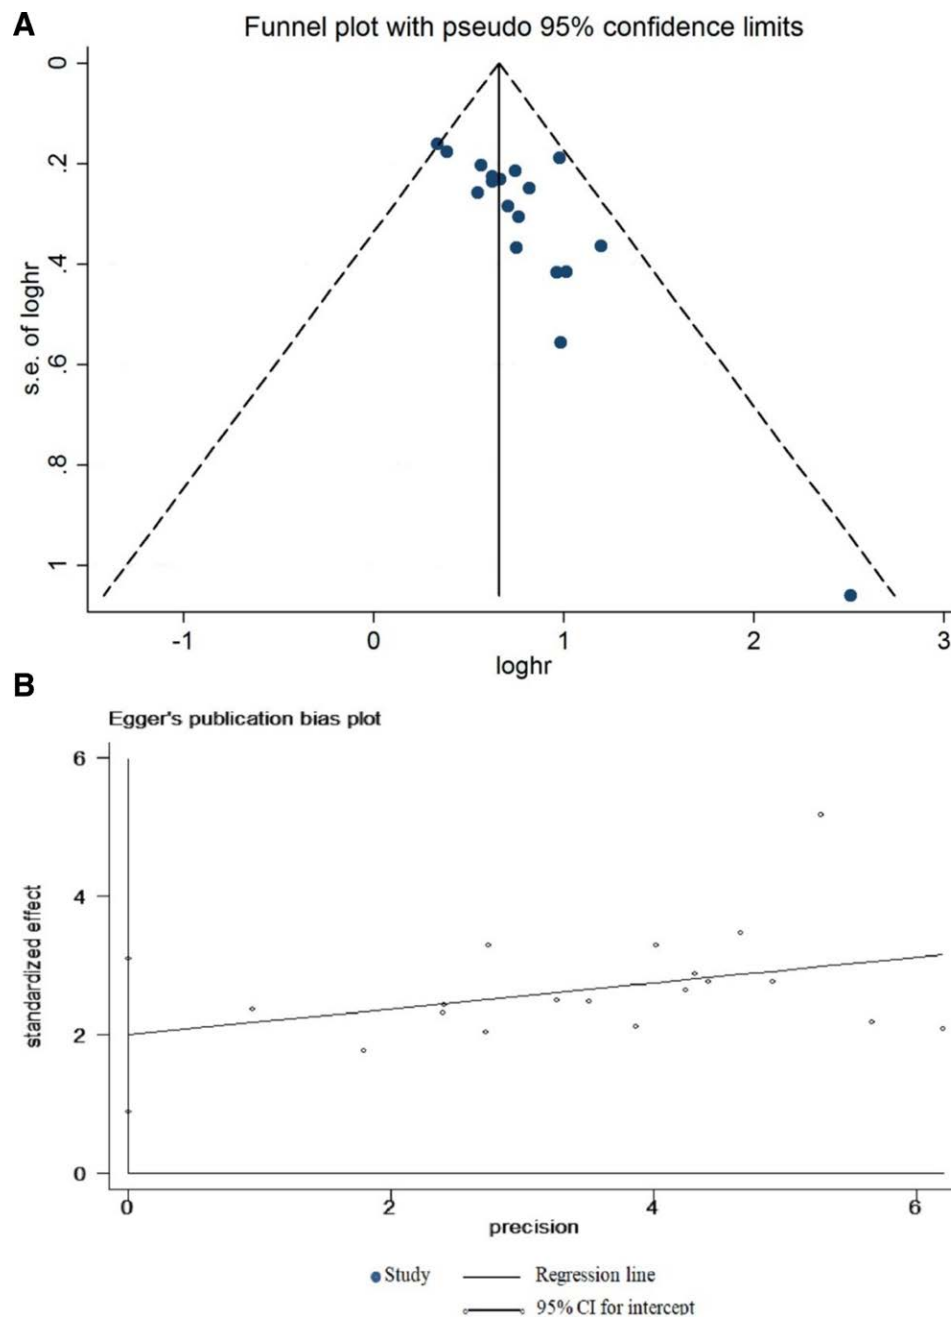

Figure 5. (A) Begg funnel diagram of publication bias on the relationship between AFAP1-AS1 expression and overall survival (OS). (B) Egger funnel diagram of publication bias on the relationship between AFAP1-AS1 expression and OS.

patients with DSC. The study has some limitations. First, not all included studies reported HR. We extracted some HRs and 95% CIs from the survival curves. This calculation method produces some errors. Second, although there is no statistical evidence of publication bias, all eligible studies have been performed in China, which may lead to publication bias. Finally, the truncated value algorithms expressed by AFAP1-AS1 are different, which may lead to errors in the results. Despite these limitations, this study provides important findings on the relationship between AFAP1-AS1 expression and the prognosis of patients with DSC.

6. Conclusion

In summary, the high expression of lncRNA AFAP1-AS1 was significantly correlated with poor prognosis in patients with

DSC patients. Therefore, it could be used as a potential marker for evaluating prognosis in DSC.
