Abstract

Background: The 12-lead surface electrocardiogram (ECG) is a useful tool to predict both atrial and ventricular arrhythmias via P-wave and QT measurements and its derivatives. Polycythemia vera (PV) is a chronic myeloproliferative disorder associated with cardiovascular events. The aim of this study was to assess ECG findings of patients with PV.

Method and materials: Sixty patients with PV (34 male, mean age 58 ± 11 years) and 60 age and gender-matched healthy volunteers were enrolled into the study. From the 12-lead surface ECG, P-wave and both conventional QT measurements and transmural repolarization parameters ($T_{\text{peak}}-T_{\text{end}}$ interval (T_p-T_e) and derivatives) were evaluated digitally by two experienced cardiologists. In addition, a novel parameter, Pi was calculated digitally as the standard deviation of the P-wave duration across the 12 ECG leads.

Results: QT duration and corrected QT interval were significantly longer in the PV group compared to healthy controls ($p < 0.01$ and $p < 0.01$, respectively). The T_p-T_e was longer and the T_p-T_e/QT ratio was significantly higher in the PV group compared to the controls. P-wave analyses showed that all P-wave parameters including Pmax, Pmin, P dispersion, and Pi were significantly prolonged in PV patients compared to the controls. The increase of both T_p-T_e and P max in the PV group was independent of age, BMI, diabetes and hypertension, gender, systolic blood pressure, hemoglobin, hematocrit, left atrial dimension, left ventricular end-diastolic diameter and early deceleration time in a univariate analysis of co-variance model ($F = 11.097$, $p = 0.001$ and $F = 31.537$, $p = 0.0001$, respectively).

Conclusion: The present study demonstrated that PV may be associated with electrocardiographic abnormalities of both atrium and ventricle.

Key words: Polycythemia Vera, electrocardiographic abnormalities, atrium, ventricle

Introduction

Polycythemia vera (PV) is a chronic myeloproliferative disorder characterized by increased formation of red blood cells. Bleeding and thrombosis are major causes of morbidity and mortality in patients with PV, occurring in 40 to 60% of the patients

(1-2). Thrombotic complications include acute cerebrovascular events, myocardial infarctions, peripheral vascular occlusions, pulmonary infarctions, and venous thromboses. The most common cause of death is myocardial infarction and heart failure (3). The pre-

cise mechanism causing this thrombotic tendency is not yet well understood. The hematocrit is the only laboratory parameter that shows clear association with thrombotic complications (4).

P-wave measurements are frequently used in clinical practice to predict atrial arrhythmias, especially atrial fibrillation (AF). It is well known that AF is associated with thromboembolic events (5). PV is a myeloproliferative disorder associated with both hyperviscosity and increase of total plasma volume which may cause atrial abnormalities. In addition, relation between hyperviscosity and AF was previously demonstrated (6). Caimi et al. (6) have suggested that hyperviscosity is frequent in patients with AF. Although mechanisms of in situ arterial thrombosis are known, the issue of thromboembolism remains controversial in patients with PV (7). Potentially, AF may contribute to arterial thrombus formation and embolism in patients with PV. However, P-wave measurements which are useful tool to predict AF have not yet been investigated in patients with PV.

Conventional QT parameters and transmural repolarization parameters including $T_{\text{peak}}-T_{\text{end}}$ interval and derivatives ($T_{\text{peak}}-T_{\text{end}}$ dispersion and $T_{\text{peak}}-T_{\text{end}}/QT$) have been used to predict cardiac arrhythmias in a number of clinical conditions with increased arrhythmia risk (8-10). About half a century ago, left ventricular (LV) hypertrophy was demonstrated in patients with PV by using 12-lead ECG. However, repolarization abnormalities were not investigated (11). Nevertheless, LV hypertrophy was related to increased total plasma volume (11). Potentially deleterious effects of hyperviscosity and LV hypertrophy on repolarization parameters have not yet been examined in patients with PV. In the present study, we aimed to evaluate electrocardiographic P-wave characteristics and ventricular repolarization parameters in patients with PV.

Method and Materials

Study Population

This is a cross-sectional case control study which was conducted at the hematology department, Selcuk University, in Konya, Turkey. Sixty PV patients (34 males, mean age 58 ± 11 years) and 60 age-matched healthy subjects were enrolled into the study. The diagnosis of PV was made according to World Health Organization criteria (12). Included patients gave their verbal and written consent for participation in the study. The study was approved by the local ethical committee of Selcuk University. All the patients in

PV group used acetylsalicylic acid (100 mg per day) for the prophylaxis of thrombosis. Most of the patients (45 of 60 patients, 75%) were on hydroxyurea (HU) (1.0 mg daily) treatment. Exclusion criteria were: history of coronary artery disease, congestive heart failure, congenital or acquired arrhythmia syndromes, use of drugs that lengthen the QT interval, current AF, bundle branch block, atrioventricular blocks, and unmeasurable T waves (<0.15 mV) on surface ECG. Blood pressure was measured with a mercury sphygmomanometer according to ESC/ESH guidelines (13).

EGG measurements

All patients had a standard surface 12-lead ECG recorded with a 50 mm/s paper speed at 10 mm/1mV amplitude. ECGs were performed while the patients were supine and breathing normally. The ECGs were scanned at a 600 dpi resolution and measurements made by electronic cursor from the screen by two experts who were blinded to the clinical status of the study population. Three consecutive ECG complexes were analyzed and given averaged measures for each lead.

Regional and transmural repolarization ECG parameters

The QT intervals were measured from the onset of the first deflection of the QRS complex to the end of the T wave in all the 12 leads. If the T wave was flat or the end of the T wave was difficult to define, or if the T wave amplitude was <0.15 mV, the lead was excluded from the measurement. The end of the QT interval was defined as the intersection of terminal part of the T wave and the isoelectric line. If a U wave interrupted the T wave before it returned to baseline, the end of the QT interval was defined as the nadir between T and U waves. Corrected QT interval (cQT) was calculated using Bazett's formula ($cQT = QT / \sqrt{R-R}$ interval). cQT dispersion (cQTd) was defined as the difference between maximum cQT and minimum cQT. The interval from the trigger point (QRS onset) to the peak of T-wave was defined as QT peak interval.

T_p-T_e interval was defined as the interval between QT peak and QT end ($T_p-T_e = QT_{\text{end}} - QT_{\text{peak}}$). The difference between maximum T_p-T_e and minimum T_p-T_e was defined as T_p-T_e dispersion. The $(T_p-T_e)/QT$ ratio was also calculated (Figure 1). Intra- and inter-observer difference of T_p-T_e was 7.7% and 9.8%, respectively.

Figure 1. Measurement of repolarization parameters on 12-lead ECG sample.

P-wave measurements

P-wave indices (P max, P min, and Pd) were measured in all 12 leads. P max was defined as the longest and P min as the shortest P-wave duration measured from the 12-lead ECG. Pd was defined as the difference between P max and P min ($P_d = P_{max} - P_{min}$). Pi was calculated digitally as the standard deviation (SD) of the P-wave duration across the 12 ECG leads. The intraobserver and interobserver coefficients of variation, standard deviation of differences between two observations divided by the mean value and expressed as a percentage, for the P-wave dispersion were found to be 8.8% and 3.8%, respectively.

Conventional Echocardiography

Examinations were performed with a Philips EnVisor C HD ultrasound machine (Royal Philips Electronics, Bothell, WA, USA) with a 2.5 MHz transducer by two experienced cardiologists, who were blinded to the patients' clinical and laboratory status. All measurements were performed during normal respiration. The LV ejection fraction (EF) was assessed by the modified biplane Simpson method (14) and the mean of three consecutive measurements was used. Cardiac dimensions were measured according to the recommendations of the American Society of Echocardiography (ASE) by M-mode and two-dimensional (2D) echo (15). 2D mode echocardiography was used to assess the LV mass (LVM) using the methodology of Devereux et al. (16).

Statistical analysis

The statistical analyses were performed with the help of the Statistical Package for Social Sciences (SPSS for Windows) software (version 15.0) (SPSS Inc.,

Chicago, IL, USA). All data are expressed as the mean \pm SD. Differences between parametric variables of the two groups were assessed by the Student-*t* test. The relation between the categorical variables was determined by the chi-square test. The distribution of the variables was analyzed with the Kolmogorow-Smirnow test. A Univariate Analysis of Covariance (ANCOVA) was applied to adjust for differences in age, body mass index (BMI), diabetes, hypertension, gender, systolic blood pressure (SBP), hemoglobin, hematocrit, left atrial dimension (LAD), left ventricular end-diastolic diameter (LVEDD) and early deceleration time (EDT) in general linear model. $T_p - T_e$ and/or P max were accepted as dependent variables, patient group was entered as a fixed factor and other variables, age, BMI, diabetes, hypertension, gender, SBP, hemoglobin, hematocrit, LAD, LVEDD and EDT were entered as covariates into the ANCOVA model. A p-value under 0.05 was considered statistically significant. Power analysis was performed by using a Minitab 16 packet program. Sample volume was calculated as 56 for each group to determine 10 ms difference of $T_p - T_e$ with 80% power. Because of probability of inadequate record quality of ECGs, a total of 60 subjects were enrolled to study.

Results

The demographic, general, and echocardiographic characteristics of the study population are listed in Table 1. There were no significant differences between the groups regarding to age, gender, body-mass index, or blood pressure levels. Hemoglobin and hematocrit levels were significantly higher in the PV group than in the control group ($p < 0.01$ and $p < 0.01$, respectively). The presence of diabetes melli-

tus and hypertension was similar between groups (Table 1). All patients were under antihypertensive and oral antidiabetic treatments. The main antihypertensive medication of study population was angiotensin-converting enzyme inhibitors. Of the 2D echocardiographic measurements, LV dimensions, and ejection fraction (EF) were similar in both groups; only LVM was significantly elevated in the PV group compared to the healthy controls (160 ± 36 g vs. 135 ± 34 g, $p=0.04$; respectively) (Table 1).

Table 1. Demographic, laboratory, and echocardiographic characteristics of the study population.

	Control (n=60)	PV (n=60)	p-Value
Age (years)	55±10	58±10	NS
Gender: Female / Male (n)	31/29	26/34	NS
HT (n)	21	19	NS
DM (n)	10	7	NS
BMI (kg/m ²)	25±1.6	27±2.0	NS
SBP (mmHg)	121±12	128±20	NS
DBP (mmHg)	76±7	81±16	NS
Heart rate (bpm)	75±8	76±9	NS
Hemoglobin (g/dL)	13.3±1.2	15.7±1.9	<0.01

HT, hypertension; BMI, Body-mass index; SBP, Systolic blood pressure; DBP, Diastolic blood pressure; LVEDD, left ventricle end-diastolic dimension; LVESD, left ventricle end-systolic dimension; IVS, interventricular septum; PW, posterior wall; EF, ejection fraction; LVM, left ventricular mass; LA, left atrium; NS, Non-significant ($p>0.05$).

Twelve-lead surface ECG analysis of atrial and ventricular arrhythmia indices are demonstrated in Table 2. QT and QTc were significantly prolonged in patients with PV compared to controls ($p<0.01$ and $p<0.01$, respectively). Other conventional QT parameters were similar between the two groups. Transmyocardial repolarization parameters including T_p-T_e and T_p-T_e/QT were significantly higher in the PV group compared to the healthy subjects (T_p-T_e $p=0.003$

and T_p-T_e/QT $p=0.02$, respectively) (Figure 2). (T_p-T_e)d was pretend to be increased in PV patients compared to controls ($p=0.07$) (Table 2). We have found that in PV group, some P wave parameters were positively correlated with ventricular abnormality parameters compared to healthy controls (Table 3). In addition, patients with P-wave abnormalities did not present with QT prolongation (Table 4).

Table 2. Electrocardiographic parameters of the PV group and controls.

	Controls (n=60)	PV (n=60)	p-Value
QT (ms)	372±32	394±29	<0.01

QTd, QT dispersion; QTp, peak QT; (QTp)d, peak QT dispersion; QTc, corrected QT; cQTd; corrected QT dispersion; T_p-T_e , difference between T-peak and T-end; (T_p-T_e)d, T_p-T_e dispersion.

T_p-T_e was increased in the PV group independent of demographic and echocardiographic findings such as age, BMI, sex, hemoglobin, hematocrit, LVEDD, EDT, and LAD in the ANCOVA model ($F=11.097$ and $p=0.001$). T_p-T_e was also related with DM and pretends to be related with HT in the ANCOVA model (Table 5).

Twelve-lead surface ECG analysis of P-wave parameters is presented in Table 2. P max, P min, Pd, and Pi showed significantly higher values in the PV group compared to the controls (Figure 3 and 4). The difference of P max between the two groups was independent of age, BMI, diabetes, hypertension, gender, SBP, hemoglobin, hematocrit, LAD, LVEDD and EDT in the ANCOVA model ($F=31.537$ and $p=0.0001$). Also, hypertension and diabetes were independent

predictors of P max (F=9.808, p=0.002 and F=4.793, p=0.03, respectively). Pmax pretends to be increased with age in the ANCOVA model (F= 3.809, p=0.06). Statistically, the effect of PV on the ECG was stronger on Pmax than on Tp-Te according to the ANCOVA analysis (Table 5).

Discussion

The present study demonstrated that P-wave measurements showed significantly higher values in patients with PV compared to healthy subjects. In addition, most of repolarization parameters (QT, QTc, T_p-T_e , and T_p-T_e/QT) were significantly prolonged in patients with PV. The relationship between PV and ECG parameters were independent of demographic features. The present study is the first one, where comprehensive analysis of both ventricular repolarization parameters and P-wave characteristics in PV patients was performed.

Recently, non-invasive ECG methods have been introduced to assess the atrial arrhythmia risk of patients. P-wave duration and dispersion are considered to be one of the most important non-invasive ECG markers (17-18). The increase in P-wave duration is considered an indicator of atrial conduction prolongation and, thus, might be useful in atrial arrhythmia risk stratification. Pd constitutes a recent contribution to the field of noninvasive ECG-prediction of AF (19). Pd represents non-homogeneous and anisotropic distribution of connections between myocardial fibers in atrial tissue (20). Non-homogeneity of atrial conduction, i.e. Pd prolongation, was considered as an independent predictor of AF. In the present study, all of the P wave measurements (Pd, P max, P min, and Pi) were increased in the PV group compared to the control group. PV is frequently associated with thrombotic complications. Also patients with AF have an increased risk for thromboembolic events (5). The relationship between PV and AF with regard to

thrombotic complications is an unknown issue. Atrial electrical abnormalities have not been investigated before in patients with PV. Based on the P-wave measurements, our study indicates that patients with PV may have an increased risk of AF development. In addition, Pi was added to the P-wave measurements as a novel parameter in the present study. Pi was increased in the PV group compared to the control group. It is thought that Pi accounts for the differences in atrial conduction across different vectors (21).

Increased non-homogeneity in the repolarization phase of the myocardial action potential can precipitate malignant ventricular arrhythmias (ventricular tachycardia and fibrillation) (22). The duration of the action potential varies between different parts of the myocardium and this difference is defined as dispersion of repolarization so called regional repolarization. A regional repolarization abnormality was represented with conventional QT measurements (QTc, QTd, and etc) in ECG. Regarding transmucardial repolarization, there are three layers in the myocardium: the endocardial, the M-cell, and the epicardial layer. The myocardial layers can be at different repolarization phases creating transmucardial non-homogeneities. This transmucardial non-homogeneity are determined by the ECG parameters T_p-T_e , $(T_p-T_e)_d$, and T_p-T_e/QT ratio in ECG. Thus, an inhomogeneity of both regional and transmucardial repolarization becomes substrates for re-entry causing ventricular arrhythmias in different populations (23). In the present study, although QT and QTc were higher in the PV group compared to controls, dispersion parameters did not show signifi-

cant difference between the two groups. Also we found higher T_p - T_e duration and T_p - T_e /QT ratio in PV patients compared to the healthy subjects. The increase of T_p - T_e in the PV group was independent of age, BMI, diabetes and hypertension in a univariate analysis. Based on the study results, transmural repolarization was impaired consistent with regional repolarization measurements in PV group. Although (T_p - T_e)d was tended to be prolonged in PV patients, both QTd and (T_p - T_e)d were comparable in both group. The effect of PV on dispersion parameters was not as strong as measurements related to repolarization duration.

PV is mainly characterized with hyperviscosity. Hyperviscosity is associated with increase of total plasma volume and reduced O_2 saturation of the erythrocytes in patients with PV (24). Thus, hyperviscosity may result in an increased myocardial workload and tissue ischemia (25). Myocardial ischemia is associated with prolongation of repolarization parameters in patients with coronary heart disease (9, 26-27). Therefore, we speculated that hyperviscosity may cause to abnormal repolarization via tissue ischemia. In addition, although patients with clinically overt coronary artery disease were excluded from the study, subclinical atherosclerosis and silent myocardial ischemia may affect repolarization parameters in the study group. It was also suggested that there is a strong relation between arterial ischemic complications, including myocardial infarction, and hematocrit levels in patients with PV (25). Recent studies have demonstrated that hyperviscosity is frequent in patients with non-valvular AF (6). Furthermore, hyperviscosity is a possible risk factor for cerebrovascular ischemic complications in patients with AF (28). A possible explanation for the higher values of the P-wave parameters in PV patients might be related to accompanying hyperviscosity. In a univariate analysis, although PV independently affected both atrial and ventricular parameters independent from the patients' demographic features, the effect of PV on the ECG was stronger on Pmax than on T_p - T_e according to the ANCOVA model.

Nevertheless, LV hypertrophy secondary to increased workload may also explain the ECG changes in PV patients. Prati et al. (11) firstly described ECG changes secondary to LV hypertrophy in patients with PV. Cobb and colleagues (24) discussed plasma rheology and physiologic consequences of PV, and LV hypertrophy was mentioned in this context. Currently, Devereux et al. (29) stated that increased blood viscosity (especially patients with hematocrit levels above 18 mg/dL) may be a potential determinant of cardiac hypertrophy in patients with systemic hyper-

tension. Therefore, we performed echocardiographic examination in PV patients in the present study. We found an increased LVM in the PV group. Although the study population and the control group were similar in demographic characteristics (age, gender, blood pressure, BMI, physical condition), an increase in LVM was attributed to PV. In addition, previous studies have demonstrated that QT, QTd and T_p - T_e prolongation well correlates with LVM (30-32). In conclusion, hyper viscosity may affect repolarization parameters in several ways.

The relation between atrial and ventricular electrical abnormality was also examined in the present study. The duration of QTc was positively corrected with Pd, Pi and Pmax in the PV group. In addition, QT and (T_p - T_e)d were positively correlated with Pmax and Pmin in the PV group. In the control group, there was no linear relation between atrial and ventricular electrocardiographic measurements. Thus, PV may concordantly impair both ventricular and atrial electrical activities. However, power of linear association was seen as a mild to moderate. When we used a universal cut-off value for group comparisons, there was no difference between groups. It may be related with small sample size and mild to moderate association. Logically, PV affected both atrial and ventricular electrical activations with same pathway. It needs to future investigations in this area.

The main limitation is that this study is a cross-sectional study and large prospective randomized studies are needed to clarify whether these abnormal ECG parameters translate into clinical outcomes and enable us to predict future arrhythmia development. Most of the PV patients were under cytoreductive therapy, and our results may not be applicable to patients not undergoing this kind of therapy. More importantly, P-wave measurements and ventricular abnormality parameters of PV patients with sinus rhythm were performed using the 12-lead ECG; however, rhythm Holter monitoring and/or an event recorder were not performed on study participants to eliminate paroxysmal AF and ventricular arrhythmias.

In conclusion, our study demonstrated that PV may affect both P-wave and ventricular repolarization parameters.

Acknowledgement

The authors disclose special acknowledgement to Dr. Kjell C. Nikus for his scientific comments on the present manuscript.

Conflict of Interest

The authors have declared that no conflict of interest exists.
