

Health Care Indicators

Carolyn S. Donham, Arthur L. Sensenig, and Stephen K. Heffler

This regular feature of the journal includes a discussion of each of the following four topics: community hospital statistics; employment, hours, and earnings in the private health sector; health care prices; and national economic indicators. These statistics are valuable in their own right for understanding the relationship between the health care sector and the overall economy. In addition, they allow us to anticipate the direction and magnitude of health care cost changes prior to the availability of more comprehensive data.

INTRODUCTION

This article presents statistics on health care use, prices, expenses, employment, and work hours, as well as on national economic activity. Some of these statistics are based on sample surveys conducted monthly or quarterly by government agencies or private organizations, and are available 1 to 3 months after the completion of the period. They provide an early indication of changes occurring within the general economy and in the health care sector.

The accompanying tables report selected quarterly statistics for 1991 through the third quarter of 1994, and the calendar year aggregation of quarterly information for the past 3 years. Additional tables show the change from the same period 1 year earlier. For quarterly information, this calculation permits analysis of quarterly data to focus on the direction and magnitude of

changes, without interference introduced by seasonal fluctuations.

In the national health accounts, indicators such as these play an important role in the estimation of the latest historical year of health care expenditures. Information that is more comprehensive tends to lag behind the close of a calendar year by 9 to 12 months or more. Therefore, we rely extensively on indicators such as these to anticipate and predict changes in health care sector expenditures for the most recent year. Other indicators help to identify specific reasons (e.g., increases in price inflation or declines in utilization) for expenditure change.

In the following sections, we will identify important indicators of health care and national economic activity and their sources. We will then describe what these indicators tell us about general economic conditions and health sector activity during the third quarter of 1994.

COMMUNITY HOSPITAL STATISTICS

Since 1963, the American Hospital Association (AHA), in cooperation with member hospitals, has been collecting data on the operation of community hospitals through its National Hospital Panel Survey. Community hospitals, which comprised more than 80 percent of all hospital facilities in the United States in 1993, include all non-Federal, short-term general, and other special hospitals open to the public. They exclude hospital units of institutions; psychiatric facilities; tuberculosis, other respiratory, and chronic disease hospitals; institutions for the mentally retarded; and alcohol and chemical dependency hospitals.

The authors are with the Office of the Actuary, Health Care Financing Administration (HCFA). The opinions expressed are those of the authors and do not necessarily reflect HCFA's views or policy positions.

The survey samples approximately one-third of all U.S. community hospitals. The sample is designed to produce estimates of community hospital indicators by bed size and region (American Hospital Association, 1963-94). In Tables 1 and 2, statistics covering expenses, utilization, beds, and personnel depict trends in the operation of community hospitals annually from 1991 and for selected quarters from 1991 through the third quarter of 1994. Figure 1 shows changes from the same quarter 1 year earlier for total hospital operating expenses and inpatient expenses for 1985-94. Figure 2 shows changes from the same quarter 1 year earlier in hospital admissions, outpatient visits, and inpatient days for 1985-94.

For purposes of national health expenditures (NHE), survey statistics on revenues (not shown on Table 1) are analyzed in estimating the growth in the largest component of health care costs—community hospital expenditures. This one segment of NHE accounted for 37 percent of all health spending in 1993 (Levit et al., 1994a). The survey also identifies important factors influencing expenditure growth patterns, such as changes in the number of beds in operation, number of admissions, length of stay, use of outpatient facilities, and number of surgeries.

PRIVATE HEALTH SECTOR: EMPLOYMENT, HOURS, AND EARNINGS

The Bureau of Labor Statistics (BLS) collects monthly information on employment for all workers, and earnings and work hours for non-supervisory workers in a sample of 392,000 establishments. Data are collected through cooperative agreements with State agencies which also use this information to create State and local area statistics. The survey is designed to collect

industry-specific information on wage and salary jobs in non-agricultural industries. It excludes statistics on self-employed persons and on those employed in the military (U.S. Department of Labor, 1994a).

Employment in this survey is defined as number of jobs. Persons holding multiple jobs would be counted multiple times. Approximately 5 percent of the population hold more than one job at any one time. (Other surveys that are household-based, such as the Current Population Survey [CPS], also record employment. In the CPS, however, each person's employment status is counted only once, as either employed, unemployed, or not in the labor force.) Once each year, monthly establishment-based employment statistics are adjusted to benchmarks created from annual establishment census information, resulting in revisions to previously published employment estimates.

Tables 3 and 4 present statistics on employment, average hourly earnings, and average weekly hours in private (non-government) health service establishments. Similar statistics for the all private non-agricultural sector, included on these tables, provide a basis for comparing the economy as a whole with the health sector in employment, earnings, and work hours. Figure 3 shows changes from the same quarter 1 year earlier in employment in the private non-agricultural sector, the health services industry, and hospitals for the years 1985-94. Table 5 summarizes business activity in the health sector and the overall economy by measuring change in the implied non-supervisory work hours and payroll. Implied work hours are the product of the number of non-supervisory employees and average weekly hours. Implied non-supervisory payrolls are calculated by multiplying implied work hours by average hourly earnings. Figures 4 and 5 show the percent

change from the same quarter 1 year earlier in implied non-supervisory work hours and payrolls for the years 1984-94.

For purposes of NHE, changes in work hours combined with changes in prices (discussed in a later section) can be used to gauge the direction and magnitude of expenditure change in specific health sector industries. We use these composite indicators in the estimation of growth in physician and dental expenditures for the most recent period. We study the historical relationship of changes in this indicator to changes in expenditures, and estimate this relationship for the most recent period.

PRICES

Consumer Prices

BLS publishes monthly information on changes in prices paid by consumers for a fixed market basket of goods and services. Tables 6 and 7 and Figure 6 present information on the all urban consumer price index (CPI) that measures changes in prices faced by 80 percent of the non-institutionalized population in the United States. (The more restrictive wage earner CPI gauges prices faced by wage earners and clerical workers. These workers account for 32 percent of the non-institutionalized population [U.S. Department of Labor, 1994b].)

The index reflects changes in prices charged for the same quality and quantity of goods or services purchased in the base period. For most items, the base period of 1982-84 is used to define the share of consumer expenditures purchasing specific services and products. Those shares or weights remain constant in all years, even though consumption patterns of the household may change over time. This type of index is called a fixed weight or Laspeyres index.

CPIs for health care goods and services depict price changes for out-of-pocket expenditures made directly by consumers. The composite CPI for medical care weights together product-specific or service-specific CPIs in proportion to household out-of-pocket expenditures for these items. For example, the composite medical care CPI measures inflation for the 3 percent of hospital expenditures that are made out-of-pocket by consumers; the remaining 97 percent of the costs of hospital care paid by private health insurers, Medicare, Medicaid, and other payers are not weighted into the CPI for medical care. In addition, some medical care sector indexes measure changes in list or charged prices, rather than in prices actually received by providers after discounts are deducted. In several health care areas, received or transaction prices are difficult to capture, although BLS is making advances in this area.

In the NHE, a combination of CPIs for selected medical care items, input price indexes for nursing homes, and the CPI for hospital and related services, adjusted by the Health Care Financing Administration (HCFA) to provide transaction price changes, are used as measures of inflation for the health industry. The indexes are used to develop a fixed-weight price index for personal health care to depict price changes affecting the entire health care industry more accurately than does the overall CPI medical care index (Levit et al., 1994b).

Background on Input Price Indexes

In 1979, HCFA developed the Medicare hospital input price index (hospital market basket) which was designed to measure the pure price changes associated with expenditure changes for hospital services. In the early 1980s, the skilled nursing facility (SNF) and home health agency (HHA)

input price indexes, often referred to as "market baskets," were developed to price a consistent set of goods and services over time. Also in the early 1980s, the original Medicare hospital input price index was revised for use in updating payment rates for the prospective payment system (PPS). All of these indexes have played an important role in helping to set Medicare payment percent increases, and in understanding the contribution of input price increases to growing health expenditures.

The input price indexes, or market baskets, are Laspeyres or fixed-weight indexes that are constructed in two steps. First, a base period is selected. For example, for the PPS hospital input price index, the base period is 1987. Cost categories, such as food, fuel, and labor, are identified and their 1987 expenditure amounts determined. The proportion or share of total expenditures included in specific spending categories is calculated. These proportions are called cost or expenditure weights. There are 28 expenditure categories in the 1987-based PPS hospital input price index.

Second, a price proxy is selected to match each expenditure category. Its purpose is to measure the rate of price increase of the goods or services in that category. The price proxy index for each spending category is multiplied by the expenditure weight for the category. The sum of these products (weights multiplied by the price index) over all cost categories yields the composite input price index for any given time period, usually a fiscal year or a calendar year. The percent change in the input price index is an estimate of price change over time for a fixed quantity of goods and services purchased by a provider.

The input price indexes are estimated on a historical basis and forecasted out several years. The HCFA-chosen price proxies are forecasted under contract with Data

Resources, Inc./McGraw Hill (DRI). Following every calendar year quarter, in March, June, September, and December, DRI updates its macroeconomic forecasts of wages and prices based on updated historical information and revised forecast assumptions. Some of the data in Tables 8 through 13 are forecasted and are expected to change as more recent historical data become available and subsequent quarterly forecasts are received.

The methodology and price proxy definitions used in the input price indexes are described in the *Federal Register* notices that accompany the revisions of the PPS, HHA, and SNF cost limits. A description of the current structure of the PPS input price index was published in the September 4, 1990, *Federal Register*. The most recent PPS update for payment rates was published in the September 1, 1994, *Federal Register*. The latest HHA regulatory input price index was published in the July 8, 1993, *Federal Register*, and the latest SNF input price index was published in the October 7, 1992, *Federal Register*.

Periodically, the input price indexes are revised to a new base year so that cost weights will reflect changes in the mix of goods and services that are purchased. Each revision allows for new base weights, a new base year, and changes to certain price variables used for price proxies.

Each input price index is presented in two tables: The first table shows the quarterly levels for each price index, and the second is a percentage change table. The hospital input price index for PPS is in Tables 8 and 9. The SNF input price index is in Tables 10 and 11. The HHA input price index is in Tables 12 and 13.

NATIONAL ECONOMIC INDICATORS

National economic indicators provide a context for understanding health-specific

indicators and how change in the health sector relates to change in the economy as a whole. Tables 14 and 15 present national indicators of output and employment.

Gross domestic product (GDP) measures the output of the U.S. economy as the market value of goods and services produced within the geographic boundaries of the United States by U.S. or foreign citizens or companies. Constant dollar or "real" GDP removes the effects of price changes from the valuation of goods and services produced, so that the growth of real GDP reflects changes in the "physical quantity" of the output of the economy (U.S. Department of Commerce, 1994).

Third Quarter Indicators

Total operating expenses in community hospitals were \$73.5 billion in the third quarter of 1994, an increase of 5.0 percent from the same quarter a year earlier. The increase in total operating expenses is attributable to the impact of a 4.9-percent increase in labor expenses and a 5.0-percent increase in non-labor expenses in the third quarter of 1994, measured over the same quarter a year earlier. Inpatient expenses grew to \$51.7 billion in the third quarter, an increase of 2.9 percent from the same quarter a year earlier (Figure 1).

Admissions to community hospitals increased 0.9 percent in the third quarter of 1994, measured over the same quarter a year earlier. The third quarter increase is a continuation of the recent trend of gradually increasing admissions. In each quarter since the third quarter of 1993, community hospital admissions increased over the same quarter a year earlier (Figure 2). Adult length of stay in community hospitals continued to decrease in the third quarter. The 3.8-percent decrease in adult length of stay since the third quarter of 1993 makes it

likely that the average adult length of stay for all of 1994 will be one of the lowest on record. The combined effect of the increase in admissions with the decrease in adult length of stay was an overall decrease in inpatient days. In the third quarter of 1994 the number of inpatient days fell 2.9 percent from the same quarter a year earlier.

Statistics on two other measures of community hospital utilization, outpatient visits and surgical operations, show that increases in these measures accelerated in the third quarter of 1994. Outpatient visits increased 7.9 percent in the third quarter of 1994 measured over the same quarter a year earlier, an acceleration in growth compared with the 6.4-percent increases registered in the third quarters of 1992 and 1993. The number of surgical operations increased 2.9 percent in the third quarter of 1994, as measured over the same quarter a year earlier. This is also an acceleration compared with growth in the number of surgical operations registered in the third quarters of 1992 and 1993.

One of the most significant developments in the third quarter of 1994 was that employment in the health services industry grew more slowly than employment in the private sector as a whole. Since the third quarter of 1985, employment has grown faster in health services than in the private sector as a whole. The recent historical relationship between the growth in health services employment and total private sector employment was reversed in the third quarter of 1994. Employment in the health services industry increased 3.0 percent in the third quarter of 1994, measured over the same quarter in the previous year, compared with an increase of 3.2 percent for all private non-agricultural establishments (Figure 3). Most of the deceleration in health services employment is attributable to very slow growth in

hospital employment. Total hospital employment growth has been decelerating since the fourth quarter of 1990. Total hospital employment actually declined from the third quarter of 1993 to the third quarter of 1994.

The combined impact of changes in employment and hours worked can be examined in statistics on implied non-supervisory work hours, which are the product of the number of non-supervisory employees and their average weekly work hours. In each of the first three quarters of 1994, implied non-supervisory work hours grew more slowly in health services than in the private sector as a whole. In the third quarter of 1994, implied non-supervisory work hours in private health service establishments increased 2.6 percent, measured over the same quarter a year earlier, compared with an increase of 3.6 percent for the private non-agricultural sector (Figure 4). The fastest growing industry in the health sector continues to be the Offices and Clinics of Dentists, which registered an increase of 4.3 percent in implied non-supervisory work hours measured over the same quarter a year earlier. The slowest growing sector in the health sector was private hospitals, where implied non-supervisory work hours actually decreased 0.1 percent from the same quarter a year earlier.

Implied non-supervisory payrolls are calculated by multiplying implied work hours by average hourly earnings. In the third quarter of 1994, implied non-supervisory payrolls in health service establishments grew 5.5 percent from the same quarter a year earlier, while in private non-agricultural establishments the growth rate was 6.3 percent. After outpacing the private sector for several years, implied non-supervisory payrolls in health service establishments grew more slowly in each of the first three quarters of 1994 than implied

non-supervisory payrolls in private non-agricultural establishments. In private hospitals, non-supervisory payrolls increased 2.9 percent in the third quarter of 1994 measured over the same quarter a year earlier, a slight acceleration from the 2.5 growth in the second quarter of 1994 (Figure 5). This was the only industry within the health sector where growth in non-supervisory payrolls accelerated in the third quarter of 1994.

Consumer prices, as measured by the Consumer Price Index (CPI) for all urban consumers, increased 2.9 percent in the third quarter of 1994, measured over the same period a year earlier. The increase in consumer prices for medical care, as measured by the CPI, was 4.6 percent in the third quarter of 1994, measured over the same period a year earlier, a deceleration from the 5.9-percent increase registered from the third quarter of 1992 to the third quarter of 1993. Consumer prices for medical care continued to increase more rapidly than consumer prices in the rest of the economy during the first three quarters of 1994. However, the price increases for medical care, as measured by the CPI, have also exhibited more rapid deceleration than price increases for all items less medical care.

The rate of increases in prices for medical commodities in the third quarter of 1994 was approximately equal to the increase in prices for all items in the CPI (Figure 6). This is a significant development since the price increases in both medical care services and medical care commodities have outpaced price increases in the rest of the CPI for many years. In the third quarter of 1994, prices for medical care commodities, as measured by the CPI, increased 2.8 percent from the same quarter a year earlier, compared with price increases of 2.9 percent for all items and 2.7 percent for all items less medical care.

Overall economic conditions were generally favorable in the third quarter of 1994. The business cycle expansion continued, as real GDP increased 4.4 percent at an annual rate. The unemployment rate fell from 6.6 percent in the first quarter of 1994 to 6.0 percent in the third quarter of 1994. Despite the significant reduction in the unemployment rate, inflation remained moderate by recent historic standards. As measured over the same quarter a year earlier, the CPI and the GDP fixed weight price index both registered increases of less than 3.0 percent. The Producer Price Index (PPI) for finished goods increased 0.9 percent from the same quarter a year earlier, reflecting continued moderation in the growth of wholesale prices.

¹ Adult occupancy rate is the ratio of average daily census to the average number of beds maintained during the reporting period.

² Adjusted patient days is an aggregate figure reflecting the number of days of inpatient care, plus an estimate of the volume of outpatient services, expressed in units equivalent to an inpatient day in terms of level of effort. It is derived by multiplying the number of outpatient visits by the ratio of outpatient revenue per outpatient visit to inpatient revenue per inpatient day, and adding the product to the number of inpatient days.

¹For data sources used to estimate the input price index relative weights and choice of price proxies, see the *Federal Register* (1990).

²Category weights may not sum to total because of rounding.

NOTES: Data through 1994, quarter 3, are historical. Data beginning with 1994, quarter 4, are forecasted. Q designates quarter of year. Percent change data shown are four-quarter moving averages. The following is an example of how a percent change is calculated: Use the quarterly index levels shown in Tables 9, 11, and 13. Choose the four-quarter period ending for which you would like to calculate the percent change (e.g., year-end 1994, quarter 3). Count back three quarters so that you have a total of four (e.g., 1994, quarter 1; 1994, quarter 2; 1994, quarter 3; 1994, quarter 4). Average these four quarters (add the index levels and divide by 4). Now take the four quarters previous to the four quarters that you just used (e.g., 1993, quarter 1; 1993, quarter 2; 1993, quarter 3; 1993, quarter 4). Average these four quarters. Finally, compute a percent change using the two averages.

SOURCES: Health Care Financing Administration, Office of the Actuary. Data from the Office of National Health Statistics, Division of Health Cost Analysis. Fourth quarter 1994 forecasts were produced by Data Resources, Inc./McGraw-Hill.

¹For data sources used to estimate the input price index relative weights and choice of price proxies, see the *Federal Register* (1992c).

²Category weights may not sum to total because of rounding.

NOTES: Data through 1994, quarter 3, are historical. Data beginning with 1994, quarter 4, are forecasted. Q designates quarter of year. Percent change data shown are four-quarter moving averages. The following is an example of how percent change is calculated: Use the quarterly index levels shown in Tables 8, 10, and 12. Choose the four-quarter period ending for which you would like to calculate the percent change (e.g., year-end 1994, quarter 3). Count back three quarters so that you have a total of four (e.g., 1994, quarter 3; 1994, quarter 2; 1994, quarter 1; 1993, quarter 4). Average these four quarters (add the index levels and divide by 4). Now, take the four quarters previous to the four quarters that you just used (e.g., 1993, quarter 3; 1993, quarter 2; 1993, quarter 1; 1992, quarter 4). Average these four quarters. Finally, compute a percent change using the two averages.

SOURCES: Health Care Financing Administration, Office of the Actuary: Data from the Office of National Health Statistics, Division of Health Cost Analysis. Fourth quarter 1994 forecasts were produced by Data Resources, Inc./McGraw-Hill.

¹Starting in January 1994 the unemployment rate is calculated on a modified basis, using the 1990 Current Population Survey. The unemployment rates shown prior to January 1994 are not comparable to the rates for January 1994 forward.

²Base period = 1982-84, unless noted.

³Formerly called the "Wholesale Price Index."

NOTES: Q designates quarter of year. Unlike data on Tables 1-13, quarterly data on GDP, personal income, disposable personal income, and savings are seasonally adjusted at annual rates. In addition, the unemployment rate is seasonally adjusted.
