Many Lamiaceae species are consumed in the Lebanese cuisine as food or condiment and are largely used in the traditional medicine of Lebanon to treat various diseases, including microbial infections. In this article we report the traditional medicinal uses of eleven Lamiaceae species: *Coridothymus capitatus* L., *Lavandula stoechas* L., *Lavandula angustifolia* Mill., *Mentha spicata* L. subsp. *condensata*, *Origanum syriacum* L., *Rosmarinus officinalis*, *Salvia fruticosa* Miller., *Satureja cuneifolia* Ten., *Satureja thymbra* L., *Thymbra spicata* L., and *Vitex agnus-castus* L. and study the chemical composition and antimicrobial activity of their essential oils (EOs). Our survey showed that Lamiaceae species are mainly used against gastrointestinal disorders and microbial infections. Chemical analysis of the EOs obtained from these plants allowed us to identify seventy-five compounds describing more than 90% of the relative composition of each EO. Essential oils with high amounts of thymol and carvacrol possessed the strongest antimicrobial activity. As expected, these two compounds demonstrated an interesting antifungal efficacy against the filamentous fungus *T. rubrum*. Our results confirmed that some of the Lamiaceae species used in Lebanon ethnopharmacological practices as antimicrobial agents do possess antibacterial and antifungal potential consistent with their use in alternative or complementary medicine.

1. Introduction

The evolution of resistance to currently used antimicrobial compounds is neither a surprising nor a new phenomenon; however, infections are becoming more common, more severe, and more easily transmitted. According to the WHO, many infectious diseases will become untreatable and uncontrollable in the upcoming years [1]. Many authors mention a possible upcoming postantibiotic era [2–4].

Aromatic plants have been recognized since antiquity and widely used as bactericides, fungicides, virucides, antiparasitics, and pesticides. Their properties are mainly attributed to

their volatile oils [5, 6]. Investigations into the antimicrobial activities, mode of action, and potential uses of plant essential oils have regained momentum [7]. These oils, representative of very wide chemical diversity, may contribute to or inspire alternative solutions against multidrug resistant infections. Recently, *in vitro* screening programs based on ethnobotanical approaches proved to be very efficient in validating traditional uses of medical plants and providing new ways in the search for active compounds [8].

Lamiaceae (formerly known as Labiate) is a large plant family of mostly shrubs and herbs. It is the largest family of the order Lamiales with 236 genera and more than 7,000

species, the largest genus being *Salvia* with around 900 species [9]. Lamiaceae are distributed globally and a particularly high concentration of them occurs in the Mediterranean region. The majority of Lamiaceae being aromatic plants, the family is economically important [10]. Many are cultivated as ornamentals, like *Ajuga*, *Coleus*, and *Salvia* but others are widely used as culinary herbs and spices, such as sage (*Salvia*), thyme (*Thymus*), mint (*Mentha*), oregano or marjoram (*Origanum*), rosemary (*Rosmarinus*), lavender (*Lavandula*), and basil (*Ocimum*). Mint and lavender are grown for their oil used in perfumery, cosmetics, pharmaceutical, and food industries as active ingredients or as flavour and fragrance. Medicinal properties of the Lamiaceae species are often attributed to their high content of volatile compounds.

The Lamiaceae family is particularly well represented in Lebanon, where 136 species belonging to 29 genera have been inventoried [11]. Many Lamiaceae are regularly consumed in the Lebanese cuisine as food or condiments. For example, the different varieties of thyme like *Origanum syriacum*, *Satureja thymbra*, and *Thymbra spicata* associated with a mixture of *Rhus coriaria* L. (sumac) and sesame seeds are the main ingredients of a very popular Lebanese pizza called "manakeesh." Others, like *Rosmarinus officinalis*, *Coridothymus capitatus*, and *Salvia fruticosa*, are eaten as salads and the leaves of *Thymus* and *Origanum* species are mixed with traditional Lebanese fresh cheese called "Shanklish" for their aromatic and antiparasitic properties.

Indigenous Lamiaceae are also frequently used in Lebanon for medical purposes and are marketed by herbalists. These include the genera *Lavandula*, *Melissa*, *Mentha*, *Origanum*, *Rosmarinus*, *Salvia*, *Satureja*, and *Thymus*. These plants are highly aromatic due to the presence of external glandular structures that produce volatile oil [12] and their essential oils are widely used in the Lebanese folk medicine [11, 13, 14].

However, there was no previous study documenting the folk medicinal usage of the Lamiaceae species in Lebanon. We have conducted a large-scale survey on the traditional medicinal uses of Lamiaceae species in different regions of Lebanon. A part of this work has already appeared in a congress report [11].

The main objectives of the present study were (1) to report on the traditional uses of eleven Lamiaceae species most used in the Lebanese folk medicine (*Coridothymus capitatus* L. Reichenb. Fil., *Lavandula stoechas* L., *Lavandula angustifolia* Mill., *Mentha spicata* L. subsp. *condensata*, *Origanum syriacum* L., *Rosmarinus officinalis* L., *Salvia fruticosa* Miller., *Satureja cuneifolia* Ten., *Satureja thymbra* L., *Thymbra spicata* L., and *Vitex agnus-castus* L.), (2) to investigate the chemical composition of the EOs extracted from these species, (3) to evaluate the antimicrobial activity of these EOs and their major constituents against opportunistic human pathogens, and (4) to correlate *in vitro* results with the ethnopharmacological uses of these plants.

2. Material and Methods

2.1. Ethnomedical Field Survey and Ethnobotanical Data Collection

The research was carried out in different regions

of Lebanon from the north to the south and from the coast to the mountains, including the anti-Lebanon mountain range and the steppe. A great variety of wild plant species according to different ecological conditions can therefore be found. The surveys were conducted in the cities and villages of the twenty-five districts ("aqdy" or "qadaa") of the six governorates ("mohaafazah") of Lebanon (Figure 1).

Ethnobotanical and ethnomedicinal information was obtained between the years 2002 and 2008 from 325 interviewees from 223 villages covering all the districts of Lebanon. Most of the participants interviewed were herbalists ("Attarin" or "dabbous"), shepherds, farmers, folk healers, or older experienced people and midwives ("daye") between 40 and 70 years old. The people interviewed declared that their knowledge about the traditional medicine was transmitted mainly orally from older generations. Interviewees were accompanied to the field individually where they would point out the herbs that have been using to cure the mentioned disease. This was also to confirm plant identification (vernacular names can be different in different regions of Lebanon) and obtain fresh samples for herbarium voucher. When the fertile part was not available, the plant was visited again at the appropriate time to obtain a fertile sample.

The obtained information was cross-checked with that of other informants, and also, after a week, the interview was repeated with the same person. Only medical usages of plants given at least by three separate informants have been reported in this investigation. It was verified that each informant is able to recognize the mentioned plant species in the wild.

The questionnaire form was based on the botanical and ethnopharmacognostic survey of traditional medicine plants, suggested by WHO [15]. The collected information included local names, used part(s) of the plant, folk medicinal uses and therapeutic properties, method of preparation, way of administration, doses, and duration of treatment. The results are recorded in a synoptic table (Table 2).

2.2. Plant Material. Plant material was collected in several locations throughout Lebanon and voucher specimens were deposited at the Herbarium of Botany of the U.S.E.K., Lebanon. Specimens of the Lamiaceae species were collected as described in Table 1.

The plants have been identified based on the "Nouvelle flore du Liban et de la Syrie" (Mouterde) [16] and the Med-Checklist (<http://ww2.bgbm.org/mcl/>). We followed the new phylogenetic classification APG II [17] in order to update the families cited in Mouterde. Voucher specimens were deposited at the Herbarium of Botany of the U.S.E.K., Lebanon.

2.3. Essential Oil Extraction. The essential oils (EOs) were obtained by hydrodistillation performed for 3 h using a Clevenger-type apparatus according to the European Pharmacopoeia [18]. Yields are given in Table 4.

2.4. Essential Oils Analyses

2.4.1. GC Analyses

Analytical gas chromatography was carried out on a Thermo Electron Corporation gas

FIGURE 1: Studied area: the governorates and districts of Lebanon.

chromatograph fitted with a DB-5 MS capillary column ($30\text{ m} \times 0.25\text{ mm}$) with $0.1\text{ }\mu\text{m}$ film thickness or a fused silica HP Innowax polyethylene glycol capillary column ($50\text{ m} \times 0.20\text{ mm}$, film thickness $0.20\text{ }\mu\text{m}$). Helium was the carrier gas (0.7 mL/min). The column temperature was initially set to 35°C before being gradually increased to 85°C at $5^\circ\text{C}/\text{min}$, held for 20 min at 85°C , raised to 300°C at $10^\circ\text{C}/\text{min}$, and finally held for 5 min at 300°C . Diluted $1\text{ }\mu\text{L}$ samples ($1/100$, v/v) were injected at 250°C manually and in the splitless mode. Flame ionisation detection (FID) was performed at 310°C .

2.4.2. GC/MS Analyses. The GC/MS analyses were performed using an Agilent 6890 gas chromatograph coupled with 5975 Mass Detector. The 7683B autosampler injected $1\text{ }\mu\text{L}$ of each oil sample. A fused silica capillary column DB-5 MS ($30\text{ m} \times 0.25\text{ mm}$ internal diameter, film thickener

$0.1\text{ }\mu\text{m}$) or a fused silica HP Innowax polyethylene glycol capillary column ($50\text{ m} \times 0.20\text{ mm}$, film thickness $0.20\text{ }\mu\text{m}$) was used. Helium was the carrier gas (0.7 mL/min). The oven temperature program was identical to that described in Section 2.4.1. The mass spectra were recorded at 70 eV with an ion source temperature of 310°C and a transfer line heated to 320°C . The acquisition was recorded in full scan mode (50 – 400 amu).

2.4.3. Identifications and Quantifications. Most constituents were identified by gas chromatography by comparing their retention indices (RI) with those from the literature [19, 20] or with those of authentic compounds obtained from Sigma-Aldrich (Lebanon). The retention indices were determined relatively to a homologous series of *n*-alkanes (C8 to C24) analysed under the same operating conditions. Further identification was obtained by comparing their mass spectra on

<i>Satureja thymbra</i>	Flowering tops	Nahr Ibrahim	Mount Lebanon	35°39'19.03"E	190	June 2012	MNV173a
<i>Thymbra spicata</i>	Leaves						MNV191
<i>Vitex agnus-castus</i>	Flowering tops	Nahr Ibrahim	Mount Lebanon	34°03'42.70"N 35°38'44.52"E	7	June 2012	MNV096

both columns with those provided in the NIST and Wiley 275 libraries, our homemade library constructed with pure compounds, and EOs of known composition or with mass spectra from the literature [19, 21]. The relative concentrations of the components were calculated based on the GC peak areas without correction; they are reported in Table 4.

2.5. Antimicrobial Activity

2.5.1. Microorganisms. The antimicrobial activity of the essential oils was investigated against the Gram (-) bacterial strain *Escherichia coli* ATCC 25922, the Gram (+) bacterial strain *Staphylococcus aureus* ATCC 29213, the yeast *Candida albicans* ATCC 10231, and a clinical isolate of the dermatophyte *Trichophyton rubrum* SNB-TR [22].

2.5.2. Microdilution Method. The antimicrobial activity of the EOs was measured using a broth microdilution method according to the Clinical and Laboratory Standards Institute (CLSI) guidelines [23–26]. The essential oils and their major components were diluted in DMSO and were tested at concentrations ranging from 512 to 16 $\mu\text{g}/\text{mL}$. The microplates were incubated at 37°C for 24 h for bacteria, 48 h for yeasts, and 5 days for dermatophytes. The minimal inhibitory concentrations (MIC) refer to the lowest concentrations preventing visible microbial growth (Table 5). Oxacillin and gentamicin (16–0.03 $\mu\text{g}/\text{mL}$) were used as reference antibiotics, while itraconazole (16–0.03 $\mu\text{g}/\text{mL}$) and fluconazole (64–0.125 $\mu\text{g}/\text{mL}$) were used as positive controls for the antifungal assays. The antimicrobial standards were purchased from Molekula, Dorset, UK, and the pure terpenes from Sigma-Aldrich, Lebanon.

3. Results and Discussion

3.1. Ethnopharmacological Data. This investigation showed that Lamiaceae species and especially the eleven ones reported in this study are still frequently used in Lebanon as herbal remedies (Table 2). *Origanum syriacum* and *Salvia fruticosa* are the two most cited plants. It should be noted that the same vernacular name is sometimes used for different species. For example, the appellation “Za’atar” is used for *Satureja thymbra*, *Thymbra spicata*, *Coridothymus capitatus*, and *Origanum syriacum*.

3.2. Plant Parts Used. The plant parts used most frequently are the flowering tops and the leaves (34.6% each), followed by the stems (11.5%), flowers (7.7%), whole plant, fruits, and seeds (3.8% each) (Table 3).

3.3. Preparation and Administration. Most of the traditional remedies are administered *per os* or internally (71.8%) although the majority of the EOs are applied externally (57.1%). The main modes of preparation are infusion (40.0%), decoction (17.5%), EO application (17.5%), and food consumption (15.0%) (Table 3). The contribution of the volatile organic compounds (VOCs) in all of these preparations is expected to be very important owing to the large amount of VOCs in Lamiaceae. The only exception is for decoctions because this process should eliminate most of the VOCs along with steam.

3.4. Traditional Medicinal Indications. Among the multiple medical usages of these plants, the eleven Lamiaceae species

Part used: Fp = flowering parts, Le = leaves, Fl = flowers, Wp = whole plant, St = stems, Ft = fruits, Se = seeds, and Dp = dried plant. Use: E = external use; I = internal use.

Numbers from 1 to 26 are abbreviations of the 25 districts of Lebanon and the governorate of Beirut (Beirut province is undivided): Akkar 1, Aley 2, Baabda 3, Baalbek 4, Beirut 6, Bint Jbeil 7, Bcharre 8, Chouf 9, Hasbayya 10, Hermel 11, Jbeil 12, Jezzine 13, Keserwan 14, Koura 15, Marjeyoun 16, Metn 17, Miniyeh-Danniyeh 18, Nabatiye 19, Rachaya 20, Sidon (Saida) 21, Tripoli 22, Tyre (Sour) 23, West Bekaa 24, Zahle 25, and Zgharta 26.

The symbols N and Fr are used to indicate the number and frequency of people mentioning the indication in a single plant from the total number of interviewees; that is, Fr = (N/total number of interviewees) × 100.

* All Lamiaceae species cited and reported in this table are indigenous to Lebanon, except *L. angustifolia* that is imported and cultivated.

are mainly used to treat gastrointestinal disorders and microbial infections (Table 3). Almost all of them are described to possess antiseptic, antimicrobial, or antifungal properties, and a significant proportion of the EOs has been reported to be applied locally to cure microbial infections (57.1%).

3.5. Number of Districts Describing the Use of Each Lamiaceae Species. The ethnopharmacological use of *Rosmarinus officinalis* and *Origanum syriacum* was mentioned by the largest number of districts (57.7 and 50%, resp.), while the medicinal use of *Coridothymus capitatus*, *Vitex agnus-castus*, and *Salvia fruticosa* was localized in certain regions of Lebanon (Table 3).

3.6. Comparison with the Ethnopharmacological Uses in Other Mediterranean Countries. Despite the ancestral use of medicinal plants including essential oils in Lebanon, literature reports on Lebanese ethnomedicinal practices are scarce. Nevertheless, previous works have reported the medicinal uses of Lamiaceae species in the Mediterranean basin. Indeed, some of the plant species pointed out in our study are widely distributed and widely acknowledged by local people for medicinal purposes. In many cases, the uses reported in other countries are somewhat comparable to those found in Lebanon. For example, the cultivated lavender *Lavandula angustifolia* is used in Italy and Turkey as a sedative and antiseptic and to treat cold and rheumatism [27–29]. As for the wild lavender, *Lavandula stoechas*, it is used in Turkey and Spain for gastrointestinal and cardiovascular diseases [30–34]. Other examples include *Coridothymus capitatus* and *Salvia fruticosa* used in Palestine and Israel to treat cold and gastrointestinal disorders [35–37], *thymbra spicata* used in Turkey for its cardiotonic and hypoglycemic properties, or to treat cough and arthrosclerosis [29, 30, 32], *Vitex agnus-castus* used in Palestine to treat eye inflammation [38], and *Mentha spicata* and *Rosmarinus officinalis* that are both used in Italy in the same way as in Lebanon as antiseptics and antimicrobials [27, 39].

On the other hand, little is known on the plant species with restricted distribution areas, like *Origanum syriacum* that is mainly used to treat cold symptoms in Turkey [40] and stomach pain in Jordan [41]. It is also the case of *Satureja cuneifolia* and *Satureja thymbra* that are used in Turkey as immunotonic and cardiotonic and to treat cold and flu symptoms [32, 42].

3.7. Essential Oils Analyses. Since the VOCs seemed to be relevant in the context of the traditional medicinal use of Lebanese Lamiaceae, it was pertinent to study the chemical composition of their EOs. These are reported in Table 4; the extraction yields and the relative proportions of the components are given.

The yields (v/w, relative to dry weight material) obtained by hydrodistillation ranged from 0.3% from *V. agnus-castus* flowering tops to 4.1% from *T. spicata* leaves. GC and GC-MS analyses led to the identification of 75 components accounting for 90.6 to 97.2% of the total oils (Table 4). It was found that the EOs were essentially composed of

oxygenated monoterpenes (51.7% to 85.9%), the only exception being that from *Vitex agnus-castus* which was mainly composed of sesquiterpene hydrocarbons (36.4%). Thymol and carvacrol were present in a high relative proportion in several EOs of these Lebanese chemotypes. Thymol was the major constituent of *Origanum syriacum* (74.4%), *Satureja thymbra* (44.5%), and *Coridothymus capitatus* (29.3%) EOs, while carvacrol was highly abundant in the EOs of *Satureja cuneifolia* (69.5%), *Thymbra spicata* (64.0%), and *Coridothymus capitatus* (29.3%). All of these species were also rich in *p*-cymene and γ -terpinene. The oils of *Salvia fruticosa*, *Rosmarinus officinalis*, and *Vitex agnus-castus* were essentially composed of eucalyptol representing 57.3%, 21.5%, and 20.5% of the total oils, respectively. Pulegone was the main component of the EO of *Mentha spicata* accounting for 78.7% of the oil. Wild and cultivated lavender EOs were significantly different; *Lavandula stoechas* (wild lavender) was mainly composed of α -fenchone (26.2%) while linalool (45.8%) was the major constituent of *Lavandula angustifolia* (cultivated lavender).

3.8. Comparison of the Main Components of the Lebanese Lamiaceae Species with Other Countries. The EOs of *Vitex agnus-castus*, *Lavandula stoechas*, and *Salvia fruticosa* have a very similar chemical composition compared to other

countries [43–48]. *Lavandula angustifolia* and *Coridothymus capitatus* Lebanese EOs are different than those from other regions. According to our study, *Lavandula angustifolia* EO contains a lower relative proportion of linalyl acetate [49] and *Coridothymus capitatus* is richer in thymol [50, 51]. The chemical composition of the EO of *Rosmarinus officinalis* is similar to that reported in Greece [52] but is different from the ones reported in Turkey and Tunisia where the main component of the Lebanese EO, eucalyptol, is absent [53, 54]. Both thymol and carvacrol chemotypes have been previously reported for our thymol-rich EOs like *Satureja thymbra* [55, 56] and *Origanum syriacum* [57] or those in which carvacrol is the main constituent such as *Thymbra spicata* [55, 58] and *Satureja cuneifolia* [59, 60]. Likewise, *Mentha spicata* oil reported in our study belongs to the pulegone chemotype, while a carvone chemotype has also been described in other regions [61, 62].

3.9. Antimicrobial Activity. The minimum inhibitory concentrations (MICs) of the Lamiaceae essential oils are presented in Table 5. An oil was considered active if the minimal inhibitory concentration was $128 \mu\text{g/mL}$ or below [63]. The clinical isolate *T. rubrum* SNB-TR1 was the most sensitive, followed by the Gram (-) bacterium *S. aureus* and the yeast *C. albicans*, whereas the Gram (+) bacterium *E. coli* was more

resistant. The oil of *Coridothymus capitatus* was the only EO to possess a significant antibacterial activity against *E. coli* with a MIC value of 128 µg/mL. This EO is rich in both thymol and carvacrol (29.3 and 41.5%, resp.). Overall, plants EOs with high relative amounts of thymol and/or carvacrol were the most active against *S. aureus*, *T. rubrum*, and *C. albicans* with MIC values in the range of 64–128 µg/mL.

To confirm the origin of the observed antimicrobial activity, the major constituents were tested against the two microorganisms that showed the greatest sensitivity, *S. aureus* and *T. rubrum*. Indeed, among the tested terpenes, only thymol and carvacrol showed significant antibacterial activity against *S. aureus* (MIC 128 µg/mL). Against *T. rubrum*, these two compounds were also very active (MIC 32 µg/mL), followed by *p*-cymene (MIC 64 µg/mL). The antimicrobial potential of a combination of thymol and carvacrol in equal proportions was also measured but no synergistic effect was detected. The MIC of the combination of these two compounds was identical to that of each separate compound. The other important constituents, that is, camphor, eucalyptol, linalool, γ -terpinene, and α -fenchone, did not show any significant antimicrobial activity (Table 5).

It has been previously reported that essential oils of *Origanum* and *Thymus* species contain mainly phenolic monoterpenes such as carvacrol and thymol and their activities are often attributed to these compounds [64–68].

Our data confirm that these plants or their EOs could indeed be used in local applications for treating mycoses and demonstrate that combinations of thymol and carvacrol are not needed to account for the antifungal property of an EO.

3.10. Correlation Ethnopharmacology: Antimicrobial Activity. Ten species out of the eleven most cited Lamiaceae are used in the Lebanese traditional medicine as antiseptic or antimicrobial agents. Some are even cited specifically as antifungals (3 out of 11). Our results corroborate the antimicrobial indications for *Coridothymus capitatus*, *Origanum syriacum*, *Lavandula stoechas*, *Satureja thymbra*, and *Thymbra spicata*, indicating that the use of these plant species is most likely linked to the antimicrobial potential of their VOCs. For example, the flowering parts of *C. capitatus* are used as antiseptic and to treat dermatosis, and our results showed that the EO of the flowering tops can be considered active on all strains tested. The flowering parts of *O. syriacum*, *S. thymbra*, and *T. spicata* are also used in Lebanon as antiseptic and antimicrobial agents and their EOs proved to be notably active against *S. aureus*, *C. albicans*, and *T. rubrum* (Table 5).

4. Conclusion

In conclusion, the ethnobotanical and ethnopharmacological survey of the Lamiaceae plants confirmed that their medical values are widely acknowledged among herbalists and rural communities and that this family of plants is still frequently used in the traditional medicine of Lebanon to treat many ailments, including microbial infections.

This study highlights the *in vitro* antimicrobial activity of some Lebanese Lamiaceae EOs against human pathogens.

The antimicrobial potential of these EOs originates from their high content in either thymol or carvacrol. These results validate the traditional antimicrobial use of Lamiaceae and lead us to believe that the use of the most active ones of these plants (or their EOs) can be promoted for the treatment of mycoses under topical applications. It should be noted that Lamiaceae herbs have high consumption in the traditional medicine in Lebanon. This might indicate innocuousness [69] although toxicological studies on these species should be encouraged.
