

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

**Background:** A surge in current second wave of COVID-19 concurrent with annual seasonal influenza is expected to create unique challenges for triaging and healthcare resource utilization. This study investigates the subtle differences in vital signs as an effective screening tool for differentiating hemodynamic presentations in patients with COVID-19 and influenza.

**Methods:** We developed a supervised machine learning pipeline to distinguish the two viral infections using dataset from the hospital/emergency room encounters of 3,883 patients who had confirmed diagnoses of influenza A/B, COVID-19 or negative test results. The models were externally validated on 15,697 encounters in 3,125 patients available on TrinetX database that contains data from different healthcare organizations.

**Results:** The models achieved an area under the receiver operating characteristic curve (AUC) of  $\geq 97\%$  using our multiclass classifier. The influenza vs. COVID-19-model had an AUC of 98%, and 92% on the internal and external test sets, respectively. Body temperature, followed by heart rate and oxygen saturation (Fig. 1) were the most predictive for discriminating the patient subgroups.

**Conclusion:** Our study illustrates the potential of machine-learning models for accurately distinguishing the hemodynamic presentations of the two viral infections. This may have utility as a frontline diagnostic tool to aid healthcare workers in triaging patients as two viral infections start cocirculating in the communities.

**Figure 1.** Shapley Additive Explanations (SHAP) summary plot depicting the relative importance, impact and contribution of different features on the output of (A) Influenza vs COVID-19-positive, (B) Influenza vs Other and (C) COVID-19-positive vs COVID-19-negative predictive models.
