Abstract

Background: The expression of major histocompatibility complex class II (MHCII) antigens in both mouse and human tumors is rare, and these antigens are not easily inducible by IFN-gamma (IFN γ). Since MHCII may play an important role in the development of host antitumor immune response, we explored the possibility of restoring MHCII inducibility in several IFN γ -resistant tumor cell lines using protein kinase C (PKC) agonists phorbol myristate acetate (PMA) or Bryostatin.

Results: Tumor cells were co-cultured with various concentrations of PMA and IFN γ for 48 hr. The expression of MHCII antigens and receptors IFN γ R1 and IFN γ R2 was determined by flow cytometry. We showed that the presence of as little as 0.1 ng/ml of PMA in tissue culture restored the ability of weakly inducible LSI034 colon carcinoma cells to express MHCII in response to IFN γ (100 – 10,000 IU/ml) in a dose-dependent manner. Likewise, Bryostatin I, as low as 10 ng/ml produced a 5–6 fold upregulation of MHCII. The effect of PMA was not observed in two other poorly responding cell lines, MSTO-211H mesothelioma and HepG2 hepatocellular carcinoma, and was abrogated by relatively high concentrations of PKC inhibitors staurosporine (100 nM) and GF 109203X (1,000 nM). Both surface and intracellular staining of all cell lines with antibodies against IFN γ R1 and IFN γ R2 failed to detect any increase in IFN γ receptor expression following incubation with PMA.

Conclusion: In this study we showed that IFN γ -inducibility of MHCII antigens in weakly inducible LSI034 colorectal carcinoma cell line can be rescued by concomitant incubation with PKC agonists. Bryostatin I may be considered for further investigation of IFN γ -dependent MHCII induction in resistant tumors *in vivo*.

Background

Major histocompatibility complex class II molecules (MHCII) are heterodimeric transmembrane glycoproteins that bind antigenic peptides and present such peptides to CD4⁺ T cells. Although MHCII are not expressed by the vast majority of studied mouse and human tumors, CD4⁺

T lymphocytes specific to MHCII-restricted tumor antigens have been found in various cancers [1]. Those lymphocytes are believed to be generated *in vivo* following the recognition of MHCII-tumor peptide complexes expressed by host antigen presenting cells and can cause regression of MHCII-negative tumors indirectly, via

secretion of cytokines such as IL-2 or IFN γ [2]. The released cytokines can recruit and activate cytotoxic CD8+ T lymphocytes and/or accessory cells (eosinophils, macrophages) which further mediate tumor destruction.

It has been recently appreciated that sufficient concentrations of secreted IFN γ may also induce susceptible tumors to express the MHCII molecules, potentially leading to increased direct contact with CD4+ T cells [3]. Even though some reports indicate that tumor sensitivity to IFN γ is not required to elicit tumor regression [4], it is conceivable that the IFN γ -induced MHCII expression on tumor cells may boost the effector phase of antitumor responses through additional cytokine release or direct tumor eradication by CD4+ T cells. Indeed, the CD4+ T cells that directly destroy MHCII-positive tumors were identified [5]. In the clinic, the expression of MHCII on colorectal carcinomas is correlated with more favourable prognosis [6]. Adoptive transfer studies show that *ex vivo* activated CD4+ T cells are able to recognize, and to eliminate, MHCII-positive tumors either by themselves [7] or in co-operation with CD8+ T cells [8]. It has been also demonstrated that the increased MHCII expression on tumor cells and macrophages following treatment with IFN γ *in vivo* was associated with enhanced efficacy of adoptive T cell therapy in a mouse model of metastatic sarcoma [9].

Unfortunately, the induction of MHCII on tumor cells by IFN γ *in vivo* is difficult [10]. In fact, the reported inducible tumors seem to be limited to freshly transplanted tumor cells [9,11] or malignant cells present in the ascitic fluid [12]. Many tumors do not express MHCII after treatment with recombinant IFN γ *in vitro* either [13].

Given the role that MHCII may play in tumor immunity, further attempts to restore inducibility in IFN γ -resistant tumors appear to be warranted. In this regard, several substances have recently been tested using *in vitro* models of noninducible tumor cell lines. It was reported that some agents, e.g. histone deacetylase inhibitors [14] or DNA methylation inhibitors [15], can rescue the IFN γ inducibility of MHCII in cultured tumor cells.

In this study, we explored whether the effect can be achieved by yet another category of modulators, the PKC agonists, chosen because PKC has been shown to function as an upstream regulator of the MAPK pathway [16] that is involved in both IFN γ signal transduction [17] and regulation of gene expression [18].

Specifically, the influence of a potent PKC activator, PMA, and clinically tested drug, Bryostatin 1, on the IFN γ -induced MHCII expression in several IFN γ -resistant tumor cell lines was examined. Previously, PMA was shown to augment IFN γ -mediated MHCII expression in MHCII-in-

ducible tumor cell lines [19,20]. Here, we report that the presence of PMA in tissue culture restores IFN γ -dependent MHCII expression in the poorly-responding LS1034 colon carcinoma cell line but fails to produce this effect in two other IFN γ -resistant cell lines, MSTO-211H mesothelioma and HepG2 hepatocellular carcinoma. We also show that the IFN γ -dependent MHCII expression in LS1034 cell line can be rescued by clinically acceptable concentrations of Bryostatin 1.

Results

Induction of MHCII molecules by IFN γ in four different tumor cell lines

We first compared the induction of MHCII molecules in SW480, LS1034, MSTO-211H and HepG2 tumor cells in response to different concentrations of IFN γ . MHCII antigens were initially undetectable in all cell lines tested. Incubation with as little as 10^2 IU/ml IFN γ induced a 10-fold increase of MHCII-specific fluorescence in SW480 colon carcinoma cell line. In contrast, LS1034 demonstrated only weak (1.4- to 1.6-fold) increases in level of MHCII, and remained weakly inducible even when concentration of IFN γ was increased to 10^4 IU/ml (Figure 1). MSTO-211H, mesothelioma, cell line also showed a weak induction of MHCII in response to IFN γ and HepG2, hepatocellular carcinoma, was completely non-inducible (data not shown).

It should be noted, however, that we observed a small population of LS1034 cells (about 5–10% of all cells) that demonstrated a modest (3- to 4-fold) increase in MHCII-specific fluorescence after incubation with 10^2 – 10^4 IU/ml IFN γ (data not shown). This could suggest that a small subset of LS1034 cells might acquire an inducible phenotype at a certain stage of cell differentiation.

PMA rescues IFN γ inducibility of MHCII in low responding LS1034 colon carcinoma cell line

We next attempted to restore IFN γ inducibility of MHCII in poorly responding tumor cell lines by adding PKC agonist PMA into culture medium containing variable concentrations of IFN γ . PMA did not improve IFN γ inducibility of MHCII in MSTO-211H and HepG2 cell lines (data not shown). The LS1034 cells, on the other hand, demonstrated a robust increase in MHCII expression.

The magnitude of response of LS1034 cells varied greatly from experiment to experiment depending not only on concentration of IFN γ , but also on concentration of PMA and even on type of the PMA agent (DMSO or ethanol). Therefore, the experiments were arranged in a factorial design for accurate analysis of possible interactive effects. For each combination of treatments, a 3-letter alphanumeric code was assigned (Table 1). Four dose levels of

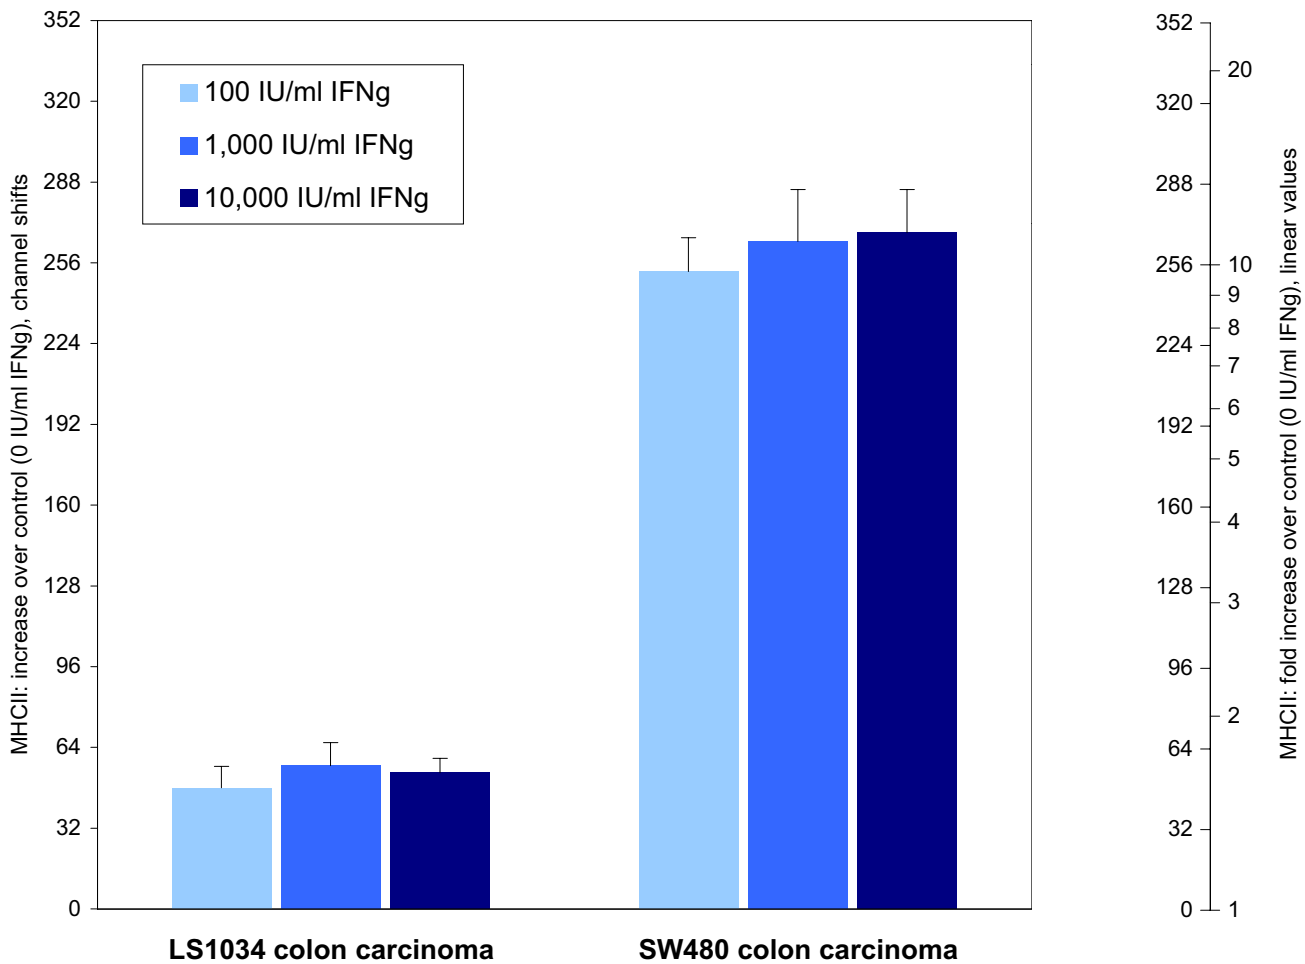

Figure 1

MHCII expression induced by IFN γ in two colon carcinoma cell lines. Cells were incubated with various concentrations of IFN γ for 48 hr. The difference in MHCII inducibility between the low responding LS1034 cell line (mean \pm sd, n = 8 independent experiments) and the high responding SW480 cell line (mean \pm sd, n = 2) is at least 5-fold.

IFN γ combined with 5 dose levels of PMA and 2 dose levels of ethanol generated 40 groups and the design was replicated 4 times.

The results demonstrated a substantial increase in MHCII expression in LS1034 cell line following combined incubation with PMA and IFN γ (Figure 2). Two-factor analysis of variance revealed that the magnitude of MHCII induction in LS1034 cells was almost totally determined by concentration of IFN γ ($F_{2;36} = 29.3$, $P < 10^{-6}$). Higher response to IFN γ tended to be associated with higher concentration of PMA in some experiments, but the overall effect of PMA did not reach a commonly accepted level of significance ($F_{3;36} = 1.9$, $P = 0.14$). Interestingly, the effect

of PMA did reach significance in cultures supplemented with 172 mM ethanol ($F_{3;36} = 3.0$, $P = 0.043$; groups 09b \rightarrow 12b, 15b \rightarrow 18b, 21b \rightarrow 24b). No interaction effect between PMA and IFN γ was found ($F_{6;36} = 0.14$, $P = 0.99$).

Since there were no 2-factor interactions, several single-factor groups were added, and data were re-analysed by using one-way ANOVA. Different combinations of PMA and IFN γ were compared to the highest dose of IFN γ used without PMA (group 20a or 20b). Multiple comparisons were made using Tukey's HSD test and Scheffe's test (the latter test is more conservative). Results demonstrate that the expression level of MHCII reached a plateau at 10^3 IU/ml IFN γ in the presence of 10^2 – 10^4 ng/ml PMA and 172

mM ethanol. Further increases in concentration of IFN γ (to 10⁴ IU/ml) did not result in statistically significant increases of MHCII expression (Figure 2B).

Figure 2 also demonstrates that ethanol was totally inactive alone (compare group 20a vs. 20b) but it significantly improved the MHCII induction in the presence of PMA. Because of variation between experiments, the effect of EtOH could not be seen clearly in Figure 2. For that reason, pair-wise comparisons were made between cell cultures incubated either with PMA or with a combination of PMA and EtOH. Specifically, group 09a was compared to group 09b, etc. Data shown in Figure 3 confirm that EtOH significantly improved PMA-potentiated response to IFN γ . Linear regression analysis also revealed that the effect of ethanol was more pronounced at 10² IU/ml IFN γ .

Taken together, the above results showed a strong potentiating effect of PMA on IFN γ -induced HLA-DR expression in LS1034 cell line and no changes in two other poorly inducible cell lines.

Expression levels of IFN γ receptors in four different tumor cell lines do not change following incubation with PMA

It has been previously shown that potentiating effect of phorbol esters on IFN γ -dependent MHCII induction in THP-1 monocytic cell line was associated with the increase in synthesis of IFN γ receptors [19]. For that reason, we questioned whether PMA could produce similar changes in LS1034 colon carcinoma cells. We compared the expression of alpha and beta chains of IFN γ receptor (IFN γ R1 and IFN γ R2) in LS1034 carcinoma and three other tumor cell lines before and after 48 hr incubation with 10³ ng/ml PMA and 172 mM ethanol. Results, plot-

ted in Figure 4, show that untreated and PMA-treated tumor cells express about the same levels of IFN γ R1 and IFN γ R2. Moreover, the level of IFN γ R1 in HepG2 cells actually drops after exposure to PMA. Therefore, we conclude that it is unlikely that PMA action in LS1034 carcinoma is mediated through increased synthesis of IFN γ receptors.

Expression of the retinoblastoma protein is not lost in LS1034, MSTO-211H and HepG2 cell lines

A substantial percentage of human tumors lose the expression of the retinoblastoma tumor suppressor protein (Rb), important as a necessary condition for IFN γ -mediated induction of MHCII [21]. Therefore, we wished to determine whether the poor IFN γ inducibility of MHCII in LS1034, MSTO-211H and HepG2 cell lines could be explained by the loss of Rb. Immunofluorescent staining with a Rb-specific mAb (clone G3-245) demonstrated that all cell lines tested expressed Rb (Figure 5).

A closer look at Figure 5 reveals that the 4 cell lines can be ranked according to their Rb contents in the following order: SW480 > LS1034 > MSTO-211H > HepG2. This ranking would be valid only if fluorescence intensity correlates closely with the absolute contents of Rb protein per cell. However, this may not always be the case. For example, the number of epitopes recognized by G3-245 mAb may be reduced if tumor cells express viral oncoproteins that bind and inactivate Rb [22].

It is important to note that certain mutations greatly reduce transport of newly synthesized Rb molecules into the nucleus where Rb performs its function [23]. As the flow cytometry protocol does not allow us to discriminate be-

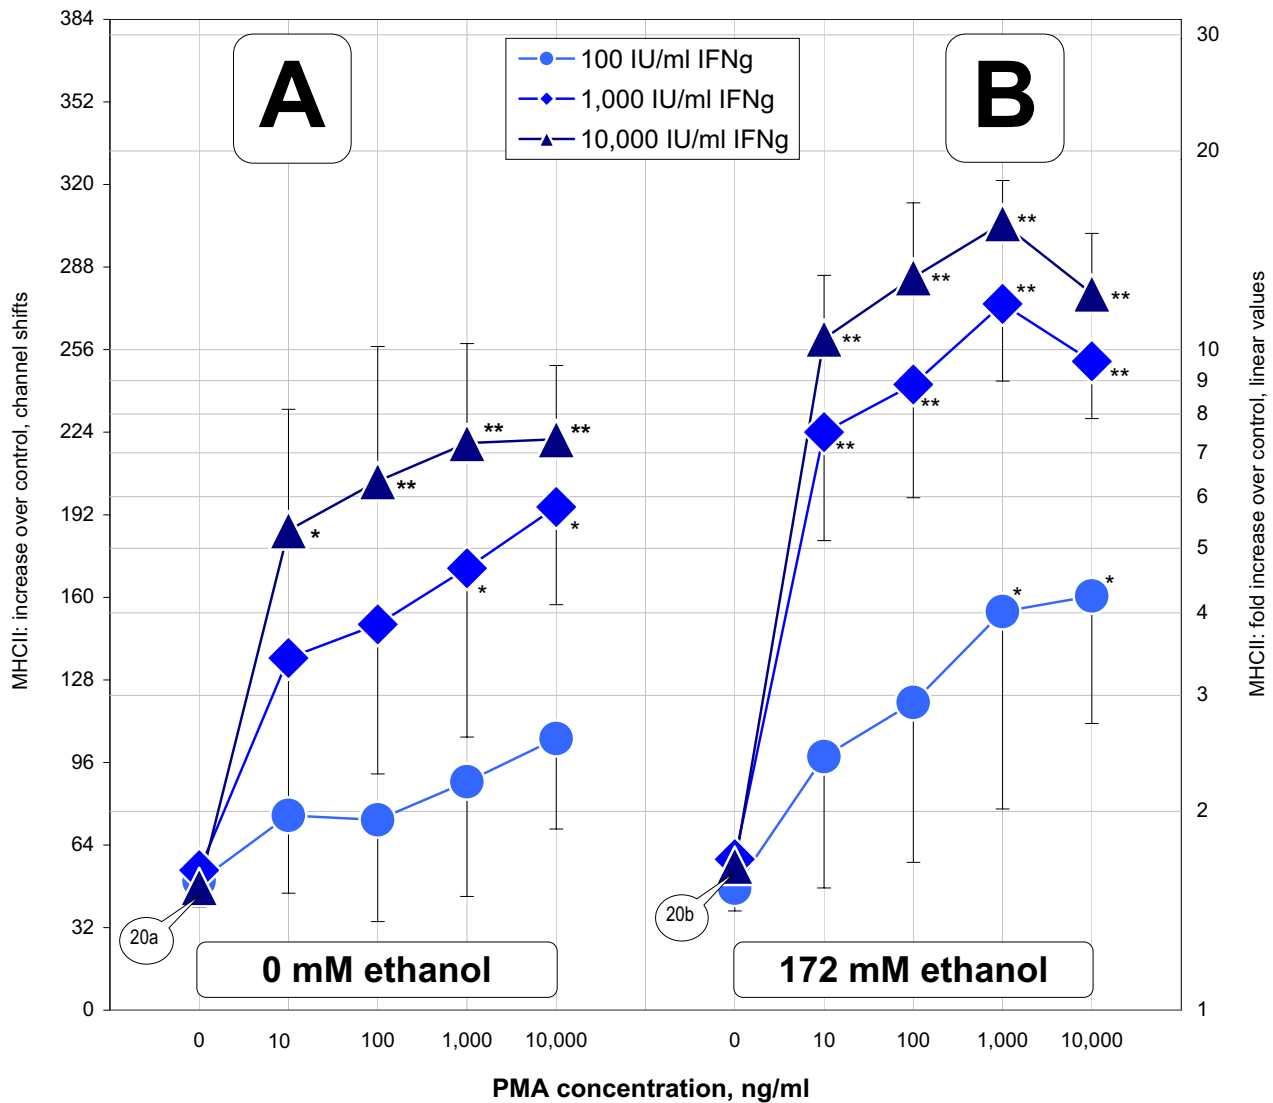

Figure 2

PMA rescues MHCII inducibility in low responding LS1034 colon carcinoma cell line. Expression levels of MHCII (mean \pm sd) induced by combined treatment with IFN γ and PMA are plotted on the left (A) and expression levels of MHCII induced by combined treatment with IFN γ , PMA and ethanol are plotted on the right (B). The experiment was repeated 4 times. Different treatments were compared to group 20a or 20b (see Table I for details on group codes). Asterisks indicate significant differences on post-hoc tests: * $P < 0.05$ by Tukey's HSD test; ** $P < 0.05$ by Scheffe's test (see the supplementary file "ANOVA.xls" for original data used to perform this analysis).

tween cytoplasmic and nuclear staining, the question about the presence of functional Rb protein in the examined cell lines remains open.

Effect of protein kinase inhibitors on physiological and PMA-potentiated response to IFN γ

The discovery of novel "non-kinase" phorbol ester receptors challenges the use of phorbol esters as selective PKC

activators [24]. Therefore, we were interested in whether a member of the PKC family mediated the effect of PMA in LS1034 cells or whether some other proteins could also be involved. Specifically, we investigated whether two inhibitors, staurosporine and GF 109203X, could abrogate PMA-potentiated response of LS1034 cells to IFN γ . Staurosporine is a wide-spectrum kinase inhibitor and its

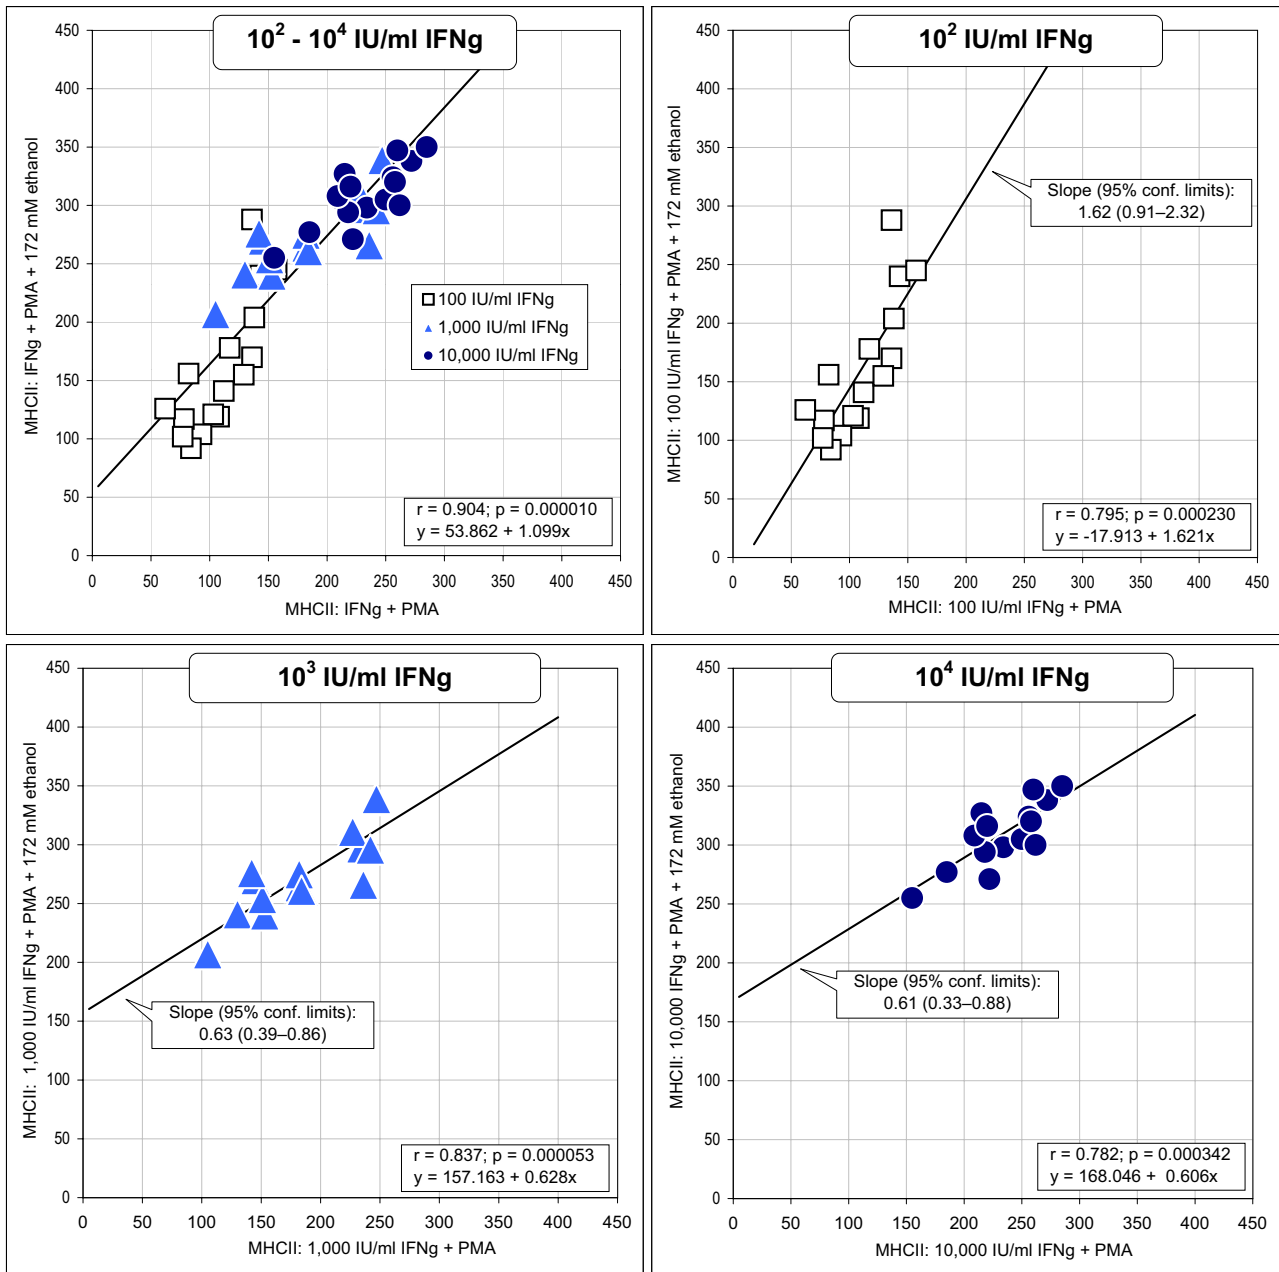

Figure 3
Ethanol potentiates PMA-rescued induction of MHCII in LS1034 colon carcinoma cells. The slope of the regression line at 10² IU/ml IFNg is significantly greater than the corresponding values at 10³–10⁴ IU/ml IFNg (1.63 vs. 0.63–0.61, $P < 0.05$).

specificity for PKC isoforms is limited to the 0.1–1 nanomolar range. In the 10–100 nM range, staurosporine inhibits more than 20 different kinases [25].

Data shown in Figure 6 demonstrate that staurosporine caused about a 50% inhibition of PMA-potentiated response in LS1034 cells at a concentration of 10 nM. Complete inhibition occurred at 100 nM. A much higher concentration of GF 109203X was required to completely

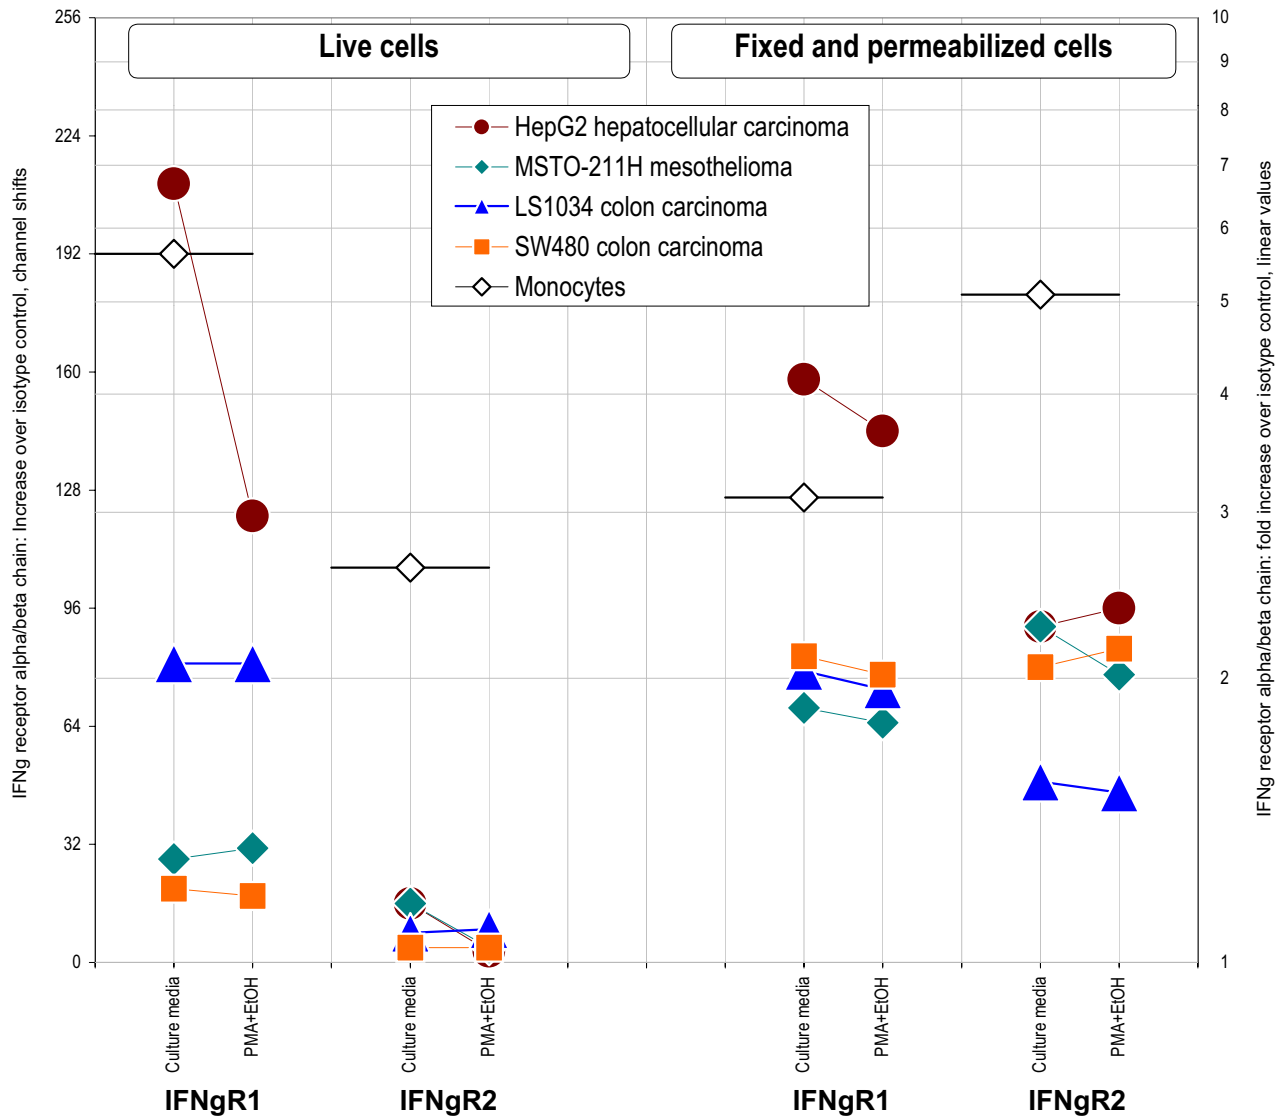

Figure 4
Expression levels of IFNγR1 and IFNγR2 subunits of the IFNγ receptor complex do not increase in four different tumor cell lines after PMA treatment. Cells were incubated in culture medium containing 10³ ng/ml PMA and 172 mM ethanol for 48 hr. Live (propidium iodide negative) cells were used to measure cell surface expression of IFNγ receptors. Fixed and permeabilized cells were used to measure total expression of IFNγ receptors (both cytoplasmic and cell surface). Mean values of two independent experiments are plotted.

suppress PMA-potentiated response in LS1034 cells. Physiological IFNγ response in SW480 colon carcinoma cells was resistant to inhibition with 1 μM GF 109203X and was suppressed only when staurosporine concentration was increased to 1 μM. We conclude that the PMA effect in LS1034 cell line is most likely mediated by a PKC isoenzyme but other protein kinases that are sensitive to inhibition with 1 μM GF 109203X.

Bryostatin 1 rescues IFNγ inducibility of MHCII in LS1034 colon carcinoma cells

To evaluate potential clinical implications of our findings, we asked whether the IFNγ-dependent MHCII expression in LS1034 cells could be restored by clinically achievable concentrations of PKC agonists. Bryostatin 1 is a potent PKC activator that has undergone extensive clinical testing for the treatment of hematological malignancies and solid

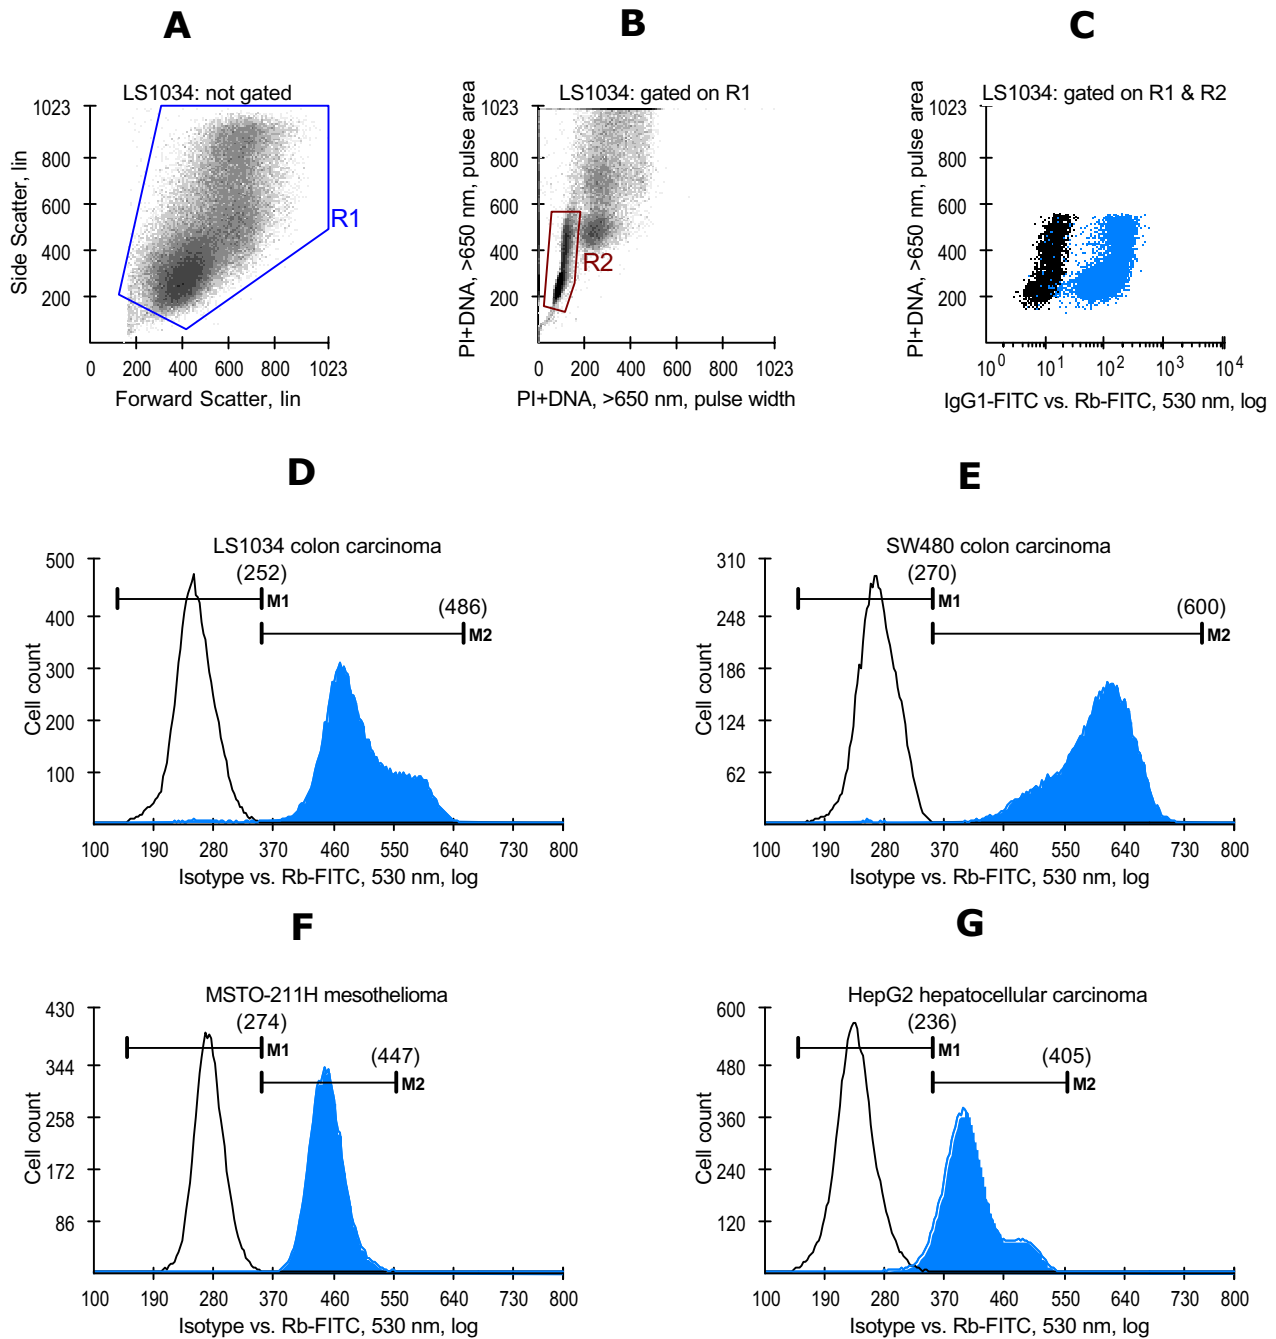

Figure 5

Expression of the Rb protein in four tumor cell lines. Rb expression is not lost in weakly inducible LS1034 colon carcinoma (**D**) and MSTO-211H mesothelioma (**F**). Rb expression is also preserved in the non-inducible HepG2 hepatocellular carcinoma (**G**). Panels **A-C** show the experimental setup for measuring Rb-specific cellular fluorescence by flow cytometry.

Figure 6
Effect of protein kinase inhibitors on physiological and PMA potentiated responses to IFN γ . Expression levels of MHCII induced by 1,000 IU/ml IFN γ alone are indicated by triangles (▲). Expression levels of MHCII induced by combined treatment with 1,000 IU/ml IFN γ , 1,000 ng/ml PMA and 172 mM ethanol are indicated by squares (■). IFN γ and PMA were added after cells had been pretreated with Staurosporine and GF 109203X for 1 hr. Incubation continued for the next 24 hr in the constant presence of inhibitors. Physiological response to IFN γ in SW480 colon carcinoma cells was abrogated by 1 μ M Staurosporine. PMA-potentiated response to IFN γ in LS1034 colon carcinoma cells was abrogated by 100 nM Staurosporine or by 1 μ M GF 109203X. Mean values of two independent experiments are plotted.

tumors [27]. Animal studies show that the concentration of Bryostatatin 1 in various tissues after a single intravenous injection stays in a range of 10–50 ng/g for a period of more than 72 hr [28].

Data, plotted in Figure 7, demonstrate that 10 ng/ml Bryostatatin added into the culture medium containing 10²–10³ IU/ml IFN γ induced a 5- to 6-fold increase in levels of MHCII expression. The potentiating effect of Bryostatatin first becomes noticeable at 1 ng/ml and then reaches a plateau at 10–100 ng/ml. At low concentration of IFN γ

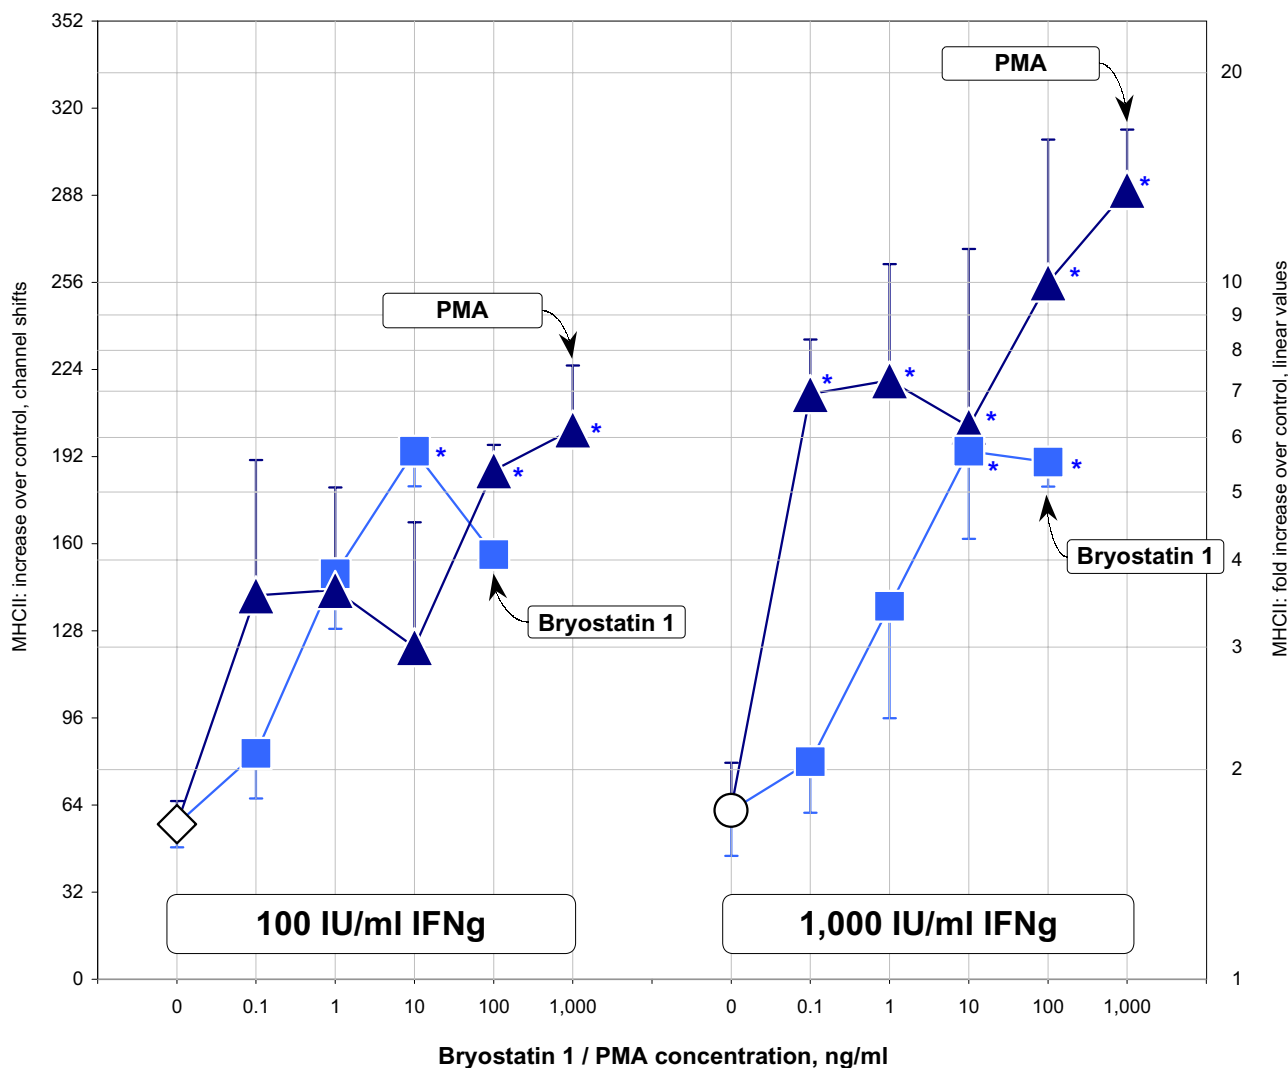

Figure 7
MHCII inducibility can be restored in LS1034 colon carcinoma cells by a clinically tested PKC activator Bryostatin 1. Cells were incubated in culture medium containing various concentrations of IFNg, PMA or Bryostatin for 48 hr. Different combinations of IFNg and PMA or IFNg and Bryostatin were compared to treatment with IFNg alone (the group indicated by the circle). Experiment was replicated 3 times. Mean values ± sd are plotted. Asterisks indicate the significant differences on post-hoc tests (* P < 0.05 by Tukey's HSD test). The potentiating effect of Bryostatin reached a plateau at a concentration of 10 ng/ml.

(10² IU/ml), the effect of Bryostatin was comparable to that of PMA. At a higher concentration of IFNg (10³ IU/ml), however, PMA was much more effective. This may suggest that either the two PKC activators act through different isoforms of PKC or PMA also activates enzymes outside the PKC family such as MAPK [18]. Whatever the mechanism, it appears possible to restore the IFNg-de-

pendent MHCII expression in LS1034 cell line by clinically acceptable concentrations of Bryostatin 1.

Discussion

The effect of PKC activators PMA and Bryostatin 1 on IFNg inducibility of MHCII in three resistant tumor cell lines of different histological origin has been examined. We found that PKC activators rescued high levels of MHCII expres-

sion in colon carcinoma cells and failed to do so in mesothelioma and hepatocellular carcinoma cells. A poor response of tumor cells to IFN γ is in agreement with previous observations that many tumors acquire such resistance upon malignant transformation, possibly important as a mechanism of tumor escape from immune surveillance [29]. The nature of this phenomenon is complex, and multiple defects that can prevent IFN γ responses in tumor lines have been described.

Most frequently, poor MHCII inducibility in response to IFN γ has been attributed to alterations in the IFN γ signalling pathway and epigenetic silencing of gene expression (reviewed in Ref [13]). The cascade of IFN γ signalling events leading to transcription activation of MHCII genes has been characterized in great detail (reviewed in Ref [30]). Binding of IFN γ to its receptor results in JAK-mediated phosphorylation of STAT1 on Tyrosine 701. In addition, IFN γ interaction with the receptor leads to p38MAPK-mediated phosphorylation of STAT1 on Serine 727 [17]. The phosphorylated STAT1 dimerizes and translocates into the nucleus where it activates transcription of several other factors including CIITA [31]. Although the results of this study do not allow us to describe the exact mechanism of PMA involvement in IFN γ signalling in LS1034 cell, at least two non-mutually exclusive scenarios can be hypothesized:

1. PMA could act through the JAK-STAT signalling pathway. It has been established that, to achieve its maximal transcriptional activity, STAT1 must be phosphorylated on both Tyr701 and Ser727 [32]. Phosphorylation of STAT1 on Ser727 occurs in response to LPS, UV irradiation and other agents that activate the p38MAPK pathway [33]. As phorbol esters can also stimulate the MAPK cascade through activation of PKC [34], it is tempting to speculate that combined treatment of cells with PMA and IFN γ could increase the pool of STAT1 molecules phosphorylated on both Tyr701 and Ser727. This effect is most likely mediated by PKC- δ isoenzyme as this particular PKC isoform appears to be critical for phosphorylation of STAT1 on Ser727 and activation of p38MAPK [16].

2. Alternatively, PMA treatment could initiate a cascade of protein phosphorylation leading to the increase in transcriptional activity of chromatin at the type IV promoter of CIITA and/or promoter of MHCII genes. Expression of many genes can be modified by treatment with agents acting at the level of enzymes and nuclear receptors that modify transcriptional activity of chromatin. Thus, histone deacetylase inhibitors – Butyrate and Trichostatin A – can rescue MHCII-inducibility in bladder carcinoma cells [14] and restore constitutive MHCII expression in plasmacytoma cells [35]. In addition to acetylation, transcriptional activity of chromatin is also regulated through

phosphorylation (reviewed in Ref. [36]). It has been shown that treatment of cells with phorbol esters leads to accumulation of phosphorylated H3 histones [37]. Therefore, it seems possible that in LS1034 cells PMA could enhance transcriptional activity of chromatin at promoters of MHCII and/or CIITA genes. This possibility appears particularly important since the specific lack of CIITA inducibility was cited as the most common basis for lack of IFN γ -induced MHCII expression among Rb-positive human tumor lines [13,21].

Another reported mechanism of IFN γ resistance in tumor cells is associated with down-regulation of IFN γ -receptors [38]. The relevance of this mechanism to MHCII inducibility was recently supported by the evidence that PMA is able to enhance IFN γ -dependent MHCII expression in THP-1 human leukemia cells through the up-regulation of IFN γ receptors [19]. In our experiments, however, the incubation of LS1034 cells with PMA and ethanol did not lead to any changes in IFN γ R expression as determined by flow cytometry (Figure 4). Therefore, it is unlikely that up-regulated IFN γ R contributed to the phenomena reported here. It should be emphasized that we determined the expression of both IFN γ R1 and IFN γ R2 receptor subunits since it has been shown that, in certain experimental systems, an IFN γ resistance was due to a lack of cellular expression of IFN γ R2 chain alone [39].

We also found that the effect of PMA in LS1034 cells can be significantly augmented by co-incubation with 172 mM ethanol. In certain types of tissues, ethanol has been shown to induce membrane translocation of PKC isoforms through activation of phospholipase A and release of diacylglycerol [40]. This mechanism, however, does not appear to be significant in our case as ethanol without PMA failed to potentiate IFN γ -induced MHCII expression in LS1034 cells. Alternatively, ethanol can modulate the activity of mitogen- and stress-activated kinase cascades. It has been shown that hepatocytes exposed to 100 mM ethanol for 16 hr have a higher activity of p38MAPK induced by EGF treatment [41]. If in our experiments PMA did act through Ser727 phosphorylation of STAT1, the potentiating effect of ethanol can possibly be explained by its ability to stimulate the MAPK kinase cascade.

It remains to be determined whether the restoration of IFN γ -induced MHCII expression by PMA is unique to LS1034 cells. A potentiating effect of PMA has been reported in thyroid carcinoma cells [20] but, in contrast to LS1034 cells, normal IFN γ response in those cells was only partially lost as a result of malignant transformation. Whether or not this phenomenon may be reproduced with other IFN γ -resistant colon carcinoma cell lines is of particular interest, since colonic epithelium is physiologi-

cally exposed to PKC activators that enhance cytokine signalling in enterocytes during inflammatory responses within the intestinal mucosa [42].

It is well established that, besides the MHCII molecules, IFN γ can induce susceptible tumors to upregulate the expression of MHC class I antigens [43], tumor associated antigens [44], costimulatory molecules [45], and heat shock proteins [46]. In addition, IFN γ may have antimetabolic and antiproliferative influence on certain types of tumor cells [47]. It has also been suggested that IFN γ may cause responding tumor cells to secrete angiogenesis inhibitors [48]. As it is not known which of those IFN γ effects are missing or restored by PMA in LS1034 cells, a thorough evaluation of the possible clinical implications of our *in vitro* findings is quite difficult. However, if clinically tested PKC agonists such as Bryostatins 1 are able to rescue the IFN γ -induced MHCII expression within the tumor bed, it might be appropriate to consider them for trials to improve the clinical efficacy of cancer immunotherapy.

Conclusions

In this study we showed that IFN γ -inducibility of MHCII antigens in weakly inducible LS1034 colorectal carcinoma cell line can be rescued by concomitant incubation with PKC agonists. Bryostatins 1 may be considered for further investigation of IFN γ -dependent MHCII induction in resistant tumors *in vivo*.

Materials and Methods

Cell lines

Human tumor cell lines – LS1034 colorectal carcinoma (ATCC Number: CRL-2158), SW480 colorectal adenocarcinoma (ATCC Number: CCL-228), MSTO-211H biphasic mesothelioma (ATCC Number: CRL-2081) and HepG2 hepatocellular carcinoma (ATCC Number: HB-8065) – were purchased from American Type Culture Collection. Cultures were routinely tested for Mycoplasma contamination by Specialty Laboratories (Santa Monica, CA) and were consistently negative.

Chemicals

Recombinant human Interferon γ_{1b} , specific activity $3 \cdot 10^7$ IU/mg, was purchased from InterMune Pharmaceuticals. Staurosporine and GF 109203X were from Calbiochem. Other chemicals used were phorbol 12-myristate 13-acetate, dimethyl sulfoxide, ethanol, propidium iodide and saponin (all from Sigma). Fetal calf serum and RPMI-1640 culture medium supplemented with 25 mM HEPES were from Irvine Scientific. Tobramycin, L-glutamine and 0.25% porcine trypsin – 0.53 mM EDTA were from Abbott Laboratories, BioWittaker and Gibco correspondingly.

Antibodies

Monoclonal antibodies used in the study were: 1) mAb against human HLA-DR, DP, DQ, FITC conjugate (anti-MHCII-FITC), clone Tü39, mouse IgG2a; 2) mAb against human IFN γ receptor R1 chain, biotin conjugate, clone MMHGR-1, mouse IgG1; 3) mAb against human IFN γ receptor R2 chain, biotin conjugate, clone MMHGR-2, mouse IgG1; 4) mouse IgG2a isotype control mAb, FITC conjugate (IgG2a-FITC); 5) mouse IgG1 isotype control mAb, biotin conjugate; 6) mAb against Rb protein, FITC conjugate (Rb-FITC), clone G3-245, mouse IgG1; 7) mouse IgG1 isotype control mAb, FITC conjugate (IgG1-FITC). Streptavidin, phycoerythrin conjugate (SA-PE) and Streptavidin, Alexa Fluor[®]488 conjugate (SA-Alexa488) were from eBioscience and Molecular Probes.

Cell culture

Cells were propagated in T75 flasks in RPMI-1640 medium supplemented with 25 mM HEPES, 10% fetal calf serum, 200 mM L-glutamine and 40 μ g/ml Tobramycin. When cells were in exponential growth phase, they were removed from plastic by trypsinization and seeded into the wells of 6-well trays (9 cm²/well) at a concentration of $3 \cdot 10^5$ to $5 \cdot 10^5$ cells / 4 ml / well. When cell cultures reached 40–60% confluency (usually, on the next day), growth medium was replaced with 2 ml of fresh medium containing variable concentrations of IFN γ . Ten minutes later, another 2 ml of medium containing variable concentrations of PMA were added into the wells and the incubation continued for the next 48 hr. Experiments involving protein kinase inhibitors were performed in a similar way, except that Staurosporine and GF 109203X were added first, and IFN γ (or PMA plus IFN γ) were added 1 hr later. Staurosporine and GF 109203X were not washed away, so the cells were incubated with IFN γ +PMA in the constant presence of inhibitors. In a first group of experiments, stock solution of PMA was prepared at 1 mg/ml in ethanol, and the final concentration of ethanol in culture medium was adjusted to 10 μ l/ml (172 mM). In all subsequent experiments, stock solution of PMA was prepared at 10 mg/ml in DMSO and the final concentration of DMSO in culture medium was adjusted to 1 μ l/ml.

Immunofluorescent staining of cell surface antigens

Cellular monolayers were rinsed 3 times with Ca/Mg-free PBS and incubated for 20 min at 37°C in Hanks' balanced salt solution containing 0.25% trypsin, 1 mM EDTA and 25 mM HEPES. Detached cells were washed twice with staining buffer (PBS containing 10% FCS, 0.1% sodium azide and 25 mM HEPES, pH 7.4) and stained as described previously [49]. Briefly, cells were transferred into the wells of round-bottom 96-well plates, the plates were centrifuged at 200 g for 30 seconds, the supernatant removed by shaking, and the cell pellets resuspended in 50 μ l of staining buffer containing saturating concentra-

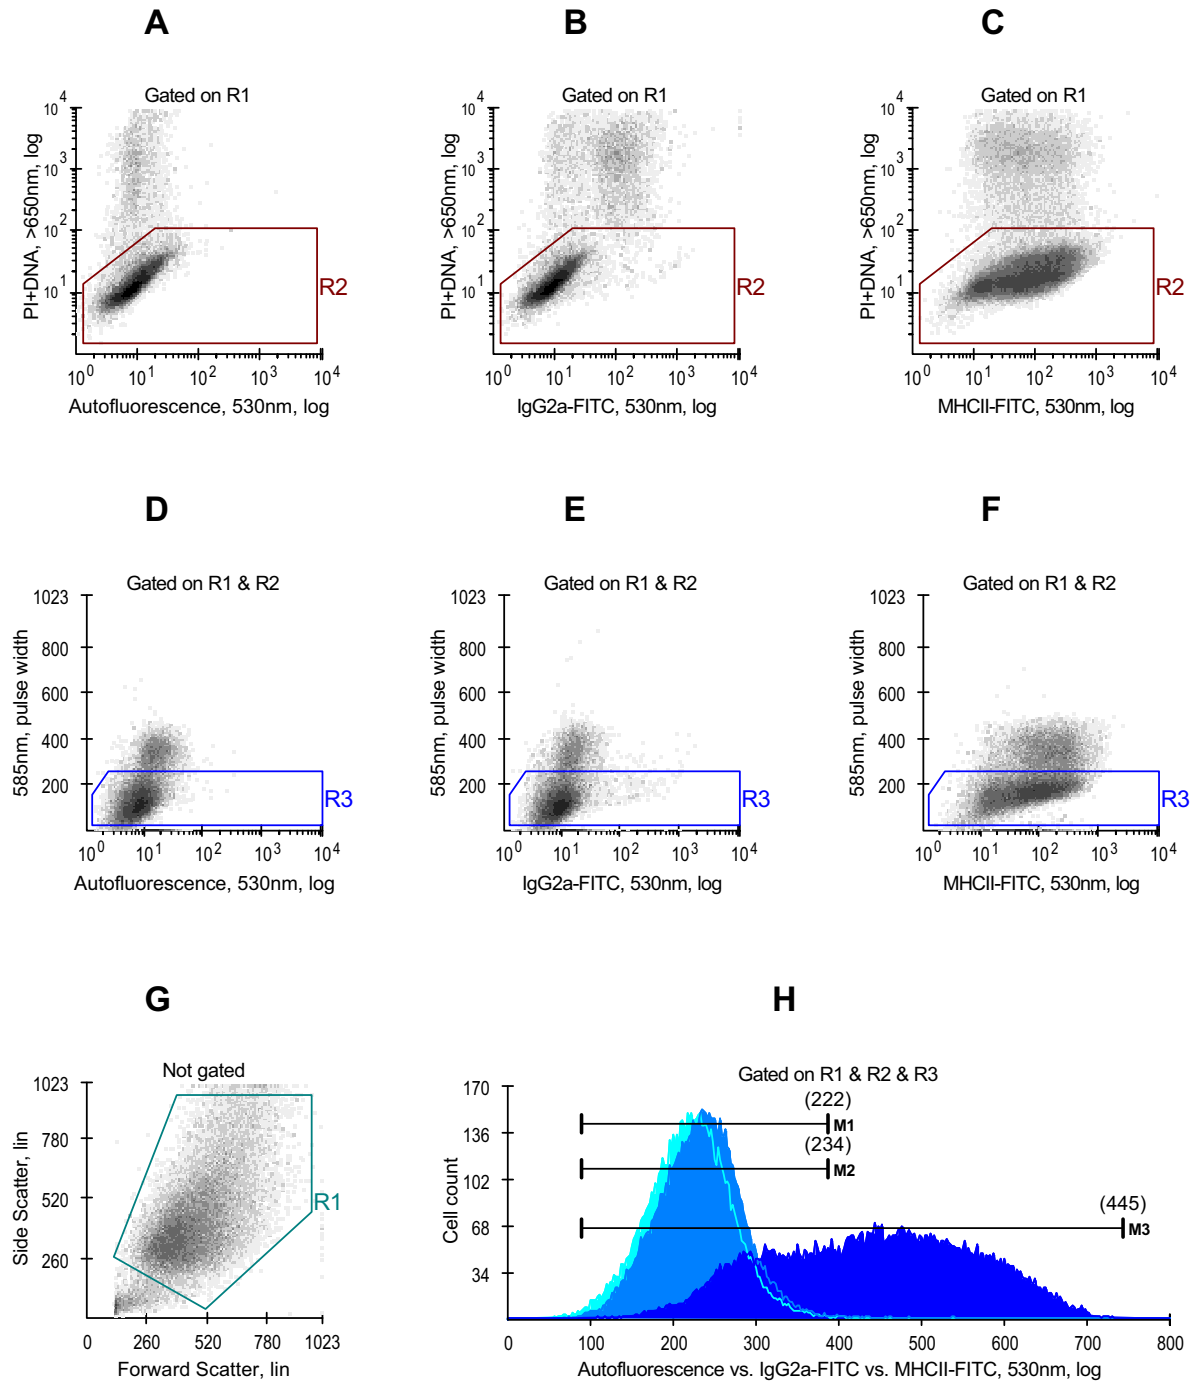

Figure 8
Experimental conditions for measuring MHCII-specific cellular fluorescence by flow cytometry. Tumor cells were removed from plastic with 0.25% trypsin and 0.53 mM EDTA, washed, stained with FITC-conjugated monoclonal antibodies (mAb) and analysed on a FACSCalibur™ flow cytometer. Regions R1, R2 and R3 were drawn to exclude debris (**G**), dead cells (**A**, **B**, **C**) and cellular aggregates (**D**, **E**, **F**). Panels **A** and **D** show cells stained with propidium iodide alone. Panels **B** and **E** show cells stained with propidium iodide and the isotype-matched control mAb (IgG2a-FITC, 1.0 µg/50 µl). Panel **C** and **F** show cells stained with propidium iodide and the mAb against human HLA-DR,DP,DQ (anti-MHCII-FITC, clone Tü39, 0.25 µg/50 µl). Panel **H** shows frequency distributions of cells that passed R1 & R2 & R3 logical gate. M1, M2 and M3 are the median values of autofluorescence peak (M1 = 222), isotype control peak (M2 = 234) and HLA-DR peak (M3 = 445).

tion of anti-MHCII-FITC. After 30-min incubation at 4°C, cells were washed twice, resuspended in staining buffer and kept on ice before analysis on a flow cytometer (FAC-SCalibur™, Becton Dickinson Immunocytometry Systems). Immediately before analysis, 1 µg/ml propidium iodide was added to exclude dead cells. Matching isotype control mAb (IgG2a-FITC) was used at the same (0.25 µg/well) or a higher (1.0 µg/well) concentration as the specific antibody. The lack of staining of controls demonstrated that non-specific binding of IgG2a-FITC to PI-negative cells was negligible in all experimental groups (Fig 8B,8E,8H). Staining for cell surface IFNγ receptors was performed similarly, except that cells were first incubated with biotin-conjugated mAb's (specific or isotype-matched) for 30 min, washed 2 times and then stained with SA-Alf488. Staining of fresh and trypsin-treated monocytes demonstrated that epitopes recognized by the mAb's against MHCII, IFNγR1 and IFNγR2 were resistant to 30 min digestion with 0.25% trypsin.

Immunofluorescent staining of cytoplasmic antigens

Cytoplasmic IFNγR1 and IFNγR2 receptor subunits were detected by using a procedure described for intracellular cytokine staining [50]. Briefly, cells were fixed in ice-cold 4% formaldehyde for 5 min, washed 2 times, permeabilized in staining buffer containing 0.2% saponin for 60 min at 4°C, incubated with biotin-conjugated mAb's (specific or isotype-matched) for 30 min, washed 2 times, incubated with SA-PE and washed again (saponin was present in staining buffer at all times). After the final wash, cells were resuspended in buffer without saponin and kept on ice until analysis. Monocytes expressing high levels of IFNγR1 and IFNγR2 receptor subunits served as a positive control. Expression levels of Rb protein was measured using a procedure described elsewhere [51].

Flow cytometry

Fluorescent emission of FITC and Alexa Fluor®488 was collected on the FL1 detector (530 ± 30 nm, log mode) and fluorescence of PI-stained DNA was collected on the FL3 detector (>650 nm, log mode). Incubation of tumor cells with PMA or staurosporine dramatically increased cell-to-cell adherence and number of cell clumps. To deal with this problem, the FL2 detector (585 ± 42 nm, linear mode) was used to measure area and width of electronic pulses. PMT voltage of the FL2 detector was set high enough to minimize the number of FL2-width events appearing in channel 1. Regions R1, R2 and R3 were drawn to exclude debris (Fig 8G), dead cells (Fig 8A,8B,8C) and cellular aggregates (Fig 8D,8E,8F). Acquisition was stopped when at least 10,000 events had passed R1 & R2 & R3 logical gate (Figure 8H). List mode data files were transferred to a Windows-based computer for off-line analysis. Data were gated and the median values of fluorescence peaks were computed by using FCSEXPRESS soft-

ware written by David Novo <http://www.denovosoftware.com>.

Data Analysis

Total fluorescence of cells stained with MHCII-FITC antibody can be divided into 3 sources: (1) fluorescence caused by specific binding of MHCII-FITC, (2) fluorescence of MHCII-FITC bound to cells non-specifically and (3) autofluorescence of intracellular molecules such as NAD(P)H. An experiment performed to assess contribution of each of the three sources demonstrated that: (1) non-specific binding of IgG2a-FITC was negligible in all experimental groups (Fig 8H); (2) tumor cells incubated with PMA alone did not bind anti-MHCII mAb above the level of isotype control and (3) tumor cells incubated with PMA (or with PMA+IFNγ) demonstrated 1.2–1.4 fold increase in autofluorescence. In order to correct for non-specific increase in autofluorescence, "brightness" of cells treated with PMA alone (Table 1, column 1) was subtracted from "brightness" of cells treated with PMA+IFNγ (Table 1, columns 2–4), e.g., group 05a value was subtracted from values of group 11a, 17a and 23a, etc. All statistics were calculated using these corrected values that represent distances (channel shifts) between median of fluorescence peaks. The additional file 1 contains both raw and corrected fluorescence values used to perform the analysis.

Note added in proof

While the manuscript was under review, results of a clinical trial had been published showing that a systemic combination treatment with IFNγ and GM-CSF for as long as 9-weeks failed to induce MHCII on tumor cells in 9 out of 15 hepatocellular carcinoma patients. However, those 6 patients with inducible MHCII on hepatoma cells had better median survival as compared to MHCII negative cases ($p < 0.0001$) [52].

List of abbreviations used

class II transactivator CIITA
dimethyl sulfoxide DMSO
fetal calf serum FCS
fluorescein isothiocyanate FITC
interferon-gamma IFNγ
interferon-gamma receptor IFNγR
interferon-gamma receptor alpha-chain IFNγR1
interferon-gamma receptor beta-chain IFNγR2

granulocyte-macrophage colony-stimulating factor GM-CSF

Janus kinase JAK

major histocompatibility complex class II antigens MHCII

mitogen-activated protein kinase MAPK

monoclonal antibody mAb

phorbol 12-myristate 13-acetate PMA

propidium iodide PI

protein kinase c PKC

signal transducer and activator of transcription 1 STAT1

the retinoblastoma tumor suppressor protein Rb

Additional material

Additional File 1

Induction of MHCII molecules is measured as the distance between the median of the experiment histogram and the median of the negative control histogram. This file contains data and charts for the majority of the subjects used in the current experiment
