Purpose: To investigate the biological effect of gyromagnetic fields (GMFs) on cell proliferation and apoptosis of human prostatic adenocarcinoma cells and explore the underlying mechanisms.

Methods: PC-3 cells were grouped into normal control (NC) and GMF treatment groups. Cell proliferation was analyzed with kit-8 and Ki67 immunofluorescence staining, while cell apoptosis was analyzed with flow cytometry double staining of Annexin V-PE/7-AAD. The Akt and p38 MAPK/Caspase signaling pathways were analyzed by western blotting and immunofluorescence staining, and cell polarization was analyzed with PARD3.

Results: Cell proliferation and activity of the Akt pathway were significantly decreased by the GMF, while cell apoptosis, activity of p38 MAPK, and PARD3-positive cell number were significantly increased in the GMF group compared to the NC group.

Conclusion: GMFs inhibit cell proliferation, induce apoptosis, and regulate tumor cell polarity conditions, potentially through down-regulating Akt, activating the p38 MAPK/Caspase pathway, and promoting PARD3 expression in PC-3 cells.

Keywords: apoptosis, gyromagnetic fields, PC-3 cells, prostate cancer

Introduction

Prostate cancer is the most common cancer in elderly men >70 years of age, especially in developed countries. Its incidence is 85.6 (per 100,000 men per year, age-standardized rate) in the USA, compared with 7.2 in Asia, while there has been a trend of increasing incidence in developing countries in recent years.¹ Older age, a positive family history, and black race are the three most common risk factors for prostate cancer.² Men at elevated risk for prostate cancer should undergo early prostate-specific antigen (PSA) testing,³ though there is no strong evidence that prostate-specific antigen screening could reduce mortality due to prostate cancer.⁴ Current treatment options are available for patients with different clinical grades and stages, including active surveillance and watchful waiting, radical prostatectomy, definitive radiotherapy, high-intensity focused ultrasound, cryosurgery, and hormonal therapy.⁵⁻⁷ However, there are complications related to treatment of prostate cancer, and this disease is doomed to progress to the final stages of metastatic androgen-independent prostate cancer with its attendant substantial threat of mortality.⁸

Recently, convergence of the life sciences, physical sciences, and engineering has brought the biomedicine world into a new era.⁹ Therapeutic magnetic fields, good paradigms of convergence medicine, have been demonstrated to have beneficial results on benign prostatic hyperplasia,^{10,11} human breast carcinoma,¹² peripheral nerve regeneration,¹³ hand osteoarthritis,^{14,15} osteonecrosis,¹⁶ and nucleic acid delivery.¹⁷ Magnetic fields have been proven to be safe, non-invasive methods for the modification of numerous cells and tissues, especially in the musculoskeletal system.¹⁸ It is interesting

to note that magnetic therapy can cause a significant reduction in prostatic volume with no side effects in a canine model¹⁰ and a significant improvement in clinical symptoms in benign prostatic hyperplasia patients.¹¹ Besides, magnetic fields induce a decrease in cell growth in human breast carcinoma cells; however, the mechanism of magnetic fields on cell growth is still not clear.¹² Gyromagnetic fields (GMFs) are a novel type of magnetic field with its field strength varying with time and obeying the distribution regularity of a sine curve. Here, to test if GMFs could be a novel method in the treatment of prostate cancer, we investigated its effect on cell growth and apoptosis in human prostatic adenocarcinoma PC-3 cells.

Materials and methods

Cell culture

Human prostatic adenocarcinoma cell line PC-3 was obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA). Cells were cultured at 37°C in a 5% CO₂ atmosphere in a humidified incubator. F-12K culture medium (Thermo Fisher Scientific, Waltham, MA, USA) was used, supplemented with 10% fetal bovine serum and 2 mM of L-glutamin. All experimental protocols in this study were approved by the Ethical Committee of Peking University First Hospital.

Gyromagnetic fields treatments

PC-3 experimental groups were exposed to GMFs by a CKJ-II (QLX-II) Gyromagnetic Therapy Machine (Beijing Gyromagnetic Medical Equipment Co., Ltd., Beijing, People's Republic of China). The work parameters were the GMF strength varied with time in the target area and obeyed the distribution regularity of a sine curve; the rotating frequency of the GMF was 6 Hz; the maximum field strength was 300 mT; and the magnetic flux density was 8.3 mT/Hz² (Figure 1). The top and bottom surfaces of the two magnetic poles were at a distance of 32 cm. Cell samples were placed in the gyromagnetic therapeutic machine according to the manufacturer's instructions.

Cell counting test

The cell proliferation assay was performed using a cell counting kit-8 (CCK-8, Dojindo Laboratories, Kumamoto, Japan) according to the manufacturer's instructions. Five-hundred cells were seeded into 96 wells and cultured in the F-12K complete medium. At 24 hours after GMF treatment according to the above mentioned method, 10 µL of CCK-8 solution was added into the 96 wells to make the working solution and incubated for 1 hour at 37°C. Absorbance at 450 nm was measured to calculate cell numbers according to optical density values.

Figure 1 Gyromagnetic field strength distribution varying with time using a CKJ-II (QLX-II) Gyromagnetic Therapy Machine.

Notes: Gyromagnetic field strength varied with time in the target area and obeyed the distribution regularity of a sine curve. The rotating frequency of the gyromagnetic field was 6 Hz, the maximum field strength was 300 mT, and the magnetic flux density was 8.3 mT/Hz².

Immunofluorescence

Twenty-four hours after treatment with a GMF according to the above mentioned method, cells were fixed with cold 4% formaldehyde for 10 minutes at room temperature and subsequently incubated with phosphate-buffered saline (PBS) containing 0.3% triton X-100 and 2% bovine serum albumin for 30 minutes at room temperature. This was followed by incubation with primary antibodies against Ki67 (Abcam, Cambridge, MA, USA), Cleaved Caspase-3 (Cell Signaling Technology, Danvers, MA, USA), and PARD3 (Abcam) overnight at 4°C. After rinsing with PBS, cells were incubated with Alexa594-conjugated goat anti-rabbit IgG antibody. After a further rinse with PBS, the cells were incubated with 1 µg/mL of 4',6-diamidino-2-phenylindole (Sigma-Aldrich, St Louis, MO, USA) for nuclear staining.

Flow cytometry

The cell flow cytometry assay was performed using an Annexin V-PE/7-AAD Apoptosis Detection Kit (KeyGEN BioTECH, Nanjing, People's Republic of China) according to the manufacturer's instructions. Cells were seeded into six wells and cultured in the F-12K complete medium. Twenty-four hours after treatment with a GMF as mentioned above, cells were collected and resuspended in 500 µL of binding buffer, after which 5 µL of 7-AAD solution and 1 µL of Annexin V-PE solution were added; cells were then incubated for 15 minutes in the dark. Finally, cells were analyzed by flow cytometry (BD influx, BD Biosciences, Franklin Lakes, NJ, USA) within 1 hour.

Western blot analysis

Whole-cell protein samples were prepared by homogenization in RIPA Lysis Buffer (KeyGEN BioTECH) supplemented with a protease and phosphatase inhibitor cocktail. Cell lysates containing 20 µg of protein were electrophoresed in sodium dodecyl sulfate polyacrylamide gel electrophoresis and then transferred to a polyvinylidene fluoride membrane (EMD Millipore, Billerica, MA, USA). The membrane was blocked with 5% skimmed milk for 1 hour at room temperature and incubated overnight at 4°C with primary antibodies against phospho-Akt (Cell Signaling Technology), Akt (Cell Signaling Technology), phospho-p38 mitogen-activated protein kinases (MAPK) (Cell Signaling Technology), p38 MAPK (Cell Signaling Technology), Cleaved Caspase-9 (Cell Signaling Technology), and GAPDH (CW BIO, Beijing, People's Republic of China). After the hybridization of secondary antibodies for 1 hour at room temperature, detection was achieved by acquiring the image directly in a chemiluminescence-compatible digital imaging system (C-DiGit Blot Scanner, LI-COR Biosciences, Cambridge, UK).

Image analysis and quantification

Images of cells were captured using a digital camera (Leica DM2500, Leica Microsystems, Wetzlar, Germany). They were then imported into Image-Pro plus software (version 6.0, Media Cybernetics Inc, Bethesda, MD, USA) for calculating the mean density and dot numbers of each sample. The cell apoptosis rates of the flow cytometry assay were analyzed with FlowJO software (version 7.6.2, Tree Star Inc., Ashland, OR, USA). The integrated density value of each protein band of the western blot images was analyzed with ImageJ software (version 1.46r, ImageJ, NIH, Bethesda, MD, USA).

Statistical analysis

The data are presented as means ± SD. One-way analysis of variance followed by the Student–Newman–Keuls test was used to evaluate whether differences among groups were significant. All calculations were performed using SPSS statistical software (version 13.0, SPSS, Chicago, IL, USA). $P < 0.05$ was considered significant.

Results

Gyromagnetic fields inhibited cell proliferation in PC-3 cells

To investigate the effects of GMFs on cell proliferation in PC-3 cells, a cell-counting assay was performed 24 hours after GMF treatment. Cell proliferation was significantly inhibited when compared with the normal control (NC)

group ($P < 0.05$), especially in the GMF 10-minute group (Figure 2A). We then checked cell numbers in the GMF 10 minutes versus the NC group for 4 days; cell growth was significantly inhibited in the GMF 10-minute group ($P < 0.05$; Figure 2B).

Ki67 was strongly associated with cell proliferation and growth; immunofluorescence staining in PC-3 cells showed that the Ki67-positive cell number was significantly decreased in the GMF 10-minute group ($P < 0.05$) 24 hours after treatment with a GMF (Figure 2C and D). These data suggested that GMFs could inhibit cell proliferation in PC-3 cells.

Gyromagnetic fields suppressed Akt signaling in PC-3 cells

To demonstrate the molecular basis of the effects of GMFs on cell proliferation, expression levels of Akt protein, a protein kinase which can promote cell survival, were detected. Twenty-four hours after treatment with a GMF, the phospho-Akt/Akt ratio was significantly decreased in PC-3 cells in the GMF 10 minutes and GMF 20 minutes groups when compared with the NC group ($P < 0.05$; Figure 3), indicating that Akt signaling was inhibited under exposure of the GMF.

Gyromagnetic fields induced cell apoptosis in PC-3 cells

To investigate if GMFs have an impact on cell apoptosis in PC-3 cells, we elucidated the rate of cell apoptosis by performing flow cytometry assays. Twenty-four hours after the influence of a GMF, late apoptotic cell rate was significantly increased in the GMF groups ($P < 0.05$), while no significant differences were observed on the early apoptotic cell rate among groups ($P > 0.05$; Figure 4). The data suggested that GMFs may have an effect of inducing cell apoptosis in PC-3 cells.

Gyromagnetic fields activated p38 MAPK/Caspase signaling in PC-3 cells

To understand the mechanism of the effects of GMFs on cell apoptosis, expression levels of proteins in apoptosis associated p38 MAPK/Caspase signaling were detected. Twenty-four hours after GMF treatment, western blot analysis showed that phospho-p38 MAPK/p38 MAPK ratio and Cleaved Caspase-9 expression levels were significantly increased in PC-3 cells ($P < 0.05$; Figure 5A–C), and also immunofluorescence staining showed that Cleaved Caspase-3-positive cell numbers were significantly increased in the GMF 10-minute group ($P < 0.05$; Figure 5D and E). These results indicated that p38 MAPK/Caspase signaling was activated under exposure to GMFs.

(B) Quantitative data of band intensity for phospho-Akt and Akt by ImageJ (n=3). * $P < 0.05$ when compared with the NC group.

Gyromagnetic fields regulated cell polarity conditions in PC-3 cells

To demonstrate the effects of GMFs on cell polarity regulation, immunofluorescence staining of PARD3, a crucial regulator of cell polarization and tumorigenesis, was detected 24 hours after treatment with a GMF. PARD3-positive cell number was significantly increased in the GMF 10 minutes group when compared with the NC group ($P < 0.05$; Figure 6). The data suggested that abnormal cell polarity conditions of tumor cells were regulated by GMFs in PC-3 cells.

Discussion

Surgery is now the most effective treatment for prostate cancer but several complications such as incontinence, hematuria, gastrointestinal toxicity, proctopathy, and erectile dysfunction have been reported.¹⁹ After the operation, patients experience extra suffering and so invasive surgery for prostate cancer treatment may not be ideal. For this reason, non-invasive methods without obvious side effects for treating prostate cancer are urgently needed. Magnetic field therapy belongs to the field of physical therapy and has been reported to play an important role in nerve regeneration, pain relief, and anti-inflammation.^{13,20,21} Furthermore, no such side effects have been revealed in the literature, making it a potential adjuvant therapy for surgical operations. Moreover, the PC-3 cell line was initiated from bone metastasis of a grade IV prostatic adenocarcinoma from a 62-year-old male Caucasian, which makes it a good model for metastatic androgen-independent prostate cancer research.

Magnetic field therapeutic modalities can be categorized into static magnetic fields and time-varying magnetic fields.²² Magnetic fields that are applied differ as their physical

parameters change. The transformation progress of magnetic stimulation into bioeffects and the mechanism of biological response to such a form of physical therapy is still not completely understood. It is believed that there are several physical and biological effects caused by the following static magnetic fields: eddy currents by displacement, Lorentz force, magnetic force, magnetic torque, and radical pair effect.²² There are two types of mechanical effects that a static magnetic field can exert on biological bodies: magneto-orientation and magneto-mechanical translation.²³ When it comes to time-varying magnetic fields, eddy currents, and thermal effects are observed.²² The frequency of time-varying magnetic fields ranges from 1 Hz to 100 kHz; thermal effects are too small to be considered.²⁴ In the present study, the GMF outputted by a CKJ-II (QLX-II) gyromagnetic therapeutic machine belonged to the time-varying magnetic fields. It is believed that the interaction between GMFs and human prostatic cancer cells induces eddy currents within the cells, which may further affect cell proliferation and apoptosis. Moreover, the International Commission on Non-Ionizing Radiation Protection guidelines recommend that the magnetic flux density of reference levels for public exposure to time-varying magnetic fields is 40 mT/Hz² for 1–8 Hz magnetic fields.²⁴ The magnetic flux density of the GMF used in the present study (8.3 mT/Hz²) was below the limits in the International Commission on Non-Ionizing Radiation Protection guidelines, and this indicates that it is a safe method for public health.

Akt, also known as protein kinase B that was discovered as an oncogene, is a serine/threonine protein kinase that functions as a critical regulator of cell proliferation and survival; phosphorylated Akt exerts cellular functions in cell proliferation, survival, and differentiation.²⁵ The significantly decreased

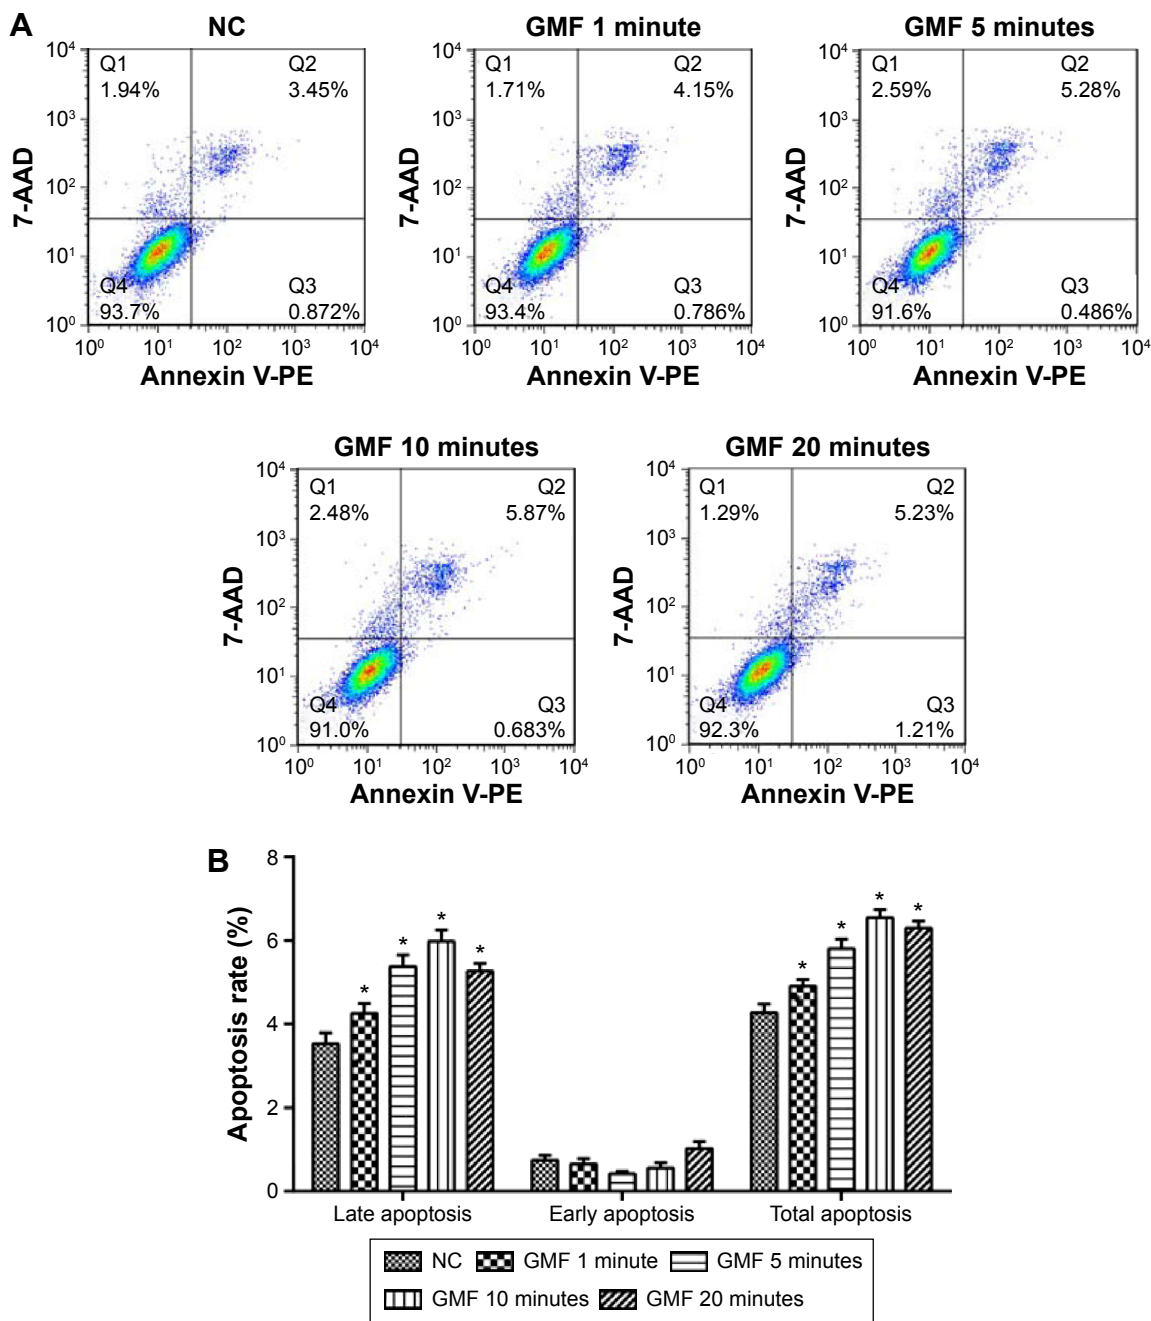

Figure 4 Effect of gyromagnetic fields on cell apoptosis in PC-3 cells. **Notes:** (A) Flow cytometry analysis using an Annexin V-PE/7-AAD Apoptosis Detection Kit on PC-3 cells 24 hours after treatment with a gyromagnetic field from the normal control (NC group) and the gyromagnetic field (GMF) groups with treatment times of 1, 5, 10, and 20 minutes. (B) Quantitative data of cell apoptosis rate by FlowJO (n=3). Cells in late apoptosis were both Annexin V-PE positive and 7-AAD positive (Q2), and cells in early apoptosis were Annexin V-PE positive and 7-AAD negative (Q3). *P<0.05 when compared with the NC group.

phospho-Akt/Akt ratio under GMFs stimulation in the study may play an important role in inhibited cell proliferation and survival in PC-3 cells. On the other hand, p38 MAPKs are subfamilies of MAPKs, and MAPKs alter cell growth, proliferative potential, metabolism rate, and apoptosis when cells respond to stress or changes in physical and chemical properties of the environment.²⁶ Caspases (cysteine-dependent

aspartate-specific proteases) play important roles in regulating programmed cell death (or apoptosis) by performing selective, limited cleavage of key cellular signaling components.²⁷ The activated p38 MAPK may regulate downstream protein Caspases to mediate its anti-proliferative functions.²⁸ In the present study, the GMF was obviously a stress source for PC-3 cells, which may induce the activation of p38 MAPK.

Figure 5 Effect of gyromagnetic fields on p38 MAPK/Caspase in PC-3 cells.

Nuclei were labeled with 4',6'-diamidino-2-phenylindole (DAPI) (blue). Scale bars =50 μ m, 200 \times . (B) Quantitative data of PARD3-positive cell number per high power field (HPF) by Image-Pro plus (n=3). * P <0.05 when compared with the NC group.

Subsequently, the activated p38 MAPK regulated protein Caspase-3 and protein Caspase-9 to exert apoptotic functions. The results indicate that GMFs may inhibit cell proliferation and induce apoptosis at least potentially through activation of the p38 MAPK/Caspase signaling pathway.

Polarization is crucial for normal cell physiology and tissue homeostasis. PARD3, a key element in the Par complex (a crucial regulator of apical-basal polarity, which includes PARD3, PARD6, aPKC, and small GTPases, such as CDC42 or RAC1), could promote junction assembly through regulation of actin dynamics, thus playing a crucial role in the formation and maintenance of cell apical-basal polarity.²⁹ In addition, tight junctions could form an apical-basal barrier that prevents paracellular leakage of fluids and intermixing of membrane proteins between the apical and basolateral surfaces. The transformations of loss of cell polarity and disruption of cell junctions are frequently observed in the process of tumorigenesis.³⁰ Zen et al³¹ demonstrated that the PARD3 gene is deleted in 15% of primary

esophageal squamous cell carcinoma and that mRNA levels are downregulated in 23 of 33 esophageal squamous cell carcinoma tumor tissues compared to matched controls. In the present study, the GMF could up-regulate the expression of PARD3, indicating that the corrupted cell polarity and cell junctions in cancer cells may be repaired to some extent under the stimulation of a GMF.

However, before wide application in clinics, optimization of frequency, magnetic field strength, and the exposure cycle for GMFs therapy need to be further investigated.

Conclusion

GMFs could potentially inhibit cell proliferation, induce apoptosis, and regulate tumor cell polarity conditions through the downregulation of Akt signaling, upregulation of p38 MAPK/Caspase signaling, and promotion of PARD3 protein expression in human prostatic adenocarcinoma PC-3 cells. Our findings suggest that GMFs may be a promising non-invasive strategy for treating prostate cancer.
