# ABSTRACT

**Aims/Introduction:** To systematically review the risk factors for new-onset diabetes mellitus after kidney transplantation, and to provide a theoretical basis for the prevention and management of new-onset diabetes mellitus after kidney transplantation.

**Materials and Methods:** We searched PubMed, Web of Science, Embase, the Cochrane Library databases and other databases for case–control studies related to risk factors for new-onset diabetes mellitus after kidney transplantation published between January 2005 and July 2019. A meta-analysis of data on risk factors for new-onset diabetes mellitus after kidney transplantation from the included studies was carried out. A narrative review of risk factors for new-onset diabetes mellitus after kidney transplantation was also carried out.

**Results:** A total of 24 case–control studies were included in the meta-analysis, with a total of 7,140 patients. There were 1,598 patients with new-onset diabetes mellitus after kidney transplantation, and 5,542 patients without new-onset diabetes mellitus after kidney transplantation. The meta-analysis results showed that age, polycystic kidney disease, family history of diabetes, body mass index, acute rejection, tacrolimus use, hepatitis B virus infection, hepatitis C virus infection and hypertension were associated with new-onset diabetes mellitus after kidney transplantation, whereas sex, sirolimus use, cyclosporin A use, steroid use and cytomegalovirus infection were not associated with new-onset diabetes mellitus after kidney transplantation.

**Conclusions:** Older age, body mass index, family history of diabetes, tacrolimus use, history of hypertension, polycystic kidney disease, acute rejection, hepatitis B virus infection and hepatitis C virus infection are risk factors for new-onset diabetes mellitus after kidney transplantation. Therefore, the clinical implications of these factors warrant attention.

# INTRODUCTION

New-onset diabetes mellitus after transplantation (NODAT) refers to the detection of diabetes after a successful organ transplantation in patients who had not previously shown abnormal blood glucose levels before surgery. With the continuous developments and improvements in the field of organ transplantation, kidney transplantation has been carried out in an increasing number of patients; however, NODAT often occurs after kidney transplantation, with an incidence rate of 2–50%<sup>1–3</sup>. NODAT can lead to related complications, such as kidney

with a kidney transplant, and increasing their economic burden.
Some studies have shown that the occurrence and development
of NODAT after renal transplantation are affected by age, body
mass index (BMI), hepatitis C virus (HCV) infection, cytomegalovirus (CMV) infection, use of immunosuppressive drugs,
polycystic kidney disease, acute rejection, family history of diabetes mellitus and other risk factors<sup>5–11</sup>; however, there are still
controversies. Therefore, a comprehensive and accurate understanding of NODAT-related risk factors after renal transplantation is necessary to prevent and clinically manage NODAT in renal transplant recipients.

transplant failure, cardiovascular disease and infection<sup>4</sup>, seri-

ously endangering the quality of life and prognosis of patients

Received 3 January 2020; revised 20 May 2020; accepted 2 June 2020

#### **METHODS**

All analyses were based on previously published studies; therefore, ethical approval and patient consent were not required.

#### Inclusion and exclusion criteria

The inclusion criteria were as follows: (i) type of study: case–control study; (ii) participants: patients aged >18 years and undergoing kidney transplantation for the first time; (iii) exposure factors: risk factors for NODAT in kidney transplant recipients; and (iv) outcome indicators: NODAT after kidney transplantation, diagnosed according to the diagnostic criteria of the World Health Organization or the American Diabetes Association.

The exclusion criteria were as follows: (i) repeated publications; (ii) too few risk factors or too few cases; and (iii) unavailable full text, incomplete data, unconvertible data or no control group.

#### Search strategy

PubMed, Web of Science, Embase, the Cochrane Library databases and other databases were searched by computer to collect case-control studies on the risk factors for NODAT after kidney transplantation. The retrieval period was from the establishment of the database through July 2019. In addition, references cited in the articles were traced to supplement the relevant literature. For retrieval, a combination of subject words and free words were used. The search terms included "kidney transplantation," "renal transplantation," "renal transplantations," "kidney grafting," "kidney transplantations," "diabetes mellitus," "diabetes insipidus," "prediabetic state," "scleredema adultorum," "glucose tolerance" and 'gastroparesis.'

#### Literature selection and data extraction

Two researchers independently screened, extracted and crosschecked the literature. Any differences were resolved through discussion and consultation with a third researcher. When selecting documents, the titles were read first. After excluding obviously irrelevant documents, the abstract and full text were read to determine their eligibility for inclusion. If necessary, the authors of the original study were contacted by email or phone to obtain any uncertain, but essential, information for the present study. The following data were extracted: (i) basic information including title, author, publication date, study type, publication area and follow-up time; (ii) baseline characteristics of the study participants, such as sample content and basic information, as well as exposure of risk factors in the case group and control group; (iii) number of cases and controls, and exposure and non-exposure in each study; (iv) key elements of bias risk assessment; and (v) outcome indicators and outcome measurement data.

#### Risk assessment of the included studies

Two researchers independently evaluated the risk of bias in the study according to the Newcastle–Ottawa Scale (NOS). In the case of disagreement, a third reviewer made the final decision.

#### Statistical analysis

Revman 5.3 software (Cochrane Collaboration, Oxford, UK) was used for meta-analysis. The mean difference was used as the effect index in measurement data and the odds ratio (OR) was used as the effect index in counting data. The point estimates and 95% confidence intervals (CIs) were calculated for each effect quantity. The heterogeneity among the results was analyzed using the  $\chi^2$ -test (test level  $\alpha = 0.1$ ), and the degree of heterogeneity was determined by the  $I^2$  statistic. If there was no statistical heterogeneity between the results of each study, the fixed effects model was used for meta-analysis; however, if there was statistical heterogeneity between the results of each study, the source of heterogeneity was further analyzed. After excluding the influence of obvious clinical heterogeneity, the random effects model was used for meta-analysis. The inspection level of the meta-analysis was set as  $\alpha = 0.05$ . Obvious clinical heterogeneities were subjected to subgroup analysis or sensitivity analysis, or only descriptive analysis. Funnel plot analysis was used to assess publication bias.

#### RESULTS

#### Literature screening process and results

A total of 1,054 related articles were collected in the initial examination. After the layer-by-layer screening, 24 articles were finally included<sup>1–3,6,9–28</sup>. The 24 studies involved 7,140 patients, including 1,598 with NODAT after kidney transplantation and 5,542 without NODAT after kidney transplantation. The process and results of the literature screening are shown in Figure 1.

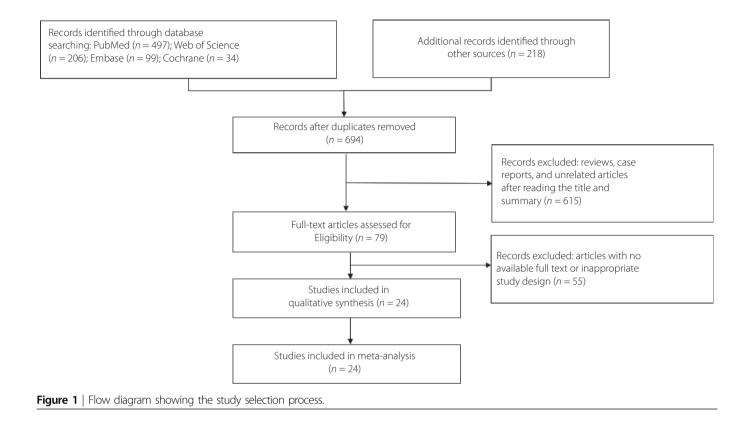

# Basic characteristics of the included studies and results of bias risk assessment

Table 1 shows the basic characteristics of the included studies and the results of bias risk assessment according to the NOS. Tables 2 and 3 summarize relevant information on meta-analysis of modifiable risk factors and non-modifiable risk factors, respectively.

#### Meta-analysis results

Non-modifiable factors

- 1. Age: 17 studies<sup>1,9–18,20,21,24,25,27,28</sup> were included, with 1,105 patients in the NODAT group and 3,530 patients in the non-NODAT group. After the heterogeneity test (P < 0.00001,  $I^2 = 78\%$ ), the random effects model was used, and the results showed that age was a risk factor for NODAT after kidney transplantation (mean difference = 6.05, 95% CI 4.33–7.78, P < 0.00001; Figure 2).
- 2. Sex: 21 studies<sup>1-3,6,9-15,17-22,24,25,27,28</sup> were included, with 1,512 patients in the NODAT group and 5,337 patients in the non-NODAT group. After the heterogeneity test (P = 0.42,  $I^2 = 3\%$ ), the fixed effects model was used, and the results showed that sex was not a risk factor for NODAT after kidney transplantation (OR 1.00, 95% CI 0.88-1.13, P = 0.97; Figure 3).

- 3. Polycystic kidney disease: 10 studies<sup>1,9,13,14,17,18,20,23,26,27</sup> were included, with 638 patients in the NODAT group and 1,824 patients in the non-NODAT group. After the heterogeneity test (P = 0.17,  $I^2 = 30\%$ ), the fixed effects model was used, and the results showed that polycystic kidney disease was a risk factor for NODAT after kidney transplantation (OR 1.69, 95% CI 1.22–2.34, P = 0.002; Figure 4).
- 4. Family history of diabetes mellitus: 14 studies<sup>1,3,9–1,3,15,17,22,23,25–27</sup> were included, with 829 patients in the NODAT group and 3,113 patients in the non-NODAT group. According to the heterogeneity test (P < 0.00001,  $I^2 = 83\%$ ) and the random-effect model, family history of diabetes was a risk factor for NODAT after kidney transplantation (OR 3.14, 95% CI 1.87–5.27, P < 0.0001; Figure 5).

#### Modifiable risk factors

- 1. BMI: 14 studies<sup>1,6,9,11,13–18,21,25–27</sup> were included, with 990 patients in the NODAT group and 2,466 patients in the non-NODAT group. After the heterogeneity test (P = 0.0006,  $I^2 = 64\%$ ), the random effects model was used, and BMI was found to be a risk factor for NODAT after kidney transplantation (mean difference = 1.82, 95% CI 1.35–2.30, P < 0.00001; Figure 6).
- 2. Tacrolimus use: 12 studies<sup>6,9–11,13,14,19,20,23,25,27,28</sup> were included, with 1,011 patients in the NODAT group and

3,398 patients in the non-NODAT group. After the heterogeneity test (P = 0.009,  $I^2 = 56\%$ ), the fixed effects model was used, and the results showed that tacrolimus use was a risk factor for NODAT after kidney transplantation (OR 1.20, 95% CI 1.02–1.41, P = 0.03; Figure 7).

- 3. Sirolimus use: five studies<sup>10,11,14,19,28</sup> were included, with 558 patients in the NODAT group and 1,814 patients in the non-NODAT group. After the heterogeneity test (P < 0.00001,  $I^2 = 86\%$ ), the random effects model was used, and the results showed that sirolimus use was not a risk factor for NODAT after kidney transplantation (OR 2.21, 95% CI 0.96–5.09, P = 0.06; Figure 8).
- 4. Cyclosporin A use: seven studies<sup>3,6,9,13,14,19,28</sup> were included, with 659 patients in the NODAT group and 2,268 patients in the non-NODAT group. After the heterogeneity test (P = 0.003,  $I^2 = 70\%$ ), the random effects model was used, and the results showed that cyclosporin A use was not a risk factor for NODAT after kidney transplantation (OR 0.91, 95% CI 0.63–1.31, P = 0.61; Figure 9).
- 5. Steroid use: eight studies<sup>3,6,9,12–14,17,18</sup> were included, with 630 patients in the NODAT group and 1,750 patients in the non-NODAT group. After the heterogeneity test (P = 0.82,  $I^2 = 0\%$ ), the fixed effects model was used, and the results showed that steroid use was not a risk factor for NODAT after kidney transplantation (OR 1.42, 95% CI 0.97–2.08, P = 0.07; Figure 10).

heterogeneity test (P = 0.05,  $I^2 = 67\%$ ), the random effects model was used, and the results showed that HBV infection was a risk factor for NODAT after kidney transplantation (OR 3.53, 95% CI 1.12–11.13, P = 0.03; Figure 12).

- 8. HCV infection: 12 studies<sup>6,10–12,15,17,18,21–23,25,27</sup> were included, with 831 patients in the NODAT group and 2,346 patients in the non-NODAT group. After the heterogeneity test (P = 0.40,  $I^2 = 5\%$ ), the fixed effects model was used, and the results showed that HCV infection was a risk factor for NODAT after kidney transplantation (OR 1.51, 95% CI 1.01–2.24, P = 0.04; Figure 13).
- **9.** CMV infection: eight studies<sup>1,2,6,17,21,22,24,27</sup> were included, with 617 patients in the NODAT group and 1,452 patients in the non-NODAT group. After the heterogeneity test (P = 0.21,  $I^2 = 27\%$ ), the fixed effects model was used, and the results showed that CMV infection was not a risk factor for NODAT after kidney transplantation (OR 1.11, 95% CI 0.81–1.53, P = 0.51; Figure 14).
- 10. Hypertension: 11 studies<sup>1–3,6,9,10,13,17,18,22,26</sup> were included, with 805 patients in the NODAT group and 2,036 patients in the non-NODAT group. After the heterogeneity test  $(P = 0.40, I^2 = 4\%)$ , the fixed effects model was used, and the results showed that hypertension was a risk factor for NODAT after kidney transplantation (OR 1.48, 95% CI 1.19–1.85, P = 0.0004; Figure 15).

#### Results of publication bias assessment

Two funnel plots were drawn based on age and HCV infection. The scatter plots were roughly symmetrical, suggesting a low likelihood of publication bias (Figures 16,17).

#### DISCUSSION

The occurrence and development of NODAT after renal transplantation are affected by many factors, including non-modifiable and modifiable factors. The non-modifiable factors include age, family history of diabetes, polycystic kidney disease, race and gene polymorphism<sup>5,9,11</sup>, whereas the modifiable factors include BMI, acute rejection, immunosuppressant use, HBV infection, HCV infection, CMV infection, hypertension and dipeptidyl peptidase-4 inhibitor use<sup>1,6,8,10,11</sup>. In the present study, age, sex, family history of diabetes, hypertension, polycystic kidney disease, BMI, acute rejection, tacrolimus use, sirolimus use, cyclosporin A use, steroid use, HBV infection, HCV infection, CMV infection were included in the meta-analysis.

A number of studies have shown that age can affect the occurrence of NODAT<sup>13–15</sup>. The present study also found that age is a risk factor for the occurrence of NODAT after kidney transplantation, which might be related to the progressive decline of islet  $\beta$ -cell function with increasing age.

Family history of diabetes mellitus is an important risk factor for NODAT in transplant recipients<sup>23,26</sup>. It has been reported that the risk of NODAT in patients with a family history of type 2 diabetes is 6.4–8.6-fold higher than that in patients without a family history of type 2 diabetes<sup>1,17</sup>. The present study suggests that a family history of diabetes can increase the risk of NODAT in renal transplant recipients by up to 3.14-fold.

Whether polycystic kidney disease is a risk factor for NODAT after kidney transplantation remains controversial. Prakash *et al.*<sup>23</sup> and other researchers reported that polycystic kidney disease is a risk factor for NODAT after kidney transplantation, whereas Cotovio *et al.*<sup>18</sup> and other groups found that polycystic kidney disease is not a risk factor for NODAT

Figure 7 | Forest plots (fixed effects model) of meta-analysis on the association between tacrolimus use and the risk of new-onset diabetes mellitus after renal transplantation.

after kidney transplantation. Through the analysis of ten casecontrol studies, the present study found that preoperative polycystic kidney disease increases the risk of NODAT after kidney transplantation by 1.69-fold, which might be related to insulin resistance and hyperinsulinemia in some polycystic kidney disease patients<sup>20,26,29</sup>.

A number of studies have shown that BMI is a risk factor for NODAT after kidney transplantation<sup>6,25,30</sup>. The mechanism of NODAT is related to the fact that obesity stimulates  $\beta$ -cells

of islets of Langerhans to induce insulin resistance, thereby weakening the ability of blood glucose clearance<sup>3,11,22,31</sup>. In the present study, the analysis of 14 case–control studies showed that BMI is a risk factor for NODAT after kidney transplantation, which is consistent with previous studies.

Acute rejection is a type of stress reaction that has been recognized as a risk factor for NODAT in kidney transplant recipients<sup>1,10,19</sup>. The mechanism of NODAT after kidney transplantation might be related to glucocorticoid shock therapy

Figure 12 | Forest plots (random effect model) of meta-analysis on the association between hepatitis B virus and the risk of new-onset diabetes mellitus after renal transplantation.

catecholamine, glucagon and glucocorticoid, and then increase the level of blood glucose<sup>34,35</sup>. The combined analysis of 12 case–control studies in the present study showed that acute rejection increases the risk of NODAT after renal transplantation by 1.95-fold.

Immunosuppressants are one of the risk factors for NODAT. The previously reported immunosuppressants that can cause NODAT include corticosteroids, calcineurin inhibitors and rapamycin target protein inhibitors<sup>6,10,27</sup>. In the present study, the combined results showed that tacrolimus use is a risk factor for NODAT after renal transplantation. The possible mechanism of NODAT caused by tacrolimus is as follows: (i) tacrolimus has a direct damage effect on  $\beta$ -cells of islets, which are morphologically manifested as the expansion, vacuolation and reduction of dense-core secretory granules of  $\beta$ -cells of islets; and (ii) the synthesis of insulin is inhibited. Tacrolimus is an inhibitor of neurocalcin, which can not only inhibit calcineurin to exert its

immunosuppressive effect, but also specifically and reversibly inhibit the transcription of the insulin gene, so as to reduce insulin synthesis<sup>35,36</sup>. However, the use of sirolimus or cyclosporin A is not a risk factor for NODAT after renal transplantation in the present study, which might be related to the short observation time of NODAT and the low dose of cyclosporine A in some studies<sup>12,13</sup>. In addition, our combined results showed that steroid use is not a risk factor for NODAT after renal transplantation, which might be related to the short use time or low dose of steroids in some studies<sup>3,12,17</sup>.

The infectious factors that affect NODAT include HBV, HCV and CMV infection. Its pathogenesis might be related to the direct damage to islet  $\beta$ -cells caused by infection, the increase of insulin resistance caused by insulin receptor deficiency, and the decrease of liver glucose uptake and glycogen production<sup>31</sup>. The present study showed that HBV and HCV infections are risk factors for NODAT after renal transplantation, but CMV infection is not.

				NODAT <non-nodat nodat="">Non-NODAT</non-nodat>								

Figure 14 | Forest plots (fixed effects model) of meta-analysis on the association between cytomegalovirus and the risk of new-onset diabetes mellitus after renal transplantation.

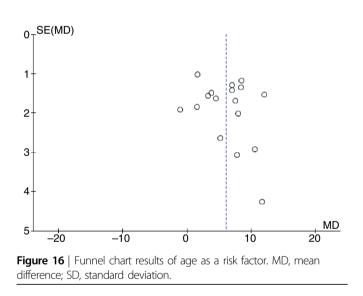

At present, there is no single study showing that hypertension is a risk factor for NODAT after renal transplantation. We have included eleven articles and found that hypertension is also a risk factor for NODAT after renal transplantation. This might be related to the increased secretion of inflammatory factors caused by the increase of homocysteine in patients with hypertension, which could lead to the abnormal function of adipose tissue, and increased production and secretion of resistin, leading to the occurrence of inflammatory reaction and insulin resistance<sup>37–39</sup>.

The present study had some limitations. The research quality of the included studies was roughly the same. Only Chinese and English studies were included. As one of the 24 included articles was written in Chinese and 23 of them were written in English, they could not fully reflect the differences in ethnicity, regions and other influencing factors. In the present study, the number of articles on some influencing factors was small. Therefore, it was difficult to determine the relationship between those factors and the occurrence of NODAT after kidney transplantation. Furthermore, the sample size of some of the included studies was small. Therefore, multicenter and largesample epidemiological studies are required to further clarify the risk factors for NODAT after kidney transplantation.

To summarize, age, BMI, family history of diabetes, history of hypertension, polycystic kidney disease, acute rejection, HBV infection, HCV infection and tacrolimus use are risk factors for NODAT in kidney transplant recipients. Therefore, the clinical implications of these factors warrant attention. More studies with high demonstration intensity are required in the future.
