Association between Surgical Technical Skills and Clinical Outcomes: A Systematic Literature Review and Meta-Analysis

Michael S. Woods, MD, MMM, Joshua N. Liberman, PhD, MBA, Pinyao Rui, MPH, Emily Wiggins, MPH, Joan White, APRN, MSN, Bruce Ramshaw, MD, Jonah J. Stulberg, MD, PhD, MPH

ABSTRACT

Background: A systematic literature review and metaanalysis was conducted to assess the association between intraoperative surgical skill and clinical outcomes.

Methods: Peer-reviewed, original research articles published through August 31, 2021 were identified from PubMed and Embase. From the 1,513 potential articles, seven met eligibility requirements, reporting on 151 surgeons and 17,932 procedures. All included retrospective assessment of operative videos. Associations between surgical skill and outcomes were assessed by pooling odds ratios (OR) using random-effects models with the inverse variance method. Eligible studies included pancreaticoduodenectomy, gastric bypass, laparoscopic gastrectomy, prostatectomy, colorectal, and hemicolectomy procedures.

Results: Meta-analytic pooling identified significant associations between the highest vs. lowest quartile of surgical skill and reoperation (OR: 0.44; 95% confidence interval [CI]: 0.23, 0.83), hemorrhage (OR: 0.66; 95% CI,

@ 2023 by SLS, Society of Laparoscopic & Robotic Surgeons. Published by the Society of Laparoscopic & Robotic Surgeons.

0.65, 0.68), obstruction (OR: 0.33; 95% CI, 0.30, 0.35), and any medical complication (OR: 0.23, 95% CI, 0.19, 0.27). Nonsignificant inverse associations were noted between skill and readmission, emergency department visit, mortality, leak, infection, venous thromboembolism, and cardiac and pulmonary complications.

Conclusions: Overall, surgeon technical skill appears to predict clinical outcomes. However, there are surprisingly few articles that evaluate this association. The authors recommend a thoughtful approach for the development of a comprehensive surgical quality infrastructure that could significantly reduce the challenges identified by this study.

Key Words: Surgical outcome, Surgical technical skill, Video-based assessment.

INTRODUCTION

The operating room is incredibly complex and potentially very dangerous. This complexity has led to substantial variation in patient outcomes, even among surgical centers of excellence.^{1,2} Decades of research have led to the identification of risk factors for poor intraoperative and postoperative outcomes, including characteristics related to the patient, the institution, the procedure, the surgical team, and the surgeon. Commonly reported patientrelated risk factors include age,^{3–5} anatomic complexity,⁶ comorbidities,^{7–9} and frailty.^{10,11} Institution-related factors typically focus on experience with a specific procedure.12-15 Procedure-related factors include total operative or anesthesia time,16,17 procedure complexity,18-20 and type of procedure.^{5,21} The most common measures of a surgeon's performance relate to experience and procedure volume.14,22,23

However, more direct assessments of a surgeon's technical performance have been developed and validated. These measures, such as the Objective Structured Assessment of Technical Skills (OSATS),²⁴ Global Evaluative Assessment

of Laparoscopic Skills (GOALS),²⁵ and Global Evaluative Assessment of Robotic Skills (GEARS),²⁶ require direct evaluation of the surgeon's technical skills while performing a surgical procedure. In addition, there are procedure-specific assessments, such as the Colorectal Objective Structured Assessment of Technical Skills (COSATS)²⁷ in use and others in development such as one for hiatal hernia²⁸ and one for laparoscopic fundoplication.²⁹

A common method for scoring surgical performance is to review surgeon-specific operative videos. Video-based assessment (VBA) in training can document consistent surgical technical skill improvement.^{30–32} Further, given the substantial variability in technical skills among surgeons, recent calls-to-action recommend the widespread implementation of VBA for continual quality improvement among practicing surgeons.^{32–34} While improving technical skills is valuable for surgical training and potentially valuable for continual learning, a technical skill score in the absence of understanding impact on patient outcome is of little meaning. Therefore, it is essential to understand whether better technical proficiency correlates with better patient outcomes.

Until recently, few research studies have explored the relationship between standardized measures of surgeon technical skills in relationship to patient outcomes.^{35,36} These studies demonstrated that surgeons scoring in the upper quartile generally had better patient outcomes than those surgeons scoring in the lowest quartile. However, these studies document this association in specific surgical settings, for specific procedures, and among specific specialties.

To assess the current state of knowledge we conducted a systematic literature review and meta-analysis to document the relationship between surgeon technical skill and patient outcomes with a focus on: 1) the consistency and magnitude of any association between technical skill and patient outcomes and 2) gaps in the inclusion of surgical specialties, procedures, and outcomes.

METHODS

Search Strategy and Eligibility

The study was conducted in compliance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA)³⁷ and Meta-analysis of Observational Studies in Epidemiology (MOOSE) guidelines.³⁸

Eligible manuscripts were English-language, original research studies that included both measurement of surgical technical skills and patient-specific intraoperative or postoperative clinical outcomes. Eligible articles were required to report on surgeon technical skills using observation of a surgeon's performance during real-world surgical procedures. Articles that met any of the following criteria were deemed ineligible: reported surgeon technical skill or performance based on outcomes (e.g. evaluation of surgical success by completion of procedure-specific tasks such as quality of suturing, or of imaging that documents correct placement of a device); nonprimary research (abstracts, conference proceedings, posters, commentaries, and editorials); review articles; or studies related to dental surgery, obstetrics, or ophthalmology.

A systematic literature search was conducted from database inception to August 31, 2021 using the PubMed and Embase library databases to identify peer-reviewed original research manuscripts that assessed the association between surgical skills and clinical outcomes. Search terms were derived from Medical Subject Heading (MeSH) and non-MeSH terms using Boolean operators applied to surgery (MeSH: "surgical procedures, operative"), level of skill (MeSH: "professional competence" and "clinical competence"), clinical outcomes (MeSH: "treatment outcome"), and surgical technical quality (see **Appendix Table 1**).

Two authors (JNL and EW) independently evaluated each manuscript title, abstracts for articles deemed potentially eligible following title review, and full manuscripts deemed potentially eligible following abstract review. To ensure complete capture of eligible articles, the reviewers screened the references and citations of each eligible manuscript. The two authors independently extracted the following data from each manuscript: study design; geographic location; surgeon and surgical patient sample size; surgeon specialty; procedure type; technical skills evaluation methodology; and outcomes. Each article was evaluated for the following: technical skill assessment method (direct observation, deidentified video submission); number and type of raters evaluating technical skill; and technical skill assessment scale used. The risk of bias in each manuscript was assessed using a modified version of the Newcastle-Ottawa Scale (Appendix **Tables 2 and 3)**.39

Analysis

Data abstracted from the full manuscript review was used to create an analytical file in Microsoft Excel. This file contained data on all outcomes reported in the eligible manuscripts, the sample size of surgeries by surgeon technical skill group (i.e. quartile 1 – quartile 4), the number of outcome events in each surgeon technical skill group, the average technical skill score by presence/absence of outcome, precalculated effect sizes and variances, etc. Eligible studies all reported technical skill scores by quartiles except for MacKenzie, et al.⁴⁰ which reported three categories based on cumulative sum chart and validated in prior publications. These three categories were assigned as Q1, Q2 – Q3, and Q4 to allow comparison and inclusion in the analysis.

The data were imported into R version 40.10.1 (R Project for Statistical Computing) and the R package 'meta' was used to synthesize results across studies to derive pooled effect sizes. Random effects models were used to estimate effect sizes and variances due to the assumption of between-study heterogeneity. Mantel-Haenszel odds ratios and Knapp-Hartung adjusted 95% confidence intervals (CI) of surgeon technical skill quartile associated with surgical complications were calculated by pooling study-specific odds ratios using random-effects models with invariance method to incorporate the heterogeneity of differences across studies. Between-study heterogeneity was measured using the Paule-Mandel method of calculating the heterogeneity variance τ^2 .

A separate meta-analysis was conducted to include studies that either reported precalculated odds ratios or information to derive odds ratios. The association between surgeon technical skill and any postoperative complications was assessed by pooling odds ratios using random-effects models with the inverse variance method. Between-study heterogeneity was measured using the Paule-Mandel method of calculating the heterogeneity variance τ^2 . Publication bias was evaluated using funnel plots and Egger's test. Statistical tests were two-sided and used a significance threshold of P < .05.

RESULTS

A total 1,513 articles were identified by the systematic search criteria and from that search, four^{35,36,40,41} were identified as eligible (**Figure 1**). Following a complete reference and citation search among these articles, an additional three articles^{42–44} were deemed eligible for inclusion (**Figure 1**). Noting that Hogg, et al.⁴⁴ reported the number of procedures but not surgeons, the seven eligible studies reported on 151 surgeons and a total of 17,932 procedures. Each study reported on a different

procedure: laparoscopic sleeve gastrectomy, laparoscopic right hemicolectomy, laparoscopic gastric bypass, laparoscopic gastrectomy for gastric adenocarcinoma, laparoscopic colorectal surgery, robot-assisted radical prostatectomy, and robot-assisted pancreaticoduodenectomy (**Table 1**).

Among the four studies in a U.S. surgical population, two were from the Michigan Bariatric Surgery Collaborative, one from the Illinois Surgical Quality Improvement Collaborative, and one from the University of Pittsburgh Medical Center (**Table 1**). Two studies reported on a Canadian surgical population, one from the University of Toronto and one for the University of British Columbia, and one reported on a U.K. population from the National Training Programme for Laparoscopic Colorectal Surgery (**Table 1**).

Technical Skills Assessment and Presentation

The technical skill assessment was completed by review of deidentified operative videos, with five articles reporting on an assessment derived from a participating surgeon's self-selected representative surgical video and three articles reporting on surgery-specific videos (**Appendix Table 2**). The number of raters for each video varied from 1 to 10 (or more), with the raters' specialty and experience varying from surgeons familiar with the surgery to individuals familiar with the surgery.

The most frequently used skills assessment instrument was the OSATS (or modified OSATS) used as the primary tool in five of the studies, followed by the GEARS⁴³ and the competency assessment tool.⁴⁰ The COSATS³⁶ and the Generic Error Rating Tool (GERT) ^{42,43} were also included complementary assessments.

Four studies^{35,36,40,41} reported outcomes as a function of technical skill, typically categorizing technical skill scores into quartiles (**Figure 2**). Three studies^{42–44} reported technical skill scores among individuals with and without poor postoperative outcomes and odds ratios of the association between surgeon technical skill and poor postoperative outcomes (**Figure 3**).

Outcomes

Two studies^{40,44} did not report the timeframe over which outcomes were measured. One article⁴³ reported on achieving postprostatectomy continence by three-months. The remaining five articles reported 30-day postoperative outcomes (**Table 1**). The most frequently reported

Figure 1. Study selection flowchart.

outcomes (reported in three studies) were mortality, reoperation, readmission, and infection, followed by the following outcomes reported in two studies: emergency department (ED) visit, any surgical complication, any medical complication, leak, obstruction, hemorrhage, venous thromboembolism (VTE), cardiac complication, and pulmonary complication. A composite measure for any postoperative complication was created to include three studies⁴²⁻⁴⁴ that reported precalculated ORs of the association between surgeon technical skill and postoperative complications (Figure 4) and three studies^{35,36,40} that reported the number of postoperative complications occurring in each quartile of surgeon technical skill in which an OR could be derived (Figure 4). The measure included the outcomes of any complication reported in four studies,^{35,36,40,45} postoperative pancreatic fistula reported in Hogg 2016,⁴⁴ and incontinence reported in Goldenberg 2017,⁴³ for a total of six studies (**Figure 4**).

Surgical Skill and Outcomes

No studies reported that higher technical skill was associated with poorer patient outcomes. All reported significant associations between surgeon technical skill and at least one outcome. Four articles categorized surgeons by technical skill scores and reported outcome events by those categories.^{35,36,40,41} Birkmeyer et al.³⁵ and Stulberg, et al.³⁶ reported on three categories of technical skill (bottom quartile, middle 50%, and top quartile) (**Figure 2**) while Varban, et al.,⁴¹ reported on top quartile vs. bottom quartile only (**Figure 3**). articles^{42–44} reported technical skill scores among individuals with and without select outcomes (**Figure 4**).

Meta-analytic pooling of the associations between the highest vs. lowest quartile of surgeon technical skill and the outcome of reoperation resulted in a summary OR of 0.44 (95% CI, 0.23, 0.83), with low heterogeneity across the three studies ($l^2 \le 0.01\%$, $\tau^2 < 0.01$, P = .48). Metaanalytic pooling of the association between the highest vs. lowest quartile of surgeon technical skill and hemorrhage resulted in a summary OR of 0.66 (95% CI, 0.65, 0.68), with low heterogeneity across the two studies ($l^2 \leq$ 0.01%, $\tau^2 < 0.01$, P = .99). The association between the highest vs. lowest quartile of surgeon technical skill and obstruction was 0.33 (95% CI, 0.30, 0.35) with low heterogeneity across the two studies ($l^2 \leq 0.01\%$, $\tau^2 < 0.01$, P =.97). The association between the highest vs. lowest quartile of surgeon technical skill and medical complication was 0.23 (95% CI, 0.19, 0.27) with low heterogeneity across the two studies ($I^2 \le 0.01\%$, $\tau^2 < 0.01$, P = .95). The association between the highest vs. lowest quartile of surgeon technical skill and the outcomes of readmission, ED visit, mortality, leak, infection, VTE, cardiac complication, and pulmonary complication did not reach statistical significance. Funnel plots are displayed for each outcome (Figure 3). Egger's test indicated no significant publication bias (p range, 0.36 - 0.75) six of the seven studies reported either precalculated ORs or information to derive ORs of the association between surgeon technical skill and any postoperative complication. Meta-analytic pooling of the odds ratios yielded a summary OR of 0.37 (95% CI, 0.21, 0.66) with moderate heterogeneity across studies $(I^2 = 55\%, \tau^2 = 0.31, P = .05)$. A forest plot of studies that reported on the association between surgeon technical skill and postoperative complications is shown in Figure 4. Egger's test indicated no significant publication bias (P = .86).

DISCUSSION

Across outcomes measured there is a consistent, albeit not always statistically significant, association between surgical technical skills and clinical outcomes. Unfortunately, very few articles met eligibility criteria, which limits the interpretation and indicates a significant opportunity for expanded, structured research. Nonetheless, our results are consistent with other studies that explore surgeon technical performance and clinical outcomes, in particular, a recently published systematic review by Balvardi et al.⁴⁶

Measuring Surgeon Performance

Top Quartile vs. Bottom Quartile

It's important to recognize that our study restricted the definition of surgeon technical performance to the most direct assessment of surgical technical skill, as epitomized by the OSATS or GEARS scales. These measure technical skill by direct observation of video of the surgeon's performance, including but not limited to respect for tissue, flow of the operation, time and motion, knowledge of the procedure, knowledge of the instruments, efficiency, bimanual dexterity, etc. The published literature, however, is replete with examples of surgeon technical skill

that use different measures of performance. Indirect measures include experience, quality, and outcomes. Common measures of surgeon experience conflate technical skills with experience and include evaluation based on residency,47,48 years of experience in practice,49 count (or recent frequency) of surgeries performed,^{50,51} or specialty.49,52 Surgical quality measures include evaluation of a procedure's end result, typically evaluated by review of medical records, operative narrative, or post hoc imaging results.53-55 Finally, surgeon performance is routinely measured using intraoperative and postoperative outcomes, such as successful completion of procedure components,

January-March 2023 Volume 27 Issue 1 e2022.00076

Figure 3. Forest plots of individual clinical outcomes, comparing top and bottom quartile of surgeon technical skill.

operative time, hospital length-of-stay, complications, reoperations, and readmissions. $^{16,56-58}$

This variability complicates the evaluation of peer-reviewed literature relating surgeon performance with peri- and postoperative clinical outcomes. This complexity is illustrated by a recently published systematic review investigating the association between surgeon technical performance and patient outcomes in surgery,⁵⁹ which includes articles that measured surgeon technical skill by completion of procedural tasks (e.g. "exploration of Cooper's ligament"),^{53,60,61} evaluation of surgical outcomes based on operative reports or post hoc imaging,^{62,63} and assignment of surgical errors following medical records review.^{64,65} Though these varying concepts of surgeon technical performance are clearly interrelated, they are not equivalent and should be carefully considered when determining the root cause of intra- and postoperative patient outcomes.

Direct, Observational Assessment of Surgical Technical Skills

A significant challenge in comparing surgeon technical skill in relation to outcomes is the variability in measurement of technical skill. In recent years, standardized and validated instruments for measuring surgeon technical skills⁶⁶ have been developed. Though not widely adopted in routine surgical practice, these measures have proved valuable for research and quality improvement efforts. Measures of technical skill can be separated into those that measure nonrobotic surgery skills, such as OSATS,

Figure 4. Forest plots of composite "any outcome" measure.

which measures respect for tissue, time and motion, instrument handling, knowledge of instruments, flow of operation, use of assistants and knowledge of the specific procedure, and those that measure technical skills during robotic surgery, such as GEARS, which measures domains such as depth perception, bimanual dexterity, efficiency, force sensitivity, and robotic control. While standardized and validated, problems with these assessments exist. For example, flow of operation is intended to be a global measure of the procedural flow. However, a significant amount of subjectivity is injected when one must score a procedure where some of the procedure flowed smoothly, and other aspects did not. Additionally, these instruments include items and response options that apply arbitrary anchors, confusing measurement focus, and subjective scoring guidelines that provide little guidance on differentiating scores along the scale continuum.

Video in Training, Certification, and Ongoing Learning

Recent calls-to-action focus on the importance of integrating VBA to evaluate surgeon skill and to support a continual learning model.^{28,34,67} Incorporation of these videos into surgical training and quality improvement programs avoids the cost and resourcing challenges of real-time measurement via observation and is of growing importance for surgical training programs.⁶⁸ An interesting perspective is provided by Blencowe et al.⁶⁹ who reported on a comparison between video and direct observation of several surgical procedures. The evaluations were not associated with outcomes (bariatric surgery) but included interviews with surgeons who agreed that there is significant variability, lack of meaningful standards, etc. in surgical procedures. This perspective is consistent with attempts to incorporate VBA into surgical qualifications. In Japan, for example, the endoscopic surgical skill qualification system includes the scoring of an operative video among other certification criteria.⁷⁰

Routine videorecording of surgeries will be essential for accelerating the training of residents, as well as implementing and supporting ongoing learning models to support surgeons through a career, such as the American Board of Surgery's continuous certification program. Despite the fact that VBA accelerates a trainee's acquisition of skills when compared to standard mentoring approaches,^{30,31} there is a poor understanding of available technology, its power, and ease of use.⁷¹ In addition, novel surgical techniques and new surgical devices evolve rapidly, and VBA can be used to ensure safe implementation, track their utilization and associated outcomes, and provide a platform for ongoing surgical skill evaluation related to their use.

To improve surgical outcomes, the American College of Surgeons (ACS) implemented the National Surgical Quality Improvement Program, a voluntary but nationally recognized surgical quality improvement program, measuring clinical quality beginning with intraoperative outcomes and continuing through 30-days postprocedure.⁷² Building on this surgical quality reporting and training capability, the ACS is embracing a concept called entrustable professional activities (EPAs).⁷³ In the surgical context, EPAs represent a way "to translate the broad concepts of competency into everyday practice".⁷⁴ VBA is ripe to fulfill this goal for surgical technical competency, as discrete phases of procedures can be scored with objective procedure-specific assessments (OPSAs)

focused on safe procedural conduct — competency — a major goal of EPAs. EPAs are not about identifying "exemplar technical skill." The authors' viewpoint is that EPAs should be constructed to define safe vs. unsafe practice, and as such, associated scales are less subjective and more reliable.

In addition to OPSAs, the degree of procedural difficulty should ideally be captured, giving depth to the meaning of a score in the context of EPAs. For example, a resident scoring at a staff level of technical competence for an easy laparoscopic cholecystectomy, may be unsafe in a hard case of laparoscopic cholecystectomy. A global operative difficulty score, similar to the System for Improving and Measuring Procedural Learning⁷⁵ construct, needs to be incorporated into VBA.¹⁵ The combination of OPSA/ EPAs and global operative difficulty goes beyond accurate assessment, enabling the identification of technical improvement opportunities specific to the phase of a procedure, as well as the creation of rich teaching libraries based upon skill level, case difficulty, and even the phase of the procedure.

Surgical specialties must come to the realization that VBA scores, regardless of the assessment scale, lose resonance in the absence of the patient's associated outcome, at least until there is definitive evidence that a specific score, in fact, results in a consistently best outcome. As this review has shown, there is significant inconsistency in the reporting of complications, how long the patient has been followed, and how the complication is categorized. This is a significant opportunity for improvement, as it is possible to not only standardize the approach to VBA, but also to patient follow-up and outcome measurement.

Our Recommendations

With the collective goal of eliminating variation in surgeon technical skill as a contributing factor to surgical outcomes, the authors propose the following four requirements for defining a comprehensive surgical quality infrastructure:

- 1. **Risk Factor Assessment and Mitigation.** Routine assessment to identify and mitigate pre-, intra-, and postoperative risk factors for suboptimal surgical outcomes, including but not limited to surgeon technical skill. Ideally, this function would be automated, with real-time, data-driven smart alerts.
- 2. **Ongoing Surgical Learning.** Transitioning VBA from generic, non-specific assessments of technical skill to objective procedure-specific assessments

linked to EPAs. Reducing subjectivity, improving reliability and accuracy, and measuring discrete, critical phases of individual procedures will result in the ability to accelerate resident training based upon data, supports safe implementation of new procedures and technologies, and establish benchmarks for safe procedural conduct.

- 3. **Routinely Assigning a Case Difficulty Score.** Routine assessment of the global operative difficulty establishes a data-driven methodology upon which to advance residents to higher case difficulties, based on their OPSAs/EPAs scores, by procedural difficulty. It also provides additional context for understanding outcomes based upon standardized case difficulty.
- 4. **Outcomes Evaluation.** Implement standardized procedures, terminology, and definitions for documenting and collecting surgical outcomes. This will enable the ability to understand the meaning of the OPSA/EPA scores in the context of the patient's outcome, as well as establish comparability across patient and provider populations for the purpose of defining optimal practice. At a minimum, especially for publication, we suggest 100% of the patient population be followed for a minimum of 30-days postoperatively, with all complications being categorized using a procedurally-adapted National Coordinating Council for Medication Error Reporting and Prevention and Clavien-Dindo classifications.

Development and implementation of this recommended system will enable — finally — apples-to-apples comparisons that have data-driven validity for technical skill and outcomes between residents, staff surgeons, departments, specialties, organizations, systems, countries, and continents. This, or a comparable system, is required for driving continuous quality improvement through shared learnings.

LIMITATIONS

Interpretation of these results is hampered by several limitations. First, only seven articles met the eligibility criteria and among those, four had modest sample sizes. This is particularly important because the results are heavily weighted to Birkmeyer,³⁵ which had the largest sample size, by far. Second, there was substantial variability among a limited number of outcomes measures included in the eligible articles. This, coupled with the relatively short follow-up period, puts a limit on the potential generalizability and value of the association (although highlights the importance of the four requirements of a comprehensive surgical quality infrastructure). One powerful association, noted in MacKenzie et al.40 and Curtis⁷⁶ indicate the potential impact of surgeon performance on long-term outcomes. Though only the MacKenzie article was eligible for inclusion, both articles include lymph node count and resection margins as outcomes. Both measures are significant predictors of cancer recurrence. In other words, not only are near-term outcomes linked to technical skill scores, but early results strongly suggest long term outcomes are too, at least in oncology. Third, the eligible studies are dominated by gastrointestinal procedures, specifically foregut surgery. The contribution of surgeon's technical skill to clinical outcomes, likely varies by surgery type and complexity. Future research should focus on both a broader array of procedure types and a consistent, standardized set of clinical outcomes, both short- and long-term.

CONCLUSIONS

Our systematic literature review and meta-analysis indicates that surgeon technical skill is a significant predictor of clinical outcomes. However, despite the development and validation of numerous scoring instruments to assess surgeon technical skills, there are surprisingly few articles that evaluate the association between skill and outcomes. Within the limited number of articles that do study this association, determining significance is hampered by low sample sizes and lack of consistency in how outcomes and complications were defined. The authors recommend a thoughtful approach for the development of a comprehensive surgical quality infrastructure that could significantly reduce the challenges identified by this study.

Appendix Table 2. Criteria for the Newcastle-Ottawa Scale regarding star allocation to assess quality of studies

Criteria	Acceptable (star awarded)	Unacceptable (star not awarded)
Cohort Studies†		
Representativeness of exposed cohort	Representative group of participating surgeons	Self-selected, volunteer sample of surgeons
Selection of non-exposed cohort	Same setting and source population as exposed cohort	Different setting from exposed cohort
Ascertainment of exposure	Operative videos evaluated by more than one independent rater	Operative videos evaluated by one rater only or raters with knowledge of surgeon identity.
Comparability	Adjusted for patient-level risk of poor outcomes.	No reported patient-level risk adjustment
	Adjusted for clustering of outcomes from multiple patients per surgeon.	No reported adjustment for clustering of patients by surgeon.
Assessment of outcomes	Secure records or independent assessment	Self-reported, not reported
Adequacy of follow up	Complete follow up or missing follow-up outcomes unlikely to introduce bias.	No statement regarding missing data or completeness of follow up
Case-Control Studies		
Case definition adequate	Case status confirmed by independent validation	Case status defined by self-report
Case representativeness	Consecutive or obviously representative case series	Potential for selection biases
Selection of controls	Controls derived from same population	Selected form independent population
Definition of controls	Same inclusion criteria related to previous or history of outcome(s) of interest	Different inclusion/exclusion criteria related to history of/prior events of outcome(s) of interest
Comparability of cases & controls	Study controls for risk factors for peri- and post-operative outcomes	No adjustment for risk factors.
Ascertainment of exposure	Operative videos evaluated for each procedure	Surgeon self-selected representative video
Same method of ascertainment for cases and controls	Yes	No
Non-response rate	Same rate for both groups	

† "Demonstration that outcome of interest was not present at start of study" was excluded as an assessment criterion.
