Introduction: To evaluate the intraocular pressure (IOP)-lowering efficacy and safety of a triple fixed-combination of bimatoprost, brimonidine, and timolol (TFC) in patients with glaucoma or ocular hypertension (OHT) treated with fixed-combination or unfixed brimonidine and timolol therapy (dual-combination therapy).

Methods: In this multicenter, open-label, phase 3 study, patients who received 4–8 weeks of dual-combination therapy twice daily and had an IOP >18 and <34 mmHg in at least one eye were switched (at baseline) to treatment with TFC twice daily for 12 weeks. At Weeks 4, 8, and 12 on TFC, IOP was assessed at Hours 0, 2, and 8. Primary efficacy variable: mean diurnal IOP change from baseline in the study eye at Week 12 (modified intent-to-treat [mITT] population). Sensitivity (per-protocol [PP] population) and subgroup (≤ 65 vs > 65 years) analyses were performed. Safety, including adverse events (AEs), was assessed at each visit.

Results: Of 126 patients enrolled, 121 and 103 formed the mITT/safety and PP populations, including 109 (90.1%) and 94 (91.3%) who completed the study, respectively. In the mITT/safety population, mean age was 58.6 years. Patients had open-angle glaucoma (51.2%), angle-closure glaucoma with patent iridotomy (36.4%), and/or OHT (13.2%). At Week 12, the mean diurnal change in IOP from dual combination-treated baseline was statistically significant ($P < 0.001$) with TFC in the mITT (-3.98 mmHg) and PP (-4.22 mmHg) populations. Results were similar at all visits, regardless of the age subgroup. The most frequent treatment-related AEs were conjunctival hyperemia (14.0%) and dry eye (4.1%); 5.8% of the patients discontinued treatment due to ocular AEs.

Conclusion: TFC offers a beneficial therapeutic alternative for patients with glaucoma or OHT whose IOP is not sufficiently controlled with dual-combination therapy. Safety and efficacy findings support those of published studies of TFC in primary open-angle glaucoma and OHT, despite differences in study designs.

Keywords: glaucoma, intraocular pressure, prostaglandin analog, alpha-agonist, beta-blocker, combination therapy

Introduction

To date, prostaglandin analogs/prostamides (PGAs) remain the most effective intraocular pressure (IOP)-lowering monotherapies for open-angle glaucoma (OAG) and ocular hypertension (OHT).^{1–6} Nonetheless, use of multiple medications is often required to maintain sufficient IOP lowering, and combination therapies are frequently used to achieve this goal and prevent disease progression.⁷ Compared with unfixed combinations, fixed combinations increase convenience, reduce costs, and improve treatment adherence, while minimizing medication washout and lowering exposure to preservatives and adverse event (AE) frequency or severity.^{8–11} PGA-containing dual fixed combinations have been shown to be more effective in lowering IOP than PGA monotherapies.^{4,12–22} Moreover, there is clinical evidence suggesting that brimonidine (an α -adrenergic agonist) has the potential to provide IOP lowering and neuroprotection.^{23–26}

Two randomized, double-masked, multicenter, phase 3 studies of a triple fixed combination (TFC) containing bimatoprost 0.01%, brimonidine 0.15%, and timolol 0.5% (corresponding to 0.68% timolol maleate in the formulation, and referred to as “timolol 0.5%” hereafter) used twice daily in patients with primary OAG and OHT have demonstrated superiority of TFC over dual fixed-combination brimonidine 0.2%/timolol 0.5%, following washout of prior therapy.^{27,28}

Findings have led to the approval of TFC by regulatory agencies in 5 countries (Brazil, Chile, Colombia, Ecuador, and Mexico). Thus, we hypothesized that TFC may result in additional IOP lowering beyond that of ongoing treatment without causing new, unexpected AEs in patients who were already treated with brimonidine 0.2%/timolol 0.5% dual-combination therapy (fixed or unfixed) at baseline, and who were not subjected to a washout period.

The present study, conducted in India, was designed to evaluate the efficacy and safety of TFC in patients with glaucoma or OHT who continued to have IOP above target after run-in on fixed or unfixed brimonidine 0.2%/timolol 0.5% dual-combination therapy.

Methods

Study Design

This open-label, multicenter, 12-week, phase 3 study (ClinicalTrials.gov identifier: NCT01216943) was conducted between November 29, 2010 and August 18, 2012 at 11 study centers in India.

Study Population

Eligible participants were ≥ 18 years of age with a diagnosis in each eye of either OHT; chronic or primary OAG; chronic angle-closure glaucoma with patent iridotomy; pseudoexfoliative glaucoma; or pigmentary glaucoma, requiring bilateral administration of IOP-lowering treatment. Additional key inclusion criteria were baseline medicated IOP > 18 mmHg and < 34 mmHg at Hour 0 (between 6:30 and 9:30 AM) in at least 1 eye after 4 to 8 weeks of treatment with the run-in dual-combination therapy, and best-corrected visual acuity (BCVA) 20/200 or better in both eyes.

Key exclusion criteria were as follows: known allergy, hypersensitivity, or contraindication to the study medication or any of its components; active ocular disease other than glaucoma or OHT (except chronic mild blepharitis, cataract, age-related macular degeneration, or background diabetic retinopathy, which could be enrolled at the discretion of the investigator); use of ocular PGAs within 4 weeks prior to baseline; recent or anticipated changes in therapy for chronic conditions with agents that could affect IOP; use of other ocular medications during the study (except intermittent use of artificial tears, topical decongestants or antihistamine > 24 h prior to a scheduled study visit); functionally significant visual field loss or evidence of progressive visual field loss within 1 year prior to baseline; corneal abnormalities that could preclude accurate IOP readings with applanation tonometry; use of corticosteroids within defined exclusion periods prior to baseline (depending on the administration route) and through the study period; incisional surgery or laser procedure within defined exclusion periods prior to baseline (depending on the procedure); and ocular hyperemia or other active ocular surface findings $\geq +0.5$ at baseline.

Treatment

At the prestudy visit, all eligible patients initiated a run-in period (at least 4 and up to 8 weeks) using only the dual-combination therapy (COMBIGAN[®] [Allergan, an AbbVie company; North Chicago, IL, USA] or two adjunctive monotherapies of brimonidine and timolol) instilled twice daily (between 7:00–10:00 AM and 7:00–10:00 PM) in each eye. Patients who were already using fixed or unfixed brimonidine 0.2%/timolol 0.5% dual-combination therapy at the time of the prestudy visit should have taken this dual combination for at least 4 weeks before the baseline visit. Patients who were taking any other IOP-lowering medications were to discontinue all of these additional medications at the prestudy visit in order to have at least 4 weeks of run-in on dual combination alone before the baseline visit. The last dose of run-in dual-combination therapy was administered after the Hour-0 assessments at the baseline visit (Day 0). The first dose of TFC was instilled the evening of the baseline visit, after completion of the Hour-8 assessments, and then was self-administered twice daily in each eye at 12-hour intervals (as described above) for 12 weeks. On visit days, the morning dose of TFC was instilled at the site after the Hour-0 measurements.

Each study medication kit contained two multidose bottles of TFC (preserved with benzalkonium chloride [BAK] 50 ppm) representing a month's supply.

Assessments

IOP was determined by Goldmann applanation tonometry at the prestudy visit, as well as Hours 0 (pre-instillation), 2, and 8 at baseline and Weeks 4, 8, and 12. Each IOP assessment consisted of two consecutive measurements in each eye; if the measurements differed by ≤ 2 mmHg, the IOP value for the given eye was the mean of both measurements. Otherwise, a third measurement was taken, and the IOP value for the given eye was the median of all three measurements. IOP was expected to be assessed at approximately the same time at each visit by the same evaluator. If it was not possible, the evaluators were to overlap (ie, examine the patient together and discuss findings) for at least one visit.

AEs were collected following standard clinical trial procedure and graded as mild, moderate, severe, or “not applicable” (for findings not graded for severity). Biomicroscopic examinations were performed without pupil dilation using a slit lamp, and assessed per a standard 5-point scale (none/0; trace/+0.5; mild/+1; moderate/+2; and severe/+3), except lens status, which was assessed for nuclear, cortical, and posterior subcapsular opacities following pupil dilation, using a 4-point scale (none/0; mild/+1; moderate/+2; and severe/+3). Specific standardized scales with pictorial or published guidelines were used for anterior chamber inflammation (which, if present, was graded based on standardized nomenclature set forth by the SUN Working Group criteria for anterior chamber cells and flare)²⁹; the optic nerve cup/disc ratio (which was reported using the standard 0–1.0 scale and pictorial Armaly chart provided); and conjunctival hyperemia (assessed using the Allergan Bulbar Hyperemia Grading Guide, which is based on a 5-point photographic grading scale of 0/none [normal]; +0.5/trace [trace flush, reddish pink]; +1/mild [mild flush, reddish color]; +2/moderate [bright red color]; and +3/severe [deep, bright, diffuse redness]). The study eye was the eye that met all eligibility criteria. If both eyes were eligible, the eye with the higher baseline IOP was designated as the study eye; if both eyes had the same IOP, the right eye was selected.

Safety variables included adverse events (AEs), BCVA (in Snellen, per a logarithmic chart for testing at 10 feet), and biomicroscopy findings (based on slit lamp evaluation of the lids, lid margins, conjunctiva, anterior chamber, and cornea without pupil dilation), assessed at each visit, as well as ophthalmoscopy findings (ie, observation of the lens, vitreous, and fundus for pathology through a dilated pupil) and cup/disc ratio (based on direct and indirect ophthalmoscopy) assessed at the prestudy visit, baseline, and Week 12 (after the last IOP reading).

Outcome Measures and Analyses

The primary efficacy outcome measure was the change in mean diurnal IOP from dual combination-treated baseline in the study eye at Week 12 in the modified intent-to-treat (mITT) population, ie, all patients with a baseline evaluation and at least one post-baseline efficacy evaluation. Mean diurnal IOP was the mean of the Hour 0, 2 and 8 values at each visit in the study eye. The null hypothesis was that there was no change in mean diurnal IOP from dual combination-treated baseline at Week 12 in the study eye. The alternative hypothesis was that TFC statistically significantly reduced mean diurnal IOP from the dual combination-treated baseline at Week 12 in the study eye. The null hypothesis was tested using a two-sided, one-sample Student *t*-test and SAS software version 9.2 (SAS Institute Inc, Cary, North Carolina). If the resulting *P* value was ≤ 0.05 , the null hypothesis was to be rejected and TFC was to be deemed superior to the dual combination.

Analyses were repeated at Weeks 4 and 8 in the mITT population, and at Weeks 4, 8, and 12 in the per-protocol (PP) population, ie, mITT subset without major protocol violations. Missing data were only imputed for the mITT population, using the last-observation-carried-forward method. Safety was assessed at each visit in all treated patients (safety population). Supplemental efficacy and safety analyses were performed on patient subgroups based on age (≤ 65 vs >65 years).

A sample size of 120 was calculated based on a paired (one-sample) Student *t*-test for a mean difference, as implemented by MOT1 procedure in nQuery Advisor 6.01,³⁰ as well as the following assumptions, which were based on primary efficacy data from two pivotal studies (NCT00332540 and NCT00332072) of dual fixed-combination bimatoprost/timolol (Ganfort; Allergan, an AbbVie company): difference of ≥ 1 mmHg in mean IOP change from dual combination-treated baseline after 12 weeks of TFC treatment; standard deviation (SD) value of 3.22 mmHg; one-sided significance level of 0.025; power of 0.90 to detect a mean decrease in IOP of 1 mmHg from dual combination-treated baseline; and discontinuation rate of 7%.

Results

Patient Disposition, Demographics, and Baseline Characteristics

In total, 126 patients were enrolled; 5/126 patients were excluded due to Good Clinical Practice violations at one investigational site, leaving 121/126 patients in the mITT/safety population (Figure 1). Of those 121 patients, 109 (90.1%) completed the study. Sensitivity analyses demonstrated no differences in efficacy and safety when patients from the excluded study site were included.

In the mITT/safety population, mean (SD) age was 58.6 (11.4) years, 62.8% of the patients were male, and the most common diagnosis was OAG (51.2%; Table 1). In the PP population (n=103), patient disposition, demographics, and baseline characteristics were similar to those of the mITT/safety population (Figure 1 and Table 1).

Treatment

In the mITT/safety population, the mean (SD) duration of treatment with TFC was 81.9 (17.9) days (range: 8–109 days).

Efficacy Analyses

At Week 12 (primary efficacy endpoint), TFC produced statistically significant IOP reductions from the already dual combination-treated baseline in both the mITT (−3.98 mmHg) and PP (−4.22 mmHg) populations (Figure 2). Mean (SD) diurnal IOP decreased from 22.4 (3.4) to 18.4 (3.7) mmHg in the mITT population, and from 22.4 (3.3) to 18.1 (3.7) mmHg in the PP population.

The change in mean diurnal IOP from the already dual combination-treated baseline was also statistically significant at Weeks 4 and 8 (Figure 2). In the mITT population, mean (SD) diurnal IOP was 17.9 (3.6) mmHg at Week 4 and 18.1 (3.7) mmHg at Week 8. In the PP population, mean (SD) diurnal IOP was 17.6 (3.4) mmHg at Week 4 and 18.3 (3.6) mmHg at Week 8. In both populations, the mean changes from baseline ranged from −4.1 to −4.6 mmHg (Figure 2). In addition, statistically significant IOP reductions from dual combination-treated baseline were observed at all follow-up visits in the mITT population stratified by age (Figure 3). In patients ≤65 years of age, mean (SD) diurnal IOP decreased from 22.5 (3.5) mmHg at baseline to 17.8 (3.8), 18.0 (3.8), and 18.4 (3.8) mmHg at Weeks 4, 8, and 12, respectively. In those >65 years of age, mean (SD) diurnal IOP decreased from 22.1 (3.1) mmHg at baseline to 18.1 (3.0), 18.4 (3.2), and 18.3 (3.5) mmHg at Weeks 4, 8, and 12, respectively. In both age subgroups, the reductions in mean diurnal IOP from dual combination-treated baseline were −3.7 mmHg or greater at all post-baseline visits ($P<0.001$; Figure 3).

Safety Analyses

Overall, 54 (44.6%) patients treated with TFC experienced ≥ 1 AE(s) during the study, regardless of causality. No serious AEs were reported and only 1 (0.8%) patient experienced a severe AE, glaucoma, which was deemed not treatment related. For all other AEs, the maximum severity was mild for 39 (32.2%) patients and moderate for 14 (11.6%) patients.

Ocular AEs were reported in 49 (40.5%) patients and considered treatment-related in 38 (31.4%) patients (Table 2). The most frequent treatment-related AE was conjunctival hyperemia (14.0%; Table 2). Conjunctival hyperemia was also

Figure 2 Change in mean diurnal IOP from dual combination-treated baseline in the mITT and PP populations after 4, 8, and 12 weeks of treatment with TFC. $P < 0.001$ at each visit, compared with baseline (for both populations).

Abbreviations: IOP, intraocular pressure; mITT, modified intent-to-treat; TFC, triple fixed-combination bimatoprost 0.01%/brimonidine 0.15%/timolol 0.5%.

the most frequently reported AE in the subgroups aged ≤ 65 years ($n=15/91$, 16.5%) and >65 years ($n=5/30$, 16.7%), regardless of causality. Overall, 7 (5.8%) patients discontinued treatment due to AEs, all of which were ocular in nature (Table 2).

During the study, 9 (7.4%) patients were reported to have clinically significant biomicroscopy findings (defined as ≥ 2 full severity grade increase from baseline in either eye during treatment), including conjunctival hyperemia ($n=7$, 5.8%);

Eye pain	2 (1.7)
Blepharitis	1 (0.8)
Dry eye	1 (0.8)
Infections/infestations	
Viral conjunctivitis	1 (0.8)

Notes: ^aHeadache was the only non-ocular treatment-related adverse event (reported by 1 patient). ^bPatients could have reported >1 treatment-related AEs. ^cSeven patients reported 12 AEs leading to treatment discontinuation.

conjunctival follicles (n=2, 1.7%); and n=1 each (0.8%) of eyelid erythema, meibomian gland dysfunction, and superficial punctate keratopathy. At study end, ophthalmoscopic examination revealed only 2 new findings (retinal vein occlusion [n=1] and worsening of glaucoma [n=1] reported in different patients), neither of which was considered treatment related. It is worth noting, however, that the worsening of glaucoma was reported in an eye that was on four topical IOP-lowering medication classes prior to study entry, and disease worsening could have been due to insufficient IOP-lowering efficacy in that TFC-treated eye.

Measured BCVA was unchanged in 98 of 108 patients with available data (Figure 4A), and the cup/disc ratio remained stable for all patients, except 1 (0.8%; Figure 4B) who had a worsened ratio (a ≥ 0.2 increase) not associated with clinical findings of increased IOP.

Discussion

In this open-label, multicenter, phase 3 study, patients with glaucoma or OHT who continued to have IOP above target after run-in on brimonidine 0.2%/timolol 0.5% therapy (administered as a fixed combination or adjunctive monotherapies) twice daily were switched at baseline to the PGA-containing TFC treatment twice daily. Clinically meaningful and statistically significant IOP lowering from an already dual combination-treated baseline was reported at all follow-up visits. Results were

Figure 4 Patients with improved, unchanged, and worsened BCVA (A) or cup/disc ratio (B) from baseline after 12 weeks of treatment with TFC (mITT population). Improved and worsened BCVA were defined as increase and decrease of ≥ 2 lines from baseline, respectively. Improved and worsened cup/disc ratios were defined as decrease and increase of ≥ 0.2 from baseline, respectively.

Abbreviations: BCVA, best-corrected visual acuity; mITT, modified intent-to-treat; TFC, triple fixed-combination bimatoprost 0.01%/brimonidine 0.15%/timolol 0.5%.

similar in the mITT and PP populations, as well as the mITT population stratified by age, supporting the IOP-lowering efficacy of TFC used twice daily. TFC also had an acceptable safety/tolerability profile, consistent with that of its individual components; no additional, unexpected AEs were reported.

In the present study, 32.2% of the patients experienced treatment-related AEs with TFC administered twice daily, all mild or moderate in intensity, highlighting the favorable tolerability profile of this triple fixed combination. As expected with a triple combination containing both bimatoprost³¹ and brimonidine,³² conjunctival hyperemia was the most frequently reported treatment-related AE (14.0%) before and after stratification by age. It is worth noting that other, more recently approved IOP-lowering medications containing fewer (1 or 2) active components than the current triple combination were associated with higher rates of conjunctival hyperemia ($\geq 47\%$ ^{12,13,33–39}) than reported herein, further supporting tolerability of TFC.

These findings are clinically relevant because in the landmark Early Manifest Glaucoma Trial, the risk of glaucomatous progression was reduced by an estimated 10% for each IOP decrease of 1 mmHg.⁴⁰ Moreover, the pivotal Ocular Hypertension Treatment Study has shown that many patients require >2 IOP-lowering agents to reach or maintain their target IOP,⁷ and yet there are very few triple-fixed combinations available.^{27,28,41,42} Safety and efficacy findings of this study support those of previously published studies of TFC in primary open-angle glaucoma and OHT,^{27,28} despite differences in study designs (ie, inclusion of a washout period^{27,28} or not [current study]), and further confirm that bimatoprost can be administered twice daily when low concentrations of bimatoprost (0.01%) and preservative (BAK, 50 ppm) are combined with adjunctive medications requiring twice-daily administration, as previously reported in pre-clinical (pharmacokinetic) and clinical evidence.^{43–45}

Phase 3 studies of the original formulation of bimatoprost monotherapy (Lumigan 0.03%; Allergan, an AbbVie company) preserved with 50 ppm BAK have shown that twice-daily administration did not result in greater IOP lowering, compared with once-daily administration.⁴⁶ After preclinical studies demonstrated that raising the concentration of BAK increased ocular bioavailability of bimatoprost,⁴⁴ the currently marketed formulation of bimatoprost monotherapy (Lumigan 0.01%; Allergan, an AbbVie company) preserved with 200 ppm BAK was developed to increase tolerability with once-daily use, and was shown to be as effective as the original once-daily formulation.⁴⁷ Development of TFC was based on a corollary concept implying that the drug dosing regimen/schedule could be manipulated by varying the concentrations of both bimatoprost and BAK. With low concentrations of bimatoprost (0.01%) and BAK (50 ppm) included in TFC, bimatoprost can indeed be used twice daily, consistent with the dosing regimens of the other two IOP-lowering agents included, provide the tolerability expected of the once-daily bimatoprost monotherapy,³¹ and substantially enhance the IOP lowering obtained with brimonidine and timolol,^{27,28} with the simplification in dosing regimen to use of one bottle, twice a day.

Potential limitations of the study include the open-label design. However, the study was designed to reflect real-world clinical settings, and switching all patients from their prescribed dual-combination therapy to TFC eliminated patient variation from analysis, while allowing assessment of the additional IOP-lowering enhancing effect obtained by adding bimatoprost on top of the already established efficacy of the dual combination. The fact that the IOP-lowering effect of TFC remained similar at all follow-up visits also suggests that the efficacy of TFC was not overestimated due to carry-over effects from previous treatments with dual-combination therapy. While the long-term use of TFC should be examined further in this patient population, safety after 12 months of continuous use of the TFC was previously described,²⁷ supporting tolerability of this triple combination containing bimatoprost when used twice daily on an ongoing basis.

In summary, TFC offers a convenient, beneficial therapeutic alternative to patients with glaucoma or OHT whose IOP is not sufficiently controlled with dual-combination therapy, with the potential to enhance patient adherence to treatment and –consequently– quality of life by including all three medications in one bottle.

Data Sharing Statement

AbbVie is committed to responsible data sharing regarding the clinical trials we sponsor. This includes access to anonymized, individual and trial-level data (analysis data sets), as well as other information (eg, protocols and Clinical Study Reports), as long as the trials are not part of an ongoing or planned regulatory submission. This includes requests for clinical trial data for unlicensed products and indications. This clinical trial data can be requested by any qualified researchers who engage in rigorous, independent scientific research, and will be provided following review and approval of a research proposal and Statistical Analysis Plan (SAP) and execution of a Data Sharing Agreement (DSA). Data requests can be submitted at any time and the data will be accessible for 12 months, with possible extensions considered. For more information on the process, or to submit a request, visit the following link: <https://www.abbvie.com/our-science/clinical-trials/clinical-trials-data-and-information-sharing/data-and-information-sharing-with-qualified-researchers.html>.

Ethics Approval and Informed Consent

This study was approved by the following independent ethics committee or institutional review board at each investigational site before initiation: Bangalore Central Ethics Committee (registration number, IORG00006039; Meena Nair, Harsh Kumar); Dr. Shroff's Charity Eye Hospital Ethics Committee (Suneeta Dubey); Ethics Committee, H.V. Desai Eye Hospital (Vidya Chelerkar); Ethics Committee Institutional Review Board, Sankara Eye Care Institutions (registration number, ECR/705/Inst/KA/2015/RR-21; Meena G Menon); Ethics Sub-Committee, Vision Research Foundation (Balekudaru Shantha); Institutional Ethics Committee for Human Research, Bombay City Eye Institute and Research Center (Rajul Parikh); Institutional Review Board, Aravind Eye Care System (Federalwide Assurances number, 00004084; Sharmila Rajendrababu); Institutional Review Board, Aravind Medical Research Foundation (Federalwide Assurances number, 00004084; Ganesh Venkataraman); and Institutional Review Board, L.V. Prasad Eye Institute (Federalwide Assurances number, 00004930; Vanitha Pathak Ray).

The study was conducted in accordance with the Good Clinical Practice guidelines, as well as the Helsinki Declaration of 1964 and its later amendments. All patients provided written informed consent before starting treatment.

Acknowledgments

We acknowledge the following institutions (researchers) for their participation in the study: Aravind Eye Hospital (Sharmila Rajendrababu), Aravind Eye Hospital Post Graduate Institute of Ophthalmology (Ganesh Venkataraman), Bombay City Eye Institute and Research Center (Rajul Parikh), Centre for Sight B-5/24 (Harsh Kumar), Chaithanya Eye Hospital & Research Institute (Meena Nair), Dr. Shroff's Charity Eye Hospital (Suneeta Dubey), H.V. Desai Eye Hospital (Vidya Chelerkar), Sankara Eye Hospital (Meena G Menon), L.V. Prasad Eye Institute (Vanitha Pathak Ray), and Sankara Nethralaya, A Unit of Medical and Vision Research Foundation (Balekudaru Shantha).

The authors would like to thank all the patients who participated in this study, as well as Trever Todd, PhD (AbbVie Inc.), for his critical review and assistance during manuscript development. Statistical analyses were generated by SIRO Clinpharm Pvt. Ltd (Mumbai, India). This work was partially presented at the 11th European Glaucoma Society Congress (June 7–11, 2014; Nice, France).

Clinical Ophthalmology

Dovepress

Publish your work in this journal

Clinical Ophthalmology is an international, peer-reviewed journal covering all subspecialties within ophthalmology. Key topics include: Optometry; Visual science; Pharmacology and drug therapy in eye diseases; Basic Sciences; Primary and Secondary eye care; Patient Safety and Quality of Care Improvements. This journal is indexed on PubMed Central and CAS, and is the official journal of The Society of Clinical Ophthalmology (SCO). The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/clinical-ophthalmology-journal>
