14 **Abstract.**

15 Arthritogenic alphaviruses, including chikungunya virus (CHIKV), Mayaro virus (MAYV), Ross
16 River virus (RRV), and O'nyong nyong virus (ONNV) are emerging and reemerging viruses that
17 cause disease characterized by fever, rash, and incapacitating joint swelling. Alphavirus infection
18 induces robust immune responses in infected hosts, leading to the upregulation of several
19 cytokines and chemokines, including chemokine C ligand 4 (CCL4). CCL4 is a chemoattractant
20 for immune cells such as T cells, natural killer cells, monocytes/macrophages, and dendritic
21 cells, recruiting these cells to the site of infection, stimulating the release of proinflammatory
22 mediators, and inducing T cell differentiation. CCL4 has been found at high levels in both the
23 acute and chronic phases of chikungunya disease; however, the role of CCL4 in arthritogenic
24 alphavirus disease development remains unexplored. Here, we tested the effect of CCL4 on
25 MAYV infection in mice through antibody depletion and treatment with recombinant mouse
26 CCL4. We observed no differences in mice depleted of CCL4 or treated with recombinant CCL4
27 in terms of disease progression such as weight loss and footpad swelling or the development of
28 viremia. CCL4 uses the G protein-coupled receptor C-C chemokine receptor type 5 (CCR5). To
29 determine whether CCR5 deficiency would alter disease outcomes or virus replication in mice,
30 we inoculated CCR5 knockout (CCR5^{-/-}) mice with MAYV and observed no effect on disease
31 development and immune cell profile of blood and footpads between CCR5^{-/-} and wild type

32 mice. These studies failed to identify a clear role for CCL4 or its receptor CCR5 in MAYV
33 infection.

38 **Introduction**

39 Arthritogenic alphaviruses, including chikungunya virus (CHIKV), Ross River virus (RRV),
40 O'nyong nyong virus (ONNV), and Mayaro virus (MAYV) are significant public health threats
41 (1, 2). Arthritogenic alphaviruses are found worldwide: CHIKV is endemic to Africa, Southeast
42 Asia, and, more recently, the Caribbean and South America, while RRV, ONNV, and MAYV
43 circulate in Australia, Africa, and South America, respectively (3). These viruses cause acute and
44 chronic disease characterized by high fever, rash, and muscle and joint inflammation, which can
45 persist for years in roughly half of affected patients (4-9). There are no specific drugs available
46 for the treatment of alphavirus arthritis except the use of anti-inflammatory drugs for
47 symptomatic relief (10, 11). Thus, there is an urgent need to understand the immune mechanisms
48 that control arthritogenic alphavirus disease outcomes in order to develop therapeutics.

49

50 During arthritogenic alphavirus infection, the virus replicates in fibroblasts, muscle satellite cells,
51 macrophages, and other cells, initiating inflammatory responses (12, 13). This results in the
52 influx of monocytes, macrophages, natural killer cells, neutrophils, and T and B lymphocytes to
53 the infection site, leading to tissue damage and expression of proinflammatory cytokines and
54 chemokines, including chemokine C ligand 4 (CCL4), further exacerbating inflammation (14-
55 16). Previous studies have shown that CCL4 (also known as macrophage inflammatory protein-
56 1 β or MIP-1 β) is upregulated in acute and chronic arthritogenic alphavirus-infected humans (17-
57 19) and mice (20-22). CCL4 is involved in orchestrating immune cell movement and activation
58 during infection or inflammation (23-26). CCL4 binds to CC motif chemokine receptor 5
59 (CCR5) (27), acting as a chemoattractant for T cells, monocytes, natural killer cells, and
60 dendritic cells, which play an important role in arthritogenic alphavirus pathogenesis (7, 13, 14,
61 24, 26, 28). Therefore, understanding CCL4's effect on disease outcomes during arthritogenic

62 alphavirus infection is critical to elucidate its contribution to pathogenesis and, thus, its potential
63 to be targeted for the development of therapeutics.

64
65 In this study, we investigated the contribution of CCL4 in the development of MAYV-induced
66 arthritis and disease. We blocked CCL4 in wild-type (WT) mice using an anti-CCL4 monoclonal
67 antibody (mAb) followed by MAYV infection and observed no effect on disease severity. We
68 also inoculated mice with recombinant mouse CCL4 and then infected with MAYV, which
69 similarly showed no effect on disease outcome. Finally, we infected mice deficient in CCR5 with
70 MAYV and observed no differences in disease severity or immune cell profiles at different
71 timepoints of infection compared to WT mice. These studies failed to identify a clear role for
72 CCL4 or its receptor CCR5 in MAYV infection.

73

74 **Materials and Methods**

75

76 **Ethics statement**

77 All experiments were conducted with the approval of Virginia Tech's Institutional Animal
78 Care & Use Committee (IACUC) under protocol number 21-041. Experiments using MAYV
79 were performed in a BSL-2 facility in compliance with CDC and NIH guidelines and with
80 approval from the Institutional Biosafety Committee (IBC) at Virginia Tech.

81

82 **Mice**

83 C57BL/6J mice (strain #000664) and chemokine C-C motif receptor type 5 knock-out (CCR5^{-/-})
84 mice (B6.129P2-CCR5^{tm^{Kuz}/J}; strain #005427) were purchased from The Jackson Laboratory at
85 6-8 weeks of age. CCR5^{-/-} mice were bred at Virginia Tech, and 6–8-week-old mice were used
86 for experiments. Mice were kept in groups of five animals per cage at ambient room temperature
87 with *ad libitum* supply of food and water.

88

89 **Cell culture and viruses**

90 Vero cells were obtained from the American Type Culture Collection (ATCC; Manassas, VA)
91 and grown in Dulbecco's Modified Eagle's Medium (DMEM, Gibco) with 5% fetal bovine serum
92 (FBS, Genesee), 1 □mg/mL gentamicin (Thermo Fisher), 1% non-essential amino acids (NEAA,

93 Sigma) and 25 mM HEPES buffer (Genesee) at 37°C with 5% CO₂. MAYV strain TRVL 4675
94 was derived from an infectious clone (29, 30). Virus titers were determined by plaque assay as
95 previously described (31).

96

97 **Mouse infections**

98 Mice were injected through both hind footpads with 10⁴ PFU of MAYV in 50 µL viral diluent in
99 each foot (32). All virus dilutions were made in RPMI-1640 media with 10 mM HEPES and 1%
100 FBS. Mice were monitored for disease development following infection through daily weighing,
101 and footpad swelling was measured using a digital caliper. Blood was collected via
102 submandibular bleed for serum isolation to determine viremia and cytokine levels. At six-,
103 seven-, or twenty-one-days post-infection (dpi), mice were euthanized, and blood and footpads
104 were collected to isolate serum and immune cells. Leukocytes were isolated from blood and
105 footpads to perform flow cytometry.

106

107 **Luminex assay and ELISA**

108 We quantified CCL3, CCL4, and CCL5 levels in the serum of mock- and MAYV-infected
109 animals using the mouse Luminex XL cytokine assay (bio-techne) and the CCL4/MIP-1 beta
110 DuoSet ELISA kit (Catalog# DY451-05, R&D Systems) according to the manufacturer's
111 instructions. The standard curve was generated using the optical density values of the standards,
112 which were used to calculate the cytokine levels in each sample.

113

114 **CCL4 antibody and cytokine treatment**

115 For *in vivo* CCL4 neutralization, 6–8-week-old C57BL/6J mice were intravenously inoculated
116 through the retro-orbital sinus with 20 µg/mouse of Rat IgG2a kappa isotype control (Cat. No.
117 50-112-9680, Fisher Scientific) or an anti-mouse CCL4 mAb (Cat. No. PIMA523742, clone
118 46907, Fisher Scientific) at -1, 1, 3, and 5 dpi, as previously described (33). Antibodies were
119 diluted in phosphate-buffered saline (PBS, Genesee) and administered in a volume of 100 µL.
120 For gain of function studies, 6–8-week-old C57BL/6J mice were administered PBS or
121 recombinant mouse CCL4 (400 ng/mouse, Cat. No. 554602, BioLegend) intraperitoneally at -3, -
122 1, 1, 3, and 5 dpi (34). Our rationale for the dosage and schedule of CCL4 treatment was based
123 on a previous study that showed that a single dose of 500 ng CCL4 increased macrophages two-

124 fold in BALF in mice with *S. aureus* infection (34). Other studies have used recombinant
125 cytokines for multiple days and observed a significant impact on immune cell mobilization (35-
126 37). Thus, we reasoned those multiple injections of CCL4 prior to and after infection would elicit
127 a more robust effect on immune cell infiltration to the infected tissues. Mice were then infected
128 with 10^4 PFU of MAYV in both hind feet and monitored for disease development until 7 dpi.

129

130 **Mouse blood and footpad immune cell isolation**

131 Mouse blood leukocytes were isolated using Mono-Poly resolving medium (M-P M; MP Bio,
132 Cat. No. 091698049) according to the manufacturer's instructions. Briefly, blood was mixed
133 with an equal volume of PBS and layered slowly onto M-P M followed by centrifugation at
134 $300 \times g$ for 30 min in a swinging bucket rotor at room temperature (20–25°C). We collected cell
135 layers between the plasma and M-P M to isolate leukocytes and added them to a 15 mL conical
136 tube containing 10 mL cold 10% FBS containing RPMI-1640 (RPMI-10). Cells were spun at
137 $500 \times g$ for 5 min at 4°C and used for flow cytometry. We isolated footpad immune cells as we
138 previously described (38). Briefly, footpads were collected above the ankle, deskinning, and
139 transferred to digestion media [RPMI-10, 2.5 mg/mL Collagenase I (Cat. No. LS004196,
140 Worthington Biochemical Corporation), 17 µg/mL DNase I (Cat. No. LS006333, Worthington
141 Biochemical Corporation)], incubated for 2 hours at 37°C, and filtered through a 70 µM cell
142 strainer followed by washing with RPMI-10.

143

144 **Flow cytometry**

145 Single cell suspensions were washed with PBS and resuspended in 100 µL Zombie aqua cell
146 viability dye solution (1:400 prepared in PBS, Cat. No. 423101, BioLegend) and incubated at
147 room temperature for 15-30 minutes. 200 µL flow cytometry staining (FACS) buffer (PBS
148 containing 2% FBS) was added and centrifuged at $500 \times g$ for 5 min at 4°C. The resulting cell
149 pellet was resuspended in FACS buffer with 0.5 mg/mL rat anti-mouse CD16/CD32 Fc block
150 (Cat. No. 553142, BD Biosciences) and incubated for 15 min on ice to block Fc receptors. For
151 extracellular staining, a combined antibody solution was prepared in FACS buffer with
152 fluorophore-conjugated antibodies: anti-mouse Alexa fluor 700 CD45 (Cat. No. 103128,
153 BioLegend), anti-mouse PerCP/Cyanine 5.5 CD11b (Cat. No. 101227, BioLegend), anti-mouse
154 brilliant violet 421 F4/80 (Cat. No. 123131, BioLegend), anti-mouse APC Ly6G (Cat. No.

155 127614, BioLegend), anti-mouse PE Ly6C (Cat. No. 128007, BioLegend), anti-mouse PE-
156 Dazzle 594 MHC II (Cat. No. 107647, BioLegend), anti-mouse PE CD3 (Cat. No. 100206,
157 BioLegend), anti-mouse PerCP/Cyanine 5.5 CD4 (Cat. No. 116012, BioLegend), anti-mouse
158 FITC CD8a (Cat. No. 100706, BioLegend), anti-mouse brilliant violet 421 NK1.1 (Cat. No.
159 108741, BioLegend), and anti-mouse Alexa fluor 488 CD11c (Cat. No. 117311, BioLegend).
160 100 μ L antibody cocktail was added to the single cell suspension, mixed, and incubated for 30
161 min on ice. Cells were washed with FACS buffer twice, and 100 μ L 4% formalin (Thermo Fisher
162 Scientific, Ref. No. 28908) was added to fix the cells. After 15 min incubation at room
163 temperature, cells were washed with FACS buffer, resuspended in 100-200 μ L PBS, and covered
164 with aluminum foil before flow cytometry analysis. For each antibody, single color controls were
165 run with Ultracomp ebeads (Cat. No. 01-2222-42, Thermo Fisher Scientific). The stained cells
166 were analyzed using the FACS Aria Fusion Flow cytometer (BD Biosciences).

167

168 **Statistical analysis**

169 All statistics were performed using GraphPad Prism version 9 and data are presented as mean \pm
170 standard deviation. The statistical tests used to analyze data are described in the figure legends.

171

172 **Results**

173

174 **CCL4 is upregulated in response to MAYV infection in C57BL/6J mice**

175 CHIKV and MAYV produce disease in C57BL/6J mice similar to outcomes in humans (32).
176 MAYV is a BSL2 virus that induces similar disease in humans and WT mice to CHIKV,
177 allowing for safer and easier handling than CHIKV, which requires BSL3 conditions; therefore,
178 to explore CCL4's effect on arthritogenic alphavirus infection, we used MAYV as a model
179 arthritogenic alphavirus (29). CCL4 is involved in inflammatory responses and is elevated in
180 humans infected with arthritogenic alphaviruses (17-19). To assess CCL4 expression induced by
181 MAYV, we infected mice with MAYV and collected blood at 2 and 7 days post-infection (dpi),
182 the peak of viremia and footpad swelling, respectively (29). At 2 dpi, we found that CCL4 was
183 significantly upregulated following MAYV infection compared to mock-infected controls (Fig.
184 1A). To assess whether CCL4 remained elevated later in infection, we measured levels in the
185 blood at 7 dpi. Similarly, CCL4 levels were higher in MAYV-infected mice compared to the

186 mock-infected group (Fig. 1B). This higher expression of CCL4 in MAYV-infected mice is
187 consistent with reports in humans infected with MAYV or CHIKV (8, 19, 39).

188

189 **Antibody-mediated CCL4 depletion and administration of recombinant mouse CCL4** 190 **cytokine failed to alter Mayaro disease severity**

191

192 CCL4 acts as a chemoattractant for different immune cells, such as monocytes, macrophages,
193 natural killer cells, dendritic cells, and T cells, which play important roles in arthritogenic
194 alphavirus pathogenesis (40, 41). After observing higher CCL4 expression following MAYV
195 infection, we asked whether *in vivo* blockade of CCL4 would alter disease severity. To that end,
196 mice were intravenously inoculated with IgG2a isotype control or anti-mouse CCL4 monoclonal
197 antibody (mAb) followed by MAYV infection and monitored for disease development as
198 previously described (32). Mice treated with anti-mouse CCL4 mAb showed modestly higher
199 weight gain and less footpad swelling but showed no statistical differences up to 7 dpi compared
200 to control mice (Fig. 2A-B). Furthermore, a similar titer of infectious virus was observed in
201 isotype and anti-mouse CCL4 mAb treated group at 2 dpi (Fig. 2C).

202

203 Next, we tested whether CCL4 protein inoculation would impact Mayaro disease. We treated
204 mice with PBS or recombinant mouse CCL4 at multiple timepoints before and after MAYV
205 infection and monitored for disease development and virus replication. We found no differences
206 in weight loss or footpad swelling up to 7 dpi (Fig. 2D-E). Likewise, no difference was seen in
207 viral replication between PBS injected and CCL4 protein treated group at 2 dpi (Fig. 2F). As
208 expected, footpad immune cells from CCL4-treated mice had a higher percentage of
209 inflammatory monocytes, dendritic cells, macrophages, and NK cells than PBS treated controls,
210 suggesting CCL4 treatment induced functional changes in immune cell mobilization
211 (Supplementary Fig. 1). Overall, these data suggest that CCL4 depletion nor CCL4 protein
212 inoculation has a significant impact on acute Mayaro disease or replication.

213

214 **CCR5 ligands are upregulated in response to MAYV infection, and lack of CCR5 does not** 215 **impact Mayaro disease severity**

216

217 CCL4 signals through the G protein-coupled receptor CCR5 (27). Lack of CCL4 or protein
218 injection from external sources showed no significant impact on disease outcome (Fig. 2). Thus,
219 we next tested whether genetic deletion of CCL4's receptor, CCR5, would impact disease
220 outcomes following MAYV infection. CCR5 also binds to other ligands, such as CCL3 and
221 CCL5, which are also upregulated during MAYV infection (22, 24). First, to validate these
222 previous reports, we evaluated the impact of MAYV infection on CCL3 and CCL5 at 2 dpi. Like
223 CCL4, CCL3 and CCL5 were significantly upregulated following MAYV infection compared to
224 mock-infected animals (Fig. 3A-B). Next, we infected WT and CCR5^{-/-} mice with MAYV and
225 monitored for disease development and virus replication. We observed no differences in weight
226 loss following infection (Fig. 3C), and similar footpad swelling and viremia at 2 dpi were
227 observed in both groups (Fig. 3D-E). Overall, this data demonstrates that CCR5 does not
228 significantly affect MAYV disease outcomes in mice.

229

230 **CCR5 deletion showed minimal effect on peripheral or footpad immune cell profiles during** 231 **MAYV infection**

232

233 Next, we aimed to explore CCR5's impact on the immune cell profile during MAYV infection.
234 We isolated blood leukocytes at 2 and 6 dpi and performed flow cytometry. At 2 dpi, we
235 observed similar percentages of CD4 T cells (Fig. 4A), neutrophils (Fig. 4C), inflammatory
236 monocytes (Fig. 4D), and dendritic cells (Fig. 4E) in both WT and CCR5^{-/-} groups. Notably,
237 CD8 T cells were reduced significantly in CCR5^{-/-} group compared to WT animals (Fig. 4B). At
238 6 dpi, no differences were observed in any of the tested immune cell types (Supplementary Fig.
239 2). We also assessed footpad immune cells at 6 dpi at peak footpad swelling. We found similar
240 levels of CD4 (Fig. 5A) and CD8 T cells (Fig. 5B), neutrophils (Fig. 5C), inflammatory
241 monocytes (Fig. 5D), dendritic cells (Fig. 5E), macrophages (Fig. 5F), and NK cells (Fig. 5G)
242 between CCR5^{-/-} and WT group. Altogether, these data highlight that CCR5 has minimal impacts
243 on immune cell profiles during MAYV infection.

244

245 **Discussion**

246

247 MAYV infection causes acute and chronic disease characterized by fever, skin rash, myalgia,
248 and debilitating joint pain. In infected mammalian hosts, immune cells migrate to target tissues
249 such as muscles, joints, and synovial tissues, leading to the initiation of inflammatory response
250 and up-regulation of several proinflammatory cytokines and chemokines, including CCL4 (19,
251 42). Here, we explored the role of CCL4 in Mayaro disease. We depleted CCL4 through
252 antibody-based neutralization and injected recombinant CCL4 protein and observed no effect on
253 disease outcomes or viral replication. Furthermore, we infected mice deficient in CCL4's
254 receptor, CCR5, and found minimal impact on disease development, likely indicating that CCL4
255 and CCR5 play a minimal role in MAYV disease.

256
257 CCL4 is produced by various cell types, including monocytes, macrophages, natural killer cells,
258 neutrophils, B and T lymphocytes, fibroblasts, and stromal cells (43-49). Plasma samples of
259 humans infected with arthritogenic alphaviruses such as CHIKV, RRV, and MAYV have high
260 levels of pro-inflammatory cytokines and chemokines, including CCL4 (15-19, 50). This
261 highlights that CCL4 is broadly upregulated in response to different arthritogenic alphaviruses.
262 Therefore, we hypothesized that CCL4 contributes to arthritogenic alphavirus disease. To test
263 this, we depleted CCL4 using a neutralizing antibody, treated mice with recombinant CCL4, and
264 used mice deficient in CCR5 followed by infection with MAYV. Following CCL4 depletion or
265 treatment with CCL4 protein, we observed no difference in disease development between the
266 groups. CCL4's receptor, CCR5, is also used by other chemokines CCL3, CCL5, CCL8, CCL11,
267 and CCL3L1 (24, 27, 51-53); as such, we hypothesized that compensation by the other ligands
268 may have obscured impacts on disease outcomes and thus tested CCR5^{-/-} mice. CCR5 is
269 expressed on T cells, dendritic cells, macrophages, and eosinophils, and ligands initiate
270 chemotaxis to the site of infection (24, 27, 51, 54). We observed that CCR5 ligands CCL3,
271 CCL4, and CCL5 were upregulated in MAYV-infected animals at 2 dpi. Surprisingly, when we
272 infected CCR5^{-/-} animals, we observed only minor or no differences in disease phenotypes, viral
273 replication, and immune cell populations compared to WT controls. One possible explanation is
274 that lack of CCR5 might lead to a stronger interaction between CCL3, CCL4, and CCL5 to other
275 receptors such as CCR1, CCR3, CXCR3, or CCR4 for compensatory immune cell activation (55,
276 56). Given the redundancy with other chemokine receptors, it is possible that other receptors
277 compensate for the loss of CCR5 in mice infected with MAYV (57). The impact of other

278 receptors such as CXCR3, CCR1, and CCR3, among others, on arthritogenic alphavirus disease
279 outcomes should be explored in future investigations. Moreover, given the redundancy of the
280 chemokine/receptor systems, mice with deletions in several ligands or multiple receptors may
281 shed light on the role of these chemokines (58) in alphavirus disease. Furthermore, these
282 chemokines can be neutralized together using monoclonal antibodies.

283

284 There are several key immune cells that express CCR5 and contribute either positively or
285 negatively to alphavirus disease and replication, including monocytes, macrophages, NK cells,
286 $\gamma\delta$ T cells, CD8⁺ and CD4⁺ T cells, and B cells (40). After alphavirus infection, chemokines like
287 CCL4 are secreted, recruiting immune cells to the site of infection (59, 60). The monocytes
288 promote local virus replication and enhance the transport of the virus to distal sites (61, 62).
289 Additionally, alphaviruses can replicate in macrophages (62, 63), which act as reservoirs for viral
290 RNA in infected tissues (64). Beyond viral replication and dissemination, tissue-resident myeloid
291 cells also produce interferons and pro-inflammatory cytokines that aid in viral clearance yet also
292 promote inflammatory tissue damage (65, 66). A pathogenic role of NK cells has been proposed
293 during arthritogenic alphavirus infection (67). CHIKV infection in mouse footpads leads to an
294 increase in $\gamma\delta$ T cells in the foot (68), where they play a protective role. CD8⁺ T cells may also
295 exert an antiviral effect during infections caused by arthritogenic and neurotropic alphaviruses
296 (69-72). However, arthritogenic alphaviruses can evade the CD8⁺ T cell response (69, 73) which
297 may partly explain why infection persists in joint-associated tissues (74, 75). Mice with genetic
298 or acquired deficiencies of CD4⁺ T cells developed minimal or no joint pathology when
299 challenged with CHIKV, suggesting a pathogenic role in disease (76). During alphavirus
300 infection, B cells produce virus-specific antibodies that clear virus from the bloodstream (77).
301 Infection of B cell-deficient mice with CHIKV resulted in persistent infection in the joint (77).
302 Considering the important role of chemokines and their receptors in the recruitment of immune
303 cells for alphavirus infection control, future studies should be conducted by neutralizing the
304 redundant chemokines together with antibodies or knockout of redundant receptors in mouse
305 models.

306

307 Despite exerting minimal impacts on Mayaro infection and disease progression, CCR5—and
308 most likely its ligands—contribute to the development of other viral diseases. For example, mice

309 deficient in CCR5 are fully protected from disease following infection with a mouse-adapted
310 dengue virus (78). Similarly, mice treated with Met-RANTES (Met-R), a CCR5 inhibitor, were
311 similarly protected against disease and DENV replication. In contrast, CCR5^{-/-} mice infected
312 with Japanese encephalitis virus (JEV) or West Nile virus (WNV) have significantly worse
313 disease outcomes and skewed immune cell profiles (79, 80). Similarly, CCR5-deficient mice
314 infected with influenza virus have increased mortality rates (81), suggesting a complex role for
315 CCR5 in viral infection. Like in influenza virus infection, CCL5^{-/-} and CCR5^{-/-} had worse disease
316 outcomes than WT mice, which was associated with virus-induced apoptosis (82). Surprisingly,
317 CCL3 deficient mice were protected from lung inflammation compared to WT controls when
318 infected with influenza virus (83), suggesting a complex interplay between various chemokines
319 and their receptors during influenza virus infection. Finally, antibody depletion of CCL3 resulted
320 in worse disease outcomes and altered immune cell activation following respiratory syncytial
321 virus infection (84). Taken together, these data further underscore the complexity and
322 redundancy of mammalian chemokine signaling and highlight the importance of virus-specific
323 impacts for each ligand and/or receptor.

324

325 In summary, our study provides insights into the role of CCL4 and CCR5 in MAYV
326 pathogenesis. The results suggest that CCL4 nor CCR5 significantly alter disease outcomes, viral
327 replication, or immune cell populations. Therefore, CCL4 or CCR5-based therapeutics may not
328 be effective for arthritogenic alphavirus disease. However, given the redundancy of mammalian
329 chemokine signaling, future studies should explore the role of other chemokine receptors
330 individually or in conjunction with CCR5.

614

615 **Figure 1. CCL4 is upregulated in response to MAYV infection in C57BL/6J mice.**

616 C57BL/6J mice were inoculated with RPMI-1640 media (mock) or 10^4 PFU of MAYV strain
617 TRVL 4675 in both hind feet and monitored for disease development until 7 dpi (n=5 or 10).
618 CCL4 was measured by Luminex assay at 2 dpi (A) and ELISA at 7 dpi (B) and is presented in
619 picograms/mL of serum. Statistical analysis was done using an unpaired t-test with Welch's
620 correction. The error bars represent the standard deviation, bars indicate mean values, and
621 asterisks indicate statistical differences; **, $p < 0.01$; ***, $p < 0.001$.

622

623 **Figure 2. Antibody-mediated CCL4 depletion and administration of recombinant mouse**

624 **CCL4 cytokine failed to alter Mayaro disease severity.** C57BL/6J mice were intravenously
625 inoculated with IgG2a isotype or anti-mouse CCL4 mAb (20 μ g/mouse) at -1, 1, 3, and 5 dpi
626 (n=5). For CCL4 cytokine treatment, C57BL/6J mice were treated with PBS or recombinant
627 mouse CCL4 (400 ng/mouse) through the intraperitoneal route at -3, -1, 1, 3, and 5 dpi (n=5).
628 Mice were inoculated with 10^4 PFU of MAYV in both hind feet after the first dose of CCL4
629 antibody or the second dose of CCL4 cytokine and monitored for disease development until 7
630 dpi. A-C. Weight loss (A), footpad swelling (B), and the development of viremia (C) were
631 determined after CCL4 depletion in C57BL/6J mice. D-E. Weight loss (D), footpad swelling (E),
632 and virus replication (F) were measured after CCL4 cytokine treatment. Weight loss and footpad
633 swelling were analyzed using multiple unpaired t-tests with the Holm-Sidak method for multiple
634 comparisons, and viremia data was analyzed by unpaired t-test with Welch's correction. The
635 error bars represent the standard deviation, the solid line indicates mean values, and the dotted
636 line represents the limit of detection.

637

638 **Figure 3. CCR5 ligands are upregulated in response to MAYV infection, and CCR5**

639 **depletion showed minimal impacts on Mayaro disease.** A-B) WT mice were inoculated with
640 10^4 PFU of MAYV strain TRVL 4675 through injection of both hind footpads. Serum samples
641 were collected at 2 dpi to measure CCL3 (A) and CCL5 (B) by Luminex assay. Data are
642 presented as picograms per milliliter of serum; unpaired t-test with Welch's correction, ** $p <$
643 0.01 , **** $p < 0.0001$. C-E. WT and CCR5^{-/-} mice were inoculated with MAYV 10^4 PFU/feet in
644 both hind feet and monitored for disease development until 21 dpi. Weight loss (C), footpad

645 swelling (D), and virus titer (E) was measured. Weight loss and footpad swelling were analyzed
646 using multiple unpaired t-tests with the Holm-Sidak method for multiple comparisons, and
647 viremia data was analyzed by an unpaired t-test with Welch's correction. The error bars
648 represent the standard deviation, bars indicate mean values, and the dotted line represents the
649 limit of detection; (three experiments, n=13-14/group).

650

651 **Figure 4. CCR5 deletion showed reduced CD8 T cell populations in blood during peak**
652 **viremia.** WT and CCR5^{-/-} mice were inoculated with 10⁴ PFU of MAYV in both hind feet, and
653 blood was collected at peak viremia (2 dpi) to determine the immune cell population. A-E Plots
654 presenting the percentage of CD4 T cells (CD45⁺CD3⁺CD4⁺) (A), CD8 T cells
655 (CD45⁺CD3⁺CD4⁺) (B), neutrophils (CD45⁺Ly6G⁺) (C), inflammatory monocytes
656 (CD45⁺CD11b⁺Ly6C⁺) (D), and dendritic cells (CD45⁺CD11c⁺MHCII⁺) (E). Immune cell
657 percentage data was analyzed with an unpaired t-test with Welch's correction. The error bars
658 represent the standard deviation, bars indicate mean values, and asterisks indicate statistical
659 differences; **p < 0.001, two experiments, n=9/group.

660

661 **Figure 5. CCR5 deficiency showed no effect on immune cell populations in footpads during**
662 **peak footpad swelling.** WT and CCR5^{-/-} mice were inoculated with 10⁴ PFU of MAYV in both
663 hind feet, and footpads were collected at 6 dpi to assess immune cell populations. A-G Plots
664 presenting the percentage of CD4 T cells (CD45⁺CD3⁺CD4⁺) (A), CD8 T cells
665 (CD45⁺CD3⁺CD4⁺) (B), neutrophils (CD45⁺Ly6G⁺) (C), inflammatory monocytes
666 (CD45⁺CD11b⁺Ly6C⁺) (D), dendritic cells (CD45⁺CD11c⁺MHCII⁺) (E), macrophages
667 (CD45⁺CD11b⁺F4/80⁺) (F), and NK cells (CD45⁺NK1.1⁺) (G). Immune cell percentage data was
668 analyzed with an unpaired t-test with Welch's correction. The error bars represent the standard
669 deviation and bars indicate mean values; two experiments, n=9/group.
