Curing kinetics of phenolphthalein based polyphosphazene towards thermal stability and flame retardancy of polybenzoxazine†

Ling Zhao,^a Chunxia Zhao,^a ^{*,a} Min Wu,^a Yuntao Li,^{*,ab} Hui Li,^a Dong Xiang^a and Cuicui Guo^a

Phenolphthalein type polyphosphazene (PZPT) microspheres were synthesized by an ultrasound assisted precipitation polymerization method, and their structures were confirmed by scanning electron microscopy (SEM) and Fourier transform infrared (FTIR) spectroscopy. Benzoxazine/PZPT (Ba/PZPT) hybrid materials were fabricated and cured to prepare polybenzoxazine/PZPT (PBa/PZPT) composites. The effects of PZPT microspheres on the curing kinetics and behaviors of Ba were systematically analyzed and supported by differential scanning calorimetry (DSC) and *in situ* FTIR. The thermogravimetric (TGA) results demonstrated good thermal stability of the PBa composites incorporating PZPT. The peak of heat release rate and total heat release values of PBa/PZPT-5% composites obviously decreased by 57.8% and 17.3% compared to those of the pristine PBa. Moreover, the smoke released from the PZPT/PBa system significantly reduced with the loading of microspheres. Finally, the dynamical mechanical analysis results demonstrated that the T_g of PBa flame retardant composites was approximately 210 °C, not affecting further applications of PBa composites.

1. Introduction

Benzoxazine, as a novel type of phenolic resin, features a benzene ring comprising a nitrogen and heterocyclic six-membered oxazine ring.¹ Polybenzoxazine can be easily produced by the ring-opening polymerization of benzoxazine without the need for hardeners or a catalyst.² Therefore, polybenzoxazine is thought to be a promising candidate in aerospace, adhesives, electronics, and other fields,³ owing to its extraordinary properties such as (i) near-zero shrinkage during curing, (ii) a high glass transition temperature, (iii) excellent mechanical properties, (iv) low water absorption, (v) high charring yield, (vi) extremely good molecular design flexibility, and (vii) low dielectric properties.⁴

Nevertheless, bisphenol A type polybenzoxazine (PBa) also has some disadvantages such as high curing temperature (>200 °C) and the lower limited oxygen index (22), restricting their further development in industrial applications.⁵ Currently, more and more studies have been focused on decreasing the curing temperature of PBa. One approach is to incorporate the special functional groups such as carboxyl, hydroxyl, formyl,

phenolic hydroxyl, and cyanate ester into the benzoxazine monomer.⁶ Other approach involves the use of catalyst or initiators including Lewis acids, bifunctional catalysts, phosphonic acids and sulfonic acids, and basic compounds such as amines and imidazoles.⁷ These catalysts or initiators can effectively deteriorate the curing temperature regardless of the catalytic mechanism. Numerous reactions occur simultaneously during the curing process, making it a relatively complicated process.⁸ However, the performance of PBa to a large extent depends on the kinetics of the curing reaction, especially with respect to the degree of cure and curing conditions. Therefore, in order to make better use of the benzoxazine resin improving the performance of the resulting product, and wide applicability, it is necessary to understand the nature of the curing process, the structure of the cured material, and the change in its kinetic parameters.⁹

The phenolphthalein-containing polymers have been extensively studied for several years. For example, Yang *et al.* synthesized a pure benzoxazine (Boz-BP) using phenolphthalein as raw material through Mannich reaction. Due to forming an additional hydrogen bond between the carbonyl group and the hydroxyl group on the phenylhydrazine structure, Boz-BP-based polymer (P(Boz-BP)) have a higher glass transition temperature, better thermal stability, good dimensional stability and flame retardant properties.¹⁰ Zhao *et al.* reported that cyanate ester (CE) resins were simply modified through melt-blending with a phenolphthalein type polyarylether sulfone (cPES). The cPES/CE resins cPES/CE resins improved integrated performances

including impact strength, flexural properties, dielectric properties and thermal-stability compared with CE resin.¹¹

Phosphate–nitrogen flame retardants, as a highly efficient and environmentally friendly and newly flame retardant, are widely available alternative feedstock.¹² These are also called intumescent flame retardants.¹³ Hexachlorocyclotriphosphazene (HCCP) consists of alternating N and P atoms and is an environmentally friendly flame retardant material.^{12a,14} The chlorine element in its structure can be substituted and decomposed into small molecules with less environmental impact and has a higher nitrogen and phosphorus content, thus exhibiting better flame retardant properties.¹⁵ With increasing understanding of cyclophosphazene compounds, many new cyclophosphazene flame retardants have been developed to replace traditional halogens and other halogen-free flame retardants for thermoset and thermoplastic materials to meet their resistance for flammability, thermal performance, and other desired properties.¹⁶

The introduction of PZPT microspheres in the thermosetting resin benzoxazine resin will inevitably affect the curing behavior of benzoxazine resin and combustion properties. In this study, one type of polybenzoxazine with good flame retardant and lower curing temperature was prepared using PZPT microspheres in benzoxazine by melt blending. To investigate this reaction in detail, three types of PBa with different PZPT contents (PBa/PZPT-1%, PBa/PZPT-3%, and PBa/PZPT-5%) were explored, and the curing behavior, thermal stability, flame retardancy, and thermomechanical properties of obtained polybenzoxazine were investigated by different scanning calorimetry (DSC), *in situ* Fourier transform infrared (*in situ* FTIR) spectroscopy, thermogravimetric analysis (TGA), cone calorimeter test (CONE), and dynamic mechanical analysis (DMA).

2. Experimental

2.1 Materials

Phenolphthalein (PT) and HCCP was supplied from Chengdu Best Reagents Co., Ltd. (China). Bisphenol A-based benzoxazine (Ba) was provided by Sichuan Tiance Jucai Technology Co., Ltd. Acetonitrile, trimethylamine (TEA), ethanol, and acetone were purchased from Chengdu Kelong Chemical Reagent Factory (China).

2.2 Synthesis of PZPT

PZPT microspheres were prepared by ultrasound-assisted precipitation polymerization. First, 0.4 g (1.15 mmol) HCCP and 2.2 g (3.45 mmol) PT were dissolved in 100 mL acetonitrile in a 250 mL single-mouth flask. Then, the solution was ultrasonicated (250 W, 40 kHz) for 10 min, followed by adding 4 mL TEA. The flask was sealed immediately, and heated at 50 °C for 4 h, successfully affording white precise PZPT microspheres. Finally, the product was washed several times with ethanol, acetone, and deionized water. Scheme 1 shows the reaction route for the preparation of PZPT.

2.3 Preparation of PBa/PZPT composites

4 g PZPT and 76 g Ba were distributed in 40 mL acetone in three-necked flask under ultrasound at room temperature. Then, the acetone was removed by gradient heating in the range 60–120 °C under reduced pressure, affording pure Ba/PZPT product. Next, the mixture was poured into a glass mold with a release agent and preheated for curing at 180 °C/2 h, followed by 200 °C/2 h. The cured product was labeled as PBa/PZPT-5%. PBa, PBa/PZPT-1% and PBa/PZPT-3% were prepared by the similar process.

2.4 Characterization

The surface functional groups of the microspheres were investigated by FTIR using a Nicolet 6700 spectrometer (Thermo Electron Co., USA). TGA was carried out using a STA 6000 (PerkinElmer, USA) under a nitrogen atmosphere at a flow rate of 50 mL min⁻¹ and a heating rate of 20 °C min⁻¹ from 40 °C to 800 °C. The morphology and elemental analysis of the microspheres were carried out by scanning electron microscopy (SEM) using a ZEISS EVO MA15 SEM from Carl Zeiss Micro Image Co., Ltd. The non-isothermal DSC curing reaction of the Ba and Ba/PZPT mixture was monitored using a Q20 equipment (TA instruments) from 40 °C to 350 °C at different heating rates of 5, 10, 15, and 20 °C min⁻¹. *In situ* FTIR spectroscopy was conducted using a frontier PerkinElmer FTIR spectrometer, and spectra were recorded every 18 s from 100 to 250 °C at a heating rate of 2.5 °C min⁻¹. DMA was carried out using a Q800 analyzer (TA Instruments) from 40 to 300 °C at a heating rate of 5 °C per step and a frequency of 1 Hz in the air. In the three-point bending mode, samples with 40 × 10 × 3.2 mm³ dimension were used.

3. Results and discussion

3.1 Characterization of PZPT microspheres

The important structural features of PT, HCCP, and PZPT were observed by FTIR, as shown in Fig. 1. In the case PZPT, the stretching vibration peaks at 1607 and 1503 cm⁻¹ are attributed to the aromatic C=C group absorption of the phenol in the PT units. Moreover, the apparent peak in the range 3100–3000 cm⁻¹ is assigned to the C–H stretching vibration of PT. In addition, the absorption peak at 1250 cm⁻¹ correspond to the stretching vibration of the P=N of the cyclotriphosphazene skeleton in the HCCP structure. Importantly, the distinct absorption peak of P–O–Ar band was observed at 956 cm⁻¹. PZPT microspheres were obtained by the polycondensation reaction between HCCP and FT, retaining the main structural features of HCCP and FT.

3.2 Morphology of PZPT microspheres

Fig. 2 shows the SEM images of PZPT microspheres, providing the microstructural information. The SEM image shows that the PZPT microsphere distinctly exhibit a regular and uniform spherical shape. Moreover, the surface of PZPT microspheres is smooth and clean, with an average diameter of approximately 1

Scheme 1 The synthesis route of PZPT microspheres.

μm . The SEM results clearly demonstrate successful fabrication of PZPT microspheres.

3.3 Curing behavior of Ba and Ba/PZPT systems

3.3.1 Curing process. The non-isothermal DSC curves of Ba, Ba/PZPT-1%, Ba/PZPT-3%, and Ba/PZPT-5% at a heating rate of $5\text{ }^{\circ}\text{C min}^{-1}$ are shown in Fig. 3. The curing characteristic parameters including the initial curing temperature (T_i), curing peak temperature (T_p), and final curing temperature (T_f) are listed in Table S1.† Fig. 3 shows a single exothermic peak of the ring-opening thermal curing of the Ba and Ba/PZPT curing systems. With increasing diameter of the PZPT microspheres, the T_i , T_p , and T_f decreased, whereas the curing temperature range (ΔT) increased. When the addition of 5% PZPT microspheres, the T_i , T_p , and T_f decreased by 31, 21, and $6\text{ }^{\circ}\text{C}$, respectively, compared to those of pure Ba. The T_i and T_p show slight obvious changes that may be ascribed to the catalytic properties of PZPT microspheres. The presence of phenols and phosphazenes form Lewis acids and organic acids can effectively shorten the induction time of benzoxazine curing and accelerate the reaction rate.^{5b} The processability of the material is related to the practical application of the material. Usually, the extrapolation method is used, *i.e.*, T_i , T_p , and T_f is separately plotted against β at different heating rates of 5, 10, 15, and $20\text{ }^{\circ}\text{C min}^{-1}$, and the static curing temperature when $\beta = 0$ is obtained. The curing reaction parameters such as T_i , T_p , and T_f at different heating rates are shown Fig. S1† and Table 1. Finally, the curing process temperature is $200\text{ }^{\circ}\text{C}/2\text{ h}$, followed by $220\text{ }^{\circ}\text{C}/2\text{ h}$.

3.3.2 Curing kinetics. To further discuss the curing behavior and curing kinetics of Ba and Ba/PZPT mixture, the non-isothermal DSC curves of Ba, Ba/PZPT-1%, Ba/PZPT-3%, and Ba/PZPT-5% at different heating rates of 5, 10, 15 and $20\text{ }^{\circ}\text{C min}^{-1}$ are presented Fig. 4. With increasing heating rate, the T_p moved to a higher temperature range. For example, when the heating rate was increased to $20\text{ }^{\circ}\text{C min}^{-1}$, the T_p of the Ba, Ba/PZPT-1%, Ba/PZPT-3%, and Ba/PZPT-5% improved by 31, 29, 28, and $28\text{ }^{\circ}\text{C}$, respectively, compared to those at a heating rate of $5\text{ }^{\circ}\text{C min}^{-1}$. Due to the thermal hysteresis effect, enough time is required for completing the curing reaction at a higher

Fig. 1 FTIR spectra of HCCP, PT, and PZPT microspheres.

Fig. 2 SEM images of PZPT microspheres under different magnifications (a and b).

heating rate. Without assuming any model of kinetic parameters and integrating the exothermic peak, the Kissinger (eqn (1)) and Ozawa (eqn (2)) methods¹⁷ are often used for curing kinetics analysis to calculate the average activation energy of the exothermic reaction.

$$\ln \frac{\beta}{T_p^2} = -\frac{E_a}{RT_p} + \ln \left(\frac{AR}{E_a} \right) \quad (1)$$

$$\ln \beta = \ln \left(\frac{AE_a}{R} \right) - \ln F(\alpha) - 1.052 \frac{E_a}{RT_p} - 5.331 \quad (2)$$

where β is the heating rate, T_p is the peak temperature, A is the pre-exponential factor, E_a is the reaction activation energy, α is the conversion factor, $F(\alpha)$ is a constant function, and $R = 8.314 \text{ J mol}^{-1} \text{ K}^{-1}$ is the universal gas constant.

Fig. S2[†] shows the plots of the plot of $\ln \left(\frac{\beta}{T_p^2} \right)$ against $\frac{1}{T_p}$ for Ba and Ba/PZPT systems. The plot of $\ln \beta$ against $\frac{1}{T_p}$ for Ba and Ba/PZPT systems is shown in Fig. S3[†]. It is obvious that the

heating rates and the reciprocal of the peak temperature have a good linear relationship. According to the Kissinger and Ozawa method, the apparent activation energy and other kinetics parameters were calculated and are listed in Table 2. These results show that the average activation energies obtained from Kissinger are much higher than that of Ozawa methods, owing to different assumptions of the two methods. The Ozawa method considers that the degree of reaction conversion at the peak is constant, while the Kissinger method follows the assumption that the reaction rate is the highest at the peak temperature (T_p) of the reaction. Otherwise, with increasing number of PZPT microspheres, the average activation energy increases slightly. The E_a reflects the energy barriers that need to be overcome in the event of a chemical reaction. The highly crosslinked structure of PZPT microspheres limits the mobility of the Ba backbone and may attribute to a uniform cross-linking reaction between the PZPT microspheres and benzoxazine, requiring more energy to overcome higher energy barriers, thus increasing the activation energy of the curing reaction.¹⁸

Furthermore, the E_a values of Ba system can be easily obtained by Flynn–Wall–Ozawa method at the entire conversion range. The slope should correspond to E_a/R at the particular conversion according to eqn (3) and (4).

$$\ln \beta = \ln \left(\frac{AE_a}{R} \right) - \ln g(\alpha) - 1.052 \frac{E_a}{RT_p} - 5.331 \quad (3)$$

$$g(\alpha) = \int_0^\alpha \frac{d\alpha}{f(\alpha)} \quad (4)$$

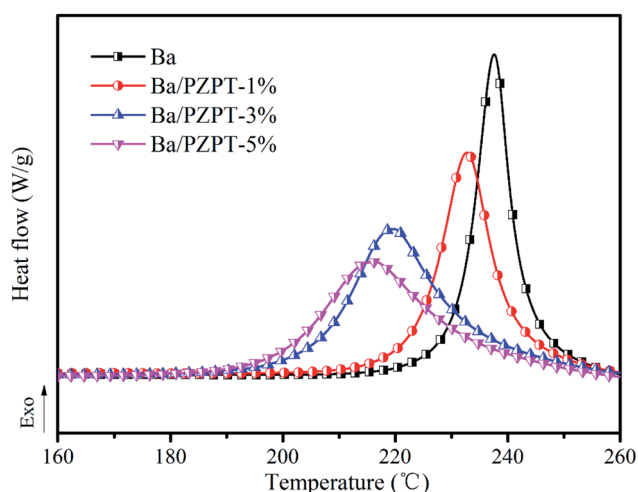

Fig. 3 DSC curves of the Ba and Ba/PZPT systems at a heating rate of 5°C min^{-1} .

Table 1 Curing characteristic parameters of Ba and Ba/PZPT systems at a heating rate of 0°C min^{-1}

Samples	T_{i0} ($^\circ\text{C}$)	T_{p0} ($^\circ\text{C}$)	T_{f0} ($^\circ\text{C}$)
Ba	224	229	235
Ba/PZPT-1%	213	223	234
Ba/PZPT-3%	198	213	229
Ba/PZPT-5%	193	208	228

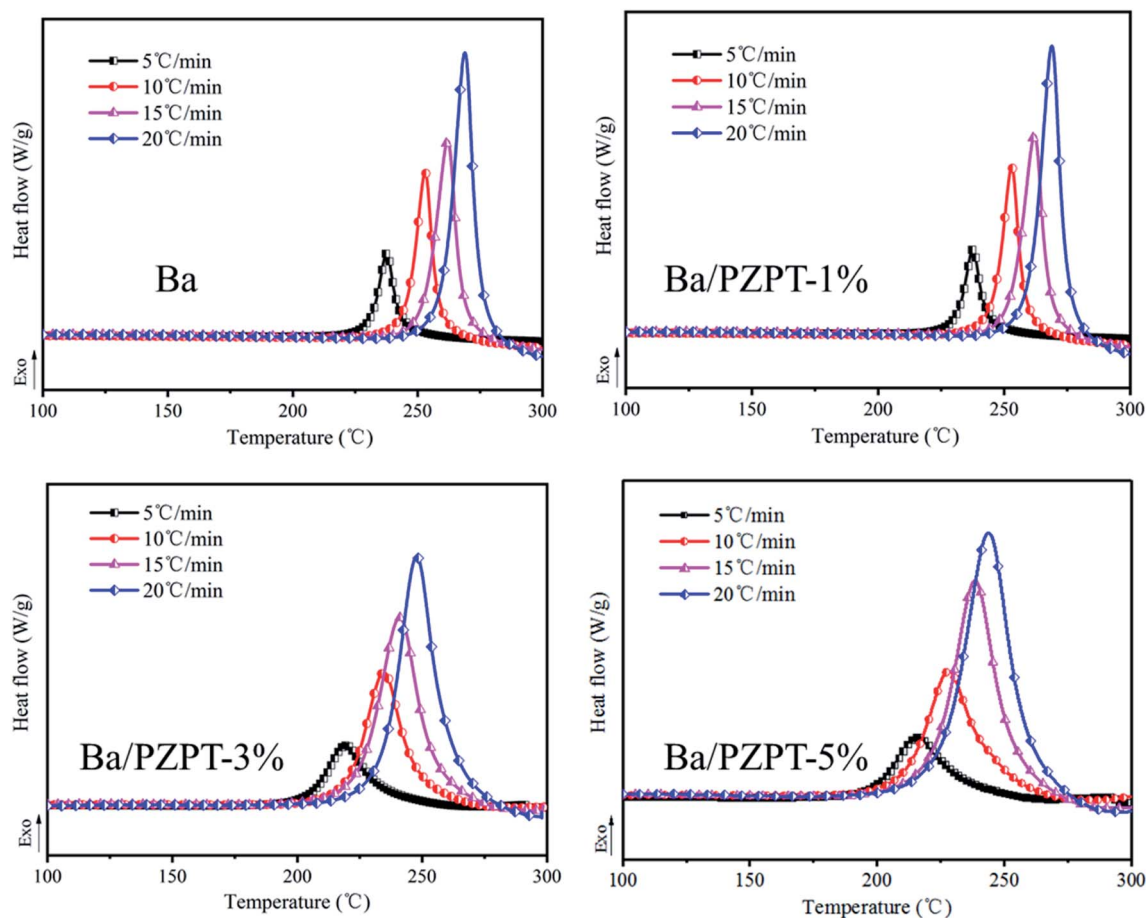

Fig. 4 Non-isothermal DSC curves of Ba, Ba/PZPT-1%, Ba/PZPT-3%, and Ba/PZPT-5%.

where $g(\alpha)$ is the integral conversion function, T is the absolute temperature, and $f(\alpha)$ is the differential conversion function.

The E_a values of Ba and Ba/PZPT system are shown in Fig. 5, calculated for different reaction degree (α) ranging from 0.2 to 0.8. Increasing α value, the E_a gradually increased that indicates the polymerization process needs more energy to achieve. At the same time, the E_a values also increased with incorporating of PZPT. It is the reason that adding PZPT to Ba resin reduces the molecular mobility and decrease in active site.

Before establishing a kinetic model, judging the type of curing mechanism is necessary. In general, the curing mechanism of thermosetting resins is divided into two categories: an

n^{th} -order and an autocatalytic reaction model, which can be judged by the Friedman method (eqn (5) and (6)).¹⁹

$$\ln \frac{d\alpha}{dt} = \ln \beta \frac{d\alpha}{dT} = \ln[Af(\alpha)] - \frac{E_a}{RT} \quad (5)$$

Fig. 5 E_a values of Ba system obtained by Flynn–Wall–Ozawa method.

Table 2 E_a and pre-exponential factor of the Ba and Ba/PZPT system

Samples	E_a (kJ mol ⁻¹)		Average E_a (kJ mol ⁻¹)	ln A
	Kissinger	Ozawa		
Ba	94.6	98.2	96.4	13.83
Ba/PZPT-1%	96.2	101.3	98.8	14.64
Ba/PZPT-3%	98.7	101.9	100.3	15.76
Ba/PZPT-5%	99.6	102.0	100.8	15.95

$$f(\alpha) = (1 - \alpha)^n \quad (6)$$

Eqn (5) is calculated by eqn (3) and (4) as:

$$\ln[Af(\alpha)] = \ln \beta \frac{d\alpha}{dT} + \frac{E_a}{RT} = \ln A + n \ln(1 - \alpha) \quad (7)$$

Fig. 6 shows the relationship between the plots of $\ln[Af(\alpha)]$ and $\ln(1 - \alpha)$. The values of $\ln[Af(\alpha)]$ can be calculated by eqn (5) using the average activation energy from the Kissinger and Ozawa method. According to Jubsilp *et al.*,²⁰ for n^{th} order curing mechanism, the relationship between the $\ln[Af(\alpha)]$ against $\ln(1 - \alpha)$ should yield a straight line with a slope. However, the plot would show a maximum of $\ln(1 - \alpha)$ approximately 0.51 to 0.22, equivalent to an α approximately in the range 0.2–0.4, indicating an autocatalytic process. In other words, the curing mechanism of Ba and Ba/PZPT systems follows an autocatalytic reaction model. Generally, the autocatalytic nature of Ba curing kinetics is that phenolic groups generated from the benzoxazine ring opening can actually further accelerate the ring opening process.^{19a} Fig. 6 shows that the Friedman curves are in good agreement with the literature data, showing the maximum reaction rate at 20–40% conversion.²¹

3.4 Curing behavior of Ba and Ba/PZPT systems

The polymerization behaviors of Ba and Ba/PZPT oligomers were also confirmed by *in situ* FTIR analyses in order to further investigate the changes in the internal chemical bonds of oligomers. Fig. 7 and 8 show the FTIR spectra of pure Ba and Ba/PZPT-3% at a heating rate of 5°C min^{-1} , respectively, in the temperature range from 160°C to 250°C at different temperatures. Fig. 7 shows the characteristic bands at 945 cm^{-1} , attributed to the stretching vibration of the oxazine ring, and the intensity of these bands gradually decreases at temperatures

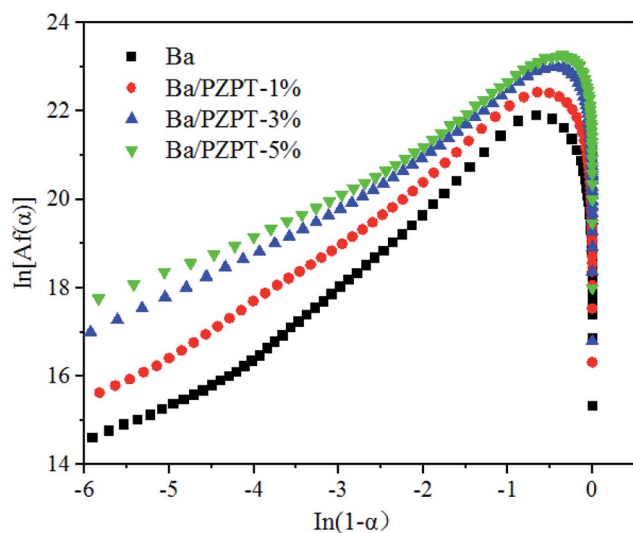

Fig. 6 Plots of $\ln[Af(\alpha)]$ and $\ln(1 - \alpha)$ of the Ba and Ba/PZPT systems at a heating rate of 5°C min^{-1} by the average activation energy from Flynn–Wall–Ozawa method.

Fig. 7 *In situ* FTIR spectra of pure Ba at different temperatures.

more than 230°C . Besides, the same phenomenon was observed for the band at 1230 and 1030 cm^{-1} , attributed to the asymmetric and symmetric stretching vibration of the C–O–C bonds in the oxazine group, respectively, clearly indicating the ring-opening polymerization of the oxazine ring.²² However, the intensity of the peak at approximately 1121 cm^{-1} attributed to the Ar–C–Ar stretching vibration increased slightly at $>230^\circ\text{C}$, suggesting the formation of more cross-linked structures during the curing process of Ba.¹⁸

With the addition of PZPT microspheres, the change in the main functional group of Ba shifts to low temperature as shown in Fig. 8. The intensity of the related absorption speaks at 945 , 1030 , and 1230 cm^{-1} begins to decrease at 210°C , and the peaks disappeared at 250°C . This phenomenon is consistent with the aforementioned DSC test results. Thus, the hydroxyl and Lewis

Fig. 8 *In situ* FTIR spectra of Ba/PZPT-3% composites at different temperatures.

Scheme 2 The thermally catalyzed reaction mechanism of the benzoxazine curing process.

acid of PZPT catalyzes the ring-opening polymerization of Ba monomers, thus decreasing the curing temperature. Based on the previous reports, the Lewis acid providing protons by microspheres can initiate the acid catalyzed ring-opening polymerization of benzoxazine, generating the cross-linked network of polybenzoxazine by further reaction with Ba monomers. Moreover, at 210 °C, the intensity of the characteristic absorption band of Ar–C–Ar at 1121 cm^{-1} gradually increases due to the formation of the cross-linking groups at higher temperatures. Otherwise, this reaction can increase the molecular weight of the polymer, illustrating the better thermal property of Ba/PZPT system. Scheme 3 shows the reaction mechanism of the Ba/PZPT system curing process.

Schemes 2 and 3 show the reaction mechanism of the Ba and Ba/PZPT system curing process, respectively. The specific pathway for the thermal ring opening of pure benzoxazine is presumed to undergo the following steps: first, the O–C bond in the Ar–O–CH₂ structure in the oxazine ring of benzoxazine is cleaved at high temperature to form a carbocation active center (C⁺) and oxygen anion (O⁻). Next, the O⁻ takes away the larger electrophilic *ortho*-position H on the other oxazine ring to form a phenolic hydroxyl group, and the N⁺CH combines at the *ortho*-position of the ring in another oxazine ring to form a Mannich bridge. At the same time, another cationic active center is generated, and the polymer chain continuously grows

until a three-dimensional network structure is formed. However, the curing of benzoxazine is characterized by the acid-catalyzed curing behavior after the addition of microspheres. At a certain heating rate, when the temperature reaches the catalytic curing temperature, first the benzoxazine monomer undergoes ring opening under phosphate catalysis, and the resulting phenolic hydroxyl group further catalyzes the curing reaction of benzoxazine.

3.5 Thermal stability

Taking into account the effect of curing temperature, 3 and 5 wt% of PZPT microspheres were selected for further study for the performance analysis. The thermal properties of PZPT, PBa and PBa/PZPT composites were tested by TGA, and the TG and DTG curves are shown in Fig. 9. Table 3 shows the temperature at 5 wt% mass loss, the temperature at the maximum mass loss rate of materials, and the weight percentage of residue at 800 °C, defined by the onset degradation temperature (T_{onset}), the maximum degradation temperature (T_{max}), and the weight residue rate (Y_c), respectively. Noticeably, with increasing of the temperature, PZPT microspheres exhibits a lower weight loss at temperatures up to 800 °C, indicating that the PZPT microspheres have high thermal stability. The pure PBa displays only one-phase weight loss in the nitrogen atmosphere with the T_{onset} of approximately 337.6 °C, followed by the Y_c of 31.8%, as

Scheme 3 The acid catalyzed reaction mechanism of the benzoxazine curing process.

Fig. 9 TGA (a) and DTG (b) curves of PZPT, pure PBa and its composites in a nitrogen atmosphere.

shown by Fig. 9(a). After the incorporation of 5 wt% PBa/PZPT, the T_{onset} of the composites slightly reduced compared to that of the pure PBa, and the Y_c increased to approximately 39.3%, showing a slightly better thermal stability. This observation is likely to be attributed to the fact that a protective barrier provided by PZPT microspheres forming cross linking network can prohibit the mass and heat transfer between the air and internal matrix to an extreme extent. However, the composites demonstrate two-phase weight loss at 334.8 and 426.3 °C as shown in Fig. 9(b), owing to the fact that the Lewis acids and organic acids generated by microspheres can effectively catalyze the dissociation of the weak bond ($-\text{CH}_2-\text{N}(\text{R})-$) in the PBa matrix, according to the degradation in the first stage. The weight loss at the higher temperature stage is attributed to the further decomposition of PZPT.

3.6 Flame retardancy of PBa/PZPT composites

PZPT microspheres is considered to have flame retardant properties attributing to the presence of phosphorus and nitrogen elements. Thus, the incorporation of microspheres into PBa resin is an effective technique for improving its fire retardant properties, and this can be confirmed by the cone calorimeter analysis. The heat release rate (HRR), total heat release (THR), carbon monoxide production (COP), and total smoke release (TSR) *versus* time curves of PBa and PBa/PZPT composites are shown in Fig. 10. The heat release rate (PHRR) peak value for pure PBa is 593 kW m⁻² as shown in Fig. 10(a). Increasing to 5 wt% PZPT, the PHRR obviously decreased by 57.8%. In addition, the THR value of 5 wt% PBa/PZPT decreased to 17.3% compared to that of the pristine PBa. The decrease in the PHRR and HRR indicates the good flame retardancy among the rest of the PBa composites. This phenomenon may be related to the physical barrier effect of PZPT microspheres that is the carbonization behavior, which inhibits the heat and mass transfer between gas and material interior. Fig. 10(c) shows that due to multi-aromatic structure, pure PBa present a higher COP and TSR values. The COP and TSR value slightly decreased with the addition of microspheres from 0.015 g s⁻¹ for pure PBa to

0.007 g s⁻¹ for PBa/PZPT-5% with a decrease of 53.3%, indicating good resistance from the toxic gases and smog production after adding microspheres.^{12a}

The digital images of the cone calorimeter test of the char residues of PBa and PBa/PZPT-5% was shown in Fig. 11. The height of the residual carbon of PBa/PZPT-5% is more than that of pure PBa. Fig. 11(c and d) shows that a compact and continuous char layer is formed after the combustion of PBa/PZPT-5%, dehydrating the charcoal while expanding to liberate the gas upon exposure to heat or flame. Under the action of gas, a carbon layer structure enclosed by a fluffy hair hole is formed. The carbon layer is non-combustible and acts as a barrier to heat, air, and hydrolysis products. When the amount of oxygen and heat in the environment is not enough, the combustion of the polymer is difficult to proceed, leading to self-extinguishment.

3.7 Dynamic mechanical properties

The $\tan \delta$ and storage modulus of pure PBa and PBa/PZPT composites were tested by DMA analysis, as shown in Fig. 12 and 13, respectively. The peak of $\tan \delta$ slightly shifts to the lower temperature, as shown in Fig. 12. With increasing loading to 5 wt% PZPT microspheres, the transition temperature (T_g) decreases to approximately 5 °C. The decrease in T_g is ascribed to the fact that PBa composites hinder the efficiency of ring-opening crosslinking of the curing process of the Ba monomers, thus decreasing the PBa crosslink density.^{2b}

Fig. 13 shows the storage modulus of PBa/PZPT-3% and pure PBa, and both the curves are basically the same with no

Table 3 Thermogravimetric analysis results of PBa and PBa/PZPT-5%

Samples	T_{onset} (°C)	T_{max} (°C)		Y_c (%)
PBa	337.6	397.0		31.8
PBa/PZPT-3%	321.8	337.8	418.7	37.4
PBa/PZPT-5%	321.0	334.8	436.3	39.3

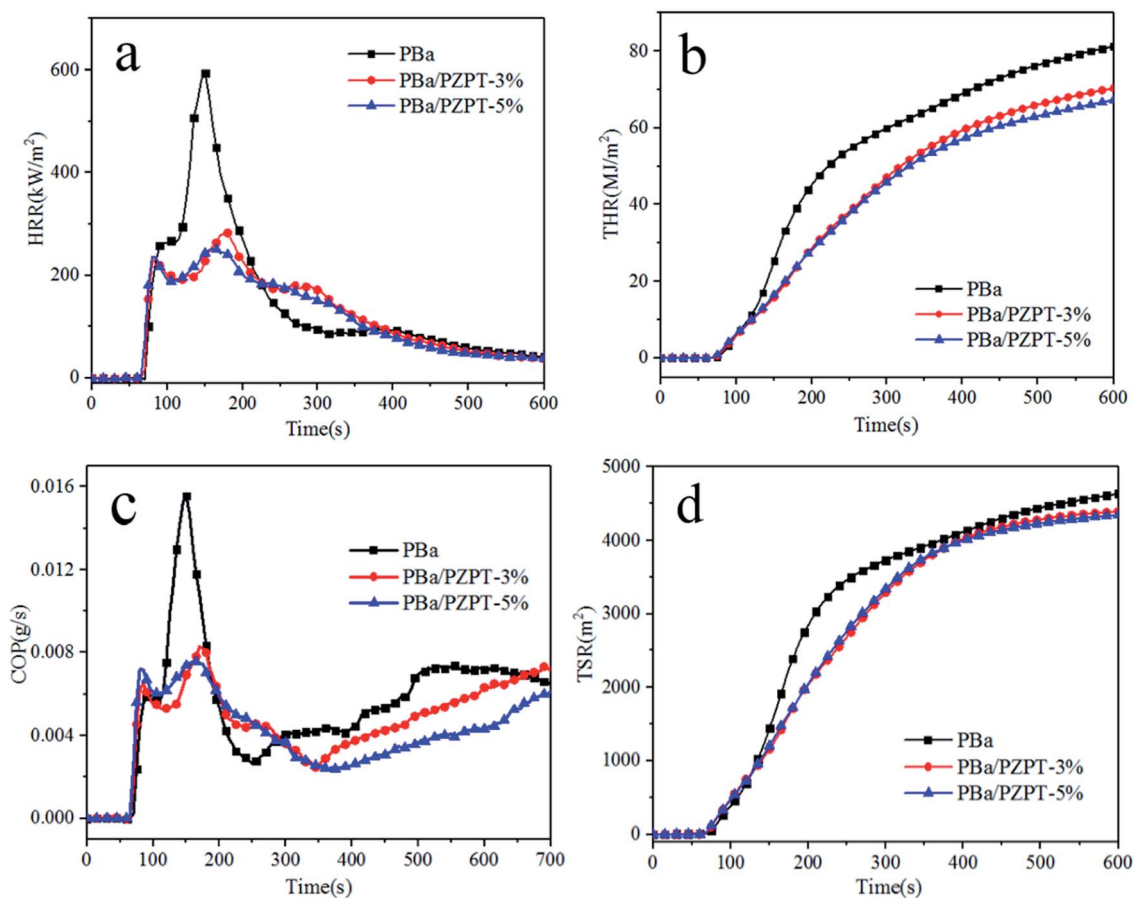

Fig. 10 HRR (a), THR (b), COP (c), and TSR (d) versus time curves of PBa and PBa/PZPT composites obtained from the cone calorimetry test.

significant change. In the presence of 5 wt% PZPT, the E value increases significantly. However, the E value is lower than that of PBa until temperature rises to approximately 200 °C, and this is attributed to the fact that the addition of highly crosslinked rigid microspheres increases the rigidity of the polymer system,

exhibiting a high modulus of storage. When the temperature rises, the storage modulus of the system was decreased due to high-temperature-induced softening of the polymer chains, indicating the transformation from the glassy to the rubbery state.

4. Conclusions

In conclusion, PZPT microspheres were successfully synthesized *via* the ultrasonic assisted condensation polymerization, followed by the melt bending incorporating the benzoxazine resin. The effects of PZPT microspheres on the curing kinetics and behaviors of Ba were systematically analyzed by DSC and *in situ* FTIR analyses. The T_i , T_p , and T_f of Ba/PZPT-5% reduced to 31, 21, and 6 °C, respectively, compared to those of the pure Ba, as evidenced by the non-isothermal DSC results. Ba and Ba/PZPT are the autocatalytic curing models based on the Friedman calculation method; however, the catalytic ring opening mechanisms of Ba and Ba/PZPT systems are obviously different as Ba is thermally catalyzed whereas Ba/PZPT systems is acid catalyzed. The TGA, CONE, and DMA analyses revealed the thermal stability, flame retardancy, and thermomechanical properties of the PBa and PBa/PZPT composites. The TGA results demonstrated that the PBa residue at 800 °C increased with the incorporation of PZPT, indicating a better char formation process. The PHRR and THR values of PBa/PZPT-5% composites obviously decreased by 57.8% and 17.3% compared to those of the pristine PBa. Moreover, the smoke released from the PZPT/PBa system significantly reduced with the loading of microspheres. The DMA results demonstrated the T_g of PBa flame retardant composites around 210 °C, suggesting many potential applications of the synthesized PBa composites.
