**Introduction:** The potential of layered double hydroxide (LDH) as a host of multiple ultraviolet-ray absorbers was investigated by simultaneous intercalation of benzophenone 4 (B4) and Eusolex<sup>®</sup> 232 (EUS) in Zn/Al LDH.

**Methods:** The nanocomposites were prepared via coprecipitation method at various molar ratios of B4 and EUS.

**Results:** At equal molar ratios, the obtained nanocomposite showed an intercalation selectivity that is preferential to EUS. However, the selectivity ratio of intercalated anions was shown to be capable of being altered by adjusting the molar ratio of intended guests during synthesis. Dual-guest nanocomposite synthesized with B4:EUS molar ratio 3:1 (ZEB [3:1]) showed an intercalation selectivity ratio of B4:EUS = 53:47. Properties of ZEB (3:1) were monitored using powder X-ray diffractometer to show a basal spacing of 21.8 Å. Direct-injection mass spectra, Fourier transform infrared spectra, and ultraviolet–visible spectra confirmed the dual intercalation of both anions into the interlayer regions of dual-guest nanocomposite. The cytotoxicity study of dual-guest nanocomposite ZEB (3:1) on human dermal fibroblast cells showed no significant toxicity until 25 µg/mL.

**Conclusion:** Overall, the findings demonstrate successful customization of ultraviolet-ray absorbers composition in LDH host.

**Keywords:** biocompatibility, cell viability, dermis, layered double hydroxide, nanocomposite

## Introduction

Layered double hydroxides (LDHs) can be represented by the general formula  $[M^{II}_{1-x}M^{III}_x(OH)_2]^{z+}A^{n-}_{z/n} \cdot yH_2O$  where  $A^{n-}$  is the interlayer anion, and  $M^{II}$  and  $M^{III}$  are di- and trivalent metallic cation, respectively.<sup>1</sup> LDH consists of a structure with positively charged layers that are electrically balanced by interlayer anions. The interlayer anion can be exchanged with a variety of inorganic and organic anions. Thus, the interlayer region of the layered material can be considered as a nanovessel in which anionic molecule can be stored.

Application of the layered material as a nanometer-sized host has garnered considerable attention due to its good biocompatibility, low cytotoxicity, ease of laboratory preparation, and ease of tailoring for required physical and chemical properties.<sup>1–5</sup> Simultaneous intercalation of two or more anions into the interlayer region of LDH was previously attempted with amino acids,<sup>6</sup> ligand and ligation activator,<sup>7</sup> diagnosis and therapy agents,<sup>8–10</sup> herbicides,<sup>11–13</sup> polymers,<sup>14</sup> nucleoside monophosphates,<sup>15</sup> and isomeric benzoates.<sup>16</sup> There is a notable paucity of scientific literature investigating interlayer region intercalation of two or more ultraviolet (UV) ray absorbers.

Eusolex<sup>®</sup> 232 (2-phenylbenzimidazole-5-sulfonic acid or EUS) is often found in sunscreen formulations due to its intense absorption at UVB wavelengths. In the past, major concerns were expressed on the usage EUS as studies on photophysical and photochemical characteristic of EUS have demonstrated the capacity of EUS to generate reactive oxygen species, including singlet oxygen, upon photoexcitation. In the cellular context, the findings suggest that the photodegraded product of EUS could possibly damage DNA, as well as proteins and lipids, through a photosensitizing mechanism.<sup>17,18</sup> Another UV ray absorbent, benzophenone 4 (2-hydroxy-4-methoxybenzophenone-5-sulfonic acid or B4) is often used as active ingredient in sunscreens as it provides shielding in a broad UV spectrum and also prevents other compounds from degrading. However, recent studies have found that benzophenones are relatively easy to be absorbed into the skin and have been shown to promote generation of reactive oxygen species and display harmful properties.<sup>19-21</sup>

In our previous work, we have prepared Zn/Al-LDH intercalated with B4 and EUS separately. The resulting nanocomposites have shown an increase in UV ray absorption capability compared to their bulk counterparts. Additionally, simulation under skin pH medium demonstrated low release of the intercalated UV ray absorbents over an extended period of time.<sup>22</sup> In the present work, we propose simultaneous intercalation of B4 and EUS into Zn/Al-LDH via coprecipitation method. The expected advantages of encapsulating organic UV ray absorbents within the interlayer region of LDHs are 1) increased photostability, 2) decreased release from formulation to skin, and 3) absence of direct contact with skin while maintaining UV ray absorption properties of anionic guest. Cointercalation by two anionic guests is expected to exhibit selective intercalation that is influenced by guest–host interaction. Our work aims to examine factors that influence the selectivity, as well as determine whether the selectivity could be altered. The present study will help elucidate the effect of intercalation of more than one organic sunscreen molecules in LDH on the resulting thermal property, surface property, controlled release property, and UV ray absorptivity of the resulting nanocomposites.

## Materials and methods

### Materials

B4 (99.0%) was purchased from Norquay Technologies (Chester, PA, USA). Zinc nitrate hexahydrate (99.0%) and aluminum nitrate nanohydrate (99.0%) were obtained from PC Laboratory Chemicals (Mumbai, India) and used without further purification. EUS (99.0%) and sodium hydroxide (99.0%) from Merck (Darmstadt, Germany), dimethyl sulfoxide (DMSO) and phosphate buffer solution from

Sigma-Aldrich (St Louis, MO, USA) and sodium chloride (99.0%) from HmbG Chemicals (Hamburg, Germany) were also used without further purifications.

### Synthesis of Zn/Al-NO<sub>3</sub> LDH

Zn/Al-NO<sub>3</sub> LDH with Zn to Al molar ratio, *R*=2 was prepared as follows. A 250 mL mixture containing 0.1 mol/L Zn(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O and 0.05 mol/L Al(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O was precipitated with 0.5 mol/L NaOH solution under nitrogen atmosphere until the final pH of 7 was reached. The resulting white slurry was aged in an oil bath shaker at 70°C for 18 h. The resulting precipitate was retrieved via centrifugation, rinsed with deionized water several times, and dried in an oven at 70°C for 3 days. The dried LDH was powdered using a mortar and pestle.

### Synthesis of dual-guest Zn/Al-LDH nanocomposite

Dual-guest Zn/Al-LDH nanocomposite was prepared by mixing 100 mL of EUS and B4 mixture solutions into 100 mL of 0.1 mol/L Zn(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O and 0.05 mol/L Al(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O under nitrogen atmosphere and vigorous stirring. The B4 and EUS mixture was prepared by keeping the concentration of B4 constant at 0.1 mol/L while varying the concentration of EUS at 0.1, 0.05, 0.033, and 0.025 mol/L to obtain B4 to EUS molar ratios of 1:1, 2:1, 3:1, and 4:1, respectively. The final pH of the solution was controlled to 8 by dropwise addition of 0.5 mol/L NaOH solution. The resulting light yellow slurry was placed in an oil bath shaker at 70°C for 18 h, before being centrifuged and rinsed with deionized water. The final light yellow solid (dual-guest nanocomposite samples) was dried in an oven at 70°C overnight and powdered using a mortar and pestle.

### Characterization

Powder X-ray diffraction (PXRD) patterns were recorded using an XRD-6000 (Shimadzu, Kyoto, Japan) using CuK<sub>α</sub> radiation ( $\lambda = 1.5418 \text{ \AA}$ ). Fourier transform infrared (FTIR) spectra were recorded over the range of 400–4,000 cm<sup>-1</sup> on a 1752X spectrophotometer (Perkin-Elmer, Waltham, MA, USA). Samples in solid state were measured in KBr matrix pellet obtained with a hydraulic press under 10 kPa pressure for 5 minutes. The carbon, hydrogen, and nitrogen contents in the nanocomposites were analyzed on a CHNS-932 (LECO Instruments, St Joseph, MI, USA). The metal contents of the nanocomposites were determined by inductively coupled plasma atomic emission spectrometry (ICP-AES) using a Perkin-Elmer spectrophotometer model Optima 2000DV (Perkin-Elmer) under standard conditions. Thermogravimetric and differential thermogravimetric analyses (TGA/DTG) were performed on a

Mettler-Toledo instrument model TGA851e (Mettler-Toledo, Greifensee, Switzerland) at a heating rate of 10°C/min in the range of 25°C–1,000°C. Surface characterization of the materials was carried out using a nitrogen gas adsorption–desorption technique at 77 K using Micromeritics, ASAP2000 (Micromeritics Instrument Corporation, Norcross, GA, USA). The surface morphology of the samples was observed by a field emission scanning electron microscopy (FESEM) using a ZEISS supra 40VP (Carl Zeiss, Oberkochen, German), and optical measurements were performed on a Shimadzu UV-visible (VIS)-near infrared (NIR) diffuse reflectance spectrometer (UV-3600 model). Direct-injection mass spectroscopy (DIMS) was performed using a Shimadzu DIMS QP5050A.

### Simultaneous release of B4 and EUS from LDH nanocomposites

Simultaneous release of B4 and EUS anions from LDH host against time was measured in situ at  $\lambda_{\text{max}} = 285$  and 311 nm for B4 and EUS, respectively, using a Perkin-Elmer UV-VIS spectrometer Lambda 35 (Perkin-Elmer) by adding 0.2 mg of sample into 3.5 mL of 0.5 mol/L NaCl and pH 5.5 phosphate buffer solution at room temperature. Data were collected and fit into zero-, first-, pseudo-second order, and parabolic diffusion kinetic models.

### Culture of human dermal fibroblasts

Human dermal fibroblasts (HDFs) were obtained from American Type Culture Collection (ATCC), (Manassas, VA, USA) and cultured at 37°C in a humidified atmosphere of 5% CO<sub>2</sub> with high glucose Dulbecco's Modified Eagle's Medium (ScienCellResearch Laboratories, Carlsbad, CA, USA) containing 2% fetal bovine serum, 0.5% penicillin–streptomycin, 1% glutamine, and 1% nonessential amino acids. For the experiment, we used a seeding density of  $1 \times 10^5$  cells/well plated onto 96-well plates.

### Cell viability assay

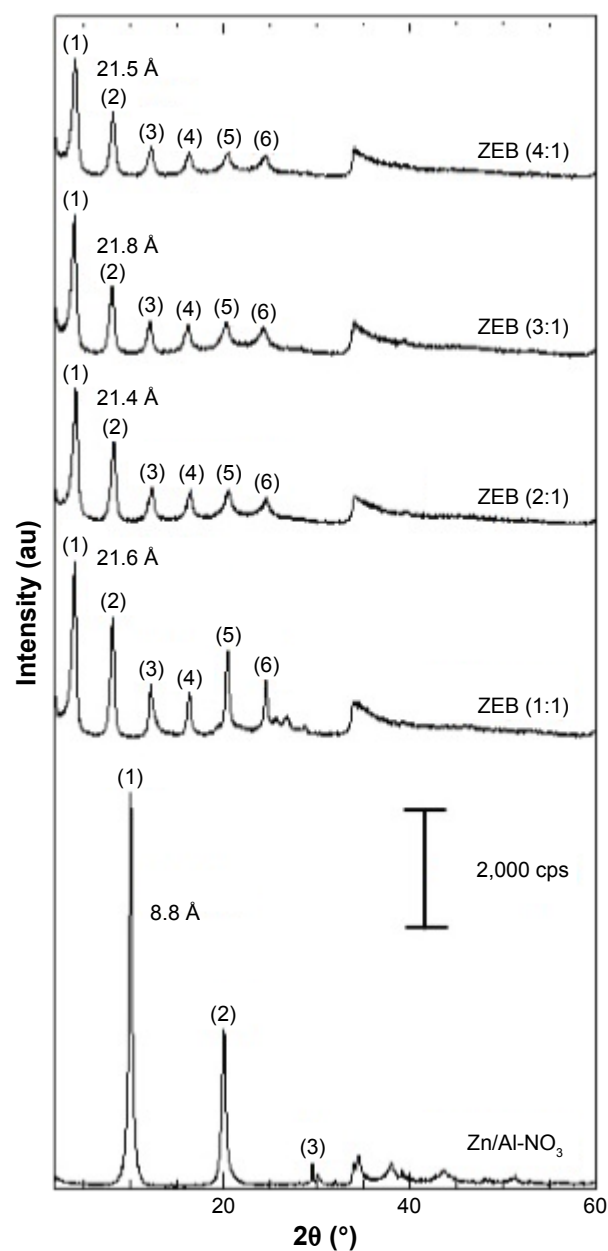

The cell cytotoxicity was determined by MTT colorimetric method.<sup>23</sup> In brief, cells were cultured in 96-well plates at a density of  $1 \times 10^5$  cells/well for cytotoxicity assessment study. After being incubated for 24 h, the cells were treated to various concentrations of test compounds including synthesized nanocomposites and incubated for 24 h. After the specific incubation period, freshly prepared tetrazolium dye (MTT; Sigma-Aldrich Co., St Louis, MO, USA) was added and then converted to purple formazan. The formazan product was dissolved with 100  $\mu$ L of DMSO which was added to each well. Finally, the formazan concentration from the 96-well plates was measured at 570 nm using an

enzyme-linked immunosorbent assay microplate reader. Cell viability was calculated as a ratio of various test compounds exposed cells to control cells.

## Results and discussion

### X-ray diffraction and spatial orientation of the guest between LDH interlayers

The PXRD pattern and average basal spacing of pristine Zn/Al-NO<sub>3</sub>-LDH as well as dual-guest nanocomposite samples are shown in Figure 1. Average basal spacing of Zn/Al-NO<sub>3</sub>

**Figure 1** PXRD patterns of Zn/Al-NO<sub>3</sub> and dual-guest nanocomposites prepared at various B4:EUS molar ratios.

and ZEB (3:1) nanocomposite based on 2 and 6 harmonics are summarized in Table 1

Factors such as anionic size, charge, orientation, and interaction with the positively charged inorganic interlayer affect the degree of intercalation and the separation between layers. Zn/Al-NO<sub>3</sub>-LDH showed basal spacing of 8.8 Å, a typical basal spacing shown by Zn/Al-NO<sub>3</sub>-LDH with nitrates as the counter anion.<sup>24</sup> Increment in basal spacing in UV absorber/LDH nanocomposites is due to displacement of nitrates with larger organic UV absorbing molecules. In the case of dual-guest nanocomposite samples, little difference in average basal spacing could be detected by varying the molar ratios of B4 to EUS.

Estimated dimensions of B4 and EUS anions were obtained using ChemBioOffice software (Perkin-Elmer),

as shown in Figure 2A and B. The anion geometry was optimized by applying molecular mechanical MM2 energy minimization calculation available in the software. Expected gallery height that can be occupied can be deduced by subtracting the layer thickness of 4.8 Å from basal spacing obtained from PXRD analysis. A new monophasic dual-guest nanocomposite was obtained with slightly larger basal spacing from values reported for single-guest intercalation of B4 (21.3 Å) and EUS (21.0 Å).<sup>22</sup> We could attribute this to the interaction of larger molecular size of EUS with B4. We foresee bilayer arrangement by alternating charge-balancing SO<sub>3</sub><sup>-</sup> groups above and below the layer with maximized π-π interaction between the benzene rings.<sup>25</sup> To form a bilayer arrangement, the most plausible orientation (Figure 2C) with maximized π-π interaction between molecules of different sizes would naturally have less compatibility than that of the same molecules. Thus, the slight increment in basal spacing compared to that of single-guest nanocomposites is expected.

## Elemental analyses

The empirical formula of Zn/Al-LDH nanocomposites listed in Table 1, was determined from ICP-AES and TGA/DTG analyses. Chemical compositions of B4, EUS, Zn/Al-NO<sub>3</sub>, and dual-guest nanocomposites are listed in Table 2.

**Figure 2** Molecular structure of and three-dimensional molecular size of B4 (A) and EUS (B) and proposed orientation of B4 and EUS in Zn/Al-LDH interlayer for the formation of dual-guest nanocomposite ZEB (3:1) (C).

**Abbreviations:** B4, benzophenone 4; EUS, Eusolex® 232; LDH, layered double hydroxide; ZEB (3:1), dual-guest nanocomposite synthesized with B4:EUS molar ratio 3:1.

**Table 2** Chemical compositions of B4, EUS, Zn/Al-NO<sub>3</sub>, ZB4, ZEUS, and dual-guest nanocomposites

Sample	C (%)	H (%)	N (%)	S (%)	Zn (%w/w) <sup>a</sup>	Al (%w/w) <sup>a</sup>	Zn <sup>2+</sup> /Al <sup>3+</sup> <sup>a</sup>	x
B4	47.5	5.2	0	10.0	0	0	0	0
EUS	54.8	3.1	17.0	9.7	0	0	0	0
Zn/Al-NO <sub>3</sub>	0.3	2.3	13.9	0.4	35.2	7.0	2.1	0.33

ZEB (2:1)	20.6	3.7	1.1	4.6	24.1	4.5	2.2	0.31
ZEB (3:1)	20.3	3.4	0.4	8.3	24.8	4.6	2.2	0.31
ZEB (4:1)	18.2	3.9	0.2	6.2	23.8	4.5	2.2	0.31

**Note:** <sup>a</sup>Estimated from ICP-AES analysis.

**Abbreviations:** ICP-AES, inductively coupled plasma atomic emission spectrometry; B4, benzophenone 4; EUS, Eusolex<sup>®</sup> 232; ZEB, dual-guest nanocomposite synthesized with B4 and EUS.

The Zn/Al molar ratios for all Zn/Al-LDH samples obtained experimentally are slightly higher than the calculated value,  $R=2$ . The slight discrepancy between calculated and observed ratio is due to the requirement to adjust the Zn to Al ratio to neutralize the charge of the anions intercalated in between the LDH interlayers.

The amount of intercalated anions was determined using UV-VIS spectrometer by treating samples with acid to disintegrate inorganic layers completely, releasing the intercalated anions. Absorbance was monitored at  $\lambda_{\max}=285$  and 311 nm for B4 and EUS, respectively. Percentage loading of the dual-guest nanocomposites was determined by solving simultaneous equation below:

$$\text{at } \lambda_1: A_1 = \epsilon_{B4} \times b \times C_{B4} + \epsilon_{EUS} \times b \times C_{EUS} \quad (1)$$

$$\text{at } \lambda_2: A_2 = \epsilon'_{B4} \times b \times C_{B4} + \epsilon'_{EUS} \times b \times C_{EUS} \quad (2)$$

where  $\lambda_1$  and  $\lambda_2$  are random wavelength points.  $A_1$  and  $A_2$  indicate the absorbance for mixture solution containing both B4 and EUS,  $\epsilon$  is the absorptivity of each anion,  $C$  (mg/L) represents the concentration of 100% release of anions, and  $b$  is the path length (1 cm).

A summary of percentage loading of intercalated anion is listed in Table 3. Elemental analysis of dual-guest nanocomposites confirmed the cointercalation of both B4 and EUS into LDH. The results also reveal that the relative contents of the cointercalated guests in LDH could be controlled by

**Table 3** Competitive intercalation between B4 and EUS at different B4:EUS ratios

Sample	Percentage B4 intercalated (%w/w)	Percentage EUS intercalated (%w/w)	Selectivity ratios B4:EUS
ZEB (1:1)	0.0	48.5	0:100
ZEB (2:1)	8.6	26.0	25:75
ZEB (3:1)	20.5	17.9	53:47
ZEB (4:1)	26.8	14.5	65:35

**Abbreviations:** B4, benzophenone 4; EUS, Eusolex<sup>®</sup> 232; ZEB, dual-guest nanocomposite synthesized with B4 and EUS.

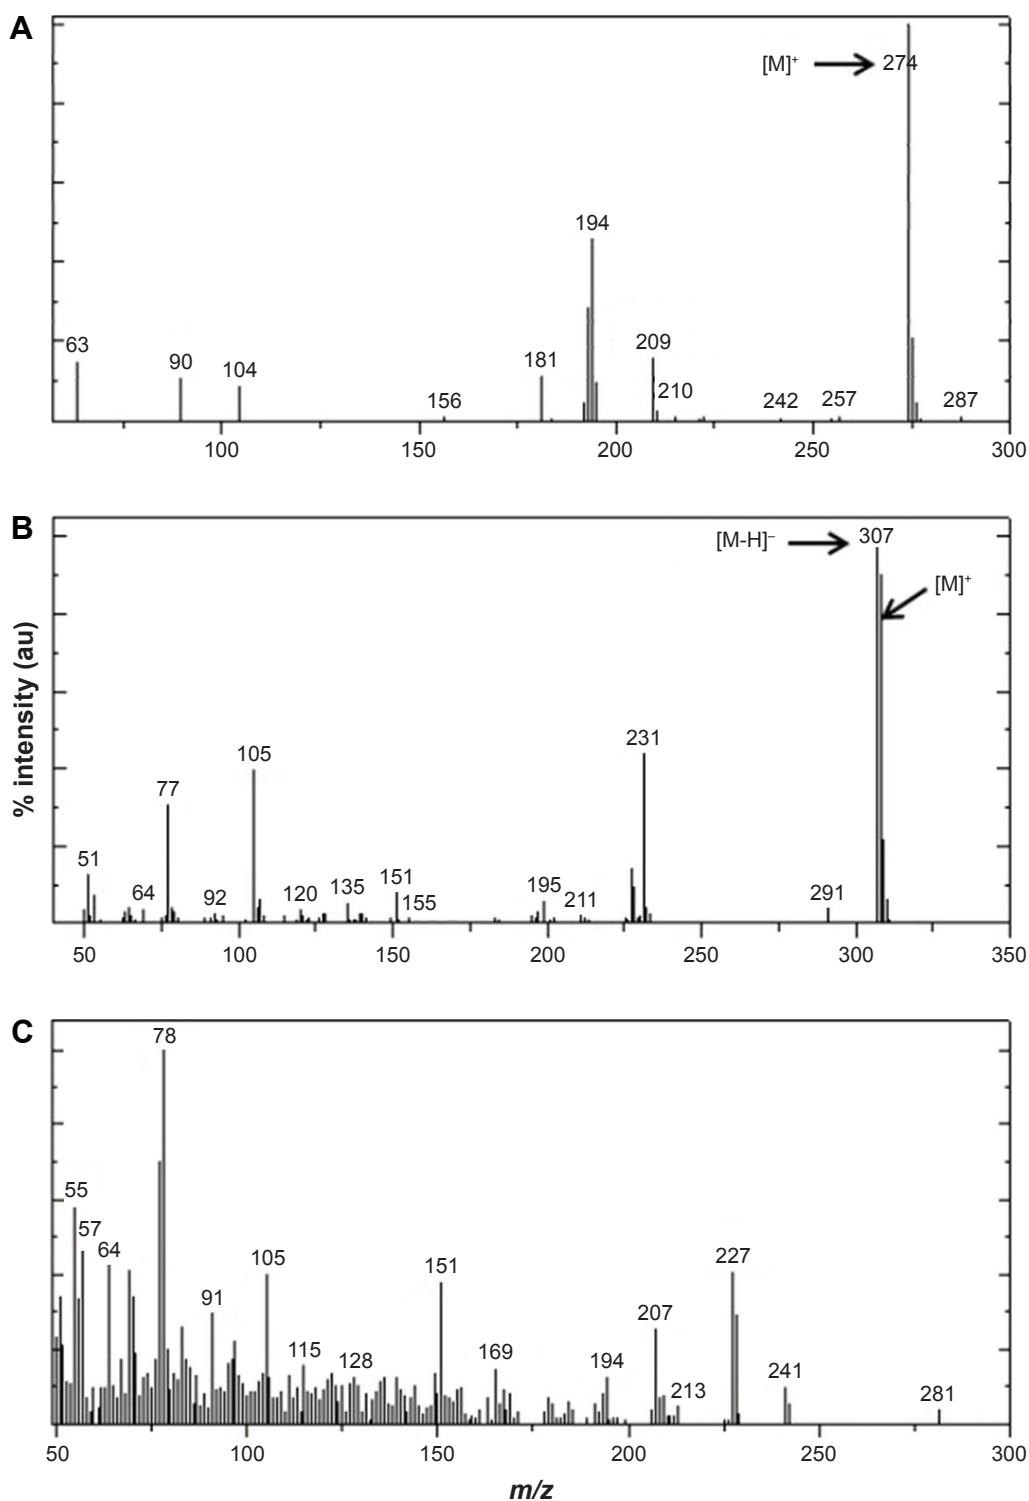

changing the ratio of guests in the reaction media. Although B4 loading was not detected in ZEB (1:1) sample, its PXRD result showed little difference in basal spacing in comparison to the rest. Therefore, it may be possible that some intercalation of B4 had occurred in negligible concentrations.

Simultaneous intercalation of B4 and EUS using the same B4:EUS ratios shows that LDH favors the intercalation of EUS. However, as molar ratio of B4 is increased and EUS is decreased, we could overcome the strong preference to EUS. Preferences to anion by an LDH are affected by the electrostatic attraction between positively charged metal hydroxide layer and the guest anions, hydrogen bonds between sulfoxyl oxygen atoms in the guest anions and hydroxyl hydrogen atoms in the hydroxide layers, and distribution of charges (dipole moment) in the guest anions.<sup>26</sup> Unlike EUS, B4 has two substituent groups on its aromatic ring that could influence the distribution of charges. Electron-donating -OH on the para position of sulfoxylate group may be reinforcing B4's electrostatic attraction to the interlayer, but we believe that in the present case, the ortho position of electron-donating -OCH<sub>3</sub> group has a more significant effect because they are able to interact with hydroxyl hydrogen atoms in the hydroxide layers. Hence, low selectivity of B4 could be attributed to the antagonistic effect of -OCH<sub>3</sub> group on the ortho position of the sulfoxylate group. As summarized in Table 3, an almost equal amount of intercalated percentage of B4 and EUS was synthesized with B4:EUS molar ratio of 3:1. Therefore, further physicochemical characterizations, UV absorptivity, and cytotoxicity studies were focused on ZEB (3:1) nanocomposite.

## DIMS

Mass spectral results of EUS, B4, and the dual-guest nanocomposite ZEB (3:1) are presented in Figure 3. DIMS serves as a fingerprinting tool to determine the intercalated components.

Mass spectra of pure EUS showed abundant peak at  $m/z$  274 corresponding to its molecular ion peak. Molecular ion peak for B4 meanwhile was slightly less prominent and was preceded by M-1 peak at  $m/z$  307 resulting from the

**Figure 3** DIMS patterns of EUS (A), B4 (B), and dual-guest nanocomposite ZEB (3:1) (C).

**Abbreviations:** B4, benzophenone 4; DIMS, direct-injection mass spectroscopy; EUS, Eusolex® 232; ZEB (3:1), dual-guest nanocomposite synthesized with B4:EUS molar ratio 3:1.

loss of hydrogen radical. We focused on ZEB (3:1) sample as it consisted of almost equal percentage of intercalated B4 and EUS. DIMS pattern of ZEB (3:1) gave rise to a peak at  $m/z$  194, corresponding to  $[C_{13}H_{10}N_2]^+$ , a product

of desulfonated fragment ion of EUS. The comparatively higher intensity of fragmentation ion  $[C_7H_3O]^+$  ( $m/z$  105) and  $[C_8H_7O]^+$  ( $m/z$  151) comes from further fragmentation of desulfonated product of B4  $[C_{14}H_{14}O_3]^+$  ( $m/z$  231). High intensity

at  $m/z$  78 corresponds to deprotonated benzene which could be attributed to fragmentation of either intercalated anions.<sup>27,28</sup> Peaks coinciding with molar mass of B4 and EUS could not be detected in our dual-guest nanocomposite. This phenomenon could be due to intermolecular bonding between dual-guest anions in the layered matrix that resulted in more complex mass fragmentation than a single-guest anion intercalation.

The observed fragmentation peaks confirm the cointercalation of both anions B4 and EUS in the LDH host. It is worth noting that ZEB (3:1) showed more prominent peaks assigned to B4 than EUS. The abundance of fragment ions representing B4 suggests higher intercalated ratio for B4 in the samples ZEB (3:1), which is in agreement with the results presented in Table 3.

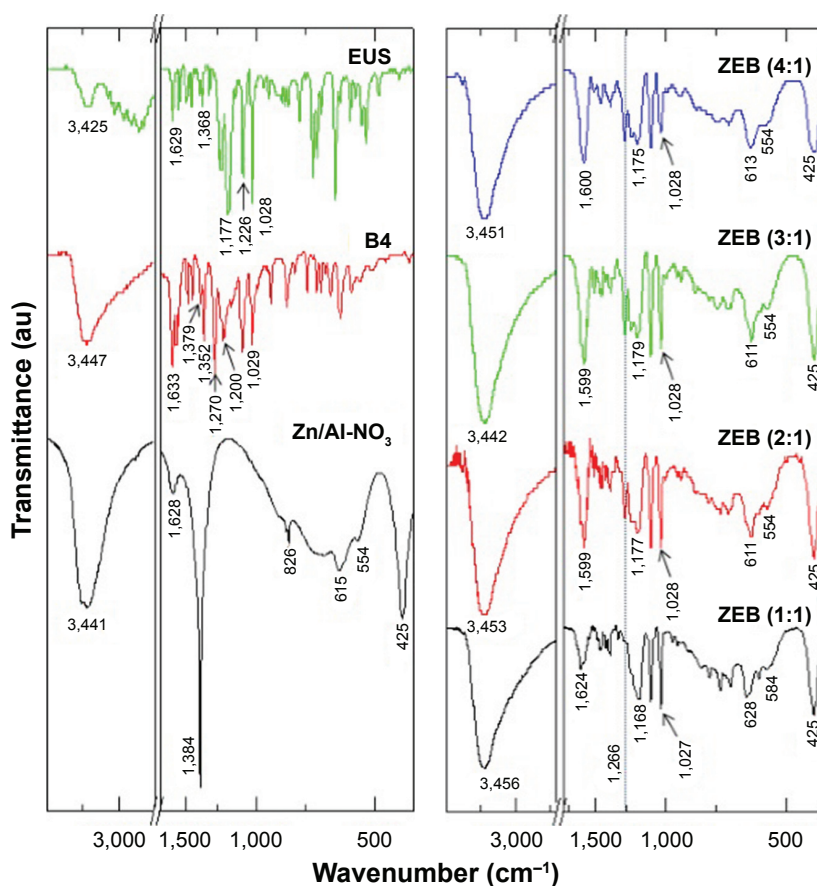

## FTIR spectroscopy

The FTIR spectra of B4, EUS, Zn/Al-NO<sub>3</sub>, and dual-guest ZEB nanocomposites are displayed in Figure 4.

The FTIR spectra for both Zn/Al-NO<sub>3</sub> and dual-guest nanocomposites show a broad absorption band commonly observed in the LDH materials centered at around 3,500 cm<sup>-1</sup>

due to the presence of O-H stretching mode of the hydroxyl group physisorbed onto LDH layers, as well as interlayer water molecules.<sup>29</sup> A weak band corresponding to the stretching vibration of H-OH appears at 1,628 cm<sup>-1</sup>.<sup>30</sup> Bands in the low-frequency region correspond to translational vibration modes of Zn-OH at 611–615 cm<sup>-1</sup>, Al-OH at around 554 cm<sup>-1</sup>, and deformation of HO-Zn-Al-OH at 425 cm<sup>-1</sup>. A sharp peak at 1,384 cm<sup>-1</sup> is attributed to NO<sub>3</sub><sup>-</sup> as an interlayer anion of Zn/Al-NO<sub>3</sub>. This peak was completely removed from ZEB nanocomposite as the intercalation of anions B4 and EUS has taken place.

FTIR spectra of pure B4 show peaks at 1,200 cm<sup>-1</sup> (symmetric) and 1,029 cm<sup>-1</sup> (asymmetric), stretching of SO<sub>3</sub><sup>-</sup> group, 1,596 cm<sup>-1</sup>, 1,490 cm<sup>-1</sup>, and 1,446 cm<sup>-1</sup> for C=C vibrations of aromatic ring, 1,379 cm<sup>-1</sup> (in plane deformation vibration of CH<sub>3</sub>), 1,352 cm<sup>-1</sup> (R-SO<sub>2</sub>-OH stretch), and 1,270 cm<sup>-1</sup> (Ar-O-CH<sub>3</sub>). The FTIR spectra of pure EUS show peaks at 1,567 cm<sup>-1</sup>, 1,497 cm<sup>-1</sup>, and 1,455 cm<sup>-1</sup> for C=C vibrations of aromatic ring, 1,368 cm<sup>-1</sup> (R-SO<sub>2</sub>-OH stretch), 1,226 cm<sup>-1</sup>, and 1,177 cm<sup>-1</sup> (C=N stretch), 3,425 cm<sup>-1</sup> (N-H stretching), and 1,629 cm<sup>-1</sup> (N-H bending). Due to the intense

**Figure 4** FTIR spectra of Zn/Al-NO<sub>3</sub>, B4, EUS, and dual-guest intercalated products; ZEB (1:1), ZEB (2:1), ZEB (3:1), and ZEB (4:1).

**Abbreviations:** B4, benzophenone 4; EUS, Eusolex® 232; FTIR, Fourier transform infrared; ZEB, dual-guest nanocomposite synthesized with B4 and EUS.

vibration of a C=N stretching at around  $1,200\text{ cm}^{-1}$  range, only asymmetric vibration band of sulfonate group could be detected at  $1,028\text{ cm}^{-1}$ .

When equal molar concentration was used, B4 failed to intercalate in a substantial amount. This was evident in the FTIR spectra of dual-guest nanocomposite as no observation of vibration band that could be assigned to O-CH<sub>3</sub> was detected at  $1,600\text{ cm}^{-1}$  (attributing to B4) for the ZEB (1:1) sample. Instead, a broad peak centered at  $1,624\text{ cm}^{-1}$  was detected, a characteristic of N-H bending of EUS. This is in accordance with high preference intercalation by EUS as shown by the UV-VIS analysis (Table 3). Successful intercalation of B4 was confirmed with the presence of Ar-O-CH<sub>3</sub> stretching at  $1,266\text{ cm}^{-1}$  for samples ZEB (2:1), ZEB (3:1), and ZEB (4:1). This nanocomposite exhibits most of the vibrational bands that can be assigned to respective guests. However, several vibrations were shifted due to interaction between guest anions and the interlayer. Absorption band corresponding to R-SO<sub>2</sub>-OH was not observed after intercalation due to immobilization of sulfoxylic guests within the LDH host.

## Thermal analysis

TGA/DTG measurement of B4, EUS, Zn/Al-NO<sub>3</sub>, and dual-guest ZEB (3:1) nanocomposites are shown in Figure 5.

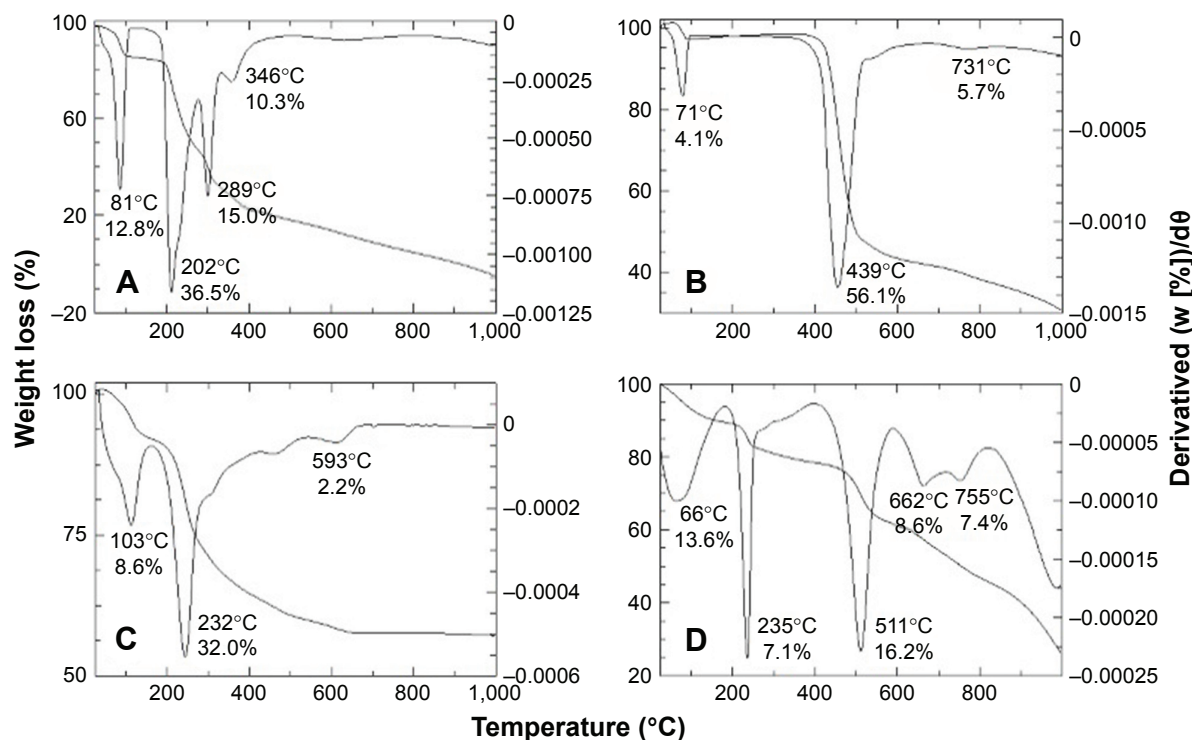

TGA/DTG thermograms exhibit the thermal decomposition behavior of samples.

Thermal decomposition of UV absorber B4 occurs in four stages. The first at the maximum temperature  $81^\circ\text{C}$  is most probably due to the removal of moisture in the sample. The rest of the stages can be attributed to decomposition and combustion of the organic compound up until the maximum temperature of  $350^\circ\text{C}$ . Pure B4 did not completely decompose at temperature until  $1,000^\circ\text{C}$ .

Thermal decomposition profile of EUS shows three main events. The first one corresponds to the removal of moisture and the subsequent stages correspond to decomposition and combustion of organic matter. However not all compounds were decomposed, as DTG curve showed weight loss peak coming up after  $450^\circ\text{C}$  and continuing above our analysis condition limit.

TGA/DTG curves of Zn/Al-NO<sub>3</sub> LDH in Figure 5C show three weight loss stages. The first event is attributed to loss of physisorbed and interlayer water molecules. The second and most prominent peak corresponds to dehydroxylation of LDH matrix, while the last step is linked to decomposition of intercalated nitrates.<sup>31</sup> Thermal decomposition eventually reached completion at around  $680^\circ\text{C}$ .

Dual-guest nanocomposite ZEB (3:1) showed characteristic decomposition peaks of LDHs with its first two

weight loss events. Subsequent weight loss events centered at 511, 662, and 755°C are attributed to the decomposition of intercalated organic species. It should be noted that the thermal decomposition region of dual-guest nanocomposite is significantly higher than pure B4 and EUS. This indicates that the thermal stability is enhanced due to interaction between B4 and EUS and the layered structure.

### Surface morphology

FESEM images of Zn/Al-NO<sub>3</sub> and dual-guest ZEB (3:1) nanocomposite are shown in Figure 6.

Pristine Zn/Al-NO<sub>3</sub> consisted of agglomerates of very thin nonuniform plate particles with sharp edges. Single intercalation of EUS and B4 reported morphologies of plate-like structures with blunt edges. The former showed 50–500 nm in size, while the latter showed smaller sizes (ca. 25–100 nm). Dual-guest nanocomposite, ZEB (3:1) showed a morphology similar to that of Zn/Al-B4 but with less agglomeration and sizes ranging from 20 to <100 nm. Furthermore, the dual-guest nanocomposite exhibited an increase in particle thickness compared to the pristine LDH.

Figure 7 shows the nitrogen adsorption–desorption isotherms of Zn/Al-NO<sub>3</sub> and dual-guest ZEB nanocomposites. The nanocomposites depict Type IV isotherm by the International Union of Pure and Applied Chemistry (IUPAC) classification.<sup>32</sup> According to IUPAC classification, the type of hysteresis loop for these nanocomposites can be classified as H3-type hysteresis loop. This type of loop is typical for mesoporous materials comprised of agglomerates of plate-like particles with slit-shaped pores.

Figure 8 shows the Barrett–Joyner–Halenda method (BJH) desorption pore size distribution for Zn/Al-NO<sub>3</sub>

and dual-guest nanocomposite ZEB (3:1). Pore size distribution showed a wide distribution of pore diameter for pristine Zn/Al-NO<sub>3</sub> (inset). On the other hand, dual-guest nanocomposite, ZEB (3:1) (outset), showed a single-peaked pore diameter distribution centered at 245 Å.

A summary of Brunauer, Emmett, and Teller method surface area, BJH pore volume, and BJH pore diameter for the nanocomposites is given in Table 4.

Varying wideness of desorption branch of the hysteresis loop and pore diameter suggests different pore texture as a result of LDH gallery occupation by different guest anions.

## UV ray absorption ability analysis

Solid-state absorbance spectra of B4, EUS, Zn/Al-NO<sub>3</sub>-LDH, and dual-guest nanocomposites are shown in Figure 9.

B4 showed a strong ability to absorb both UVB (280–320 nm) and UVA (320–400 nm), while EUS showed a weak ability to absorb short UVA. UVA absorption ability of B4 was superior to that of EUS. This is due to the substituent of aromatic ring in B4, the methoxy group, and the hydroxy group.<sup>33</sup> UV absorption ability of pristine Zn/Al-NO<sub>3</sub> LDH was shown to be poor. UV absorption peak at 300 nm for Zn/Al-NO<sub>3</sub> is ascribed to the presence of NO<sub>3</sub><sup>-</sup> in LDH interlayer.<sup>34</sup>

However, as a result of intercalation with UV ray absorbing molecules, LDH nanocomposites exhibit broad and strong UV-shielding capability that mimics intercalated compound. This is an indication that the inorganic lattice retains UV absorbent molecules and attains chromophores that influence absorption characteristic of those molecules. The effect of broadened absorption range is due to spatial confinement and host–guest interactions, namely electrostatic attraction, hydrogen bonding, and van der Waals forces.

The dual-guest nanocomposite experienced an absorption peak shift to the higher wavelength region, also known as

**Table 4** Surface properties of Zn/Al-NO<sub>3</sub> and ZEB (3:1) nanocomposites

Sample	BET surface area (m <sup>2</sup> /g)	BJH pore volume (m <sup>2</sup> /g)	BJH pore diameter (Å)
Zn/Al-NO <sub>3</sub>	1	0.01	166
ZEB (3:1)	41	0.22	147

**Abbreviation:** BET, Brunauer, Emmett, and Teller method; BJH, Barrett–Joyner–Halenda method; ZEB (3:1), dual-guest nanocomposite synthesized with B4:EUS molar ratio 3:1.

red shift, which happened as a result of edge-to-edge arrangement of intercalated B4 and EUS molecules (Figure 2C) when electron-donating groups –OCH<sub>3</sub> and –OH induced conjugation.<sup>35</sup> UV absorption spectrum of dual-guest nanocomposites showed that the ratio of guest anions intercalated does not impart a significant effect on absorption range or intensity. ZEB nanocomposites maintained a broad and intense absorption similar to that of the organic UV absorbent, B4. A slight decrease in absorption ability in comparison to B4 can be attributed to the dilution effect of intercalation in LDH host. UV rays in sunlight which reach the ground are mainly UVA (90%–99%) and UVB (1%–10%).<sup>36</sup> Therefore, a shift to the UVA range as observed is preferable for higher protection against the sun. Although B4 loading was not detected in the ZEB (1:1) sample by FTIR and UV–VIS spectrometer, solid-state absorbance spectrum of ZEB (1:1) showed broad absorbance that is more similar to B4 intercalation rather than EUS. Thus, it may be possible that intercalation and surface absorption of B4 had occurred at a negligible amount that could not be detected by FTIR or UV–VIS spectrometer.

UV absorption spectrum corresponds to electron excitation from valence band to conduction band. The spectrum can be used to determine the band gap values using the Kubelka–Munk equation:<sup>37</sup>

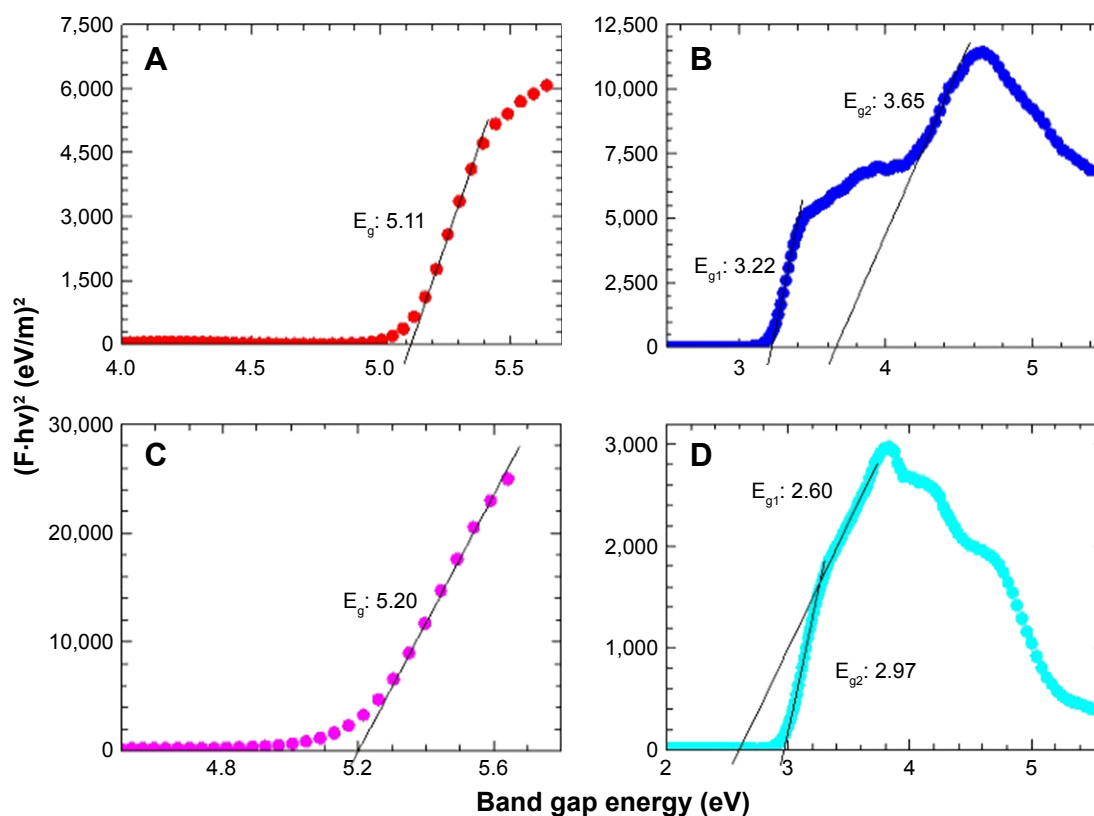

$$(F \cdot hv)^2 = A (hv - E_g) \quad (3)$$

where  $F$  is the Kubelka–Munk,  $h$  is Planck's constant,  $A$  is a proportionality constant,  $hv$  is the photon energy, and  $E_g$  is the band gap energy. Band gap values were extracted by

**Figure 9** Solid-state absorbance spectra of B4, EUS, Zn/Al-NO<sub>3</sub>, and dual-guest intercalated products; ZEB (1:1), ZEB (2:1), ZEB (3:1), and ZEB (4:1).

**Abbreviations:** B4, benzophenone 4; EUS, Eusolex® 232; ZEB, dual-guest nanocomposite synthesized with B4 and EUS.

**Figure 10** Kubelka–Munk transformed reflectance spectra of Zn/Al-NO<sub>3</sub> (A), B4 (B), EUS (C), and dual-guest intercalated product; ZEB (3:1) (D).

plotting Eq 3 as  $(F \cdot hv)^2$  against  $hv$  and extrapolating the linear region straight line to the  $hv$  intercept. Band gaps of B4, EUS, Zn/Al-NO<sub>3</sub>, and dual-guest nanocomposite ZEB (3:1) were investigated by these measurements, as shown in Figure 10.

Pristine Zn/Al-NO<sub>3</sub> showed a single band gap at 5.11 eV. B4 exhibited band gaps at 3.22 and 3.65 eV, while EUS exhibited a single band gap at 5.20 eV. Dual-guest nanocomposites ZEB (3:1) exhibited a shift to narrower band gap values, 2.60 and 2.97 eV. A narrower band gap value accounts for its high visible-light photocatalytic availability.<sup>38</sup> It is generally known that high photocatalytic activity is brought upon by high specific surface area.<sup>39</sup> Thus, we could attribute the shift to narrower band gap value to the specific surface area increase pattern, as discussed in the “Surface morphology” section.

## Retention of sunscreen molecules in dual-guest nanocomposites

Interlayer anions of LDH are held by weak electrostatic attraction and can be exchanged with anions of higher affinity to the layered host. Retention of organic sunscreen molecules in LDH matrices was studied in a release medium

of 0.5 mol/L NaCl (Figure 11A) and pH 5.5 phosphate buffer (Figure 11B) using a dual-guest sample prepared at B4:EUS =3:1. ZEB (3:1) nanocomposite was selected as it contains almost equal percentage of intercalated anion. Respective release media were chosen in order to simulate the application condition of the new sunscreen formulation. 0.5 mol/L NaCl represented artificial sea water, while pH 5.5 phosphate buffer reproduced skin pH condition.

The release profiles showed that accumulated release was rapid for the first 4 hours of contact with pH 5.5 phosphate buffer. Then, the release slowed down until equilibrium was achieved of about 73.65% and 65.98% for B4 and EUS, respectively, after 1,250 minutes (roughly 20 hours). Similarly, in the case of artificial sea water, for the first 2,000 minutes, rapid release was observed. The release was progressively slower after that and achieved a maximum accumulated release of 61.86% and 58.24% for B4 and EUS, respectively, after almost 7 days in artificial sea water. It was predetermined that sample ZEB prepared at B4:EUS =3:1 contained a larger amount of intercalated B4. Therefore, higher release of B4 than EUS is expected.

Although the release of sunscreen molecules from the formulation was observed, the results demonstrated that

**Figure 11** Controlled release of B4 (□) and EUS (△) from dual-guest nanocomposite ZEB (3:1) in 0.5 mol/L NaCl (A) and pH 5.5 phosphate buffer solution (B). **Abbreviations:** B4, benzophenone 4; EUS, Eusolex® 232; ZEB (3:1), dual-guest nanocomposite synthesized with B4:EUS molar ratio 3:1.

direct contact of sunscreen molecules with skin could be reduced with inhibition of UV absorbents in the LDH host. Furthermore, the inorganic metal layer extended UV protection compared to pure sunscreen compounds. This was achieved by retention in host and eventually slowing down of the exposure of sunscreen molecules to photodegradable conditions.

### Release kinetics of EUS and B4 from ZEB nanocomposite

Kinetic release of UV absorbing anions from ZEB (3:1) nanocomposite was investigated by fitting the release profiles of the EUS and B4 into the following kinetic models; zeroth- (Eq 4),<sup>40</sup> first- (Eq 5),<sup>41</sup> pseudo-second order kinetics (Eq 6),<sup>42</sup>

and parabolic diffusion (Eq 7).<sup>43</sup> The equations are expressed below, where *c* is a constant, and *C<sub>eq</sub>* and *C<sub>t</sub>* are the concentration of anion at equilibrium and time *t*, respectively.

$$C_t = kt + C_o \tag{4}$$

$$-\log(1 - C_t) = kt \tag{5}$$

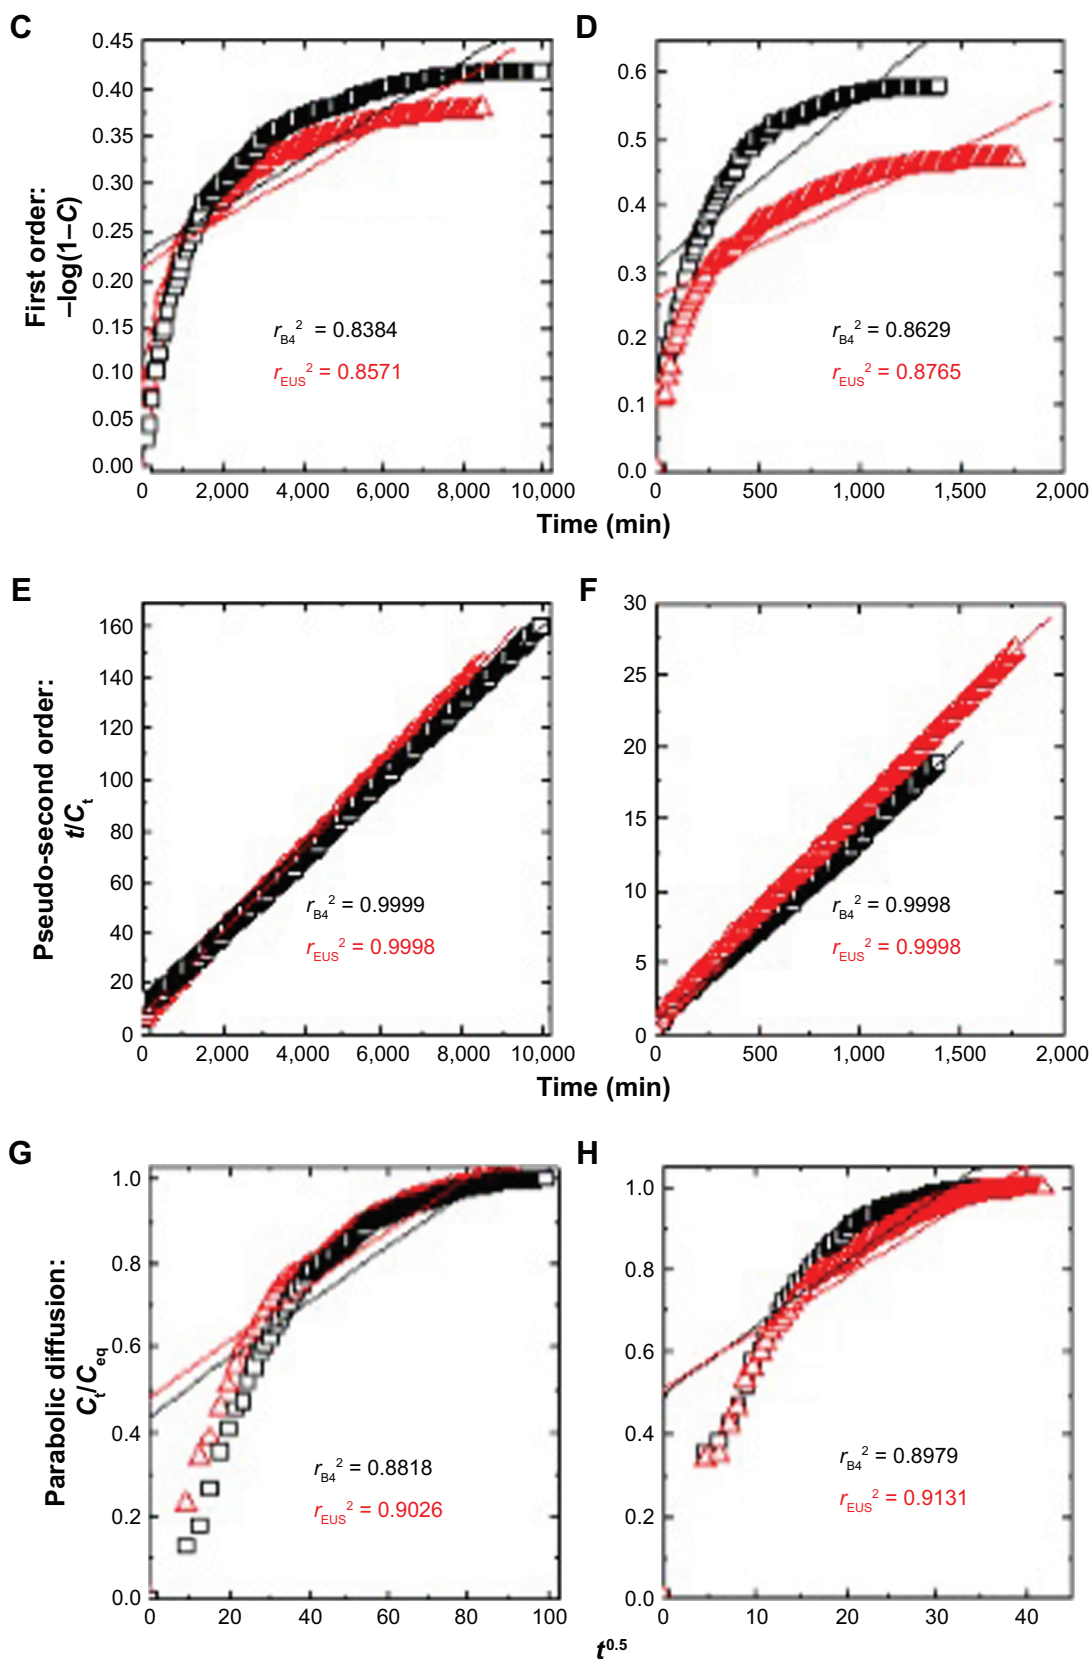

$$t/C_t = 1/k_2 C_{eq}^2 + (1/C_{eq})t \tag{6}$$

$$C_t/C_{eq} = c + kt^{0.5} \tag{7}$$

The fitting results are shown in Figure 12. Correlation coefficient values for all kinetic models are summarized in Table 5.

**Figure 12 (Continued)**

**Figure 12** Fitting the data release of B4 ( $\square$ ) and EUS ( $\triangle$ ) from dual-guest nanocomposite ZEB (3:1) into media for zero-, first-, pseudo-second order, and parabolic diffusion kinetics for 0.5 mol/L NaCl (**A**, **C**, **E**, and **G**, respectively) and pH 5.5 phosphate buffer solution (**B**, **D**, **F**, and **H**, respectively).

**Abbreviations:** B4, benzophenone 4; EUS, Eusolex<sup>®</sup> 232; ZEB (3:1), dual-guest nanocomposite synthesized with B4:EUS molar ratio 3:1.

**Table 5** Correlation coefficient, rate constant, and half time obtained by fitting the release data of B4 and EUS from ZEB (3:1) into various media using zeroth-, first-, pseudo-second order, and parabolic diffusion kinetic models

Media	Saturated release (%)	Correlation coefficient, $r^2$				Rate constant of pseudo-second order, $k$ (L mg <sup>-1</sup> min <sup>-1</sup> )	$t_{1/2}$ of pseudo-second order (min)
		Zeroth order	First order	Pseudo-second order	Parabolic diffusion		
<b>B4 release</b>							
0.5 mol/L NaCl	61.86	0.7751	0.8384	0.9999	0.8818	$2.44 \times 10^{-5}$	619
Phosphate buffer pH 5.5	73.65	0.7993	0.8629	0.9998	0.8979	$1.70 \times 10^{-4}$	75
<b>EUS release</b>							
0.5 mol/L NaCl	58.24	0.8037	0.8571	0.9998	0.9026	$3.40 \times 10^{-5}$	479
Phosphate buffer pH 5.5	65.98	0.8201	0.8765	0.9998	0.9131	$1.47 \times 10^{-4}$	98

**Notes:** Zeroth order:  $C_t = kt + c$ , first order:  $-\log(1 - C) = kt + c$ , pseudo-second order:  $t/C_t = 1/k_2 C_{eq}^2 + (1/C_{eq})t$ , parabolic diffusion:  $C_t/C_{eq} = c + kt^{0.5}$ ,  $c = a$  constant;  $C_{eq}$  = concentration of anion at equilibrium;  $C_t$  = concentration of anion at time  $t$ .

**Abbreviations:** B4, benzophenone 4; EUS, Eusolex® 232; ZEB (3:1), dual-guest nanocomposite synthesized with B4:EUS molar ratio 3:1.

By comparing the correlation coefficient values, we found that the release patterns of EUS and B4 anions from LDH host best fit the pseudo-second order kinetic.

Using the pseudo-second order equation, we could calculate the  $t_{1/2}$  value.  $t_{1/2}$  is defined as time taken for the release to be half of the accumulated release.  $t_{1/2}$  values for release in pH 5.5 phosphate buffer solution were 75 and 98 min for B4 and EUS release, respectively. On the other hand,  $t_{1/2}$  values for release in 0.5 mol/L NaCl were 619 and 479 min for B4 and EUS, respectively. Release rate constant,  $k$ , quantifies the speed of anion release. As can be seen in Table 5, the rate constants for release in skin pH condition are  $2.44 \times 10^{-5}$  and  $3.40 \times 10^{-5}$  L mg<sup>-1</sup> min<sup>-1</sup> for B4 and EUS anions, respectively. In artificial seawater, the rate constants are  $1.70 \times 10^{-4}$  and  $1.47 \times 10^{-4}$  L mg<sup>-1</sup> min<sup>-1</sup> for B4 and EUS anions, respectively.

Higher  $t_{1/2}$  value and lower  $k$  value indicate slower release of the anion from the LDH interlayer. As supported by  $t_{1/2}$  and  $k$  values, anion release under skin pH condition was significantly faster than artificial seawater. This can be explained by the slight dissolution of LDH under a slightly acidic condition.<sup>44</sup> Moreover, the presence of phosphate combined with other anions in phosphate buffer solution induces multiple hydrolysis of phosphate and speeds up the ion-exchange process.<sup>45,46</sup> Slower release in 0.5 mol/L NaCl was attributed to the low ion-exchange affinity of the incoming anion, chloride, toward the interlayer gallery of LDH.<sup>47</sup>

## Cytotoxicity induction on HDF cells

Cytotoxicity induced by the nanocomposite and test compounds on HDF cells was investigated by cell viability assays. HDF cells were exposed to the LDH nanocomposites B4 and EUS at the concentrations of 1.562, 3.125, 6.25, 12.5, 25, and 50 µg/mL for 24 h and cell viabilities were determined

by MTT assay. The cytotoxicity findings have shown that pristine Zn/Al-NO<sub>3</sub>-LDH, pure guest, B4 and EUS, as well as dual-guest nanocomposite ZEB (3:1) up to the test concentration of 25 µg/mL did not produce any significant cytotoxicity to HDF cells. Irrespective of intercalation of two active agents of sunscreen into the LDH matrix, the dual-guest nanocomposite maintained a nontoxic nature up to 25 µg/mL. As the concentrations of all samples were increased to 50 µg/mL, cytotoxicity was observed to significantly increase (Figure 13).

Therefore, we concluded that the cytotoxicity of samples acted in a dose-dependent manner. Based on this fruitful investigation, we will use the nontoxic concentration of the dual-guest nanocomposites for further therapeutic investigations.

## Conclusion

The present study was designed to determine the effect of simultaneous intercalation of UV ray absorbent agents in Zn/Al-LDH on its resulting properties. It was discovered that using equimolar concentrations of B4 and EUS intercalation selectivity is favorable to EUS. Based on the results presented, we have demonstrated that this selectivity is tuneable by changing the molar ratio of the guests during the synthesis. We could manipulate this nature to ration out guests, and thus produce nanocomposites of customized composition. Dual-guest nanocomposites combined showed excellent absorption capacity in the UV region of both guest anions while the inorganic host improved thermal stability, broadened UV absorptivity range, and provided retention of photodegradable organic UV ray absorbing molecules. The cytotoxicity study of dual-guest nanocomposites ZEB (3:1) on dermal cells showed no significant toxicity up to 25 µg/mL. However, further therapeutic study is required to shed light on the toxicity

**Figure 13** Concentration–response curves obtained by plotting the percentage of viability of HDF cells exposed to B4, EUS, nanocomposite ZEB (3:1), and Zn/Al-NO<sub>3</sub> for 24 hours.

**Note:** Results are presented as mean  $\pm$  SD of triplicate values.

mechanism of LDH nanocomposite on dermal cells. Even though the intercalated guest could be released from LDH host during application on skin via ion exchange, a simulation in sea water and pH of skin showed a slowing down of exposure of sunscreen molecules to photodegradable conditions. These findings demonstrate the potential for UV ray absorbent guest-intercalated LDHs to be used as a versatile, efficient, and tailor-made sunscreen formulation.

## International Journal of Nanomedicine

### Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Submit your manuscript here: <http://www.dovepress.com/international-journal-of-nanomedicine-journal>

Dovepress

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
