of rectal CT infection underwent additional testing to identify LGV serovars utilizing novel real-time PCR assays specific for the L serovars of CT Chlamydia trachomatis.

Results. From 28 April 2014-19 July 2016, 420 men underwent screening for rectal STIs, including 66 (15.7%) who had prevalent rectal infection with CT. An additional 68 participants developed incident infections during 208 person-years of follow-up. Of 134 eligible rectal swab specimens, 128 underwent further testing for LGV serovars. Seven (5.5%) of the tested samples were identified as LGV serovars of CT. None of the seven participants with LGV reported any symptoms such as fever or rectal pain. Two of the participants with LGV were simultaneously co-infected with rectal gonorrhea. HIV co-infection was common among participants with both LGV and non-LGV serovars of CT (71% and 77%, respectively, P = 0.74).

Conclusion. LGV was uncommon but present among Nigerian MSM in this study. LGV needs to be considered even in asymptomatic cases, particularly if anorectal CT infection fails to respond to the usual course of therapy. Consistent screening for L serovars of CT, or empiric treatment for LGV in cases with a high suspicion for this diagnosis, could potentially improve patient outcomes and decrease transmission. 2501. Real-Time PCR Targeting Mosaic penA XXXIV for Prediction of Extended-Spectrum Cephalosporins Susceptibility in Clinical Neisseria Gonorrheae Isolates Peera Hemarajata, MD, PhD<sup>1</sup>; Lisa Wong, MPH<sup>2</sup>; Olusegun Soge, PhD<sup>3</sup>; Romney Humphries, PhD<sup>4</sup>; Jeffrey Klausner, MD, MPH<sup>5</sup>; <sup>1</sup>Department of Pathology and Laboratory Medicine, David Geffen School of Medicine at University of California at Los Angeles, Los Angeles, California; <sup>2</sup>Emory University School of Medicine, Atlanta, Georgia; <sup>3</sup>Neisseria Reference Laboratory, University of Washington, Harborview Medical Center, Seattle, Washington; <sup>4</sup>UCLA David Geffen School of Medicine, Los Angeles, California and, <sup>5</sup>Division of Infectious Diseases, Department of Medicine, University of California, Los Angeles, Los Angeles, California

# Session: 279. STIs - Diagnostics and Therapy

Saturday, October 7, 2017: 2:00 PM

Background. Antimicrobial-resistant Neisseria gonorrheae (NG) is a global public health problem, resulting in limited empirical treatment options. Due to increasing minimum inhibitory concentrations (MICs) of ESCs against NG in the US, it is critical that susceptibility to ESCs be monitored. Since few laboratories routinely perform culture and susceptibility testing for NG, there is a need for a rapid test to predict susceptibility to ESCs. More than 98% of isolates with decreased susceptibility to cefixime (CFM) in the US carry mosaic penA XXXIV. In this study, we developed a multiplex real-time PCR for mosaic penA XXXIV and previously validated gyrA to predict ESCs MICs and ciprofloxacin (CIP) susceptibility.

Methods. 150 NG isolates with known cefpodoxime (CPD), CFM, ceftriaxone (CRO) and CIP MICs were obtained from Neisseria Reference Laboratory at University of Washington and CDC Antimicrobial Resistance Bank. DNA extracted from culture was used in multiplex HybProbe real-time PCR on Lightcycler 480. gvrA was genotyped by melt curve and served as internal control, while presence of mosaic penA XXXIV was detected by selective amplification.

Results. All 32 (100%) CIP-susceptible and 118 (100%) CIP-resistant isolates, as determined by Clinical and Laboratory Standards Institute breakpoints, demonstrated wild-type and Ser91 mutant gyrA genotype, respectively. Melt curve genotyping demonstrated mosaic penA XXXIV melt patterns in 66/68 (97%) isolates with at least one ESC MIC above alert value set forth by the CDC (CPD and CFM MICs ≥0.25 µg/ ml; CRO MIC ≥0.125), while all 82 (100%) isolates with ESC MICs under alert values did not amplify. The first of the 2 false-negative isolates had MICs above alert values for all ESCs tested and harbored IX mosaic type, while the second one had CRO MIC above alert value and harbored XII mosaic type. Both of these mosaic types did not share homology with mosaic penA XXXIV in the region targeted by the assay

Conclusion. The mosaic penA XXXIV assay demonstrated 97% sensitivity and 100% specificity in predicting alert ESCs MIC values among clinical isolates tested, and was successfully multiplexed with gyrA assay. Clinical utility of this assay may be limited due to false negativity in isolates with non-XXXIV mosaic types, but it could serve as a useful surveillance tool for XXXIV mosaic.

### 2502. Electronic Reminder Notifications Improve Uptake of Targeted Ciprofloxacin Therapy for Neisseria gonorrheae Infections at the University of California, Los Angeles Health System

Lao-Tzu Allan-Blitz, BA<sup>1</sup>; Romney Humphries, PhD<sup>2</sup>; Peera Hemarajata, MD, PhD<sup>3</sup>; Mabel Kimble, MPH<sup>4</sup>; Samuel Elias, MD<sup>5</sup>; Jeffrey Klausner, MD, MPH<sup>6</sup>; <sup>1</sup>Medicine, University of California Los Angeles, Los Angeles, California; <sup>2</sup>Department of Pathology and Laboratory Medicine, University of California, Los Angeles, Los Angeles, California; <sup>3</sup>Department of Pathology and Laboratory Medicine, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, California; <sup>4</sup>Division of Infectious Diseases, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, California; <sup>5</sup>Arthur Ashe Student Health & Wellness Center, University of California Los Angeles, Los Angeles, Los Angeles, California and, 6Division of Infectious Diseases, Department of Medicine, University of California, Los Angeles, Los Angeles, California Session: 279. STIs - Diagnostics and Therapy Saturday, October 7, 2017: 2:00 PM

Background. A wild-type gyrase A (gyrA) genotype of N. gonorrheae reliably predicts susceptibility to ciprofloxacin, which can reduce selection pressure for ceftriaxone-resistant infections, an urgent public health threat. In November 2015, UCLA Health began gyrA genotyping all N. gonorrheae positive specimens. In May 2016, we began sending reminder notifications of treatment recommendations to providers of patients with wild-type infections.

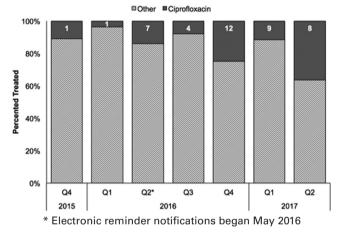

Methods. We reviewed records for all laboratory confirmed N. gonorrheae cases from November 1, 2015-April 30, 2017. Infections in different anatomic sites were considered unique infections, while unique infections in a single patient on the same date were considered a case. Empiric therapy was defined as treatment within 1 day of specimen collection. We also collected test-of-cure data among patients with wild-type infections treated with ciprofloxacin.

Results. Among 423 patients (23% HIV infected) there were 460 cases and 514 anatomic site-specific N. gonorrheae infections. Of infections, 218 (43%) had a wildtype gyrA genotype, 138 (27%) mutant, 153 (30%) indeterminate, 4 were not attempted, and 1 had missing data. There were 255 (55%) cases and 283 (55%) infections treated non-empirically. The median time-to-treatment among those cases was 4 days (interquartile range 3–6 days). Ciprofloxacin was used in 2 (3%) of 66 nonempirically treated infections prior to the start of reminder notifications, compared with 40 (18%) of 217 nonempirically treated infections after notifications began (P = 0.002). Of the 55 providers who received an email on or before the day of treatment for non-empirically treated patients, 32 (58%) used ciprofloxacin. There was no ciprofloxacin use prior to assay implementation. The trend in treatment by quarter among non-empirically treated infections is shown the Figure.

Among 30 patients treated with ciprofloxacin, 6 had a test of cure at one week, and all (100%; 95% CI 61%-100%) of those tests were negative for N. gonorrheae; 5 were from urethral specimens, and 1 was from the pharynx

Conclusion. Electronic provider notifications augmented targeted ciprofloxacin therapy for N. gonorrheae infections. Preliminary test-of-cure data are promising.

## Session: 279. STIs - Diagnostics and Therapy Saturday, October 7, 2017: 2:00 PM

Background. In the US military, routine extra-genital (EG) GC/CT testing in persons living with HIV was implemented in 2012. This study examines the prevalence/incidence and risk factors associated with genital (GU) and EG GC/CT
