

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

A rapid review of the use of face mask in preventing the spread of COVID-19

Respiratory viral infection

Rapid review

ABSTRACT

Introduction: The original use of face masks was to help protect surgical wounds from staff-generated nasal and oral bacteria. Currently governments across the world have instituted the mandatory use of masks and other face coverings so that face masks now find much broader usage in situations where close contact of people is frequent and inevitable, particularly inside public transport facilities, shopping malls and workplaces in response to the COVID-19.

Objective: We conducted a rapid review to investigate the impact face mask use has had in controlling transmission of respiratory viral infections.

Method: A rapid review was conducted in line with Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidance. Five electronic databases (CINAHL, Embase, Medline, PsycINFO and Global Health) were searched from database inception to date, using pre-defined search terms. We included all studies of any design and used descriptive analysis to report summary statistics of search results. Data were extracted including sample characteristics, study design, respiratory virus being controlled, type of face masks used and their effectiveness.

Results: 58 out of 84 studies met the inclusion criteria, of which 13 were classified as systematic reviews and 45 were quantitative studies (comprising randomised controlled trials, retrospective cohort studies, case control, cross-sectional, surveys, observational and descriptive studies). $N = 27$ studies were conducted amongst healthcare workers wearing face masks, $n = 19$ studies among the general population, $n = 9$ studies among healthcare workers the general population and patients wearing masks, and $n = 3$ among only patients. Face masks use have shown a great potential for preventing respiratory virus transmission including COVID-19.

Conclusion: Regardless of the type, setting, or who wears the face mask, it serves primarily a dual preventive purpose; protecting oneself from getting viral infection and protecting others. Therefore, if everyone wears a face mask in public, it offers a double barrier against COVID-19 transmission.

What is already known about the topic

- The effectiveness of face masks for preventing respiratory virus transmission is still under debate
- Despite face masks being cheaper and easier to use, more research has been carried out on the efficacy of respirators than on face masks

What this paper adds

- Findings suggest that the correct and early use of facemask or face covering could prevent the spread respiratory virus transmission including COVID-19 than when it is not used
- Regardless of the type, setting, or who wears the face mask, it serves primarily a dual preventive purpose of protecting oneself from getting viral infection and protecting others.
- The prolong use of face masks may affect a person's oxygen concentration level and may lead to dizziness due to repeated rebreathing of carbon dioxide retention.

1. Introduction

Since Wells (Wells, 1934) first hypothesised droplet nuclei transmission of airborne infections in the 1930s, and many pathogens have been identified as transmittable through airborne routes (Fiegel et al., 2006, Eames et al., 2009). When a contagious person coughs or sneezes, droplets containing infectious particles (bacteria and viruses) are released (Nicas et al., 2005, Chao et al., 2009). Despite the potential public health implications of airborne transmission, it had not garnered serious global attention until the severe acute respiratory syndrome and human swine influenza pandemics in 2003 and 2009 respectively, which revealed the ramifications of such pandemics on global health and economy. After these pandemics, diverse studies have been conducted to investigate ways to control and reduce infections caused by airborne pathogens.

Respiratory infections can be transmitted by droplets of varying sizes: >5–10 μm in diameter (respiratory droplets), and <5 μm in diameter (droplet nuclei) (World Health Organization, 2014). Airborne transmission, which is the presence of microbes within droplet nuclei, is different from droplet transmission and can remain in the air for long periods of time and be transmitted to others over distances greater than 1 m. Although initial evidence suggested that COVID-19, which was declared a pandemic within three months of its emergence (World Health Organization, 2020), is primarily transmitted through respiratory droplets and contact routes (Liu et al., 2020, Chan et al., 2020, Li et al., 2020, Huang et al., 2020, Burke and Midgley, 2020), more recent research suggests that airborne transmission plays a very significant role in propagating the infection, similar to what was found in severe acute respiratory syndrome coronavirus 1 (SARS-COV1), its predecessor. There are different groups of approaches to control airborne diseases. Ventilation and air flow patterns have been widely investigated to study their influence on droplet transmission (Li et al., 2007, Strasser and Schlich, 2020). Active devices such as air cleaners may also be an effective control measure to reduce exposure when they are properly located relative to the infected person (Chen et al., 2010). Respiratory protective equipment such as facemasks and N95 respirators also provide personal protection against infection (Jefferson et al., 2009, van der Sande et al., 2008). Despite face masks being cheaper and easier to use, more research has been carried out on testing the efficacy of respirators than on face masks (Bałazy et al., 2006, Beest et al., 2010).

The original use of face masks was to help protect surgical wounds from staff-generated nasal and oral bacteria (Meleny and Stevens, 1926, Romney, 2001), among others. Currently governments across the world have instituted the mandatory use of masks and other face coverings so that face masks now find much broader usage in situations where close contact of people is frequent and inevitable, particularly inside public transport facilities, shopping malls and workplaces in response to the COVID-19 (GOV.UK, 2020). However, despite much research effort, the effectiveness of face masks for preventing the contraction of respiratory virus influenza is still under debate and the results presented are not viewed as conclusive (van der Sande et al., 2008, Cowling et al., 2008, Jacobs et al., 2009). Nevertheless, some recent research results have observed that face masks significantly reduce the risk of contracting influenza-like illnesses in households (Perski et al., 2020).

A rapid systematic review of randomised controlled trials using different interventions to assess the efficacy of face masks and respirators against respiratory virus transmission including coronaviruses found masks to be effective in the community; respirators worn by healthcare workers were also found to be effective, but only if worn continually; however, medical and cloth masks were less effective (MacIntyre and Chughtai, 2020). Owing to these varying medical and public perceptions of the impact of wearing face masks in preventing COVID-19, we aimed to conduct a rapid review of all study designs to investigate the impact face mask use has had in controlling transmission of respiratory viral infections.

2. Method

2.1. Review questions

1. What useful lessons exist from the use of face masks in controlling respiratory virus transmission in the past?
2. Which group of people would benefit the most from the use of face masks, to guide the efficient use and allocation of limited supplies and save cost?

Table 1
Inclusion and exclusion criteria.

Inclusion	Exclusion
Qualitative, quantitative, mixed methods research, systematic reviews and randomised controlled trials, All persons/study participants who have used face masks to prevent the transmission of respiratory viral infections. All countries and settings (health institutions, community settings, residential and care homes)	Protocols, opinion, discussion and editorial papers, including letters. Persons wearing face masks for purposes other than the prevention of the transmission of respiratory viral infections.

Data selection and extraction.

2.2. Design

We conducted a rapid review in line with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (Moher et al., 2009).

2.3. Search strategy

Relevant studies were identified by searching electronic databases: CINAHL, Embase, Medline, PsycINFO and Global Health, and searching reference lists of included studies to identify additional studies. Studies published in English from inception of these databases to June 2020 were included.

The search strategy combined the keywords i) 'Face mask' OR 'Respiratory protective equipment' OR 'face covering' AND ii) 'Severe Acute Respiratory Syndrome' OR 'Coronavirus/ COVID-19' OR 'Middle East Respiratory Syndrome' OR 'Respiratory virus' OR 'Influenza virus' OR 'Respiratory infection' OR 'Adult respiratory distress syndrome' OR 'Respiratory distress syndrome' AND iii) 'Cough' OR 'Sneeze' OR 'Droplet' AND iv) 'Impact' OR 'Effectiveness'. **Multiple keywords were used including the abbreviated names of all respiratory viral infections (SARS-CoV-1, SARS-CoV-2, H1N1, among others) to broaden the search and increase sensitivity to the databases.**

2.4. Inclusion and exclusion criteria

The inclusion criteria were primary and secondary studies of all designs including peer-reviewed research studies, review papers, dissertations and grey literature. Details of inclusion and exclusion criteria are listed in Table 1.

The first reviewer (MA-O) imported all search results to Endnote reference manager version X9, de-duplicated, then screened titles and abstracts of all identified studies. Three authors (MA-O, BA, RO-P) screened retained studies against inclusion/ exclusion criteria, any article for which inclusion was unclear was discussed and adjudicated by authors (JB and YS). Full texts of the articles were obtained if abstracts did not contain sufficient information to determine the relevance of an article. We extracted variables such as sample size and characteristic, aims/objectives, design, respiratory virus being controlled by face mask, type of face mask used, impact/effectiveness of face mask controlling respiratory virus and sample size and final conclusions drawn to a common table (see Table 3). Studies not meeting the inclusion criteria were excluded from the analysis.

2.5. Analysis

Summary statistics were used to report the number of published studies and presented in a PRISMA flow diagram in Fig. 1. We analysed descriptions of types of face masks by comparing masks vs. no masks, N95 vs. surgical/ medical face masks and other respirators; respiratory virus being controlled and effectiveness of face masks in controlling transmission of respiratory pathogens. All studies (qualitative, quantitative and systematic reviews) were analysed descriptively, and then findings synthesised. All studies addressing any type of respiratory virus/ infection and any type of face mask used were retained in the final analysis.

3. Results

3.1. Study characteristics

A total of 84 studies were retrieved through database and reference list search as shown in Fig. 1. Of the 84 studies, 19 irrelevant studies were excluded, leaving 65 studies for full-text review: 7 papers were excluded as they did not meet the inclusion criteria (reasons reported in Fig. 1) and 58 studies met the inclusion criteria. These 58 studies were retained for final analysis. Study designs included were mainly systematic reviews and quantitative studies (comprising randomised controlled trials, retrospective cohort studies, case control, cross-sectional, surveys, observational and descriptive studies). Of the 58 papers included in this review, 13 of them were systematic reviews and 45 were quantitative studies. Countries where these studies were conducted included Mainland China ($n = 10$); United States of America (USA) ($n = 9$); Canada ($n = 4$); Hong Kong ($n = 4$); South Korea ($n = 4$); Australia, Japan, Singapore, Thailand, and Vietnam each have two studies; and France, Germany, Mexico and Saudi Arabia each have one study.

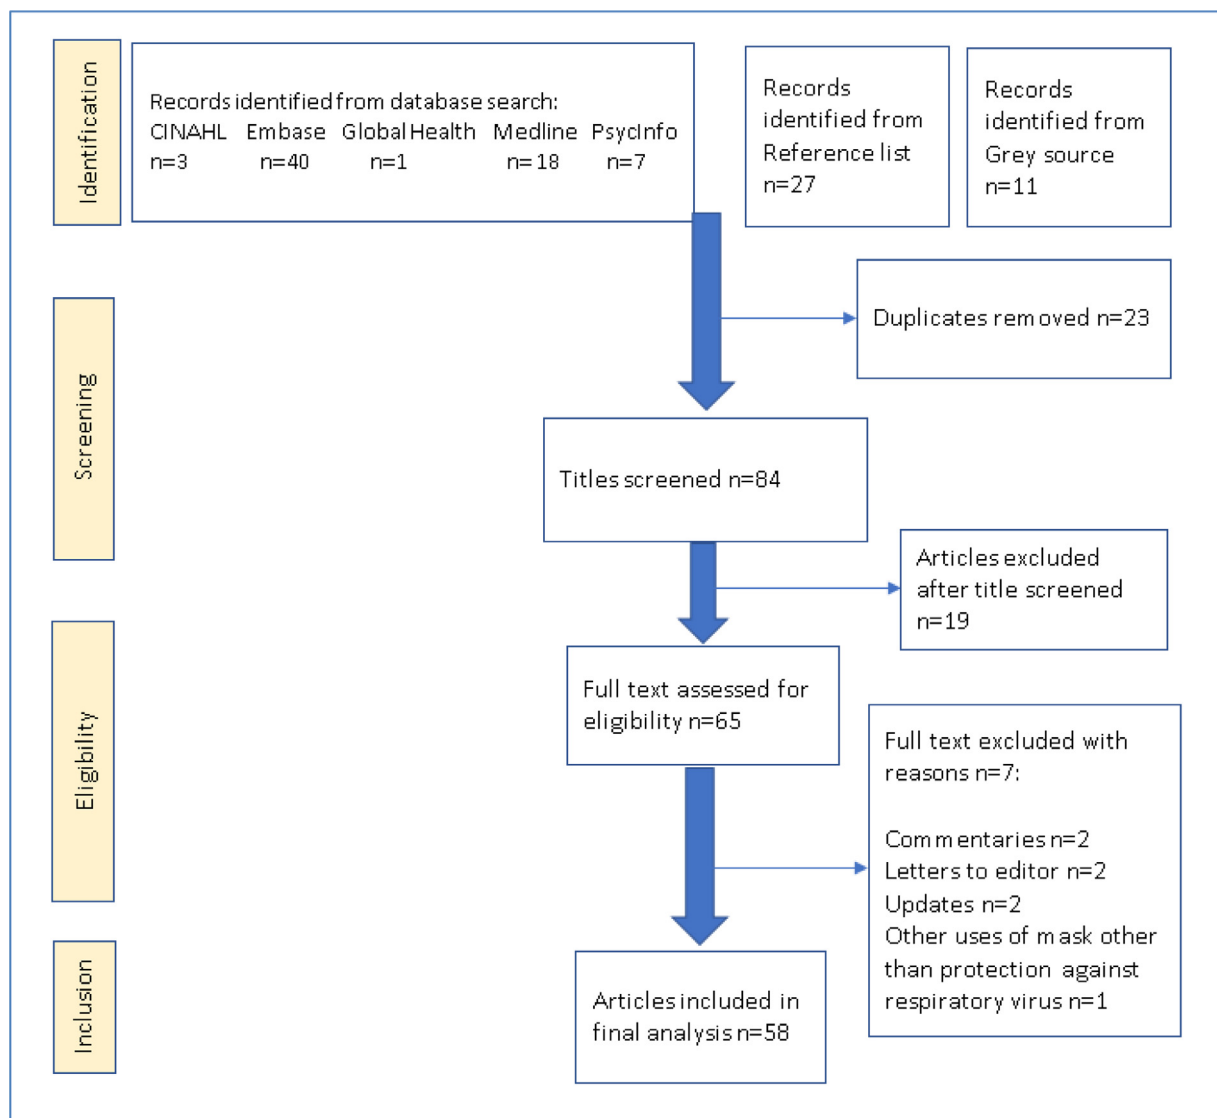

Fig. 1. PRISMA flow diagram.

13 systematic reviews were conducted by authors from multiple countries (see Table 3 for details of study designs and respective countries where the studies were conducted).

Fig. 2 represents the characteristics of the study samples in the various papers. $n = 27$ of the papers reported studies conducted amongst healthcare workers wearing face masks, $n = 19$ studies focused on wearing masks among the general population, $n = 9$ of the papers focused on a combination of studies of healthcare workers, the general population and patients wearing masks, and $n = 3$ focused on only patients wearing masks.

Table 2 also represents the distribution of the types of face masks that were studied in the various studies reviewed. $n = 14$ studies did not mention the type of face masks used, $n = 13$ studies used surgical masks, $n = 12$ studies used both surgical and N95 masks, $n = 10$ used N95, $n = 5$ studied all types face masks (N95, Surgical Masks, Cotton, Paper, Fabrics etc.), $n = 2$ used paper, cotton and gauze masks, $n = 1$ used surgical masks and cloth mask, and $n = 1$ used N95, surgical masks and paper masks.

4. Data synthesis

4.1. Types of face masks used to control various respiratory viruses

Majority of the studies ($n = 55$) included in the review reported the use of various types of face masks to control the transmission of respiratory viruses. Table 4 summarises the types of masks used to control the various respiratory viruses.

Fig. 2. A plot showing the distribution of participant groups included in the studies reviewed.

Table 2
Types of face masks and corresponding number of studies that used them.

Type of face mask used	Number of studies (n)
Specific mask not mentioned	n = 14
Surgical masks	n = 13
Both N95 and surgical mask	n = 12
N95	n = 10
All types (N95, Surgical Masks, Cotton, Paper, Fabrics etc.)	n = 5
Paper, cotton and gauze masks	n = 2
Surgical masks and cloth mask	n = 1
N95, surgical masks and paper masks	n = 1

5. Effectiveness of face masks in controlling transmission of respiratory pathogens

5.1. Masks vs. no masks

All studies that compared the use of face mask, irrespective of the type, to non-use of face mask observed a significantly higher rate of infection among the participants who did not use mask. For instance, Wang et al. (2020a) reported no SARS-CoV-2 infection among participants who wore a face mask whilst 10 participants in the no mask group were infected. In similar lines, the risk of contracting SARS-CoV-2 was reported to be 36.9 times higher in those who used no masks (Wang et al., 2020a). In addition, Kim et al. (2016) noted that two participants who did not wear a mask contracted MERS-CoV. Despite the findings above, two studies observed no significant change regarding the use or non-use of face masks in controlling influenza (GOV.UK 2020) or common cold (Cowling et al., 2008).

5.2. N95 vs. surgical/ medical face mask

Mixed findings were reported by studies that compared N95 to surgical/ medical masks. Six studies observed that both forms of face mask offered similar levels of protection in controlling the transmission of respiratory pathogens (Benkouiten and Brouqui, 2014, Johnson et al., 2009, Ki et al., 2019, Kim et al., 2016, Radonovich et al., 2019, Smith et al., 2016). Despite the notion of both forms of face masks offering similar levels of protection in controlling the transmission of SARS-CoV, one study observed that this did not apply to H1N1 influenza (Offeddu et al., 2017). Four studies further highlighted that N95 offered a better form of protection when compared with surgical masks (Loeb et al., 2009, MacIntyre et al., 2017, Scales et al., 2003, Seto et al., 2003). Further, in this regard, MacIntyre et al. (2013) observed that it is the continuous use of N95, rather than the intermittent use that offered an effective protection against clinical respiratory illness. Although Inouye et al. (Jefferson et al., 2011) observed that face masks made from paper, cotton gauze or non-woven fabric provided some protection, Offeddu et al. (2017) highlighted that paper or reusable cotton face masks offered no protection and were associated with a higher risk of harbouring various pathogens when compared to N95 or medical masks. Similarly, MacIntyre et al. (2015) also noted that the use of a double-layered cloth face mask led to a high rate of influenza-like illness as compared to those who used other types of masks. These findings notwithstanding, the study findings

Table 3Studies included on face mask use to prevent respiratory virus transmission $n = 58$.

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
1	(Aiello et al., 2010) USA	1437	College students	To examine whether use of face masks and hand hygiene reduced the incidence of influenza-like illness	Randomised controlled trial	Seasonal Influenza-like illness	Masks + hand washing Control	We observed significant reductions in influenza-like illness during weeks 4–6 in the mask and hand hygiene group, compared with the control group, ranging from 35% (confidence interval 9%–53%) to 51% (Confidence Interval 13%–73%), after adjusting for vaccination and other covariates. Face mask use alone showed a similar reduction in influenza-like illness compared with the control group, but adjusted estimates were not statistically significant.	These findings suggest that face masks and hand hygiene may reduce respiratory illnesses in shared living settings and mitigate the impact of the influenza A pandemic.
2	(Aiello et al., 2012) USA	1178	College students	To examine if the use of face masks and hand hygiene reduced rates of influenza-like illness and laboratory-confirmed influenza in the natural setting.	Randomised controlled trials	influenza-like illness and laboratory-confirmed influenza	Masks Masks + hand hygiene Control	A significant reduction in the rate of influenza-like illness was observed in weeks 3 through 6 of the study, with a maximum reduction of 75% during the final study week (rate ratio = 0.25, [95% Confidence Interval, 0.07 to 0.87]). Both intervention groups compared to the control showed cumulative reductions in rates of influenza over the study period, although results did not reach statistical significance.	Face masks and hand hygiene combined may reduce the rate of influenza-like illness and confirmed influenza in community settings. These non-pharmaceutical measures should be recommended in crowded settings at the start of an influenza pandemic.

3	(Barasheed et al., 2014) Saudi Arabia	164	Hajj pilgrims	To test the effectiveness of face masks against syndromic and laboratory-confirmed infections among Australian pilgrims to assess the feasibility of such a large-scale trial in the coming years.	A randomised pilot study	Influenza and other respiratory infections	Mask and control	Mask use compliance was 76% in the 'mask' group and 12% in the 'control' group. Based on developing syndromic influenza-like illness, less contacts became symptomatic in the 'mask' tents compared to the 'control' tents (31% versus 53%, $p = 0.04$). However, laboratory results did not show any difference between the two groups.	This pilot study shows that a large trial to assess the effectiveness of face masks use at Hajj is feasible.
4	(Bartoszko et al., 2020)	4 studies	Healthcare workers	To compare medical masks to N95 respirators in preventing viral respiratory infections	Systematic review and meta-analysis	SARS-CoV, SARS-CoV-2, influenza	Surgical mask, N95 mask	Medical masks are as good as N95 masks in protecting healthcare workers against laboratory confirmed viral respiratory infections when performing routine care including non-aerosol-generating care.	N95 masks required during aerosol-generating care
5	(Benkouiten and Brouqui, 2014)	17 studies	General population on Hajj pilgrimage	To summarize evidence related to the effectiveness of non-pharmaceutical measures in preventing spread of respiratory diseases during Hajj	Systematic review	Respiratory infection	Surgical mask	3 studies showed significant reduction in respiratory symptoms with surgical mask use. Several other studies found no significant effect of surgical mask use on respiratory symptoms.	None of the studies established conclusively any relationship between mask use and prevention of respiratory infection.
6	(Bin-Reza et al., 2012)	17 studies	Healthcare workers and general population	To review face mask and respirator use in an influenza pandemic	Systematic review	Influenza Virus	Surgical mask, N95 mask/respirator	None of the studies provided conclusive evidence of a relationship between mask or respirator use and prevention of influenza transmission.	Evidence on influenza transmissibility is limited and conflicting.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
7	(Bischoff et al., 2007) USA	10	Healthcare workers	Exploring the efficacy of the barrier precautions currently used in the healthcare setting for preventing airborne dispersal, as well as in how a common cold might impact the efficacy of these precautions.	Quantitative study	Rhinovirus induced common cold	N95	Decrease in airborne spread when participants wear facemasks.	Wearing a face mask can prevent the spread of some microorganisms to some extent.
8	(Canini et al., 2010) France	306	Household subjects	To evaluate the effectiveness of surgical face masks for limiting influenza transmission by large droplets produced during coughing.	A cluster randomised controlled trial	Influenza	Surgical masks	influenza-like illness was reported in 24/148 (16.2%) of the contacts in the intervention arm and in 25/158 (15.8%) of the contacts in the control arm and the difference between arms was 0.40% (95%CI: -10% to 11%, P= 1.00). We observed a good adherence to the intervention. In various sensitivity analyses, we did not identify any trend in the results suggesting effectiveness of face masks	This study should be interpreted with caution since the lack of statistical power prevents us from drawing formal conclusions regarding effectiveness of facemasks in the context of a seasonal epidemic.
9	(Cheng et al., 2020) China	10,050	General population	To assess the effect of community-wide mask usage in controlling COVID-19	Observational study	SARS-CoV-2	Any mask	961/10,050 infected with COVID-19. 113/infected 961 were engaged in mask-off activities in recreational settings. 11/961 were engaged in mask-on settings at the workplace. The number of people infected with SARS-CoV-2 were significantly higher amongst those engaged in mask-off activities in public.	Compliance with mask wearing in public settings significantly reduces the incidence of COVID-19.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
14	(Cowling et al., 2009) Hong Kong	407	Households	To investigate whether hand hygiene and use of face masks prevents household transmission of influenza	A cluster randomised controlled trial	Influenza	Hand hygiene masks + hand hygiene control	Sixty (8%) contacts in the 259 households had confirmed influenza virus infection in the 7 days after intervention. Hand hygiene with or without face masks seemed to reduce influenza transmission, but the differences compared with the control group were not significant. In 154 households in which interventions were implemented within 36 h of symptom onset in the index patient, transmission of confirmed infection seemed reduced, an effect attributable to fewer infections among participants using face masks plus hand hygiene	Hand hygiene and face masks seemed to prevent household transmission of influenza virus when implemented within 36 h of index patient symptom onset. These findings suggest that non-pharmaceutical interventions are important for mitigation of pandemic and inter-pandemic influenza.
15	(Heinzerling et al., 2020) USA	43	Healthcare workers	To investigate risk factors for covid-19 infection	Retrospective cohort study	SARS-CoV-2	No face mask	All healthcare workers wore no masks during routine care and aerosol generating procedures. 3/43 got infected.	Sample size too small to draw any conclusion. However, wearing a mask is better than not wearing one.
16	(Hogg et al., 2006) Canada	163	53 participating offices. 110 physicians	The study aims to assess whether a short-term outreach facilitated intervention could be effective in improving practices for control of respiratory infections in family physicians' offices.	Quantitative study	SARS	Specific type of face masks was not mentioned	Before the intervention, Physicians barely (17%) offered masks to patients presenting with symptoms of fever and cough. However, after the intervention this increased (66%).	Enforcing preventive measures amongst health care professionals is effective for control of respiratory infections.

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
23	(Kim et al., 2016) South Korea	737	Healthcare workers	To evaluate the prevalence and incidence of MERS-CoV in healthcare workers exposed to MERS-CoV patients	Survey	MERS-CoV	N95, Powered Air-Purifying Respirator	Almost all MERS-CoV infected healthcare workers did not wear an N95 mask during contact with Middle East Respiratory Syndrome positive patients. However, 2 wore N95 during aerosol-generating care and were infected. The authors were of the view that N95 masks are not totally effective in preventing MERS-CoV infection during aerosol-generating care due to the associated micro droplets.	Appropriate use of N95 masks is important in preventing MERS-CoV transmission.
24	(Larson et al., 2010) USA	617	Households,	To compare the impact of three household interventions: education, education with alcohol-based hand sanitizer, and education with hand sanitizer and face masks on incidence and secondary transmission of upper respiratory infections (URIs) and influenza, knowledge of transmission of URIs, and vaccination rates.	A Randomized Intervention Trial	Upper respiratory tract infection and Influenza	Health education Hand hygiene + health education Masks + hand hygiene +health education	Despite the fact that compliance with mask wearing was poor, mask wearing as well as increased crowding, lower education levels of caretakers, and index cases 0–5 years of age (compared with adults) were associated with significantly lower secondary transmission rates (all $p < 0.02$).	There was no detectable additional benefit of hand sanitizer or face masks over targeted education on overall rates of upper respiratory tract infection, but mask wearing was associated with reduced secondary transmission and should be encouraged during outbreak situations.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
25	(Lau et al., 2008a) Hong Kong	1214	Adults (18–60) General population including persons with influenza-like illness	To investigate use of face mask and exposure to live birds and perceptions related to bird-to-human H5N1 avian influenza.	Quantitative, Cross Sectional telephone survey. Structured Questionnaires were used.	H5N1 avian influenza Flu.	Type of mask not mentioned	36% said the use of the face masks when they had influenza-like illness symptoms. 92.1% of the respondents believed that wearing face mask in public places could prevent contracting bird-to-human H5N1. Factors associated with the use of face masks when having influenza-like illness symptoms include exposure to live birds, perceived similar symptoms between influenza and bird-to-human H5N1 avian influenza.	The use of face masks can prevent the transmission of a respiratory viral infection through droplets spread in public places, and from the bird (carrier) to humans.
26	(Lau et al., 2004) Hong Kong	1097	General population	To investigate the risk factors associated with household attack rates and the household member attack rate for different categories of SARS patients	Case-control study	SARS-CoV	Mask type unspecified	The risk of transmission higher when the infected person and the household member were both not wearing mask	Transmission rates may be greatly reduced with precautionary measures taken by household members of SARS patients
27	(Liang et al., 2020)	21 studies	Healthcare workers and general population	To evaluate the effectiveness of mask-use to prevent transmission of laboratory-confirmed respiratory virus	Systematic review and meta-analysis	Influenza, SARS-CoV, SARS-CoV-2	N95 mask, surgical mask, other mask types (paper, reusable cotton)	Masks significantly reduce the risk of transmission of respiratory viruses in both hospital and community settings.	Appropriate use of masks in healthcare and community settings might help mitigate transmission of respiratory virus infections.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
28	(Liu et al., 2009) China	477	Healthcare workers	To investigate risk factors for SARS transmission	Retrospective case-control study	SARS-CoV	Multiple layered mask, 16-layer cotton mask, 12-layer cotton mask	27.3% wore one-layered cotton mask, 7.0% wore multiple layered masks	Any mask found to be better than no mask in preventing infection. However, a multiple-layered mask is better.
29	(Liung et al., 2020) Hong Kong	246	Children and adults	To determine the potential efficacy of surgical face masks to prevent respiratory virus transmission.	Randomised controlled trial	Respiratory virus infections	Mask and control	Surgical face masks significantly reduced detection of influenza virus RNA in respiratory droplets and coronavirus RNA in aerosols, with a trend toward reduced detection of coronavirus RNA in respiratory droplets.	Our results indicate that surgical face masks could prevent transmission of human coronaviruses and influenza viruses from symptomatic individuals.
30	(Loeb et al., 2004) Canada	43	Healthcare workers	To determine risk factors for SARS transmission	Retrospective cohort study	SARS	Surgical mask, N95 mask	3/23 who consistently wore either of the masks got infected. 5/9 did not consistently wear a mask and got infected.	Risk of infection reduced by 80% when one wore either of the masks consistently. Risk of infection was associated with N95 half that of the surgical mask.
31	(Loeb et al., 2009) Canada	446	Healthcare workers	To compare the surgical mask with the N95 respirator in protecting health care workers against influenza	Non-inferiority randomized controlled trial	Influenza	Medical masks, targeted N95	225 were allocated to receive surgical masks and 221 to N95 respirators. Influenza infection occurred in 50 nurses (23.6%) in the surgical mask group and in 48 (22.9%) in the N95 respirator group (absolute risk difference, -0.73%; 95% CI, -8.8% to 7.3%; $P = 0.86$), the lower confidence limit being inside the non-inferiority limit of -9%.	Use of a surgical mask compared with an N95 respirator resulted in non-inferior rates of laboratory-confirmed influenza

32	(MacIntyre et al., 2009) Australia.	143	Households	To test the effectiveness of using face masks to prevent or reduce transmission of influenza-like illness.	A cluster-randomised household study	Influenza-like illness	Medical masks P2 masks Control	1. Samples were collected from 141 children; respiratory viruses were detected in 90 (63.8%) children. In 79 (56.0%) of 141 cases, a single pathogen was detected: influenza A in 19/141 (13.5%); influenza B in 7/141 (4.9%).	Masks may therefore play an important role in reducing transmission.
33	(MacIntyre et al., 2011) China	1441	Healthcare workers	To compare the efficacy of medical masks, N95 respirators (fit tested and non-fit tested), in healthcare workers.	A cluster randomised controlled trials	Clinical respiratory illness, influenza-like illness, laboratory-confirmed respiratory virus infection and influenza.	Masks N95 respirators, fit tested N95 respirators, non-fit tested Control	The rates of clinical respiratory illness N95 group compared to medical masks. By intention- to-treat analysis, when p-values were adjusted for clustering, non- fit-tested N95 respirators were significantly more protective than medical masks against clinical respiratory illness, but no other outcomes were significant. The rates of all outcomes were higher in the convenience no-mask group compared to the intervention arms. There was no significant difference in outcomes between the N95 arms with and without fit testing.	Rates of infection in the medical mask group were double that in the N95 group. A benefit of respirators is suggested but would need to be confirmed by a larger trial, as this study may have been underpowered.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
34	(MacIntyre et al., 2013) China	1669	Healthcare workers	To compare three policy options for the use of medical masks and N95 respirators in healthcare workers	Randomised controlled trial	Clinical respiratory illness and laboratory-confirmed respiratory pathogens in symptomatic subjects.	Medical Mask N95 (continuous) N95 (targeted)	N95 Bacterial respiratory tract colonization in subjects with clinical respiratory illness was highest in the medical mask arm (14.7%; 84 of 572), followed by the targeted N95 arm (10.1%; 52 of 516), and lowest in the N95 arm (6.2%; 36 of 581) (P 1/4 0.02). After adjusting for confounders, only continuous use of N95 remained significant against CRI and bacterial colonization, and for just CRI compared with targeted N95 use. Targeted N95 use was not superior to medical masks.	Continuous use of N95 respirators was more efficacious against clinical respiratory illness than intermittent use of N95 or medical masks.
35	(MacIntyre et al., 2015) Vietnam	1607	Healthcare workers	To compare the efficacy of cloth masks to medical masks in hospital healthcare workers. The null hypothesis is that there is no difference between medical masks and cloth masks.	A cluster randomised controlled trial	Clinical respiratory illness, influenza-like illness and laboratory-confirmed respiratory virus infection.	Medical masks, cloth masks, control	The rates of all infection outcomes were highest in the cloth mask arm, with the rate of influenza-like illness statistically significantly higher in the cloth mask arm compared with the medical mask arm. Cloth masks also had significantly higher rates of influenza-like illness compared with the control arm. An analysis by mask use showed influenza-like illness and laboratory-confirmed virus were significantly higher in the cloth masks group compared with the medical masks group. Penetration of cloth masks by particles was almost 97% and medical masks 44%.	This study is the first randomised controlled trial of cloth masks, and the results caution against the use of cloth masks. This is an important finding to inform occupational health and safety. Moisture retention, reuse of cloth masks and poor filtration may result in increased risk of infection. Further research is needed to inform the widespread use of cloth masks globally. However, as a precautionary measure, cloth masks should not be recommended for healthcare workers, particularly in high-risk situations, and guidelines need to be updated.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
36	(MacIntyre and Chungtai, 2015)	13 randomised controlled trials, 33 Non-randomised controlled trials	Healthcare workers and general population	To summarize available evidence on efficacy of face masks and respirators	Systematic review	Respiratory infections	Surgical masks, N95 mask, any face mask (paper mask, reusable cotton mask)	Respirators offer greater protection to healthcare workers than surgical masks. Use of any facemask in community settings associated with reduced community transmission of respiratory infections.	There is a lack of randomised controlled trials on reusable cloth masks.
37	(MacIntyre et al., 2016) China	245	Household	To determine whether medical mask use by sick individuals with influenza-like illness protects well contacts from related respiratory infections	A cluster randomised controlled trial	Influenza-like illness	Medical mask worn by sick case Control (no mask) Household contacts Followed for infection.	Rates of clinical respiratory illness (relative risk (RR) 0.61, 95% CI 0.18 to 2.13), influenza-like illness (RR 0.32, 95% CI 0.03 to 3.13) and laboratory-confirmed viral infections (RR 0.97, 95% CI 0.06 to 15.54) were consistently lower in the mask arm compared with control, although not statistically significant. A post hoc comparison between the mask versus no-mask groups showed a protective effect against clinical respiratory illness, but not against influenza-like illness and laboratory-confirmed viral respiratory infections.	The study indicates a potential benefit of medical masks for source control but is limited by small sample size and low secondary attack rates. Larger trials are needed to confirm efficacy of medical masks as source control.
38	(MacIntyre et al., 2017)	2 Randomised control trials,	Healthcare workers	To examine the efficacy of medical masks and N95 masks against respiratory infections	Systematic review	Respiratory infections	N95 mask, surgical mask	Viral respiratory infections significantly lower in the continuous N95 arm and targeted N95 arm.	N95 masks are more beneficial either for use (continuous or targeted). Medical masks do not appear to offer significant protection.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
39	(MacIntyre and Chughtai, 2020)	19 Randomised controlled trials	Healthcare workers, sick patients and the general public	To review the evidence around the efficacy of masks and respirators for healthcare workers, sick patients and the general public.	A systematic review of randomised controlled trial	Coronaviruses and other respiratory transmissible viruses	Masks and respirators	Most of these randomised controlled trials used different interventions and outcome measures. In the community, masks appeared to be effective with and without hand hygiene, and both together are more protective. Randomised controlled trials in health care workers showed that respirators, if worn continually during a shift, were effective but not if worn intermittently. Medical masks were not effective, and cloth masks even less effective. When used by sick patients randomised controlled trials suggested protection of well contacts.	The study suggests that community mask use by well people could be beneficial, particularly for COVID-19, where transmission may be pre-symptomatic. The studies of masks as source control also suggest a benefit and may be important during the COVID-19 pandemic in universal community face mask use as well as in health care settings.
40	(Milton et al., 2013) USA	38	Patients	To report the culturability of virus in fine particle fraction and the effect of surgical mask	Quantitative Study	Seasonal Influenza	Surgical mask	a. Wearin Surgical mask nearly eliminated viral RNA detection in the coarse aerosol fraction. When not wearing mask viral RNA in coarse particles exhaled by 43% and in fine particles exhaled by 92% of influenza patients was detected.	Wearing of surgical masks reduces the spread of the virus from infected persons to others.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
41	(Offeddu et al., 2017)	29 studies	Healthcare workers	To assess the effectiveness of medical masks and respirators in protecting healthcare workers from respiratory infections	Systematic review and meta-analysis	Viral respiratory infections	N95 respirator, surgical mask, paper mask, reusable cotton mask	Meta-analysis of randomised controlled trials - masks and respirators are protective against clinical respiratory illness and influenza-like illness but not laboratory confirmed infection. N95 confers greater protection. Meta-analysis of observational studies - both respirators and masks confer protection against SARS but not HINI influenza	Both respirators and masks are effective in preventing healthcare workers from SARS-CoV infection but not HINI influenza. Paper masks and reusable cotton masks offer no protective benefit and may harbor infections that are not decontaminated appropriately.
42	(Park et al., 2004) USA	110	Healthcare workers	To determine the extent of SARS transmission	Survey	SARS-CoV	N95 mask or higher respirators	44/110 had at least one exposure without a respirator (N95 mask or higher respirators).	None of the healthcare workers got infected. Lack of infection may have resulted from relative absence of highly infectious patients or high-risk procedures.
43	(Radonovich et al., 2019) USA	2371	Healthcare workers	To compare the effect of N95 respirators vs medical masks for prevention of influenza and other viral respiratory infections among healthcare workers	A cluster randomized pragmatic effectiveness study	Incidence of laboratory-confirmed influenza; incidence of acute respiratory illness, laboratory-detected respiratory infections, laboratory-confirmed respiratory illness, and influenza-like illness.	Medical masks, targeted N95 (when 2 m from confirmed respiratory infection) in Outpatient setting.	There were 207 laboratory-confirmed influenza infection events in the N95 respirator group and 193 in the medical mask group There were 1556 acute respiratory illness events in the respirator group vs 1711 in the mask group; 679 laboratory-detected respiratory infections in the respirator group vs 745 in the mask group; 371 laboratory-confirmed respiratory illness events in the respirator group vs 417 in the mask group; and 128 influenza-like illness events in the respirator group vs 166 in the mask group. In the respirator group, 89.4% of participants reported "always" or "sometimes" wearing their assigned devices vs 90.2% in the mask group.	N95 respirators vs medical masks as worn by participants in this trial resulted in no significant difference in the incidence of laboratory-confirmed influenza.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
44	(Ryu et al., 2019) South Korea	34	Public health workers	To determine degree of exposure of public health workers and whether they were infected	Cross-sectional study	MERS-CoV	N95 mask	All wore N95 masks. 1 in full personal protective equipment developed fever. None was infected with laboratory confirmed MERS-CoV.	Risk of transmission of MERS-CoV outside hospitals is low.
45	(Saunders-Hastings et al., 2017) Canada	16 studies	Healthcare workers and general population	To assess the effectiveness of personal protective measures in reducing risk of influenza transmission	Systematic review and meta-analysis	Influenza	Surgical mask	8/16 studies measured effectiveness of face mask use. They found face mask use to be not significantly protective	Surgical masks have demonstrated mixed results in various studies. A randomised controlled trial has suggested it is effective.
46	(Scales et al., 2003) Canada	69	Healthcare workers	To investigate risk associated with SARS transmission after exposure infected patients	Retrospective survey	SARS-CoV	Surgical mask, N95 mask	7/69 developed SARS. 6/31 who entered the patient's room got infected. 6 wore surgical masks and 2 got infected. 6 wore N95 masks and 1 got infected. 8 observed no precautions and 1 got infected.	Airborne transmission may have occurred in some of the situations.
47	(Seto et al., 2003) China	254	Healthcare workers	To assess the effectiveness of droplet precautions for prevention of nosocomial transmission	Case-control study	SARS	Paper mask, N95 Mask, surgical mask	13 infected; 241 control 2/13 infected used paper masks. None of those infected used surgical masks or N95 masks.	Mask use was the significant predictor of prevention from being infected. Paper mask did not significantly reduce the risk of infection because it easily gets wet with saliva.

(continued on next page)

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
48	(Smith et al., 2016)	27 studies	Healthcare workers	To review clinical and surrogate exposure data comparing N95 respirators and surgical face masks for the prevention of transmission of respiratory infections	Systematic review and meta-analysis	Influenza	Surgical facemask, N95 mask	Clinical studies - There was no significant difference between N95 and surgical facemasks in rate of infection. Surrogate exposure studies: N95 respirators were associated with less filter penetration, less face-seal leakage, and less total inward leakage	Healthcare workers wearing N95 respirators are more likely to contaminate their faces while wearing the mask because it is generally uncomfortable to wear, may be worn improperly and may be adjusted more frequently. Thus, the potential benefits of N95 over surgical masks may be negated.
49	(Simmerman et al., 2011) Thailand	465	General population	To estimate the efficacy of handwashing and face mask use in decreasing influenza transmission	Randomised controlled trial	Influenza virus	Paper surgical mask	No statistically significant benefit found with the use of paper surgical masks in either secondary attack rate or multivariate analysis	There was a poor adherence to interventions - handwashing and face mask use. This may have contributed to the lack of efficacy seen.
50	(Suess et al., 2012) Germany	84 index cases and 218 household contacts,	Index cases and household contacts,	To test the efficacy, adherence and tolerability of facemasks and intensified hand hygiene to prevent influenza transmission in households.	A cluster randomised controlled trial	Influenza virus	Masks and Masks + hand hygiene Control	There was no statistically significant effect of the Masks and Mask + Hand hygiene interventions on secondary infections. However, within households where intervention was implemented within 36 h of symptom onset of the index case, secondary infection in the pooled Mask and Mask+Hand hygiene groups was significantly lower compared to the control group. In a per-protocol analysis odds ratios were significantly reduced among participants of the Mask group. With the exception of Masks+Hand hygiene index cases in 2010/11 adherence was good for adults and children, contacts and index cases.	Results suggest that household transmission of influenza can be reduced by the use of facemasks and intensified hand hygiene, when implemented early and used diligently. Concerns about acceptability and tolerability of the interventions should not be a reason against their recommendation.

Table 3 (continued)

No.	Author/ Year/ Country	Sample size	Sample characteristics	Study aim	Design	Respiratory virus being controlled by face mask	Type of face mask used	Impact/ Effectiveness of face mask controlling respiratory virus	Conclusion/ Comments
56	(Wu et al., 2004) China	94 case-patients, 281 matched controls	General population	To assess the risk factors for SARS among persons without known contact to SARS patients	Matched case-control study	SARS-CoV	Masks type unspecified	There was a 70% reduction in the risk of infection with SARS when participants wore a mask consistently as compared to not wearing a mask. Intermittent wearing of masks was also found to offer some protection.	Wearing a mask is significantly protective against development of clinical SARS.
57	(Xiao et al., 2020)	10 randomised controlled trials	General population	To evaluate the effectiveness of personal protective measures on transmission of influenza virus	Systematic review and meta-analysis	Influenza	Surgical mask	There was no statistically significant reduction in influenza transmission with the use of surgical mask (RR 0.78, 95% CI 0.51–1.20; I ² =30%, <i>P</i> = 0.25)	Surgical mask use either by the infected or infected person does not affect influenza transmission significantly.
58	(Laosiritaworn, 2014) Thailand		General Public (students and workers)	The study aimed to use an agent-based model to estimate influenza burden in Thailand and assess impact of control measures.	Quantitative study Dissertation	Influenza virus	Surgical mask	The use of face masks is a non-pharmacological intervention that can spread the virus. The use of face masks is an effective strategy for countries that cannot afford vaccines. Face masks are used to limit influenza transmission by minimizing the distribution of large secretion droplets produced during sneezing or coughing.	Wearing of face masks can be used to reduce the spread of the influenza virus.

Table 4

Types of face masks used in controlling respiratory virus.

Type of face mask	Target respiratory virus	Author(s)
Surgical/ medical face mask	Influenza	(MacIntyre and Chughtai, 2020, Aiello et al., 2012, Barasheed et al., 2014, Bartoszko et al., 2020, Cheng et al., 2020, Cowling et al., 2009, GOV.UK 2020, Heinzerling et al., 2020, Jefferson et al., 2011, Lau et al., 2008a, Lau et al., 2004, Loeb et al., 2009, MacIntyre et al., 2011, MacIntyre et al., 2013, MacIntyre et al., 2015, MacIntyre et al., 2016, MacIntyre et al., 2017, Milton et al., 2013, Radonovich et al., 2019, Saunders-Hastings et al., 2017, Smith et al., 2016, Simmerman et al., 2011, Suess et al., 2012, Xiao et al., 2020, Laosiritaworn, 2014)
Surgical mask, N95 mask	SARS-CoV, SARS-CoV-2, influenza	(MacIntyre and Chughtai, 2020, Benkouiten and Brouqui, 2014, Liu et al., 2009, Liung et al., 2020, Scales et al., 2003, Teleman et al., 2004, Tuan et al., 2007, Wang et al., 2020a,b, Wilder-Smith et al., 2005, Chou et al., 2020).
Surgical mask	Not specified	(Bin-Reza et al., 2012, Loeb et al., 2004)
Surgical mask, N95 mask/respirator	Influenza	(Bischoff et al., 2007, Johnson et al., 2009, Ki et al., 2019, MacIntyre and Chungtai, 2015)
Any type of mask	SARS-CoV-2	(Christie et al., 1995, Park et al., 2004)
N95 mask, surgical mask, other mask types (paper, reusable cotton)	SARS-CoV-2, SARS-CoV, MERS-CoV	(Condon and Sinha, 2009)
No face mask	SARS-CoV-2	(Hogg et al., 2006)
Unspecified	SARS	(Inouye et al., 2006, Loeb et al., 2009, Seto et al., 2003, Wu et al., 2004)
Surgical mask; N95; Powered Air-Purifying Respirator	MERS	(Kim et al., 2015, Kim et al., 2016, Larson et al., 2010, Ryu et al., 2019)
Unspecified	SARS-CoV	(Liang et al., 2020)
N95 respirator, surgical mask, paper mask, reusable cotton mask	Viral respiratory infections	(Offeddu et al., 2017)

by [Smith et al. \(2016\)](#) offers a caution to healthcare professionals as the authors noted that nurses/ physicians are more likely to contaminate their faces while wearing the N95 mask due to the discomfort associated with their use.

5.3. Other respirators

Beside N95 and surgical facemasks, the use of other advanced respirators were noted in the review. One study reported the enhanced efficacy of the Powered Air-Purifying Respirator in controlling/ preventing the transmission of MERS-CoV in comparison to N95 ([Larson et al., 2010](#)). The use of other advanced respirators also protected healthcare professionals from contracting SARS-CoV ([Park et al., 2004](#)).

5.4. Combined use of masks and hand hygiene

Five studies evaluated the combined effects of face masks and hand hygiene in reducing transmission ([Aiello et al., 2012](#), [Barasheed et al., 2014](#), [Heinzerling et al., 2020](#), [Lau et al., 2008a](#), [Suess et al., 2012](#)). Three studies observed that the utilization of mask and hand hygiene significantly lowered the transmission of influenza-like illness ([Aiello et al., 2012](#), [Barasheed et al., 2014](#), [Heinzerling et al., 2020](#)). Although [Suess et al. \(2012\)](#) did not observe a statistically significant difference on the combined effects of mask and hand hygiene, the authors noted that commencement of these interventions within 36hours of symptom onset of the index case led to lower rates of transmitting secondary infection among contacts.

6. Discussion

Findings suggest that the correct and early use of facemask or face covering could save many more lives than when it is not used. Mask use could lower the risk of COVID-19 transmission ([MacIntyre and Chughtai, 2020](#), [Christie et al., 1995](#), [Hogg et al., 2006](#), [Loeb et al., 2004](#)), SARS ([Inouye et al., 2006](#)), Influenza ([Ki et al., 2019](#), [Laosiritaworn, 2014](#)), MERS ([Kim et al., 2015](#)) and recommended for use in the public ([Condon and Sinha, 2009](#)). Additionally, N95 masks seem to provide a better form of protection from influenza-like illness than the other types of masks when used continuously, rather than intermittently ([MacIntyre et al., 2009](#), [MacIntyre et al., 2013](#), [MacIntyre et al., 2017](#)) and a multi-layered mask offered better protection ([Liung et al., 2020](#)). However, in a randomised controlled trial [Smith et al. \(2016\)](#) concluded that the process of wearing N95 respirators might lead to contamination due to the following factors; 1) N95 is mostly uncomfortable to wear, 2) may be worn improperly and 3) may be adjusted often. This will have implication for clinical practice where the setting could lead to transmission of disease to vulnerable patients, and therefore proper hand washing should be ensured in addition to mask use ([Adhikari et al., 2020](#)).

The use of cloth masks was cautioned as it has a greater moisture retention, likely to be reused and may have poor filtration that may result in increased risk of infection when not properly decontaminated (MacIntyre et al., 2015, Offeddu et al., 2017). Paper mask was identified as the worst of them all because they easily moisten and disintegrate (Seto et al., 2003). This, therefore, means that when people use cloth mask; it must be washed after each use and dried and or ironed to reduce the risk of contamination. The general use of face masks was recommended in several countries, such as Mainland China, Hong Kong Special Administrative Region, Singapore, Japan, USA, UK, and Germany in the early period of the outbreak of COVID-19 pandemic (Feng et al., 2020). Additionally, the review findings suggest a need to consider the utilisation of other adjunct measures such as hand hygiene in order to decrease the risk of transmission further. Taken together, the findings offer support to enforce the early and correct use of face masks and meticulous hand hygiene.

Our review shows that wearing a face mask has a great potential in controlling airborne transmitted viruses including COVID-19. This corroborate previous works that indicated that mask use is beneficial to prevent the transmission of COVID-19 (Greenhalgh et al., 2020). Greenhalgh et al. (2020) concluded that wearing a face mask in public should be encouraged regardless, even if the protection it offers is limited. This they argued, will limit transmission of COVID-19 and save some lives. In a narrative rebuttal to critics who disagreed with the contention by Greenhalgh et al. (2020) that face mask could be used as a 'precautionary measure' when in public, the author maintained that in time of global health and economic crises a reliance on only 'perfect evidence' such as randomised controlled trial evidence, may be the enemy of good policy. A recent rapid systematic review on face mask use and its efficacy against coronavirus and other respiratory viruses found that mask use in public could be beneficial within in the community and clinical settings for the prevention of COVID-19, especially those who have not yet started showing clinical symptoms (MacIntyre and Chughtai, 2020). Their study also indicated that mask use offered respiratory protection from patients (source control) to others. Although this review focused only on randomised controlled trial, which is widely believed to be the 'gold standard' for evidence, we contend that for people to accept the use of mask, they do not only need the evidence for its use, but also require the potential and actual problems associated with mask use to be addressed. This study addresses this loophole, since it included all study designs.

We are also cognisant of all the systematic reviews conducted on the use of face masks and other face-covering (MacIntyre and Chughtai, 2020, Bartoszko et al., 2020, Benkouiten and Brouqui, 2014, Bin-Reza et al., 2012, Chu et al., 2020, Jefferson et al., 2011, Liang et al., 2020, MacIntyre and Chungtai, 2015, MacIntyre et al., 2017, Offeddu et al., 2017, Saunders-Hastings et al., 2017, Smith et al., 2016, Xiao et al., 2020). These reviews have mainly focused on: (a) a combination of different primary study designs (Bartoszko et al., 2020, Benkouiten and Brouqui, 2014, Bin-Reza et al., 2012, Chu et al., 2020, Jefferson et al., 2011, Liang et al., 2020, Offeddu et al., 2017, Saunders-Hastings et al., 2017, Smith et al., 2016); (b) only randomised controlled trials (MacIntyre and Chughtai, 2020, MacIntyre and Chungtai, 2015, MacIntyre et al., 2017, Xiao et al., 2020); (c) studied multiple interventions in addition to face-covering (Bin-Reza et al., 2012, Chu et al., 2020, Liang et al., 2020, Offeddu et al., 2017); (d) only healthcare workers and general population (Bin-Reza et al., 2012, Chu et al., 2020, Jefferson et al., 2011, Liang et al., 2020, MacIntyre and Chungtai, 2015, Saunders-Hastings et al., 2017); (e) only healthcare workers (Bartoszko et al., 2020, MacIntyre et al., 2017, Offeddu et al., 2017, Smith et al., 2016); (f) only general population (Benkouiten and Brouqui, 2014, Xiao et al., 2020); and (g) a combination of healthcare workers, general population and patients (MacIntyre and Chughtai, 2020).

Therefore, the findings from this study which reviewed all study designs (including systematic reviews), focusing on all types of study population (healthcare workers, general population and patients), and using face mask to prevent all types of respiratory viral transmission will reinforce the evidence presented in the above reviews. Additionally, these findings could help in drawing a holistic conclusion of the impact of face masks in preventing the spread of respiratory viral infection in order to make policy recommendation for their use. Wearing face masks will not only protect lives but can protect the economy because people can engage in their work, less likely to be infected, are able to prevent possible future lockdowns, and ensure people stay healthy enough to work.

The study findings have significant bearing on nursing practice particularly, regarding the education of the populace and patients on the early and continuous use of appropriate face masks, in addition to other measures (such as hand hygiene) as we navigate the pandemic. As nurses continue to play critical roles as frontline workers, the findings of this review can enhance infection control measures instituted during the COVID-19 pandemic. As noted in the review, the efficacy of some face masks used such as those made from paper and cloth has not been established therefore, further research is required in this regard to strengthen the evidence base. Additionally, the effectiveness of reusable face masks after being washed is another area requiring more evidence. Despite the extensiveness of the current review, some limitations are noteworthy, including reviewing only studies published and reported in English thereby missing out on grey literature and studies published in other languages.

7. Conclusion

This rapid review highlights the impact of face mask use in preventing respiratory virus transmission among healthcare workers, patients and the general population. Findings demonstrate that, regardless of the type, setting, or who wears the face mask, it serves primarily a dual preventive purpose; protecting oneself from getting viral infection and protecting others. Therefore, if everyone wears a face mask in public, it offers a double barrier against COVID-19 transmission. In addition, this review reveal that the prolonged/continuous use of face masks may affect a person's oxygen concentration level and may lead to dizziness due to repeated rebreathing of carbon dioxide retention. Consequently, we recommended that any future study conducted on the use of masks, investigates the length at which mask can be used at a particular time in order to mitigate these negative health effects.

Controlling the spread of COVID-19 could save lives, prevent possible reintroduction of lockdowns, and ensure that health systems are not overwhelmed with severe cases of COVID-19.

Acknowledgements

I acknowledge all authors for their contribution to this rapid review.

This review was conceived and designed by, and The first reviewer imported all search results to Endnote reference manager version X9, de-duplicated, then all authors screened titles and abstracts of all identified studies, any article for which inclusion was unclear were discussed and if necessary adjudicated by the last reviewer. All authors critically appraised and contributed to the manuscript.
