Hip Pain Associated with Acetabular Dysplasia in Patients with Suspected Axial Spondyloarthritis: DESIR Cohort Data

Dewi Guellec¹, Guillaume Prado², Corinne Miceli-Richard³, Guillermo Carvajal-Alegria⁴ and Alain Sarau^{4*}

Abstract

Objectives: To determine whether acetabular dysplasia is associated with hip pain at physical examination among adults with recent-onset inflammatory back pain (IBP) suggesting axial spondyloarthritis (axSpA).

Methods: This cross-sectional ancillary study was conducted on the prospective DESIR cohort, which enrolled patients aged 18–50 years who had recent-onset IBP. Two readers used antero-posterior pelvic radiographs to assess the Tönnis angle, acetabular angle (AA), lateral centre-edge angle (LCEA), and femoral head extrusion index (FHEI). Abnormality of one or more of these four variables defined acetabular dysplasia. Hip pain upon physical examination was assessed based on Ritchie's articular index.

Results: The overall prevalence of acetabular dysplasia was 22% (139/636). The proportion of females was higher in the group with acetabular dysplasia. Hip pain was found in 21% (29/139) of patients with versus 12% (59/497) without acetabular dysplasia (OR, 1.96; 95% CI, 1.20 to 3.20); the association was significant in males (OR, 3.14; 95% CI, 1.44 to 6.86) but not females (OR, 1.39; 95% CI, 0.74 to 2.62). Results were similar when acetabular dysplasia was defined on the basis of LCEA alone (OR, 2.15; 95% CI, 1.18 to 2.62).

Conclusion: Among patients with recent-onset IBP suggesting axSpA, acetabular dysplasia was significantly associated with hip pain in males. Hip pain related to acetabular dysplasia might result in overdiagnosis of hip involvement by axSpA.

Keywords: Axial Spondyloarthritis, Acetabular dysplasia, Hip

Key messages

What is already known about this subject?

- Undiagnosed mild acetabular dysplasia is common in adults and may cause hip pain.
- Axial spondyloarthritis is challenging to diagnose and can involve the hips.

What does this study add?

- In patients with recent-onset inflammatory back pain suggesting axial spondyloarthritis, the common disorder of acetabular dysplasia was significantly associated with hip pain upon physical examination in males but not in females.

How might this impact on clinical practice or future developments?

- Acetabular dysplasia should be sought routinely in patients with suspected axial spondyloarthropathy

and, if present, should be considered among the possible causes of hip pain.

Introduction

Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease that predominantly affects the axial skeleton, causing inflammatory back pain (IBP) [1]. The diagnosis and treatment may raise challenges, as many patients have associated conditions that produce overlapping symptoms and signs. In patients with inflammatory joint disease, common conditions responsible for joint symptoms and/or functional impairment may mistakenly suggest treatment failure by increasing disease activity scores or the global burden of symptoms [2, 3]. Better identification of these associated conditions should improve the management of patients with suspected or confirmed axSpA by avoiding overtreatment and/or resulting in specific treatments [4].

Inflammatory hip involvement is common in axSpA. In a retrospective single-centre observational study, radiological evidence of inflammatory hip disease was found in 18% of patients with axSpA, often within the first few years after the diagnosis and was mostly bilateral [5]. In addition, joint replacement surgery was required in a third of patients with hip involvement, suggesting an association with greater axSpA severity [5]. Hip involvement must therefore be identified early, to ensure that treatment is optimal. In patients with hip pain but no radiological evidence of hip inflammation and/or no joint effusion, the possibility that another disease is causing the hip symptoms should be assessed to avoid overtreatment of axSpA.

Conditions that can cause unilateral or bilateral hip pain in adults include tendinitis, osteoarthritis, impingement syndrome, and acetabular dysplasia. Acetabular dysplasia is common in adults (overall prevalence ranging from 5 to 25% according to population and definition) and can cause pain even before the common complication of premature osteoarthritis [6–8]. Pain due to mild acetabular dysplasia may not be sufficiently severe to lead patients to seek medical advice. In patients undergoing an overall articular assessment, for instance for suspected axSpA, the presence of acetabular dysplasia may generate confusion about the source of the symptoms.

Here, our objective was to determine whether radiological acetabular dysplasia was associated with hip pain upon physical examination in adults with recent-onset IBP suggesting axSpA and might, therefore, mistakenly suggest clinical hip disease related to axSpA.

Methods

The prospective DESIR (*DEvenir des Spondylarthropathies Indifférenciées Récentes*, outcomes of recent-onset undifferentiated spondyloarthritis) cohort included 708 patients aged 18–50 years who had IBP for at least 3 months with onset within the past 3 years and symptoms suggesting axSpA according to the local investigator [9]. Patients were included in 25 centers throughout France between December 2007 and April 2010 and were monitored prospectively for at least 5 years. The DESIR study was approved by the appropriate ethics committee and was conducted according to good clinical practice guidelines.

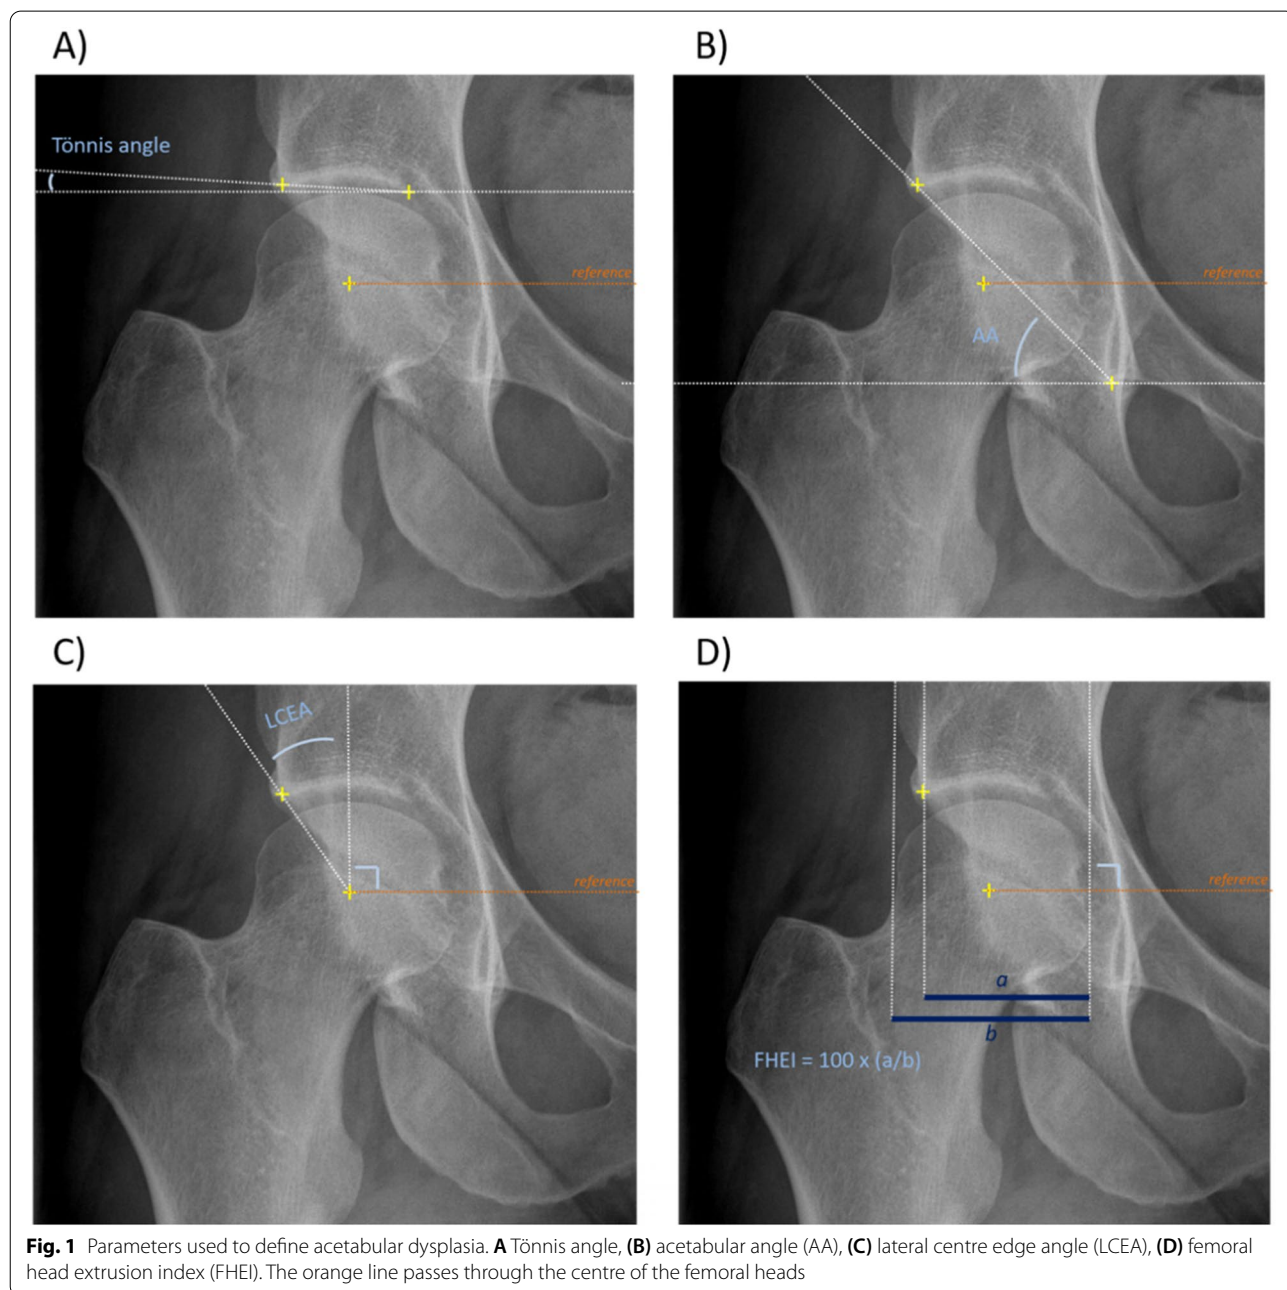

Clinical data collected at baseline and relevant to the present ancillary study included age, sex, body mass index (BMI), smoking history, and ethnicity. Presence of hip pain at physical examination was prospectively assessed by determining the Ritchie Articular Index (RAI) for both hips, with 0 indicating no tenderness; 1, pain reported by the patient; 2, reported pain and wincing; and 3, reported pain, wincing, and effort to withdraw [10]. Significant hip pain upon physical examination was defined as $RAI \geq 1$. We recorded the criteria used to classify axSpA according to Amor [11], the European Spondyloarthropathy Study Group (ESSG) classification [12], and the Assessment in SpondyloArthritis international Society (ASAS) [13, 14]. For the assessment of axSpA disease activity and functional impairment, we collected the C-reactive protein (CRP) level, Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and Bath Ankylosing Spondylitis Functional Index (BASFI). All patients underwent antero-posterior pelvic radiographs at baseline, as well as radiographs and magnetic resonance imaging (MRI) of the sacro-iliac joints. Patients were routinely evaluated for sacro-iliitis according to ASAS criteria and to the modified New York classification (mNY) [15]. As patients did not undergo profile radiographs, assessment of the anterior coverage of the femoral heads was not possible.

Patients whose antero-posterior pelvic radiographs allowed a valid assessment of both hips and who had no history of hip surgery were considered for the present study and assessed for acetabular dysplasia, using widely accepted morphological parameters. All radiographs were evaluated twice, by two experienced rheumatologists (DG and GP), who were blinded to all other study data. As a preliminary step, reliability and repeatability of the assessment were evaluated using an independent dataset of 50 antero-posterior radiographs including 25 anonymised radiographs from patients with acetabular dysplasia and 25 anonymised radiographs from consecutive patients admitted for sciatica. To measure the

Tönnis angle, acetabular angle (AA), lateral centre-edge angle (LCEA), and femoral head extrusion index (FHEI) (Fig. 1) [16] on DICOM-format images, the readers used a specific macro implemented via ImageJ software [17]. Users were asked to position the medial and lateral edges of the acetabular sourcil as well as the inferior margin of the pelvic teardrop, at both hips. They also positioned at least 7 points on the outline of the femoral head in order to accurately determine the coordinates of its center. The line passing through the inferior margin of both pelvic

teardrops was chosen, as an alternative to the horizontal line, to serve as the reference for measurements.

Values of the parameters were calculated automatically from these data. For each parameter measured in DESIR-cohort patients, the mean of the two values obtained by each independent reader was taken as the reference. Cut-offs used to define acetabular dysplasia were Tönnis angle >12°, AA>45°, LCEA<20°, and FHEI<70%, in agreement with many previous studies [16]. At the hip level and patient level, having at least one abnormal

parameter defined acetabular dysplasia. Radiographs were also evaluated by both readers for the presence of hip osteoarthritis stage 2 or higher in the Kellgren-Lawrence classification [18], including final adjudication of discordant cases.

Statistical analysis

In the dataset of 50 radiographs, inter-observer and intra-observer reproducibility of radiographic parameter measurement was evaluated by computing the intraclass correlation coefficients (ICC), which were interpreted as follows: < 0.50, poor; 0.50 to < 0.75, moderate; 0.75 to < 0.90, good; and ≥ 0.90, excellent [19].

The variables from DESIR-cohort patients were described as mean ± SD if continuous and n (%) if categorical. We reported the prevalence of acetabular dysplasia and of each abnormal acetabular-dysplasia parameter at the patient level and hip level, overall and separately for females and males. Prevalence of hip pain upon physical examination and radiological hip osteoarthritis were also reported. The groups with acetabular dysplasia (i.e., with at least one abnormal acetabular-dysplasia parameter) and without acetabular dysplasia were compared regarding general characteristics and features relevant to the diagnosis of axSpA. Association between acetabular dysplasia and hip pain upon physical examination was then assessed, at the patient level and hip level, considering assessment at the patient level as the main objective of the study. Given that LCEA is the most consensual indicator of acetabular dysplasia, we then conducted similar analyses with acetabular dysplasia defined as LCEA < 20°. Finally, we performed sub-groups analyses in groups defined by sex and age (18–24 years, 25–34 years, 35–44 years, and ≥ 45 years). Differences were assessed using the Mann-Whitney test for continuous variables and the χ² test or Fisher’s exact test, as appropriate, for categorical variables. We performed logistic regression to ensure that significant associations found at individual level persisted after adjusting on main potential confounders for which data were available (age, sex and BMI). Values of *p* smaller than 0.05 were taken to indicate statistically significant differences. The statistical analyses were performed using SPSS software version 23.0 (IBM, Armonk, NY).

Results

Patient characteristics

Among the 708 patients in the DESIR cohort, 636 had baseline antero-posterior pelvic radiographs that allowed valid measurement of acetabular-dysplasia parameters, 341 (53.6%) females and 296 (46.4%) males. Mean age at inclusion was 33.7 ± 8.5 years and mean BMI was 23.9 ± 4.7 kg/m².

The ICC values indicated excellent intra-observer and inter-observer reproducibility of radiographic measurements at both hips (≥ 0.93), except for AA at the left hip, for which reproducibility was good (inter-observer ICC = 0.78; intra-observer ICC = 0.86). Of the 636 patients, 139 (21.9%) had acetabular dysplasia at one or both hips. The prevalence was 26.4% (90/341) in females and 16.6% (49/295) in males. Table 1 reports additional details related to parameters assessing acetabular dysplasia at both sides. The only significant difference between the two groups, regarding general and axSpA characteristics, was a higher proportion of females in the group with acetabular dysplasia (Table 2).

Overall, the RAI indicated unilateral or bilateral hip pain at the baseline physical examination in 88 (13.8%) patients. Right hip pain was found in 64 patients and left hip pain in 52 patients. The analysis by sex showed hip pain in 53 (15.5%) females and 35 (11.9%) males.

Hip osteoarthritis was present in 8 (1.3%) patients at baseline; all 8 had osteoarthritis of the right hip and 3 also had osteoarthritis of the left hip. Of these 8 patients, 3 (37.5%) had at least one abnormal acetabular-dysplasia parameter. Of the 8 patients with radiological hip osteoarthritis, only 1 had hip pain.

Association of acetabular dysplasia with hip pain

In the groups with vs. without acetabular dysplasia of the right and/or left hip, the prevalence of hip pain at the baseline physical examination was 20.9% (29/139) and 11.9% (59/497), respectively (OR, 1.96; 95% CI, 1.20 to 3.20; $p = 0.007$). Logistic regression analysis showed that this association persisted after adjusting for age, sex and BMI (aOR, 1.89; 95% CI, 1.15 to 3.10; $p = 0.01$). When we separately assessed the patients with RAI values of 1, 2, and 3, we found that the prevalence of acetabular dysplasia was 26.3% (15/57), 44.0% (11/25), and 50.0% (3/6), respectively. The analysis by sex showed that acetabular dysplasia was significantly associated with hip pain in males (OR, 3.14; 95% CI, 1.44 to 6.86; $p = 0.003$) but not in females (OR, 1.39; 95% CI, 0.74 to 2.62. $p = 0.31$) (Table 3). The association found in males persisted after adjusting for age and BMI (aOR, 3.19; 95% CI, 1.45 to 7.04; $p = 0.004$). At the hip level, the presence of acetabular dysplasia was significantly associated with pain. The findings were similar when LCEA < 20° was required to define acetabular dysplasia in the whole population, for both unadjusted (OR, 2.15; 95% CI, 1.18 to 2.62. $p = 0.01$) and adjusted analysis (aOR, 2.13; 95% CI, 1.17 to 3.88; $p = 0.00X$). In contrast, the association between

acetabular dysplasia and hip pain was similar in all age groups.

Discussion

This study provides the first evidence that mild acetabular dysplasia in adults may be associated with hip pain upon physical examination in patients with suspected axSpA, in the same way it has been previously associated with self-reported hip pain in the general population. Hip pain was present in twice as many patients with vs. without acetabular dysplasia. Thus, the presence of acetabular dysplasia may carry a risk of overestimating hip involvement related to axSpA, in such population subject to systematic and repeated musculoskeletal evaluations.

Previous studies have established that acetabular dysplasia is common among adults and can be the sole reason for hip pain [6, 8, 20, 21]. Conflicting results have been reported [22] but are probably ascribable to differences in the definition and assessment methods of acetabular dysplasia and of hip pain. We used a standardised method for assessing hip pain and had two readers evaluate reproducible radiological signs of acetabular dysplasia. Our results support an

association between acetabular dysplasia and hip pain, in the absence of clinically significant radiological hip osteoarthritis.

In our study, 22% of patients had at least one of the four radiological signs of acetabular dysplasia but only 11% had LCEA < 20°, in keeping with earlier data in various geographic areas and ethnic groups [23]. Acetabular dysplasia was more common in females, for both the right and the left hips, in agreement with other studies [16]. This was the only significant difference between the groups with vs. without acetabular dysplasia. Notably, no significant differences were shown in the parameters assessing disease activity and functional impairment in relation to axial SpA, which is hardly surprising given the global nature of these tools.

The association between acetabular dysplasia and hip pain at the patient level was confirmed at the hip level and persisted when LCEA < 20° was required to define acetabular dysplasia. The prevalence of acetabular dysplasia increased with the severity of the hip pain. The low prevalence of radiological osteoarthritis may explain the absence of association with pain or acetabular dysplasia. We found no differences across age groups but the small number of patients in each category resulted in limited statistical power, and our population was relatively young (18–50 years at enrolment).

The association between acetabular dysplasia and hip pain was significant in males but not in females. We suggest two hypotheses to explain this finding. First, conditions other than acetabular dysplasia and likely to

be responsible for hip pain, such as fibromyalgia, may be more common in females [24]. However, hip pain was not significantly more common in females than in males in our study. Second, the same cut-offs were used for acetabular dysplasia in males and females. Conceivably, different cut-offs might be appropriate, and we may therefore have underestimated the prevalence of acetabular dysplasia among females [16].

Analyses at hip level showed some counter-intuitive results regarding the association between acetabular dysplasia at hip level and contralateral pain upon physical examination. For example, the results highlighted a strong association between right hip acetabular dysplasia and left hip pain among men, more marked than with the ipsilateral hip. Beyond type I error, there is no unequivocal explanation to these intriguing findings. This potentially illustrates the limits of the current definition of acetabular dysplasia, based on several parameters which are assessed binary, not accounting for global hip morphology and not accounting for subtle morphological differences that exist between right and left hip, at population level [21]. It may also illustrate the complexity of the relationship that exists between hip morphology and symptoms, that is likely to be influenced by multiples parameters, including activities and laterality. At the end, such results suggest that the presence of one or more abnormal parameters consistent with acetabular dysplasia accounts for a relevant disorder at the individual level just as much or even more than at joint level.

This study has several limitations. First, data on the characteristics of hip pain are limited, because the DESIR cohort was designed to assess axSpA. We assessed only hip pain elicited during a physical examination by a senior rheumatologist. No data were available on self-reported hip pain or on features suggesting inflammatory vs. mechanical hip pain. As a result, the possibility of an underlying coxitis in some participants cannot be formally ruled out. Regarding this last point, however, a study has shown that acetabular dysplasia can be responsible for pain at night [25]. Second, we did not have information on other common conditions potentially responsible for hip pain, such as impingement syndrome [26]. Finally, among the many parameters that have been used to diagnose acetabular dysplasia on standard antero-posterior radiographs, we selected only four. More specifically, we did not assess anterior coverage of the femoral head.

In conclusion, among males with recent-onset IBP suggesting axSpA, acetabular dysplasia was associated with hip pain upon physical examination. Thus, the common disorder of acetabular dysplasia may mistakenly suggest hip involvement by axSpA in patients with

recent-onset IBP. Acetabular dysplasia should be sought routinely on radiographs in patients with suspected axSpA. Studies are needed to further characterise the association between acetabular dysplasia and hip pain and its potential effects on the diagnosis of axSpA.

Acknowledgements

We thank all DESIR-cohort patients and all individuals involved with creating and maintaining the cohort. The DESIR cohort was sponsored by the Département de la Recherche Clinique et du Développement, Assistance Publique-Hôpitaux de Paris. This study was conducted under the umbrella of the French Society of Rheumatology and INSERM (Institut National de la Santé et de la Recherche Médicale). The database is managed by the department of epidemiology and biostatistics of Montpellier University (Professor Paul Landais, D.I.M., Nîmes, France). We are also grateful to the heads of the participating regional centres: Prof. M. Dougados (Paris, Cochin B), Prof. A. Kahan (Paris, Cochin A), Prof. P. Dieudé (Paris, Bichat), Prof. L. Gossec (Paris, Pitié-Salpêtrière), Prof. F. Berenbaum (Paris, Saint Antoine), Prof. P. Claudepierre (Créteil), Prof. M. Breban (Boulogne Billancourt), Dr. B. Saint-Marcoux (Aulnay-sous-Bois), Prof. P. Goupille (Tours), Prof. J-F. Maillfert (Dijon), Dr. E. Dermis (Le Mans), Prof. D. Wendling (Besançon), Prof. B. Combe (Montpellier), Prof. L. Euler-Ziegler (Nice), Prof. P. Orcel (Paris, Lariboisière), Prof. P. Richette (Paris, Lariboisière), Prof. P. Lafforgue (Marseille), Dr. P. Boumier (Amiens), Prof. M. Soubrier (Clermont-Ferrand), Dr. N. Mehzen (Bordeaux), Prof. D. Loeuille (Nancy), Prof. R-M. Flipo (Lille), Prof. A. Saraux (Brest), Dr. S. Pavy (Kremlin-Bicêtre), Prof. A. Cantagrel (Toulouse), and Prof. O. Vittecoq (Rouen). We are indebted to the URC-CIC Paris Centre for coordinating and monitoring the study.

Authors' contributions

DG and AS contributed to the study conception and design. Material preparation, data collection and analysis were performed by DG and GP. The first draft of the manuscript was written by DG and AS. All authors significantly contributed to the revision of the manuscript. All authors read and approved the final manuscript.

Funding

An unrestricted grant from Pfizer was allocated for the first 10 years of patient follow-up. No specific funding was received for this ancillary study.

Availability of data and materials

The study data are available upon reasonable request to the principal DESIR-cohort investigator Maxime Dougados, Paris (maxime.dougados@aphp.fr).

Declarations

Ethics approval and consent to participate

The DESIR study was conducted according to good clinical practice guidelines and was approved by the appropriate local medical ethical committees (Comité de Protection des Personnes Ile de France III). All participants gave written informed consent before inclusion. All methods were carried out in accordance with relevant guidelines and regulations. Patients and members of the public were involved in the design, conduct, and reporting of the research via a detailed description of the protocol available at <http://www.lacohortedesir.fr/desir-in-english/>.

Consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
