ABSTRACT

Crop male sterility has great value in theoretical research and breeding application. HTS-1, whose stamens transformed into pistils or pistil-like structures, is an important male sterility material selecting from Chinese Spring three-pistil (CSTP) wheat. However the molecular mechanism of pistillody development in HTS-1 remains a mystery. RNA-seq data of 11 wheat tissues were obtained from the National Center for Biotechnology Information (NCBI), including the stamens of CSTP and the pistils and pistillodic stamen of HTS-1. The Salmon program was utilized to quantify the gene expression levels of the 11 wheat tissues; and gene quantification results were normalized by transcripts per million (TPM). In total, 58,576 genes were used to construct block-wise network by co-expression networks analysis (WGCNA) R package. We obtained all of modules significantly associated with the 11 wheat tissues. AgriGO V2.0 was used to do Gene Ontology (GO) enrichment analysis; and genes and transcription factors (TFs) in these significant modules about wheat pistillody development were identified from GO enrichment results. Basic local alignment search tool (BLAST) was used to align HTS-1 proteins with the published pistillody-related proteins and TFs. Genes about wheat pistillody development were analyzed and validated by qRT-PCR. The MEturquoise, MEsaddlebrown, MEplum, MEcoral1, MELightsteelblue1, and MEdarkslateblue modules were significantly correlated to pistillodic stamen (correlation $p < 0.05$). Moreover, 206 genes related to carpel development (GO:0048440) or gynoecium development (GO:0048467) were identified only in the MEturquoise module by Gene Ontology (GO) analysis, and 42 of 206 genes were hub genes in MEturquoise module. qRT-PCR results showed that 38 of the 42 hub genes had highly expressed in pistils and pistillodic stamens than in stamens. A total of 15 pistillody development-related proteins were validated by BLAST. Transcription factors (TFs) were also analyzed in the MEturquoise module, and 618 TFs were identified. In total, 56 TFs from 11 families were considered to regulate the development of pistillodic stamen. The co-expression network showed that six of HB and three of BES1 genes were identified in 42 hub genes. This indicated that TFs played important roles in wheat pistillody development. In addition, there were 11 of ethylene-related genes connected with TFs or hub genes, suggesting the important roles of ethylene-related genes in pistillody development. These results provide important insights into the molecular interactions underlying pistillody development.

INTRODUCTION

Common wheat (*Triticum aestivum* L.) is a major source of protein, vitamins, and minerals for humans (Ramírez-González *et al.*, 2018). Although the global wheat output has steadily increased in recent years, some studies showed that wheat yields hardly meet the increasing demand of the human population (*The International Wheat Genome Sequencing Consortium*, 2014; Marcos-Barbero *et al.*, 2021). Thus, many researchers strive to improve grain productivity and qualities. The development of wheat flowers affects grain yields and qualities (Yang *et al.*, 2015; Ullah *et al.*, 2022). Various wheat flower mutant materials have been reported in the past decade (Murai & Tsunewaki, 1993; Murai *et al.*, 2002; Murai, 2013). Mutant (cr)-N26 and (cr)-CSdt7BS are male sterility materials, whose stamen transforms into pistil or pistil-like structure, a phenomenon called pistillody (Murai & Tsunewaki, 1993; Murai *et al.*, 2002; Murai, 2013). (cr)-N26 and (cr)-CSdt7BS mutants contain the exogenous genes of goat weed; therefore, the pistillody of (cr)-N26 and (cr)-CSdt7BS are caused by heterologous cytoplasmic male sterility (Murai *et al.*, 2002). In 2013, Peng *et al.* found a new pistillody mutant called HTS-1 from Chinese Spring three-pistil (CSTP) wheat (Peng, 2003; Peng *et al.*, 2013). CSTP is a near-isogenic line of the common wheat variety, Chinese Spring, with the *Pis1* gene derived from the three-pistil mutant (Peng *et al.*, 2013). The genetic base of HTS-1 was different from those of (cr)-N26 and (cr)-CSdt7BS (Murai, 2013; Peng *et al.*, 2013). HTS-1 mutants do not contain an exogenous cytoplasm; therefore, the pistillody of HTS-1 is controlled by nuclear genes (Peng *et al.*, 2013). Previous reports showed that the molecular mechanisms of wheat stamen transformation into pistils were very complex (Murai *et al.*, 2002; Zhu *et al.*, 2008; Yamamoto *et al.*, 2013; Yang *et al.*, 2018). Murai *et al.* (2002) found that reduced wheat *APETALA3* homolog (*WAP3*) expression could be associated with the induction of pistillody in (cr)-CSdt7BS. The mitochondrial gene *orf25* of *Aegilops crassa* cytoplasm is considered a candidate as the cytoplasmic factor related to pistillody in alloplasmic wheat (Hama *et al.*, 2004). Zhu *et al.* (2008) reported a mitochondrial gene called *orf260^{cra}*, which could lead to pistillody in the stamen of (cr)-CSdt7BS. *In situ* hybridization analysis showed that the calmodulin-binding protein gene, WHEAT CALMODULIN-BINDING PROTEIN 1 (*WCBP1*), was highly expressed in pistil-like stamens at early to late developmental stages (Yamamoto *et al.*, 2013). This finding suggests that the *WCBP1* gene plays an important role in pistil-like stamen development (Yamamoto *et al.*, 2013). The homologous transformation of stamens into pistils in HTS-1 florets is determined by the interaction of two recessive karyo genes, *hts1* and *hts2* (Peng *et al.*, 2013). Yang *et al.* (2015) identified 206 differentially expressed genes (DEGs) correlated to HTS-1 stamen and pistil development using RNA-seq analysis. Among them, 123 genes were down regulated and 83 genes were up regulated. But genes about pistillody development have never been identified in this study. Sun *et al.* (2019) reported that the EPIDERMAL PATTERNING FACTOR-LIKE (*TaEPFL1*) gene has a higher expression in pistillodic

stamens than in pistils and stamens. The heterologous expression of the *TaEPFL1* gene in *Arabidopsis* causes shortened filaments and pedicels, which might induce stamens to transform into pistils or pistil-like structures in wheat. Furthermore, some transcription factors (TFs) of MADS-box (e.g., MCM1 in yeast, AG in *Arabidopsis*, DEFICIENS in *Antirrhinum*, and SRF in mammals) and the DROOPING LEAF (*DL*) gene of the YABBY family regulate the development of wheat pistillodic stamens (Murai, 2013; Hama et al., 2004; Meguro et al., 2003; Ishikawa et al., 2009; Zhang et al., 2015; Wang et al., 2015; Zhu et al., 2015). The expression pattern analysis indicates that *TaDL1*, *TaDL2*, and *TaDL3* might cause the stamen of HTS-1 to completely or partially transform into pistils (Zhang et al., 2015). These researches reported on the development of wheat pistillody. However, the mechanisms of pistillody are still unclear.

With the rapid improvement of high-throughput sequencing and computer analysis technology, complex biological problems can be systematically studied using a variety of high-throughput sequenced data. Various network analysis methods, such as neural network analysis (Greenside et al., 2018), protein–protein interaction network analysis (Stelzl et al., 2005), and WGCNA (Zhang & Horvath, 2005), have been constructed and widely applied to reveal molecular mechanisms using high-throughput sequenced data. WGCNA is an efficient method for studying correlation networks of highly correlated genes (Langfelder & Horvath, 2008). According to gene expression levels in different tissues, genes with similar expression patterns can be clustered into the same module by WGCNA (Zhang & Horvath, 2005). Therefore, WGCNA is widely used to explore the hub genes, module–trait relationships, and gene interaction networks of flower development in various plants (Hollender et al., 2014; Roberts & Roalson, 2017; Ma, Ding & Li, 2017). In particular, Ramírez-González et al. (2018) using 209 RNA-seq samples from 22 tissue types, analyzed the gene expression pattern of wheat Azhurnaya cultivar; and established tissue- and stress-specific co-expression networks that revealed the extensive coordination of homoeolog expression throughout wheat development. These networks, including spikelet development networks, and detailed gene expression atlases were deposited in wheat electronic fluorescent pictographic (eFP) browser (<http://bar.utoronto.ca>) (Ramírez-González et al., 2018). However, networks in the wheat eFP browser do not reveal and provide information about the mechanisms of genes for pistillody development. The Azhurnaya cultivar is not a pistillodic wheat. Furthermore, the systematic identification of genes associated with pistillody development by WGCNA has not been reported yet.

The present study employed WGCNA to analyze 11 RNA-seq data from wheat tissues, including the normal stamens of CSTP and the pistils and pistillodic stamens of HTS-1, to explore genes related to wheat pistillody development and their interaction mechanisms (Yang et al., 2015). The relationships between modules and specific flower tissues from the wheat RNA-seq data were explored. Then, genes related to pistillody development were identified from the modules that were remarkably associated with pistillody by GO analysis. Quantitative real-time PCR (qRT-PCR) was used to validate the expression pattern of candidate genes related to the development of pistillodic stamens in HTS-1 to validate the WGCNA results. This work provides further insights into the molecular mechanisms underlying wheat pistillody development.

MATERIALS & METHODS

Plant materials and RNA extraction

CSTP and its pistillody mutant, HTS-1, were planted in the experimental field of China West Normal University, Nanchong, China in the last week of October 2020. The pistils and pistillodic stamens of HTS-1 were collected at the early flowering stage in the middle of February 2021, and the normal stamens of CSTP were harvested at the same time. The three flower materials were collected from 30 HTS-1 and CSTP plants. Each material had two biological replicates. Particularly, only the first florets of the central spikes were collected. The flower materials were immediately frozen with liquid nitrogen and maintained in an ultra-low temperature freezer (Forma 900 Series; Thermo Scientific, Waltham, MA) at -80°C . The total RNAs of the pistils and pistillodic stamens of HTS-1 and the stamens of CSTP were extracted using a Plant Easy Spin RNA Miniprep Kit (Biomiga, San Diego, CA). DNase treatment was performed before proceeding with complementary DNA (cDNA) synthesis. The quality of the cDNA was determined by gel electrophoresis. cDNA concentration was calculated and adjusted to $500\text{ ng}/\mu\text{L}$ using a spectrophotometer (Thermo, NanoDrop 2000).

Data source

The following RNA-seq data of common wheat were obtained from the National Center for Biotechnology Information (NCBI) Sequence Read Archive database (SRA, <http://www.ncbi.nlm.nih.gov/sra>): root (ERR424732), stem (ERR424762), flag leaf (SRR3068439), booting spike (SRR6802610), ear spike (SRR6802611), rachis (SRR6802608), early ovary (SRR6802613), late ovary (SRR6802612), HTS-1 pistil (SRR1175868), HTS-1 pistillodic stamen (SRR1177760), and CSTP stamen (SRR1177761). CSTP is a backcross descendant of Chinese spring and three-pistil wheat, and each CSTP floret has three pistils and three stamens (Peng *et al.*, 2013). HTS-1 is a pistillody mutant from CSTP (Peng *et al.*, 2013). Some HTS-1 stamens transform into pistils or pistil-like structures (Peng *et al.*, 2013). Therefore, the RNA-seq data of HTS-1 pistil (SRR1175868) and CSTP stamen (SRR1177761) are wild types, and HTS-1 pistillodic stamen (SRR1177760) is a wheat flower mutant. All of the RNA-seq data were generated by the Illumina HiSeq series platform, and the layout were in paired end reads. Wheat coding sequences (CDSs) and protein sequences were downloaded from the Ensembl Plants database (version 41, <http://ftp.ensemblgenomes.org/pub/plants/release-41/>). A total of 133,346 CDSs and protein sequences were obtained.

Gene quantification analysis

Salmon (Patro *et al.*, 2017) was utilized to quantify the gene expression levels of the 11 wheat tissues mentioned above. First, Salmon index program was employed to create a wheat index using the default parameters, and the 133,346 CDSs of wheat were used as the input data. Next, the 11 RNA-seq data were quantified by the Salmon quant program against the wheat index using the quasi-mapping-based mode. The gene quantification results were normalized by transcripts per million (TPM). The genes in the pistillodic

stamens with TPM values less than 0.5 were filtered out to reduce the interference of low expression genes. A total of 58,576 genes remained.

WGCNA

The WGCNA R package ([Langfelder & Horvath, 2008](#)) was applied to construct the co-expression network of the 11 wheat tissues (58,576 genes). A soft threshold (power) was set to make the genes in the network conform to the scale-free topology distribution. The first soft threshold (power) was used to construct the WGCNA using the scale-free topology-fitted index of 0.9 ([Fig. 1A](#)). Then, the block-wise Modules function was applied to construct block-wise networks with the following parameters: power = 21, networkType = “unsigned”, maxBlockSize = 10000, TOMType = “unsigned”, minModuleSize = 30, mergeCutHeight = 0.15. [Figure 1B](#) depicts the hierarchical cluster tree and merged modules. If a module was highly correlated to other modules, they should be merged into one module. The module eigengenes (MEs) were defined as the first principal component in the module, representing the gene expression profiles in this module. The module eigengenes function was applied to calculate the MEs. Then, the model matrix function was used to build a binary matrix for each trait, including 11 vectors with 11 elements each. In this matrix, when the position was equal to 1, it represented the stated trait; otherwise, the position was 0. Afterward, the correlations between MEs and traits were analyzed by module–trait relationship analysis. The *P*-values of the module–trait relationships were estimated by using the corPvalueStudent function. Then, the module–trait relationship heatmap was plotted ([Fig. 2](#)). A module was considered significantly associated with a trait, when the *P*-value of the module was less than 0.05. Afterward, the modules significantly associated with booting spike, early ovary, late ovary, ear spike, pistil, stamen, and pistillodic stamen were selected as candidate modules for further analysis.

GO enrichment analysis of genes from candidate modules

AgriGO V2.0 (<http://systemsbiology.cau.edu.cn/agriGOv2/index.php>) ([Tian et al., 2017](#)) was employed in the GO enrichment analysis. The singular enrichment analysis (SEA) tool and the *Triticum aestivum* species were selected for this analysis. The query IDs were the Ensembl ID of wheat from the candidate modules that were remarkably related to the seven wheat flower tissues. The other parameters of AgriGO were set as follows: Fisher’s test as the statistical test method, Yekutieli (false discovery rate (FDR) under dependency), significance level of 0.05, one minimum number of mapping entries, and complete GO type. [Table S1](#) displays the significant GO terms of wheat flower development from the candidate modules mentioned above with FDR values less than 0.05. Then, ggplot2 was applied to build the bubble diagram of the flower development GO terms in different modules ([Fig. 3](#)).

Hub gene identification

Hub genes were the genes with high connectivity (top 10%) in the modules. The hub genes were determined using the absolute values of eigengene-based connectivity (kME) and gene significance (GS). kME measures the distance from the expression profile of a gene to the module eigengene, and the signedKME function in WGCNA was used to calculate kMEs.

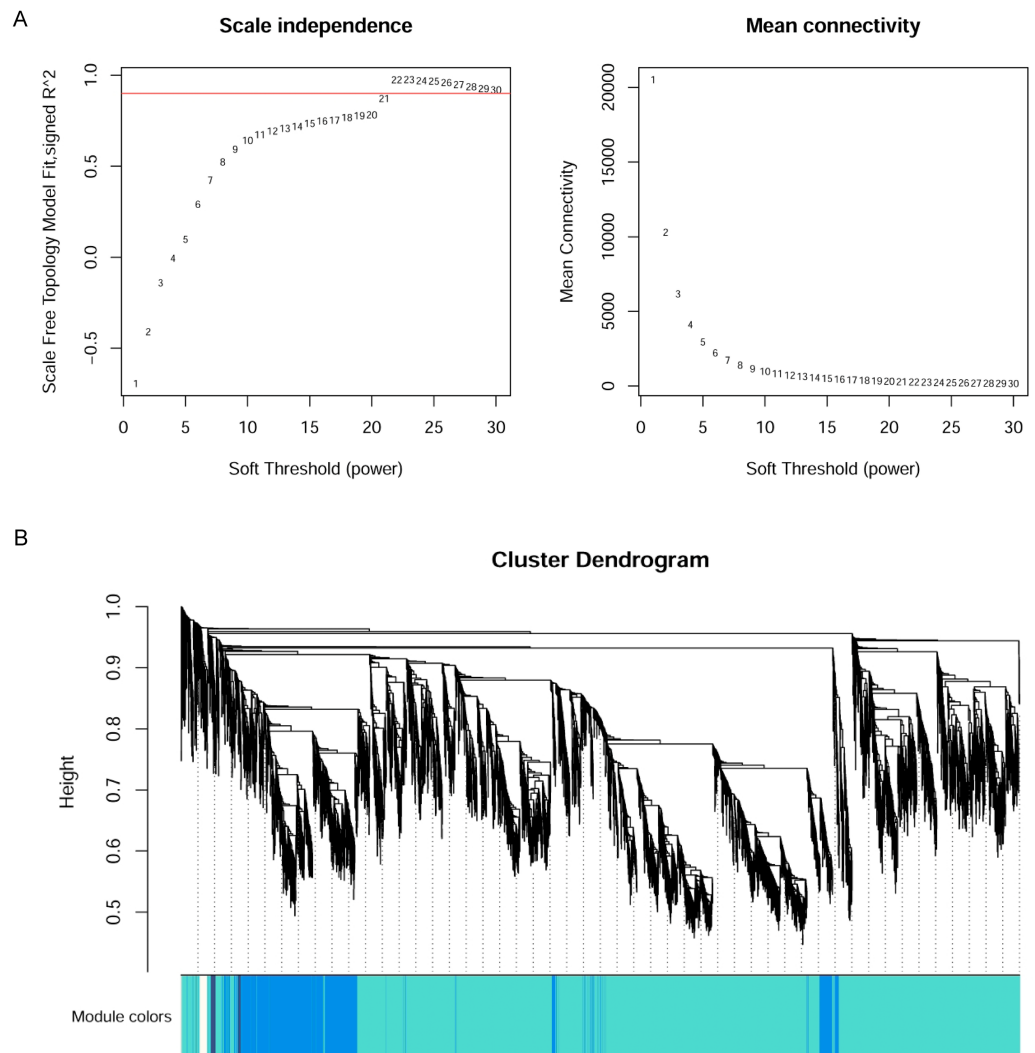

Figure 1 Co-expression network analysis of 11 RNA-seq datasets for wheat flower development. (A) Determination of soft threshold of WGCNA. (B) Modules identified by the dynamic tree cut and the merged modules with similar expression pattern.

Full-size DOI: [10.7717/peerj.13902/fig-1](https://doi.org/10.7717/peerj.13902/fig-1)

GS is the association of each gene with a trait. The hub genes from the modules that were significantly associated with pistillody were determined using the following thresholds: absolute values of $GS > 0.2$ and $kME > 0.8$. Then, the information of the hub genes were integrated with flower development-related genes and displayed in [Table S1](#).

Similarity analysis between proteins of hexaploid wheat and published pistillodic stamen proteins

The published proteins related to pistillody development are listed in [Table S2](#), including the protein accession and origin reference information. The BLASTP program of BLAST was employed to investigate the similarity between published pistillodic stamen proteins against the obtained wheat proteins (-b 1 -m 8 -F F). A total of 172 published pistillodic

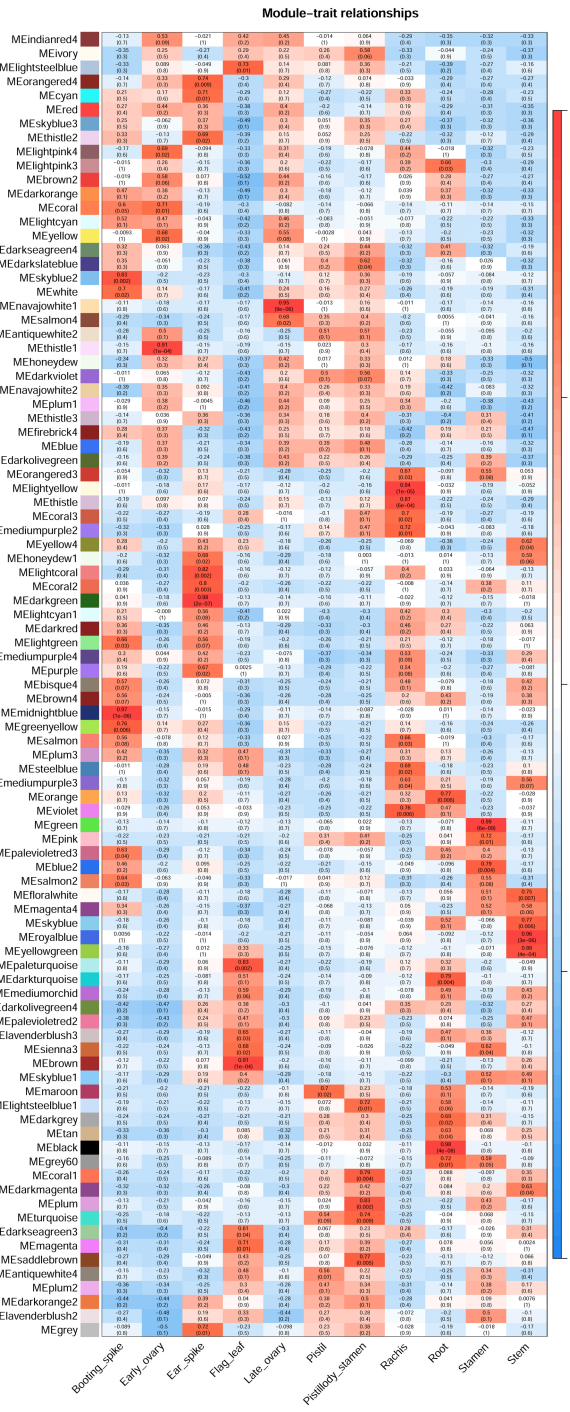

Figure 2 Heatmap of module-trait relationships. Each row in the heatmap represents a module. Each column represents a wheat tissue. The color of each cell represents the association coefficient between the module and the tissue type. Red color indicates the positive relationship between module and tissue type. Green color indicates the negative relationship between module and tissue type.

Full-size DOI: 10.7717/peerj.13902/fig-2

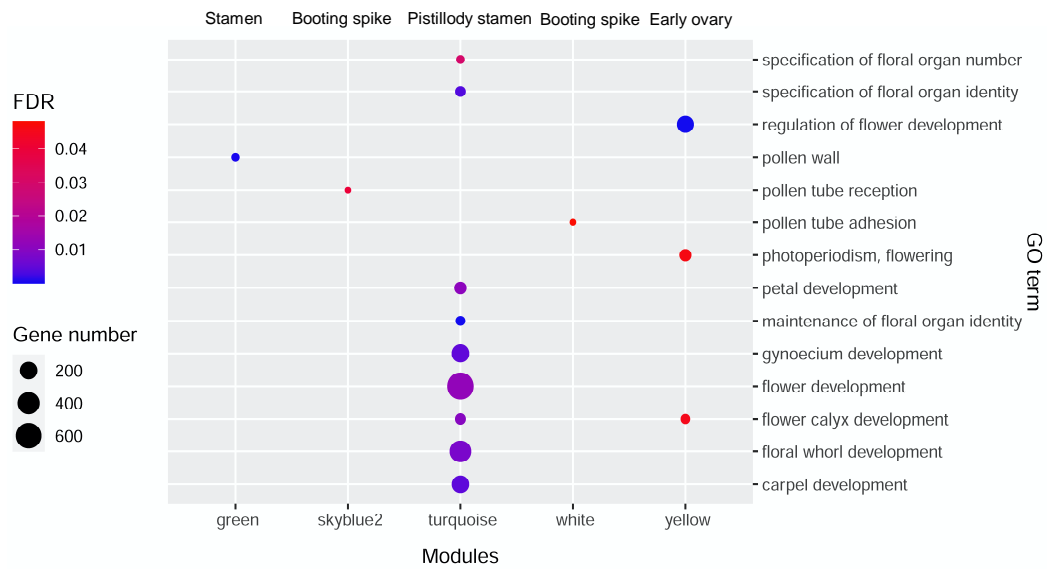

Figure 3 Bubble diagram of significant GO terms in wheat flower development in different modules. [Full-size !\[\]\(5f471a71b78d7676bc356df190b88ab4_img.jpg\) DOI: 10.7717/peerj.13902/fig-3](https://doi.org/10.7717/peerj.13902/fig-3)

stamen proteins were used as the query sequences, and the proteins of hexaploid wheat were used as the subject sequences (or database). The alignment results are shown in [Table S2](#). The identity in [Table S2](#) was defined as the matching base number over the number of alignment sequences. The closer the identity value to 100%, the more matched base pair between the query and subject sequences had. The coverage of query sequences was calculated using the following method to assess the similarity between the query and subject sequences. First, the alignment end position (query end) was subtracted from the start position (query start). Then, the difference was added with one. Moreover, the coverage value of the query sequence was obtained by dividing the length of the query sequences with the sum from the previous step. In [Table S2](#), AgriGO V2.0 was used to do the GO enrichment of the subject sequences, but only the GO terms related to wheat flower development were displayed. The subject sequences were used for further analysis, whose similarities and coverage values were up to 95% against the query sequences. Finally, the subject sequences were considered as the candidate genes of pistillody development, if they met the following criteria: (i) the GO analysis results were related to wheat carpel development (GO:0048440), or (ii) they are hub genes in significant modules.

TF analysis

The sequences from wheat Ensembl proteins were extracted using the gene IDs of the modules that were remarkably related to pistillody to identify the TFs for pistillody development. Next, the hmmsearch program of the HMMER V3.0 package was employed to predict the TFs using proteins from the significant modules against HMM profiles. In total, 75 HMM profiles belonging to 69 TF families were used to identify the TFs ([Chen et al., 2015](#)). The default parameters of hmmsearch were employed. The proteins were considered TFs when their e-values were less than 0.01. The predicted TFs of HTS-1 are

listed in [Table S3](#). The hub gene IDs of the MEturquoise module were integrated with the predicted TFs. Then, AgriGO V2.0 was applied for the GO enrichment analysis using the same parameters above. The protein IDs of the identified TFs were used as the input data. The GO analysis results are displayed in [Table S3](#). The published TFs related to pistillody development were surveyed ([Table S4](#)). Furthermore, the BLASTP program was utilized to compare the published TFs with the predicted TFs from HTS-1 (-b 1 -m 8 -F F) for figuring out their similarities. The BLAST results are displayed in [Table S4](#). The TFs were considered the candidate genes regulating pistillody development if they met the following criteria: (i) the GO analysis results were related to carpel development (GO:0048440) or gynoecium development (GO:0048467); (ii) the similarity and coverage values of the BLAST alignments were less than 95%.

Visualization of co-expression network for wheat pistillody development

According to the GO enrichment results, hub genes for carpel development (GO:0048440) and gynoecium development (GO:0048467) were obtained from [Table S1](#). Then, flower development target nodes connected with these hub genes were identified from the pistillody-related significant correlation module. Cytoscape V3.3 was applied to visualize the networks for wheat carpel development ([Shannon et al., 2003](#)). The network only displayed the connection with a corresponding topological overlap greater than 0.08. After the data was imported, we selected Tools → NetworkAnalyzer → Network Analysis → Analyze Network. Next, general style from the statistics menu was selected to set map the node size to the degree and map the edge size to the weight. [Figure 4](#) displayed the network of the hub genes relating to carpel development (GO:0048440) and gynoecium development (GO:0048467).

qRT-PCR and statistical analyses

qRT-PCR assays were performed with SsoFast™ EvaGreen (Bio-Rad, Hercules, CA, USA) using the Bio-Rad CFX96 real-time PCR platform (Bio-Rad, Hercules, CA, USA). The primers for the 42 hub genes associated with wheat pistillody development were shown in [Table 1](#). Each biological replicate had three technical replicates. Each reaction contained 5 μL of Ssofast (Bio-Rad, Hercules, CA), 1 μL of gene-specific primers, 0.5 μL of cDNA and 3.5 μL of ddH₂O, in a final volume of 10 μL. The 18S (GenBank accession number [AY049040](#)) and actin genes (GenBank accession number [AB181911](#)) were used as the reference genes ([Liao et al., 2015](#)). Fold-changes in RNA transcripts were carried out by the $2^{-\Delta\Delta C_t}$ method ([Livak & Schmittgen, 2001](#)). The expression patterns of the 42 genes associated with pistillody development were displayed in [Fig. 5](#). The relative expression level of each gene in the stamen was normalized to 1.

The differences in the relative gene expression levels among the pistil, pistillodic stamen, and stamen were determined by one-way ANOVA followed by least significant difference test. Statistical analyses were performed by SPSS V26 software at the significance level of $p < 0.05$.

Figure 4 Co-expression network visualization of hub genes in the METurquoise module associated with pistil development. Each node represents a gene, and lines between genes represent co-expression relationships. The node size indicates the connectivity degree of the input genes. The red square nodes represent ethylene-related genes. ARF TFs are marked with turquoise triangles. BES1 TFs are marked with navy blue triangles. bHLH are marked with purple triangles. C2H2 TFs are marked with yellow triangles. GARP TFs are marked with green triangles. HB TFs are marked with orange triangles. MADS-box TFs are marked with dark green triangles. MYB TFs are marked with blue triangles. SRS TFs are marked with light purple triangles. YABBY TFs are marked with pink triangles.

RESULTS

Overview of WGCNA networks construction and module detection

The 58,576 genes obtained by Salmon were used to construct WGCNA networks for investigating the molecular mechanism of pistil development in HTS-1. [Figure 1A](#) showed that the soft threshold (power) of 21 was used to construct the networks. [Figure 1B](#) showed the gene dendrogram clustering on Tom-based dissimilarity and modules obtained by the dynamic tree cut. [Figure 1B](#) depicted the major tree branches that constitute 93 merged modules labeled by different colors (cutHeight = 0.15). The gene number in the modules ranged from 32 to 8,764 with an average of 630 genes per module.

Identification of significant modules related to trait

[Figure 2](#) revealed the relationships between the modules and tissue types. A module has a significant correlation with the tissue type when $p < 0.05$. [Figure 2](#) depicted that the number of significant modules associated booting spike, early ovary, ear spike, late ovary, pistil, pistilodic stamen, and stamen development were 7, 4, 8, 2, 1, 6, and 4, respectively.

Figure 2 displayed that MEsalmon2, MEpalevioletr3, MEgreenyellow, MEMidlightblue, MELightgreen, MEwhite, and MESkyblue2 were remarkably related to booting spike development. The MEthistle1, MEyellow, MECoral, and MELightpink4 modules were the modules remarkably associated with early ovary development. The modules considerably related to pistillodic stamen development were METurquoise, MESaddlebrown, MEplum, MECoral1, MELightsteelblue1, and MEDarkslateblue. MESienna3, MEblue2, MEPink, and MEgreen were remarkably related to stamen development (Fig. 2).

Gene Ontology (GO) enrichment analysis of genes from significant modules

Gene Ontology enrichment analysis by AgriGO V2.0 was performed to investigate the genes related to wheat floral organ development in the significant modules displaying in Fig. 2. Table S1 showed the genes of significant GO terms about wheat floral organ development identified by AgriGO, such as stamen, early ovary, and pistillody stamen development. In Table S1, 1,844 genes were substantially related to wheat flower development. A bubble diagram was employed to clearly illustrate the flower development-related genes (Table S1), whose FDR values were less than 0.05. In Fig. 3, the MEgreen module enriched eight genes about pollen wall, and the MEgreen module was remarkable related to stamen development (Fig. 2). The MESkyblue2 module identified three genes about pollen tube reception, and three pollen tube adhesion genes were found in the MEwhite module (Table S1). The MESkyblue2 and MEwhite modules were remarkably associated with booting spike development (Fig. 2). In the MEyellow module, remarkably relating to early ovary development in wheat, 180, 18, and 53 genes participated in regulating flower development, flower calyx development, and flowering photoperiodism, respectively (Table S1). The METurquoise module, which was remarkably related to pistillodic stamen development, enriched genes related to the specification of floral organ number (10 genes), the specification of floral organ identity (31 genes), the maintenance of floral organ identity (21 genes), flower development (645 genes), flower calyx development (33 genes), floral whorl development (377 genes), carpel development (198 genes), gynoecium development (206 genes), and petal development (58 genes). Next, the genes related to carpel and gynoecium development were investigated. The analysis implied that 198 genes for carpel development can be found in the 206 genes for gynoecium development. Moreover, Table S1 also showed the hub gene information of 1,844 genes in the MEgreen, MESkyblue2, METurquoise, MEwhite, and MEyellow modules. None of the hub genes was found in the other four modules, except in the METurquoise module. A total of 264 hub genes were found in the METurquoise module (accounting for 14.3% of the 1,844 genes). Among the 264 hub genes, 42 hub genes were related to carpel (GO:0048440) and gynoecium development (GO:0048467). The IDs of the 42 hub genes were listed in Table 1.

Figure 5 Expression patterns of 42 hub genes associated with pistillody development verified by real-time PCR. *P* represents the fully developed normal pistil of HTS-1. *PS* represents the completely developed wheat pistillodic stamen of HTS-1. *S* represents the fully developed normal stamen of CSTP.

Similarity analysis between proteins of HTS-1 and the published pistillody development proteins

The BLASTP program was used to compare the similarity between the published pistillody development proteins and the proteins of hexaploid wheat (Table S2). In Table S2, the alignment results included the identity, start and end positions, expect value, and score. In the eleventh column, we calculated the coverage parameter of query sequences. If the coverage and identity of query sequence were 100% similar, then the query sequence was the same as the subject sequence. 24 subject sequences had 100% coverage and identity against the query sequences. The expect values of the 24 proteins were very close to zero. None of the 24 subject sequences was found in the 42 hub genes listed in Table 1. A total of 80 query sequences were highly similar with the subject sequences, whose identities and coverage values between them were up to 95%, respectively (Table S2). Among the 80 subject sequences, only *TraesCS2A02G397200.1* was hub genes in METurquoise module (Table 1). The 12th to the 17th columns of Table S2 provided the GO annotation information of the subject sequences related to wheat flower development. Three GO terms about pistil development were found. The number of sequences related to plant ovule development (GO:0048481), plant type ovary development (GO:0035670), and carpel development (GO:0048440) were 7, 7, and 10, respectively (Table S2). Thus the number of sequences about wheat pistil development was 10 (Marked with green background in Table S2). According to the GO analysis, *TraesCS2A02G397200.1* and *TraesCS3D02G502600.1*, which were associated with anther and carpel development, were found in the 42 hub genes listed in Table 1. Furthermore, the significant module information of the subject IDs were provided in the 18th column of Table S2.

Identification of TFs about pistillody development

The TFs in the METurquoise module were listed in Table S3. A total of 618 TFs were identified from 50 different families in the METurquoise module (Table S3). Then, the TFs were integrated with the hub gene information of the METurquoise module listed in Table S1. In total, 62 of the 618 TFs were hub genes (accounting for 10%, Table S3). Moreover, AgriGO V2.0 was used in the GO enrichment of the 618 TFs. 17 GO terms, including GO:0048440 (carpel development), GO:0048467 (gynoecium development), and GO:0048443 (stamen development), were associated with wheat flower development. Among them, 67 TFs were related to carpel development (GO:0048440) or gynoecium development (GO:0048467). The 67 TFs were identified from 12 different families. The number of TFs from different families were as follows: auxin response factors (ARFs, 6 genes), brassinosteroid insensitive 1-EMS-suppressor 1 (BES1, 3 genes), basic helix-loop-helix (bHLH, 2 genes), Cys2His2 (C2H2, 2 genes), GARP (Golden2, ARR-B, Psr1; 3 genes), homeobox (HB, 13 genes), MIKC of MADS-box (13 genes), M-type of MADS-box (6 genes), MYB (7 genes), squamosa-promoter binding protein (SBP, 3 genes), SHI related sequence (SRS, 8 genes), and YABBY (1 gene). Among the 67 TFs, 9 hub genes were from the BES1 (3 genes) and HB families (6 genes). Subsequently, the similarities of the published wheat TFs for pistillody development were aligned against the 618 TFs by BLASTp (Table S4). 25 published TFs had more than 95% of identity and coverage values with 15 TFs

in the MEturquoise module, whose families were MADS-box, YABBY, and MYB families (Table S4). 20 of the 25 published TFs had high similarity with 12 different MADS-box genes identified in the MEturquoise module. 4 of the 25 published TFs were highly similar to 2 YABBY sequences. The remaining one was identified in the MYB family. Among the 25 TFs from the MEturquoise module, GO analysis showed that 18 TFs participated in regulating carpel development (GO:0048440). In particular, two published MADS-box TFs (*ALM58843.1* and *TraesCS6A02G259000.1*) had 100% of identity and coverage values with the TFs in the 618 sequences (Table S4).

Visualization of co-expression network about pistillody development

Cytoscape V3.3 was utilized to visualize gene networks for wheat pistillody development in the MEturquoise module. Figure 4 depicted the co-expression network relating to wheat carpel development (GO:0048440) and gynoecium development (GO:0048467). 42 hub genes for wheat pistil development were located in the inner circle, and 142 nodes connected with the 42 hub genes were located in the outer circle (Fig. 4). The node size represented the connectivity degree of the nodes. The bigger the node, the more connectivity that node had in the networks. The top 10 nodes among the 42 nodes by connectivity were: *TraesCS1A02G066200.1*, *TraesCS1A02G233800.1*, *TraesCS1B02G084500.1*, *TraesCS1B02G479300.1*, *TraesCS2A02G187800.1*, *TraesCS2A02G397200.1*, *TraesCS2D02G199900.1*, *TraesCS2B02G219300.1*, *TraesCS2B02G497500.1*, and *TraesCS2B02G415500.1*. In total, 11 ethylene-related genes were identified using AgriGO, and the ethylene-related genes were marked with red squares and labeled in red (Fig. 4). Among the 11 ethylene-related genes, only *TraesCS4A02G133800.1* is one of the top 10 hub genes. Among the 42 hub genes, three BES1 TFs (marked with navy blue triangle) were connected with five ethylene-related nodes. The IDs of the BES1 TFs are *TraesCS2A02G187800.1*, *TraesCS2B02G219300.1*, and *TraesCS2D02G199900.1*. The ethylene-related nodes are *TraesCS2A02G338200.1*, *TraesCS4A02G133800.1*, *TraesCS4D02G173100.1*, *TraesCS3A02G093000.1*, and *TraesCS7D02G338800.1*. Five of the HB family hub genes were linked to four of the ethylene-related genes in the networks. The HB hub genes are *TraesCS2B02G497500.1*, *TraesCS2D02G473700.1*, *TraesCS4A02G016600.1*, *TraesCS7D02G305200.2*, and *TraesCS7A02G308400.1*, and the ethylene-related genes connected with them are *TraesCS3A02G093000.1*, *TraesCS4A02G133800.1*, *TraesCS4D02G173100.1*, and *TraesCS7D02G338800.1*. Furthermore, the TFs of the 142 nodes in the outer circle were analyzed. 52 TFs belonging to 11 families were identified. Among them, 17 MADS-box and 13 HB TFs were identified, which accounting for 32.7% and 25% of 52 TFs, respectively. GO analysis by AgriGO revealed that only 2 TFs were associated with ethylene: *TraesCS1B02G091700.1* (HB family) and *TraesCS2A02G338200.1* (MYB family).

qRT-PCR verification of hub genes about pistillody development

The expression profiles of the 42 hub genes listed in Table 1 were validated by qRT-PCR to validate the genes that regulate wheat pistillody development (Fig. 5). In Fig. 5, the expression features were divided into three categories. The first category

was that the relative expression levels of pistil and pistillodic stamen were lower than that in the stamen. This category maintained four genes: *TraesCS1A02G066200.1*, *TraesCS2A02G187800.1*, *TraesCS3A02G495400.1*, and *TraesCS7A02G308400.1*. The second category was that the relative expression levels of genes among the three flower tissues were less than two times, and the gene expression levels in the pistillodic stamen or pistil were slightly higher than those in the stamen. The genes in the second category were: *TraesCS1B02G084500.1*, *TraesCS3B02G475600.1*, *TraesCS2B02G219300.1*, *TraesCS5A02G407500.2*, *TraesCS3B02G248200.1*, *TraesCS3B02G543300.1*, and *TraesCS7B02G181700.1*. The last category was composed of the remaining 31 genes. In this category, the gene expression levels in the pistillodic stamen and pistil were remarkably higher than those in the stamen. The expression levels of *TraesCS7D02G305200.2* in the pistillodic stamen and pistil were more than 150 fold greater than that in the stamen. The results of ANOVA showed that the expression levels of four genes in the pistil and pistillodic stamen were remarkably different from those in the stamen. The IDs of the four genes were: *TraesCS2A02G187800.1*, *TraesCS1B02G479300.1*, *TraesCS3A02G495400.1*, and *TraesCS7A02G308400.1*. In addition, the expression levels of the remaining 38 genes in the pistil, pistillodic stamen, and stamen were significantly different ($p < 0.05$).

DISCUSSION

Pistillody development is a rare phenomenon of male sterility in common wheat (Murai et al., 2002; Yamamoto et al., 2013; Peng et al., 2013). However systematical identification of pistillody-related genes and their interaction networks have never been reported. In this research, WGCNA was applied to identify hub genes in tissue-specific modules and explore gene interaction networks from RNA-seq of 11 wheat tissues. Six modules were remarkably associated with the development of the pistillodic stamen of HTS-1, such as MEturquoise, MEsaddlebrown, and MEplum (Fig. 2). However, the 206 genes correlated to wheat carpel or gynoeceum development were identified only in the MEturquoise module (Table S1). Meanwhile, correlation values of the MEturquoise module about pistillodic stamen, pistil, and stamen were 0.74, 0.54, and 0.068, and their p value were 0.009, 0.09, and 0.8 (Fig. 2), respectively. This result indicated that genes of the MEturquoise module were positively correlated with pistillodic stamen development. In addition, eight genes about pollen wall in the MEgreen module were enriched in the stamen. The correlation values of the MEgreen module about pistillodic stamen, pistil, and stamen were 0.022, -0.065, and 0.99, respectively (Fig. 2). It demonstrated that the MEgreen module had highly positive correlation with stamen development. Pollen tube reception and pollen tube adhesion genes were enriched in the MEwhite and MEskyblue2 modules of booting spike. Some genes about flower development (180 genes), flower calyx development (18 genes), and flowering photoperiodism (53 genes) were remarkably associated with early ovary development (Table S1, Fig. 3). These results indicate that the module classification of WGCNA is accurate. The gene expression patterns of the 42 hub genes were validated by qRT-PCR to verify whether the candidate genes were related to pistillody development (Fig. 5). Figure 5 displayed that most of the 42 genes, except four genes, had higher expression

levels in the pistil and pistillodic stamen comparing with those in the stamen. The IDs of the four genes were: *TraesCS1A02G066200.1*, *TraesCS2A02G187800.1*, *TraesCS3A02G495400.1*, and *TraesCS7A02G308400.1*. The q-PCR results imply that the 38 hub genes associated with pistillody development identified by WGCNA are very reliable (Fig. 5); and the 38 hub genes play critical roles in pistillody development of HTS-1.

The development of flower features directly affects crop yield and other agronomic traits. Male sterility has been widely studied in flower development and has very important application value in breeding (Peng et al., 2013). Stamen transformation into pistil or pistil-like structure (called pistillodic stamen) is a rare phenomenon in male sterility. Previous studies reported some pistillodic stamen material in wheat, such as (cr)-n26, (cr)-csdt7bs, and HTS-1 (Murai & Tsunewaki, 1993; Murai et al., 2002; Peng et al., 2013), which provided some insight into understanding the molecular interaction mechanism of wheat pistillody genes (Murai et al., 2002; Zhu et al., 2008; Yamamoto et al., 2013; Yang et al., 2015). The published pistillody-related proteins were compared with the proteins of HTS-1 by BLAST. The alignment results have been shown in Table S2. The BLAST results display that the protein of the *WAP3* gene (NCBI accession number *BAA33459.1*) (Murai et al., 2002) is highly similar with the hexaploid wheat proteins of *TraesCS7B02G286600.2* (highlighted with a green background in Table S2). The identity value and the ratio of alignment sequence that cover the total length between the *WAP3* gene and the HTS-1 genes were greater than 99% (Table S2). Murai et al. (2002) reported that the decreased expression level of *WAP3* could induce the pistillody of (cr)-csdt7bs. *TraesCS7B02G286600.2* was confirmed to be related to stamen development (GO:0048443) and carpel development (GO:0048440, Table S2). Therefore, this result consists with the published results of Murai et al. The protein of the mitochondrial gene *orf25* (*BAA82046.1*) is a candidate gene related to pistillody in alloplasmic wheat (Hama et al., 2004). *BAA82046.1* had 100% of similarity and coverage with *TraesCS4D02G236200.1* in HTS-1 (highlighted with a red background in Table S2). This result suggests that *TraesCS4D02G236200.1* can induce the pistillody of HTS-1. The protein of the *orf260^{cra}* gene (*BAG84632.1*) is associated with pistillody induction (Zhu et al., 2008). *TraesCS7A02G237800.1* in HTS-1 had 94% identity and 52% coverage with *BAG84632.1* (highlighted with a red background in Table S2). This result implies that *TraesCS7A02G237800.1* might be associated with pistillody development and can be used as a candidate gene for further study. The protein of the *WCBP1* gene (*BAM65843.1*) is remarkably up regulated in the young spikes of pistillodic stamens in (cr)-csdt7bs inducing by mitochondrial retrograde signaling (Yamamoto et al., 2013). *BAM65843.1* shows high similarity with the HTS-1 proteins of *TraesCS5D02G102100.1*, whose identity and coverage ratio are greater than 97% (highlighted with a red background in Table S2). Thus, *TraesCS5D02G102100.1* could be associated with pistillody development. The *WPPK1* gene (*BAF79635.1*) is strongly expressed in developing pistils and pistil-like stamens (Saraïke et al., 2007). *BAF79635.1* had a high similarity with *TraesCS2B02G309900.1*, which identity and coverage were up to 99% (highlighted with a red background in Table S2). The result suggests that *TraesCS2B02G309900.1* could be associated with pistillody development. Yang et al. (2015) reported the 167 proteins of 206 DEG that might be related to the flower development

of HTS-1. 80 of the 167 protein sequences were highly similar to 107 of the subject sequences, whose identities and coverage values were above 95% (Table S2). 4 proteins of the 107 proteins were associated with carpel development (GO:0048440) (marked with a green background in Table S2). In addition, there were 10 genes about carpel development (marked with a green background in Table S2). These results indicate that the 10 proteins have important roles in the development of pistillody in HTS-1. Sun *et al.* (2019) reported that the *TaEPFL1* gene (comp109492_c0) played an important role in stamen development and *TaEPFL1* over expression results in pistillodic stamens. The alignment identity and coverage of the *TaEPFL1* gene against *TraesCS6D02G296500.1* were 100% and 75%, respectively (highlighted with a red background in Table S2). Therefore, *TraesCS6D02G296500.1* is considered to be a candidate gene related to the development of wheat pistillody. Finally, 15 pistillody development associated genes were validated by BLAST in HTS-1 (shown with a red or green background in Table S2), which will be considered candidate genes related to pistillody development for further studies. In particular, *TraesCS2A02G397200.1* and *TraesCS3D02G502600.1* are belonging to the 42 hub genes (Table 1). This result demonstrates that *TraesCS2A02G397200.1* and *TraesCS3D02G502600.1* have important roles in pistillody development.

TFs play an important role in regulating plant development. Some previous studies reported that MADS-box (Hama *et al.*, 2004; Meguro *et al.*, 2003; Zhang *et al.*, 2015; Wang *et al.*, 2015; Yang *et al.*, 2017; Su *et al.*, 2019; Paolacci *et al.*, 2007) and the *DL* gene of the YABBY family (Murai, 2013; Ishikawa *et al.*, 2009; Zhang *et al.*, 2015) were associated with wheat pistillody development. The results provide insights into the effect of other TF families on the mechanisms of the regulation of pistillody development. 67 TFs regulating carpel development (GO:0048440) or gynoecium development (GO:0048467) were identified from the METurquoise module (Table S3). 19 of MADS-box TFs (MIKC, 13 genes; M-type, 6 genes) were accounting for 28.36% of the 67 sequences (Table S3). This finding suggests that the MADS-box gene plays an important role in the regulation of pistillody development. In addition, 12 TF families were found to regulate carpel development (Table S3). Among the 67 TFs, the HB, MYB, and SRS families comprised 13, 7, and 8 sequences, respectively (Table S3). The results indicate that the mechanism of pistillody development is very complex, and many TFs from different families work together to regulate the pistillody development. In addition, 9 hub genes from the BES1 and HB families were identified in the 67 TFs (Table S3). The BLASTP program was used to determine the similarity of the published TFs with the 618 TFs in the METurquoise module. Twenty-five published TF sequences had more than 95% similarity and coverage with the 15 TFs in the METurquoise module (Table S4). Thus, the 15 different TFs need to be removed from the 67 sequences. The 15 TFs were highlighted with a red background in Table S3. Finally, 56 TFs from 11 families remained (highlighted with green background in Table S3). These TFs provide useful information for further research on the mechanism of pistillody development.

As a natural mutant of male sterility, HTS-1 has great value in scientific research and genetic breeding. Figure 4 displays the networks of genes associated with carpel development in HTS-1. 3 BES1 and 6 HB TFs associated with pistillody development were

identified in the 42 hub genes (Table S3), and 11 ethylene-related genes were identified from all nodes (Fig. 4). Previous studies reported that the *BES1* gene played an important role in plant reproduction, including flowering and the development of ovules, pollen, and seeds (Li et al., 2018). Low *BES1* levels can inhibit ethylene biosynthesis (Li et al., 2018). Moreover, ethylene plays a remarkable role in sex determination, and ethylene-related genes may result in the male and female differentiation of flowers (Sun et al., 2019; Wang, Kong & Hong, 2009; Du et al., 2016). 3 *BES1* hub TFs were identified in HTS-1 (marked by navy blue triangles in Fig. 4). 2 of 3 *BES1* hub genes (*TraesCS2B02G219300.1* and *TraesCS2D02G199900.1*) had higher expression levels in the pistil and pistillodic stamen than in the stamen (Fig. 5). This result indicates that *TraesCS2B02G219300.1* and *TraesCS2D02G199900.1* may positively regulate pistillody in HTS-1. The higher expression levels of *BES1* genes in HTS-1 can increase ethylene, which can result in the transformation of stamens to pistils or pistil-like structures. Previous studies reported that HB TFs determined the number of flower organ and the flowering time in wheat (Li et al., 2020). However, in *Arabidopsis thaliana*, the HB gene of KNOTTED-like from *A. thaliana* 2 (KNAT2) played a role in carpel development. All ovules of a KNAT2-GR lfy-6 plant were converted to pistils (Pautot et al., 2001). In total, six hub genes of HB TFs were identified among the 42 hub genes for carpel development (marked in orange triangles in Fig. 4). The qPCR results exhibited that the expression levels of the six HB genes in the pistil and pistillodic stamen were greater than those in the stamen (Fig. 5). These results suggest that HB TFs may positively regulate pistillodic development in HTS-1. A total of 17 MADS-box and 13 HB TFs were identified from 142 nodes (marked in dark green and orange triangles in Fig. 4, respectively). These results illustrate that MADS-Box and HB TFs play an important role in regulating pistil and stamen differentiation in plants. Moreover, *TraesCS1B02G091700.1* (HB family) and *TraesCS2A02G338200.1* (MYB family) are the ethylene-related genes in the networks (Fig. 4). Four hub genes, namely, *TraesCS1A02G066200.1*, *TraesCS1A02G233800.1*, *TraesCS1B02G084500.1*, and *TraesCS1B02G479300.1* were linked to the ethylene-related genes (Fig. 4). In particular, *TraesCS1A02G233800.1* is an ethylene-related gene linked to another ethylene-regulating gene (*TraesCS1B02G091700.1*, Fig. 4). This result indicates that these genes play an important role in pistillody development by regulating ethylene-related genes.

CONCLUSIONS

The current study identified 38 hub genes from the METurquoise module, which played important roles in the pistillody development of HTS-1. A total of 15 pistillody-associated proteins were validated in HTS-1 by BLAST. 56 TFs were considered to regulate the development of pistillodic stamen. The co-expression networks illustrated that ethylene-related genes played an important role in pistillody development. The results provide insights into the pistillody development of HTS-1.

ACKNOWLEDGEMENTS

We would like to thank Shinewrite Company for the language editing of this manuscript.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This study was supported by the National Natural Science Foundation of China (Grant No. 31760425), the Innovation Team Project of China West Normal University (Grant No. CXTD2018-6), the Doctoral Scientific Research Startup Found of China West Normal University (18Q039), and the Meritocracy Research Funds of China West Normal University (17YC321 and 17YC322). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:

National Natural Science Foundation of China: 31760425.

Innovation Team Project of China West Normal University: CXTD2018-6.

Doctoral Scientific Research Startup Found of China West Normal University: 18Q039.

Meritocracy Research Funds of China West Normal University: 17YC321, 17YC322.

Competing Interests

The authors declare there are no competing interests.

Author Contributions

- Zhenyong Chen conceived and designed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the article, and approved the final draft.
- Mingli Liao performed the experiments, analyzed the data, prepared figures and/or tables, and approved the final draft.
- Zaijun Yang analyzed the data, prepared figures and/or tables, and approved the final draft.
- Weiying Chen analyzed the data, authored or reviewed drafts of the article, and approved the final draft.
- Shuhong Wei performed the experiments, authored or reviewed drafts of the article, and approved the final draft.
- Jian Zou analyzed the data, authored or reviewed drafts of the article, and approved the final draft.
- Zhengsong Peng conceived and designed the experiments, authored or reviewed drafts of the article, and approved the final draft.

Data Availability

The following information was supplied regarding data availability:

The RNA-seq datasets are available at the NCBI SRA database: [ERR424732](#), [ERR424762](#), [SRR3068439](#), [SRR6802610](#), [SRR6802611](#), [SRR6802608](#), [SRR6802613](#), [SRR6802612](#), [SRR1175868](#), [SRR1177760](#), and [SRR1177760](#).

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.13902#supplemental-information>.
