GPR78 is an orphan G-protein coupled receptor (GPCR) that is predominantly expressed in human brain tissues. Currently, the function of GPR78 is unknown. This study revealed that GPR78 was expressed in lung cancer cells and functioned as a novel regulator of lung cancer cell migration and metastasis. We found that knockdown of GPR78 in lung cancer cells suppressed cell migration. Moreover, GPR78 modulated the formation of actin stress fibers in A549 cells, in a RhoA- and Rac1-dependent manner. At the molecular level, GPR78 regulated cell motility through the activation of Gαq-RhoA/Rac1 pathway. We further demonstrated that *in vivo*, the knockdown of GPR78 inhibited lung cancer cell metastasis. These findings suggest that GPR78 is a novel regulator for lung cancer metastasis and may serve as a potential drug target against metastatic human lung cancer. [BMB Reports 2016; 49(11): 623-628]

INTRODUCTION

G-protein-coupled receptors (GPCRs or GPRs) are among the largest and most diverse membrane protein families in mammalian genomes (1). These receptors contain seven transmembrane helices with an extracellular N terminus and an intracellular C terminus. Activated GPCRs transduce extracellular stimuli to give intracellular signals, through interaction of their intracellular domains with heterotrimeric G proteins. Till date, 18 different human G protein α subunits (Gα proteins) were identified to be coupled with GPCRs (2, 3). Depending on the α subunit type when GPCRs are activated, these Gα proteins can dissociate from the β and γ subunits to affect intracellular signaling proteins or target functional

proteins (1). For most GPCRs, the physiologic function is currently unknown, and these receptors are referred to as orphan GPCRs (4). GPR78 is an orphan GPCR first identified by sequence comparison with GPR26 (5). Expression analysis revealed it was highly expressed in human brain tissue. Later studies demonstrated that GPR78 overexpression in HEK293 cells was constitutively active, and induced the cAMP production (6). However, the cellular function of GPR78 remains unknown.

The Rho family GTPases, including RhoA, Rac1, and Cdc42, are a family of small (~21 kDa) signaling G proteins (7). They are regulators of actin cytoskeleton rearrangements, and thus modulate cell migration (8). For example, RhoA regulates stress fiber formation, and Rac1 modulates a meshwork of actin filaments at the cell periphery to produce lamellipodia and membrane ruffles (9). Rho proteins act as switches by alternating between inactive guanosine diphosphate (GDP)-bound and active guanosine triphosphate (GTP)-bound states. This process can be accelerated by a large family of Rho guanine nucleotide exchange factors (10). GPCR can activate Rho GTPases by coupling Rho-GEFs through their heterotrimeric guanine nucleotide-binding protein. This signaling transduction pathway is involved in multiple physiologic functions, including cell migration and invasion (10, 11).

In this study, we found that GPR78 was expressed in lung cancer cells, and promoted cell migration and metastasis in a Gαq-Rho GTPase-dependent manner. Our results suggest that GPR78 is a potential regulator for lung cancer metastasis that may serve as a potential drug target for lung cancer metastasis.

RESULTS

GPR78 is expressed in lung cancer cells and promotes cell migration

GPR78 is an orphan G-protein coupled receptor (GPCR) that is highly expressed in human placenta and brain tissues (6). However, the expression pattern and function of GPR78 in human cancer cells is still unknown. To explore the role of GPR78 in cancer cells, we first examined the expression of GPR78 in several lung cancer cells by western blotting. Interestingly, we found that GPR78 expressed in several lung

Results shown are averages \pm S.E.M. ** $P < 0.01$, compared with control.

level of GPR78 was also dramatically increased in lung cancer cells but not in normal cells (Fig. 1B). Since GPR26 shares more than 50% sequence similarity with GPR78 (6), we then examined the mRNA expression of GPR26 in these cells by real-time PCR. As shown in Fig. 1B, the mRNA level of GPR26 was extremely low in both normal and lung cancer cells, when compared with the human brain glioma cell line A172 cells, which was used as a positive control for detecting the expression of GPR78 and GPR26. To investigate the cellular function of GPR78 in lung cancer cells, we then established two stable shRNA-mediated knockdown cell lines in A549 cells (Fig. 1C), in which GPR78 was highly expressed (Fig. 1A and B). We observed that knockdown of GPR78 did not influence the number and size of the colonies in the colony formation assay (Fig. 1D). However, the knockdown of GPR78 significantly inhibited cell migration, as measured by the Transwell migration assay (Fig. 1E). In addition, this inhibitory effect on cell migration was also confirmed in other metastatic lung cancer cell lines, including H1975, H1299 and SPC-A1 cells (Fig. 1F). To further confirm the role of GPR78 in promoting cell migration, we ectopically overexpressed GPR78 in A549 cells (Fig. 1G), and found that overexpression of GPR78 promoted cell migration (Fig. 1H). Collectively, our data suggests that GPR78 expresses in lung cancer cells and promotes the cell migration.

GPR78 regulates cell migration by targeting RhoA- and Rac1-dependent pathways

We observed that GPR78 knockdown A549 cells exhibited an elongated morphology compared to shRNA control cells (Fig. 2A, Left). Quantification of these cells indicated that the percentage of elongated cells significantly increased by GPR78 knockdown in A549 cells (Fig. 2A, right). Since elongation of cell morphology is related to the reduction of stress fibers (F-actin) (12), we stained the stress fibers in both control and GPR78 shRNA cells. As shown in Fig. 2B, knockdown of GPR78 decreased stress fibers in A549 cells. It has been reported that small GTPase RhoA and Rac1 play an important role in regulating cellular morphology and stress fiber formation (13); therefore, our next query was whether GPR78 regulates the activity of RhoA and Rac1. Interestingly, evaluating by GTPase assay, we found that knockdown of GPR78 significantly suppressed the RhoA and Rac1 activity in A549 cells (Fig. 2C). Importantly, overexpression of constitutive active RhoA or Rac1 in GPR78-knockdown A549 cells partially restored cell migration (Fig. 2D and E). Collectively, our data suggests that GPR78 regulates cell morphology and migration by modulating the activity of RhoA and Rac1 in lung cancer cells.

Gαq/11 mediates GPR78-induced activation of RhoA and Rac1

Previous reports have shown that Gα12/13 and Gαq/11 are the major Gα proteins involved in activation of the Rho family

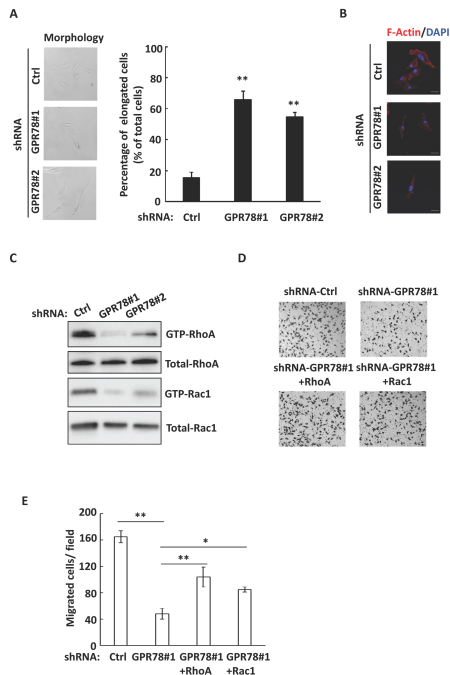

Fig. 2. GPR78 regulates cell morphology by activating small GTPases. GTPases (14-16). Similar to our previous conclusion (Fig. 2C), we found that overexpression of GPR78 in A549 cells induced the activation of RhoA and Rac1 (Fig. 3A). To investigate whether $G\alpha_{12/13}$ or $G\alpha_q/11$ mediates GPR78-induced activation of RhoA and Rac1, we co-expressed GPR78 with RGS domains of p115Rho-GEF regulator (p115-RGS) or GRK2 (GRK2-RGS), which selectively block the activity of $G\alpha_{12/13}$ or $G\alpha_q/11$ (17, 18), respectively. We found that GPR78-induced activation of RhoA and Rac1 was inhibited by co-expression of GRK2-RGS, but not p115-RGS (Fig. 3A). Moreover, overexpression of a constitutively active mutant of $G\alpha_q/11$ (CA Gq) in GPR78 knockdown A549 cells partially restores the activity of RhoA and Rac1 disrupted by GPR78 knocking down (Fig. 3B). Thus, these data suggest that $G\alpha_q/11$ mediates the GPR78-induced activation of RhoA and Rac1. To further investigate whether GPR78-regulated cell migration was dependent on $G\alpha_q/11$, we expressed the active mutant of

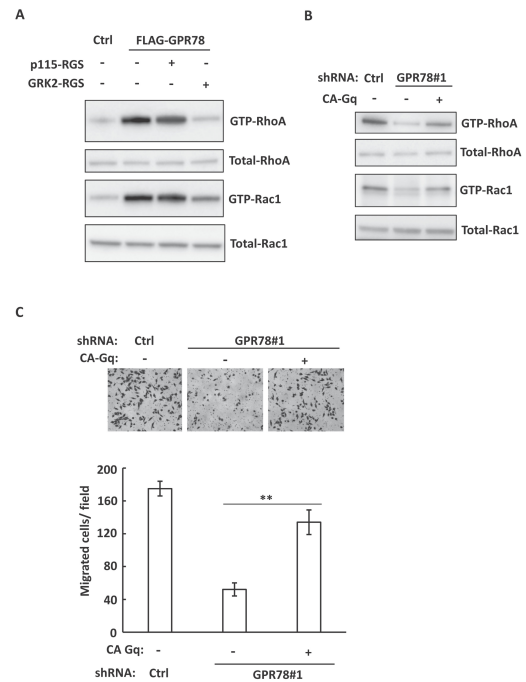

Fig. 3. $G\alpha_q/11$ signaling pathway mediates GPR78-regulated cell invasion. (A) Control or FLAG-GPR78 overexpressed A549 cells were transfected with $G\alpha_{12/13}$ inhibitor p115-RGS, or $G\alpha_q/11$ inhibitor GRK2-RGS, as indicated. The activation of RhoA and Rac1 was analyzed by GTPase assay. (B) shRNA-control or shRNA-GPR78#1 A549 cells were transfected with constitutively $G\alpha_q/11$ protein CA-Gq, as indicated. The activation of RhoA and Rac1 was analyzed by GTPase assay. (C) The cells used in (B) were analyzed for invasion ability by Transwell migration assay. Upper panel, Representative images of Transwell assay. Lower panel, Quantitative data of migrated cells are shown. Results shown are averages \pm S.E.M.

$G\alpha_q/11$ in GPR78 knockdown A549 cells, and analyzed the cell migration. As shown in Fig. 3C, expression of CA Gq partially rescued cell migration in GPR78 knocking down cells. Thus, these data indicate that $G\alpha_q/11$ mediates GPR78-regulated cell migration by activation of RhoA and Rac1.

Knockdown of GPR78 in lung cancer cells suppresses metastasis *in vivo*

To examine whether GPR78 regulates lung cancer cell growth and metastasis *in vivo*, we investigated lung metastasis of A549 cells using xenograft mouse model. We discovered that GPR78 knockdown in A549 cell did not influence the tumor growth *in vivo* (Fig. 4A and B). However, knockdown of GPR78 significantly suppressed lung metastasis *in vivo* (Fig. 4C and D). Taken together, these data suggest that GPR78 regulates breast tumor cell metastases *in vivo*.

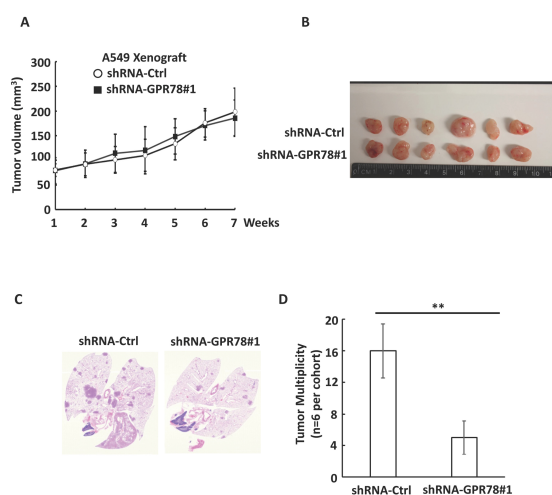

Fig. 4. Knockdown of GPR78 inhibits lung tumor metastasis *in vivo*. (A) Control or GPR78#1 shRNA A549 cells were injected s.c. into 6-week-old female nude mice. Tumor growth curve or (B) final images for A549 tumor xenografts are shown. (C) Representative H&E images of lungs of mice from (A). (D) Lung tumor multiplicity of mice from (A) was determined by counting total tumor foci in 5 serial sections at 400 mm intervals. **P < 0.01.

DISCUSSION

GPR78 is an orphan G-protein coupled receptor (GPCR), highly expressed in human placenta and brain tissues (6). However, the expression pattern of GPR78 in human cancer cells is currently unknown. In this study, we found that GPR78 was expressed in multiple human lung cancer cell lines but not in normal bronchial epithelial cells. GPR26, a paralog gene of GPR78 (6), expressed very low levels in lung cancer cells, it probably has a redundant function, since GPR78 is present in these cells. We investigated the cellular function of GPR78 by GPR78 knockdown in lung cancer cells. Interestingly, knockdown of GPR78 significantly inhibited cell migration but not cell proliferation. Although identification of endogenous ligand(s) for GPR78 will facilitate in examining its role in the cells, a previous study suggested that constitutive activation of GPR78 can be induced by overexpression of itself (6). We thus overexpressed GPR78 in A549 cells, and found that overexpression of GPR78 promoted cell migration, further confirming that GPR78 functions as a regulator for cell migration in lung cancer cells. It has been reported that certain haplotypes of GPR78 were linked to increased susceptibility to bipolar disorders (BPD) and schizophrenia (SZ) in a Scottish family (19). However, the function of GPR78 in modulating cell migration was not reported. Thus, for the first time, our results demonstrate that GPR78 expresses in lung cancer cells and functions as a regulator for cell migration.

Subsequently, we investigated the molecular mechanism of GPR78 in regulating cell migration. We found that knockdown

of GPR78 significantly suppressed activity of RhoA and Rac1, while overexpression of GPR78 induced RhoA and Rac1 activity. Previous studies demonstrated that RhoA and Rac1 modulate elongation of cell morphology, and regulate cancer cell migration (20, 21). Our study further presented that RhoA and Rac1 are responsible for GPR78-regulated cell migration. Moreover, GPR78-induced activation of RhoA and Rac1 is mediated by Gαq-signaling pathway, since blocking of Gαq-signaling inhibited the activation of RhoA and Rac1. It has been reported that GPR78 is a Gs-coupled receptor in regulating cellular level of cAMP. Our study indicates that GPR78 is involved in cell migration through the classical Gα protein-mediated signaling pathway. We observed that the ectopic expression of active mutant CA Gq partially rescued cell migration in GPR78 knockdown cells. These results suggested that other downstream targets of GPR78 may also contribute to GPR78-regulated cell migration. Several GPCRs are known to regulate tumor progression by coupling to the Gα protein signaling pathway. For example, GPR56 is involved in the progression of pancreatic cancer and glioblastoma by coupling to Gα12/13 and Gαq/11(22, 23). CD97 promoted thyroid cancer progression by coupling to Gα12/13 (16). GPR116 promoted breast cancer metastasis by activating Gαq-Rho GTPase pathway (24). Thus, our study indicates that GPR78 can couple with the classical Gαq protein to mediate cancer cell migration and metastasis in lung cancer.

Collectively, this study is the first to demonstrate that GPR78 expresses in lung cancer cells, and plays an important role in promoting tumor cell migration and metastasis. Mechanistic studies identified that GPR78 activates RhoA and Rac1 by coupling to the Gαq-mediated signaling pathway. Importantly, a mouse xenograft model further demonstrated that knockdown of GPR78 inhibited lung cancer cell metastasis *in vivo*, confirming that GPR78 is a novel regulator for lung cancer metastasis, and may serve as a potential drug target against metastatic human lung cancer.

MATERIALS AND METHODS

Reagents

Antibodies to GPR78 (Cat. No. ab121390), RhoA (Cat. No. ab187027), Rac1 (Cat. No. ab33186) and β-actin (Cat. No. ab8226) were purchased from Abcam (Cambridge, MA, USA). Antibodies to FLAG (Cat. No. F7425) were purchased from Sigma-Aldrich (St. Louis, MO, USA). Alexa Fluor[®] 568 Phalloidin was purchased from ThermoFisher Scientific (Grand Island, NY, USA).

Cell culture

HBEC3, HBEC4, A549, H1975, H1299, SPC-A1 and A172 cell lines were purchased from ATCC. Cells were maintained in DMEM medium (Invitrogen, USA) supplemented with 10% fetal bovine serum, 100 units/ml penicillin G, 100 μg/ml streptomycin, and 2 mM L-glutamine, at 37°C with 5% CO₂.

Immortalized HBEC3 and HBEC4 cells were cultured in Keratinocyte Serum Free media (KSFM) (Gibco) at 37°C and 5% CO₂. The KSFM media contained 50 µg/ml of bovine pituitary extract and 5 µg/ml of epidermal growth factor.

Western blotting

Cells were lysed in M2 lysis buffer (150 mM NaCl, 50 mM Tris-Cl (pH 8.0), 5 mM EDTA, 1% Nonidet P-40) containing a protease inhibitor mixture (Roche Applied Science) and a phosphatase inhibitor mixture (Sigma, MO, USA). Equal amounts of total protein were subjected to SDS-PAGE analysis and immunoblotting with the appropriate antibodies.

Real-time PCR assay

RNA was extracted using TRIzol (ThermoFisher, Grand Island, USA) and quantified by spectrophotometry (NanoDrop, Peqlab, Germany). RNA was reverse transcribed using Superscript III reverse transcriptase (ThermoFisher, Grand Island, USA), according to the manufacturer's protocol. PCR was conducted using the MyiQ Real-Time PCR Detection System (Bio-Rad, USA). The Taqman probe for *gpr78* (Assay ID: Hs01574416_m1), *gpr26* (Hs00538034_m1), and *actin* (Assay ID: Hs.PT.56a.21538384) were purchased from Thermo Scientific (Waltham, MA, USA). The threshold cycle number for each gene was normalized to that of actin, and the resulting value was converted to a linear scale.

Plasmid construction and transfection

Full-length DNA coding sequence of human GPR78 (NM_080819) was amplified using the forward primer 5'-GGATCCCATGGGCCCGCGAG-3' and the reverse primer 5'-GTCCGACGCCAGGCCCTCAGTGTG-3. The amplified PCR product was then cloned into the BamH1/ Sal1 site of pCMV-Tag2A construct and verified by DNA sequencing. Both p115-RGS (amino acid residues 1-252) and GRK2-RGS (amino acid residues 54-175) were amplified by PCR and sub-cloned into the BamH1/ EcoR1 site of pCMV-Tag2A construct. The constitutively active mutants of RhoA, Rac1, and Gq were cloned as previously described (25).

The lentivirus silencing vector expressing shRNA targeting human GPR78#1 (TRC number: TRCN0000357332) and GPR78#2 ADAM10 (TRC number: TRCN0000357333) were obtained from Sigma (St. Louis, MO, USA). Following the manufacturer's instructions, plasmids were transfected into cells using lipofectamine 2000 (ThermoFisher Scientific, Grand Island, USA). For lentivirus production, HEK293T cells were co-transfected with pCMV-VSV-G, pCMV-dr8.2-dvpr and shRNA plasmids. After 24 h, the supernatant was collected and this lentiviral preparation was used to infect cells. After 24 h of infection, cell selection was accomplished by incubating with puromycin for an additional 48 h.

GTPase activity assay

For RhoA activity, a fusion protein of glutathione S-transferase

(GST) with the RhoA binding domain of Rhotekin was used (GST-RBD). For Rac1 activity, a GST fusion protein with the binding domain of PAK was used (GST-PBD). Briefly, both fusion proteins expressed in BL21 were purified with glutathione Sepharose beads (GE Healthcare). Cell lysates were prepared with RhoA lysis buffer [50 mmol/L Tris-HCl, pH 7.4, 150 mmol/L NaCl, 5 mmol/L MgCl₂, 1 mmol/L dithiothreitol, 1 mmol/L phenylmethylsulfonyl fluoride (PMSF), 1% Triton X-100, proteinase inhibitor cocktail] or Rac1 lysis buffer (20 mmol/L HEPESNaOH, pH 7.5, 120 mmol/L NaCl, 10% glycerol, 2 mmol/L EDTA, 0.5% Nonidet P-40, 1 mmol/L PMSF, proteinase inhibitor cocktail], and incubated with GST-RBD or GST-PBD precoupled to glutathione Sepharose beads, at 4°C for 45 minutes; this precipitates the GTP-bound RhoA or Rac1. The precipitant was then boiled in Laemmli sample buffer, and the eluted product was separated on a 12% SDS-PAGE gel. Immunoblotting was used to detect the protein level of total and GTP-bound RhoA or Rac1.

Transwell migration assay

The transwell migration assay was performed using 6.5-mm-diameter polycarbonate filters (8-µm pore size). Cells (4×10^4) suspended in 100 µl of DMEM containing 0.5% FBS, were seeded in the top chambers. The bottom chambers were filled with 500 µl of DMEM containing 10% FBS. Cells were allowed to migrate for 12 hours. The unmigrated cells were removed with cotton swabs. Migrated cells were fixed with cold 4% paraformaldehyde and stained with 1% crystal violet. Images were taken using an inverted microscope (10X magnification; Olympus, Tokyo, Japan), and migrated cells were quantified by manual counting.

in vivo A549 xenograft model

A549 cells (2×10^6) were mixed with matrigel and subcutaneously (s.c.) injected into nude mice (n = 6 for each group) under aseptic conditions. Tumors were measured in 2 dimensions, and volume was calculated according to the formula: $V = 0.5 (\text{length} \times \text{width}^2)$. The tumor was monitored and evaluated every week. After 7 weeks, the tumor and lung were excised and evaluated. The total number of tumor foci was determined by five serial sections at 400 µm intervals.

Statistical analysis

Data were analyzed using the SPSS (version 20.0; IBM Corporation, Armonk, NY, USA) software program. Results are expressed as means ± S.D. and are representative of at least three separate experiments. The two-sample t-test was used to determine statistical differences in the means of two columns. P value less than 0.05 (P < 0.05) was regarded as statistically significant.
