ABSTRACT

In this study, the complete chloroplast (cp) genome of *Ixora chinensis* was sequenced by next-generation sequencing for the first time. The complete cp genome is 154,787 in length and contained 131 genes, consisting of 86 protein-coding genes, eight ribosomal RNA genes, and 37 transfer RNA genes. The phylogenetic position based on chloroplast genomes suggests that *I. chinensis* was closely related to *I. chinensis* (MN850660.1) within the *Ixora* clade, which may provide useful information for further understanding the evolution of *I. chinensis*.

Ixora chinensis Lam. also named 'Dauk Chem' is native to China and Malaysia, belonging to the genus of *Ixora* in the Rubiaceae family. In recent years, the flower has become more and more popular in China. It is widely distributed in the southwest and southeast regions of China, such as Hainan, Fujian, Guangdong and Guangxi (Li et al. 2019). *Ixora chinensis* has a longer vase life than other *Ixora* species which makes it an outstanding cut flower (Chen et al. 2003). In addition, most of the activities reported on leaves and flowers of *I. chinensis* were anti-oxidants, anticancer, anti-microbial activities (Bhagyasri et al. 2019). Interestingly, the flower with bright and abundant flowers has a long blooming term lasting for almost the entire year. *Ixora chinensis* with red flowers is one of the most common native species in southern China, not only with ornamental value but more importantly with its medicinal values which it is rich in flavonoids and anthocyanins (Rastogi and Mehrotra 1990). Recently, *I. chinensis* was assembled by Ly et al. (2020) to comparative genomics and molecular phylogeny in subfamily Ixoroideae. However, it was not assembled into a circular chloroplast genomes and the cp genome was not annotated. In addition, the chloroplast sequence (accession number: MN850660.1) is not verified by NCBI. There is yet little information on the complete

chloroplast (cp) genome of *I. chinensis*. Here, the complete chloroplast (cp) genome of *I. chinensis* was assembled and annotated for the first time. We also carried out a systematic comparative genomic study of *I. chinensis* plastome and those from another two *Ixora* species, in order to explore its phylogenetic relationship and identify new regions of genomic variability.

The plant material of fresh leaves for extraction was collected from Caiban Village, Jiuhu Town, Zhangzhou (Fujian, China, 117°59'56"E, 24°48'40"N). Total chloroplast DNA was extracted following Kim et al. (2006) with the optimized CTAB method, and used to construct to build an Illumina pair-end library. Then the library was done on Illumina Novaseq 6000 platform at Beijing Genomics Institute (BGI, Shenzhen, China) and generating approximately 3.6 G of raw data. The quality of reads was filtered using the FastQC program (Andrews 2014). High-quality clean reads were de novo assembled using SPAdes version 3.11.0 software (Bankevich et al. 2012) the cp genome was annotated using the online program GeSeq (Tillich et al. 2017) with the chloroplast genome of *Vangueria infausta* (accession number MN851269) as reference. The annotated chloroplast genome sequence of was deposited in GenBank under the accession number

Figure 2. Gene deletion in *Ixora* genus.

Figure 3. Gene polymorphism in *Ixora* genus.

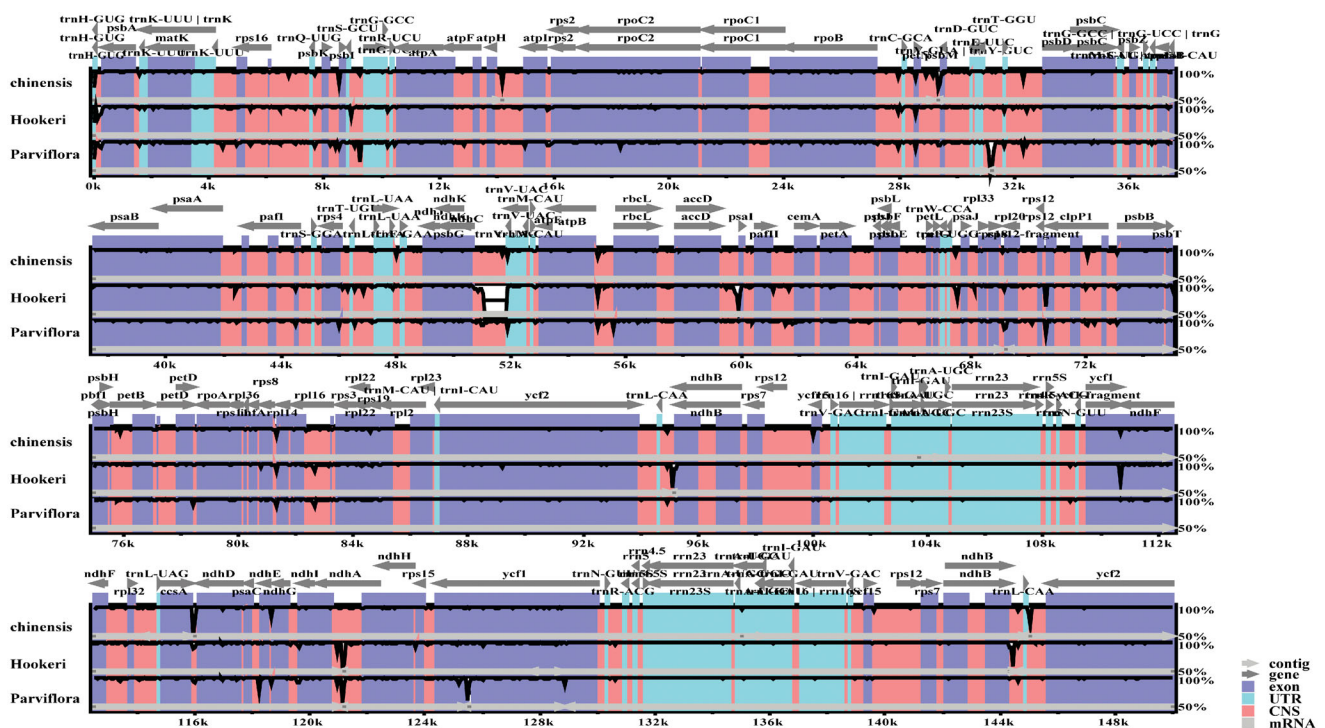

Figure 4. Sequence identity plot comparing four species of subfamily *Ixora* with *I. chinensis* (MN850660.1) as the reference annotated genome.

Untranslated Transcribed Regions (UTR). However, variation among species seemed to be negligible for UTRs located in the IR region. Substitutions were more frequent but indels (trnV-UAC) were observed as well in *I. hookeri* (Figure 4).

In order to understand the phylogenetic relationship between *I. chinensis* and other species of *Ixora*, the complete chloroplast sequence of 43 species was downloaded from NCBI as the phylogenetic dendrogram. The tree phylogenetic with maximum likelihood (ML) analysis method was performed using RaxML software v 8.2.9, of which the

bootstrap values were calculated using 1000 replicates under the GTRGAMMAI substitution model in CIPRES (Stamatakis 2014). The reconstructed phylogeny showed that *I. chinensis* had the closest relationship with *I. chinensis* (MN850660.1) (Figure 4), which can provide a theoretical basis for further study on the phylogeny and evolution of Rubiaceae plants (Figure 5).
