#### Abstract

Bambusurils, BU[4] and BU[6], were used for the first time as multivalent scaffolds to link glycosidases inhibitors derived from 1-deoxynojirimycin (DNJ). Two linear DNJ ligands having six or nine carbon alkyl azido linkers or a trivalent DNJ dendron were grafted onto octapropargylated BU[4] and dodecapropargylated BU[6] using copper-catalyzed cycloaddition (CuAAC) to yield corresponding neoglycobambus[4] and neoglycobambus[6]urils bearing 8 to 24 iminosugars. The inhibition potencies of neoglycoBU[4], neoglycoBU[6] and neoglycoBU[6] caging anions were evaluated against Jack Bean $\alpha$-mannosidase and compared to monovalent DNJ derivatives. Strong affinity enhancements per inhibitory head were obtained for the clusters holding trivalent dendrons with inhibitory constants in the nanomolar range ( $K_{i}=24 \mathrm{nM}$ for $\mathrm{BU}[4]$ with 24 DNJ units). Interestingly, the anion (bromide or iodide) encapsulated inside the cavity of $\mathrm{BU}[6]$ does not modify the inhibition potency of neoglycoBU[6], opening the way to water-soluble glycosidase-directed anion caging agents that may find applications in important fields such as bio(in)organic chemistry or oncology.

## 1. Introduction

Bambus[ $n$ ]urils, $\mathrm{R}_{2 n} \mathrm{BU}[n](n=4,6)$, are synthetic neutral cyclooligomers composed of $\mathrm{R}_{2}$ disubstituted glycoluril units connected by $n$-methylene bridges [1]. BU[4,6] show a rigid conformation in an alternate arrangement that looks similar to a double-cup jigger. The well-defined cavity of $\mathrm{BU}[6]$ is of ideal size to entrap anions [1-3]. This strong anion-caging property of BU[6] was utilized for anion sensing, [4,5] transport [6,7] and extraction [8-10] as well as in photoinduced electron transfer [11]. However, BU[4], having a smaller internal cavity than BU[6] derivatives, is unable to include any anions and so far does not have any applications. Nevertheless, the modular valency of 8 to 12 for $R_{8} B U[4]$ and $R_{12} B U[6]$, respectively, their topology allowing ligands to be grafted on upper and lower rims, their arm flexibility and, even more importantly, their cheap and easy synthesis make BU[4] and BU[6] attractive scaffolds for the construction of multivalent derivatives. We have previously synthesized allylated bambus[4,6]urils that were submitted to thiol-ene click coupling (TEC) with thiosugars to generate the corresponding 8-12 thiosugar-functionalized bambus[4,6]urils [12,13]. As a proof of concept, we recently developed an alternative strategy using propargylated bambus[4,6]urils able to be post-functionalized by click chemistry (CuAAC) so as to afford multivalent architectures bearing 8 or 12 glucose units [14].

In the present work, we report the first examples of multivalent bambus[ $n$ ]urilsiminosugar conjugates. N-alkyl analogs of 1-deoxynojirimycin (DNJ) were chosen as
inhitopes (inhibiting epitopes) since the best inhibitory multivalent effects were reported with these motifs on Jack Bean $\alpha$-mannosidase [15-20]. Despite the large number of scaffolds used for multimerization of iminosugar inhitopes [15-26], starting from $\mathrm{C}_{60}$, polyols, cyclodextrins, porphyrins, calixarenes and gold nanoparticles to the most effective cyclopeptoids, it is still relevant to study new structures that might have different topologies and contact points with glycosidases together with other physical properties of interest, such as anion binding ability. Indeed, it was shown that the binding modes of Jack Bean $\alpha$-mannosidases with iminosugar-based multivalent inhibitors not only depend on the nature and number of bioactive inhitopes, but more importantly on the shape and size of the multivalent scaffold as well as ligand density [15-20]. Multimerization of inhitopes proved to be an attractive strategy, enabling valency-corrected inhibition enhancements of up to three [26] to four [27] orders of magnitude, inhibition selectivity refining or enzyme activation [28,29]. Multivalent drugs on nanoparticles also proved efficient for escaping efflux pumps [30]. Originally discovered with glycosidases [15-20], the inhibitory multivalent effect has been generalized to other enzymes such as glycosyltransferases and carbonic anhydrases [31-34]. In the case of enzyme inhibition, multivalent inhibitors may interact with enzymes by numerous mechanisms, such as the bind-and-recapture process, the chelate effect or receptor clustering [15-20,35].

Since anions such as bromide and iodide can easily and strongly be complexed inside $\mathrm{BU}[6]$, we have explored whether they would impact the rigidity and shape of the scaffold, and thus possibly the interaction with the model glycosidase used for studying inhibitory multivalent effects. Our objective was to access unprecedented water-soluble glycosidasedirected anion caging agents. Here, we describe the full details of our study, from the synthesis of bambus[ $n$ ]urils-iminosugar conjugates to the quantification of host-guest interaction of these neoglycoclusters with iodide anion and their evaluation as Jack Bean $\alpha$-mannosidase inhibitors.

## 2. Results and Discussion

2.1. Preparation of DNJ-Functionalized Bambusuril neoglyco ${ }_{8} B U[4]$, neoglyco ${ }_{12}$ BU[6] and X@neoglyco ${ }_{12}$ BU[6]

The best multivalent effects in glycosidase inhibition using non-polymeric inhibitors were obtained thanks to a study relying on a gradual increase in cyclopeptoid scaffold size and valency, which led to small aggregates between two enzymes and the multimeric inhibitor being highlighted as the best cluster of the series [26,36]. Important click partners of this study were azide-armed N-C6 and N-C9 alkyl DNJ [37] and tripod DNJ derivatives [38]. These building blocks were consequently selected for the synthesis of the first examples of bambus[n]urils-based iminosugars 3-11 (Figure 1). Based on our recent results [14], octapropargylated BU[4] 1 and dodecapropargylated BU[6] 2 were used as clickable platforms to generate architectures decorated with 8 and 12 DNJ inhitopes, respectively. For this purpose, azide-armed $N$-hexyl DNJ 12, $N$-nonyl DNJ 13 and N -nonyl-trivalent DNJ-dendron (tripod) 14 were chosen as peripheral ligands to generate corresponding neoglyco ${ }_{8} \mathrm{BU}[4] 3-5$ and neogluco ${ }_{12} \mathrm{BU}[6]$ 6-11 derivatives. The syntheses of DNJ-functionalized bambusuril BU[4] 3-5 and the structures of azide DNJ ligands 12-14 are shown in Scheme 1.

Figure 1. Structures of propargyl $\mathrm{l}_{8} \mathrm{BU}[4]$ 1, propargyl $\mathrm{l}_{12} \mathrm{BU}[6]$ 2, neoglycobambusurils $\mathrm{BU}[4]$ 3-5 and BU[6] 6, 7 and $\mathrm{Br}^{-} @ B U[6] . \mathrm{TBA}^{+} 8,10-11$ and $\mathrm{I}^{-} @ B U[6] . \mathrm{TBA}^{+} 9$ bearing DNJ ligands studied in this paper.

Scheme 1. Synthesis of neoglycobambus[4]urils BU[4] 3, 4 and5 decorated with C-6, C-9 monovalent DNJ and C-9 trivalent tripod DNJ, respectively.

First, the dipropargylated BU[4] platform 1 was prepared in one step and with $60 \%$ yield by condensation of propargylglycoluril and formaldehyde following our reported procedure [14]. Propargyl ${ }_{8} \mathrm{BU}[4] 1$ was then reacted with peracetylated azido-functionalized C6-DNJ 12 [37,39] through a copper(I)-catalyzed azide alkyne cycloaddition reaction $(\mathrm{CuAAC})$ in the presence of sodium ascorbate in $\mathrm{DMSO} / t \mathrm{BuOH} / \mathrm{H}_{2} \mathrm{O}$ to acquire pro-
tected (DNJ-OAc-C6) ${ }_{8} \mathrm{BU}[4] 15$ with $54 \%$ yield. Use of microwave irradiations shortened the reaction time and increased yield. Subsequently, deacetylation of $\mathbf{1 5}$ was set up using anion exchange $\left(\mathrm{OH}^{-}\right)$amberlite IRN 78 resin as described [37,40] to generate (DNJ-C6) $)_{8} \mathrm{BU}[4]$ 3 with $97 \%$ yield. Following the same synthetic procedure, (DNJ-OAc-C9) ${ }_{8}$ BU[4] 16 was isolated with $53 \%$ yield from the CuAAC reaction of propargyl $\mathrm{l}_{8} \mathrm{BU}[4] 1$ and peracetylated azido-functionalized C9-DNJ 13 [37]. Basic cleavage of OAc groups of 16 afforded (DNJ-C9) ${ }_{8} \mathrm{BU}[4] 4$ decorated with 8 DNJ (C-9 linker) with $87 \%$ yield. Grafting of 24 DNJ derivatives was made possible by the click coupling of protected azido trivalent-C9-DNJ dendron $14[38,41]$ on $\mathrm{BU}[4] 1$ to give (DNJ-OAc-Tripod) ${ }_{8} \mathrm{BU}[4] 17$ with $46 \%$ yield. Basic treatment of 17 generated (DNJ-Tripod) ${ }_{8} \mathrm{BU}[4] 5$ with $74 \%$ yield.

A larger platform, $\mathrm{Br}^{-}$@propargyl ${ }_{12} \mathrm{BU}[6] . \mathrm{TBA}^{+} 2$, that was able to be decorated with 12 iminosugar inhitopes was then submitted to azide-armed DNJ derivatives 12 and 13 to generate, after decomplexation and deprotection steps, the corresponding 12 -valent clusters (DNJ-C6) ${ }_{12} \mathrm{BU}[6] 6$ and (DNJ-C9) ${ }_{12} \mathrm{BU}[6] 7$, respectively (Scheme 2).

Scheme 2. Synthesis of neoglyco ${ }_{12}$ BU[6] 6, 7 bearing 12 (C-6, C-9) monovalent DNJ ligands.
First, following our reported procedure, condensation of dipropargyl glycoluril with formaldehyde and TBABr as template promoted the formation of $\mathrm{Br}^{-}$@propargyl ${ }_{12} \mathrm{BU}[6] \mathrm{B}-$ U.TBA ${ }^{+} 2$ with $55 \%$ yield [14]. A subsequent CuAAC reaction of 2 with azide-armed DNJ 12 (C6 linker) afforded fully functionalized $\mathrm{Br}^{-} @(\mathrm{DNJ}-\mathrm{C} 6-\mathrm{OAc})_{12} \mathrm{BU}[6] . \mathrm{Na}^{+} 18$ with $70 \%$ yield. Click reaction of BU 2 with azide-armed DNJ 13 (C9 linker) provided 12-valent $\mathrm{Br}^{-}$@(DNJ$\mathrm{C} 9-\mathrm{OAc})_{12} \mathrm{BU}[6] . \mathrm{Na}^{+} 19$ with $74 \%$ yield. Decomplexation reactions of $\mathrm{Br}^{-} @ \mathrm{BU} \mathbf{1 8}$ and 19 were then performed with $\mathrm{AgSbF}_{6}$ [13] to generate the corresponding anion-free 12-valent iminosugars that were directly submitted to basic resin for the final deprotection step, yielding (DNJ-C6) ${ }_{12} \mathrm{BU}[6] 6$ ( $94 \%$ yield) and (DNJ-C9) ${ }_{12} \mathrm{BU}[6] 7$ ( $93 \%$ yield), respectively.

To obtain the $12 \times 3$-valent DNJ-BU[6] conjugate, $\mathrm{Br}^{-}$@propargylBU[6].TBA ${ }^{+} 2$ was reacted with clickable dendron 14 [38] in the presence of $\mathrm{CuSO}_{4}$ and sodium ascorbate using microwave irradiations to promote full click coupling (Scheme 3). However, using our general click procedure, only partial functionalization of 2 was observed, affording $6 \times 3$ valent-DNJ-Tripod-BU[6] 20 with $84 \%$ yield. Despite many attempts to optimize the reaction conditions (solvent, stoichiometry, microwave power, temperature, reaction time), it was not possible to obtain fully functionalized BU[6]. We hypothesized that the steric hindrance of the DNJ Tripod 14 did not allow the total functionalization of BU[6] 2. Mass spectra analysis allowed for quantification of the presence of six grafted tripods. The six remaining alkyne functions were observable on the ${ }^{1} \mathrm{H}$ NMR spectrum of 20.

Despite its partial functionalization, $\mathrm{Br}^{-}$@(DNJ-Tripod-OAc) ${ }_{6} \mathrm{BU}[6] . \mathrm{Na}^{+} 20$ was submitted to basic resin deprotection to give $\mathrm{Br}^{-}$@(DNJ-Tripod) ${ }_{6} \mathrm{BU}[6] \cdot \mathrm{Na}^{+} \mathbf{1 1}$ with $84 \%$ yield. This interesting cluster bearing 18 DNJ units has been also evaluated as a glycosidase inhibitor.

Interestingly, bambusurils BU[6] are known to complex halides, especially iodides, with very high affinity forming a rigid assemblage [1,42]. We hypothesized that such a rigid structure could influence the glycosidase inhibition power of iminosugar-BU conjugates. Towards this goal, TBABr was added to anion-free (DNJ-C6-OH) ${ }_{12} \mathrm{BU}[6] 6$ in $\mathrm{H}_{2} \mathrm{O} / \mathrm{MeOH}$ to generate $\mathrm{Br}^{-}$@(DNJ-C6-OH) ${ }_{12} \mathrm{BU}[6] . \mathrm{TBA}^{+} 8$ ( $98 \%$ yield). Similarly, addition of TBAI to $(\mathrm{DNJ}-\mathrm{C} 6-\mathrm{OH})_{12} \mathrm{BU}[6] 6$ yielded $\mathrm{I}^{-} @(\mathrm{DNJ}-\mathrm{C} 9-\mathrm{OH})_{12} \mathrm{BU}[6] . \mathrm{TBA}^{+} 9$ ( $97 \%$ yield) and reaction of anion-free (DNJ-C9-OH) ${ }_{12} \mathrm{BU}[6] 7$ with TBABr gave $\mathrm{Br}^{-} @(\mathrm{DNJ}-\mathrm{C} 9-\mathrm{OH})_{12} \mathrm{BU}[6] . \mathrm{TBA}^{+} 10$ ( $98 \%$ yield). The synthesis of anion@BU[6] 8-10 is reported in Scheme 4.

Scheme 4. Synthesis of $\mathrm{Br}^{-}$@(DNJ-C6) ${ }_{12} \mathrm{BU}[6] \cdot \mathrm{TBA}^{+} 8, \mathrm{I}^{-}$@(DNJ-C6) ${ }_{12} \mathrm{BU}[6] . \mathrm{TBA}^{+} 9$ and $\mathrm{Br}^{-}$@(DNJC9) ${ }_{12} \mathrm{BU}[6] \mathrm{TBA}^{+} \mathbf{1 0}$.

The hostguest interaction of anion-free (DNJ-C6) ${ }_{12} \mathrm{BU}[6] 6$ with iodide anion was evaluated using a direct isothermal titration calorimetry (ITC) method [4,14]. BU[6] 6 bearing 12 DNJ arms (C6 linker) was found to have a good affinity for iodide ( $K_{a}=4.8 \times 10^{5} \mathrm{M}^{-1}$ in water) (Supplementary Materials Figure S1), similar to our reported results for (Dglucose) ${ }_{12} \mathrm{BU}[6]$ derivatives ( $K_{a}=2.2 \times 10^{5}$ and $1.7 \times 10^{5} \mathrm{M}^{-1}$ for iodide complexation in $\mathrm{H}_{2} \mathrm{O}$ ) [14]. Interestingly, this study shows that C 6 linkers, or the nature of the peripheral head (DNJ compared to D-glucose), did not affect complexation. In addition, ITC data clearly indicate that the formation of the iodide complex 9 is driven by enthalpy $(\Delta \mathrm{H}=-33,47 \mathrm{~kJ} / \mathrm{mol})$ and that 9 displays a $1: 1$ stoichiometry in water.

### 2.2. Glycosidase Inhibition Study

All the new clusters were evaluated against Jack Bean $\alpha$-mannosidase, a glycosidase highly sensitive to multivalent inhibitor presentation [15-20]. The corresponding inhibition constants are summarized in Table 1. The evaluated DNJ-bambusuril conjugates acted as
competitive inhibitors, with the notable exception of the series of 12 -valent clusters with the shorter C6 linker obtained with the BU[6] scaffold which behaved as mixed inhibitors (Table 1, entries 6-8). The inhibition potency of those new clusters was compared to their corresponding monovalent inhibitors, 21 [22] and 22 [37] (Figure 2), to calculate their relative potency $(r p)$. Dividing the relative potency by the number of active units gives the relative potency per inhitope ( $r p / n$ ).

${ }^{[a]} r p=K_{\mathrm{i}}$ (monovalent reference) $/ K_{\mathrm{i}}$ (neoglycocluster), $n=$ number of inhitope units.

Figure 2. Structure of monovalent inhibitors 21-22.
As in a previous study with calix[8]arene-based clusters [43], the scaffold has a strong impact on inhibition with the C6 shorter linker. Whereas the inhibitory heads of cluster 3 based on the smaller BU[4] scaffold are individually four times more potent than the reference $(r p / n=4)$, the ones of clusters 6,8 and 9 based on BU[6] are less active than the monovalent reference $(r p / n<1)$ and show a different inhibition mode (Table 1 entries 6-8). Noticeably, the inhibition mode and power of the three BU[6] binding bromide or iodide ions (or with a free cavity) are similar, suggesting an overall similar shape. We previously obtained crystals of $\mathrm{Cl}^{-}$, $\mathrm{Br}^{-} \mathrm{I}^{-}$@allyl ${ }_{12} \mathrm{BU}[6] . \mathrm{TBA}{ }^{+}[12,13]$ and of $\mathrm{Br}^{-}, \mathrm{I}^{-}$@propargyl ${ }_{12} \mathrm{BU}[6] . \mathrm{TBA}^{+}$[14], showing that the halides are included in the cavity and that the geometry of these $\mathrm{CH} \cdots$ halide bonds are similar, with distances varying with the halogen ionic radius which thus indicates that the macrocycle retains some flexibility [12-14]. Similarly, with C9 linkers, the activities and inhibition mode are not impacted by the presence of anions in the bambusuril cavity (Table 1 entries 9-10). With the longer C9 linker, the impact of the central scaffold, whatever its size, is abolished, giving similar affinity enhancement per DNJ (entries 4, 9 and 10) with C9 enhancement being at least one order of magnitude higher than for the C6 series. This result is in line with previous findings using other scaffolds [15-20,43]. The best results were obtained with clusters $\mathbf{5}$ and $\mathbf{1 1}$ grafted with the trivalent dendron with affinity enhancements one order of magnitude higher than those of compounds 4,7 and 10. The affinity enhancement per inhibitory head of compound 5 is in the same range as for the 24 -valent cyclopeptoid bearing the same trivalent dendron [26]. Altogether, those results show that bambusuril scaffolds allow for efficient grafting of glycosidase inhibitors and that
this multimerization induces strong affinity enhancements. Moreover, the fact that activity is not influenced by anion binding opens the way to potential therapeutic applications by inducing accumulation of the encaged anion, and potentially radioactive iodide, in a glycosidase rich environment. It is, for example, well-known that $\beta$-glucuronidases are present at high concentration in the microenvironment of most solid tumours [44] and that radioactive iodine is used for the treatment of cancers, including thyroid cancers [45-47].

## 3. Material and Methods

### 3.1. General Information and General Experimental Procedures for the Syntheses

Commercially available reagents were used without further purification. All reactions were performed under inert atmosphere using anhydrous solvents which were dried and distilled before being used. Thin-layer chromatograms (TLC) and flash chromatography separations were respectively performed on precoated silica gel 60 F254 plates ( 0.25 mm ) and on Merck Kieselgel 60 (grading 40-63 $\mu \mathrm{m}$ ). Microwave syntheses were conducted using a CEM Focused Microwave Discover ${ }^{\circledR}$ SP-X System reactor. The reactions were performed for $2-4 \mathrm{~h}$ under magnetic stirring in 10 or 35 mL sealed Discovered SP vessels closed with Activent ${ }^{\circledR}$ caps. The dynamic control method was used for all microwave reactions where the temperature and the pressure were set ( $\mathrm{P}=50 \mathrm{~W}, \mathrm{~T}=80^{\circ} \mathrm{C}$, PowerMax on). ${ }^{1} \mathrm{H}$ NMR spectra ( 400 MHz ) and ${ }^{13} \mathrm{C}$ NMR spectra ( 100 MHz ) were recorded on a Brucker Avance 400 MHz spectrometer. Chemical shifts and coupling constants are reported in parts per million (ppm) and in Hertz (Hz), respectively. HRMS and electrospray mass spectra (ESIMS) were obtained from an LCT Premier XE using electro spray ionization coupled with a time flight analyzer (ESI-TOF). Infrared spectra (IR) were recorded on a Perkin Elmer UAR Two Spectrum spectrometer. Electrospray mass spectra were obtained using an ESI-Quadripole autopurify Waters (pump: 2545, mass: ZQ2000) mass Spectrometer. Optical rotations were measured on a JASCO P-2000 Polarimeter. Melting points were measured on a Büchi Melting point B540.

### 3.1.1. General Procedure A for CuAAC Reaction of Propargyl ${ }_{8} \mathrm{BU}[4]$

To a solution of octapropargyl bambus[4]uril 1 ( 10 to $15 \mathrm{mg}, 1 \mathrm{eq}$. ) and azide ligand ( 9 eq. ) in DMF $/ \mathrm{H}_{2} \mathrm{O}(0.6 \mathrm{~mL}, 5 / 1)$ in a microwave reactor, a solution of sodium ascorbate 1 M in water ( 0.4 eq .) and a solution of $\mathrm{CuSO}_{4} 5 \mathrm{H}_{2} \mathrm{O} 1 \mathrm{M}$ in $\mathrm{H}_{2} \mathrm{O}$ ( 0.8 eq.) were added. The reaction was subjected to microwave irradiations under magnetic stirring from 30 min to 4 h at $80^{\circ} \mathrm{C}$. A solution of $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{H}_{2} \mathrm{O} / 30 \mathrm{w} \% \mathrm{NH}_{4} \mathrm{OH}(16 \mathrm{~mL}, 15 / 0.5 / 0.5, v / v / v)$ was then added to the crude and the mixture was filtered on a small pad of $\mathrm{SiO}_{2}$ and eluted with a solution of $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{H}_{2} \mathrm{O} / 30 \mathrm{w} \%-\mathrm{NH}_{4} \mathrm{OH}(15: 0.5: 0.5, v / v / v)$. The filtrate was concentrated under vacuum and purified by flash silica gel chromatography $\left(\mathrm{SiO}_{2}\right.$; $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}, 99: 1$ to $95: 5$ ) to afford the corresponding 8-clicked iminosugars $\mathrm{BU}[4]$.

### 3.1.2. General Procedure B for CuAAC Reaction of Propargyl ${ }_{12}$ BU[6]

To a solution of dodecapropargybambus[6]uril tetra-butyl bromide 2 ( 10 to $15 \mathrm{mg}, 1 \mathrm{eq}$. ) and azide ligand (16 eq.) in $\mathrm{DCE} / \mathrm{H}_{2} \mathrm{O} / t \mathrm{BuOH}(0.5 / 1 / 1.2 \mathrm{~mL})$ in a microwave reactor, a solution of sodium ascorbate 1 M in water (4 eq.) and a solution of $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O} 1 \mathrm{M}$ in $\mathrm{H}_{2} \mathrm{O}$ ( 2 eq. ) were added. The reaction was subjected to microwave irradiations under magnetic stirring for 2 h at $80^{\circ} \mathrm{C}$. The mixture was then concentrated under vacuum and diluted with $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{H}_{2} \mathrm{O} / 30 \mathrm{w} \% \mathrm{NH}_{4} \mathrm{OH}(9 / 1 / 1,11 \mathrm{~mL})$. The mixture was filteredon a small pad of $\mathrm{SiO}_{2}$ (typically 1 cm thick) that was washed with this same eluent, $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{H}_{2} 0 / 30 \mathrm{w} \%$ $\mathrm{NH}_{4} \mathrm{OH}(9 / 1 / 1,25 \mathrm{~mL})$. The filtrate was concentrated under vacuum and purified by flash silica gel chromatography $\left(\mathrm{SiO}_{2} ; \mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}, 99: 1\right.$ to 90$)$ to afford the corresponding 12-clicked iminosugars BU[6].

### 3.1.3. General Procedure $C$ for Deacetylation of Sugars

Amberlite IRN $78\left(\mathrm{HO}^{-}\right)(\mathrm{ng} / \mathrm{mmol}$ with $\mathrm{n}=$ number of OAc$)$ was added to a solution of acetylated-iminosugars bambusuril (1 eq.) in $\mathrm{H}_{2} \mathrm{O} / \mathrm{MeOH}(1 / 1,600 \mu \mathrm{~L}$ ). The suspension
was stirred from 4 h to 12 h at $40^{\circ} \mathrm{C}$. The resin was removed by filtration and washed with methanol and water. The filtrate was concentrated under vacuum to give BU-iminosugars.

### 3.2. Isothermal Titration Calorimetry Experiments

ITC measurements were performed with a VP-ITC microcalorimeter (Microcal, GEHealthcare). Experiments were carried out in water and in a solution of $\mathrm{K}_{2} \mathrm{HPO}_{4}(1.5 \mathrm{mM})$ in mili-Q water at $298.15 \pm 0.1 \mathrm{~K}$. Anion binding to BU was investigated via a classical isothermal titration experiment ( $10 \mu \mathrm{~L}$ additions) and a single injection method (SIM). Injection of sodium iodide solution was added automatically to the BU solution present in the calorimeter cell while stirring at 307 rpm . Integrated heat effects were analyzed by nonlinear regression using a single-site binding model (Microcal Origin 7). The experimental data fitted to a theorical titration curve, giving the association constant $K_{a}$, the enthalpy of binding $\Delta \mathrm{H}^{\circ}$ and the entropy $\Delta \mathrm{S}^{\circ}$. The free energy $\Delta \mathrm{G}^{\circ}$ was calculated from the equation: $\Delta \mathrm{G}^{\circ}=\Delta \mathrm{H}^{\circ}-T \Delta \mathrm{~S}^{\circ}$, where $T$ is the absolute temperature. The first smaller addition $(2 \mu \mathrm{~L})$, which was used to compensate for diffusion of the guest from the injector during equilibration, was discarded prior to data fitting.

### 3.3. Inhibition Assays on Jack-Bean $\alpha$-Mannosidase

$p$-nitrophenyl- $\alpha$-D-mannopyranoside and $\alpha$-mannosidase (EC 3.2.1.24, from Jack Bean) were purchased from Sigma Aldrich, St. Louis, MO, USA. Inhibition constants were determined spectrophotometrically by measuring the residual hydrolytic activities of the $\alpha$-mannosidase against $p$-nitrophenyl- $\alpha$-D-mannopyranoside in the presence and absence of an inhibitor. Each well was filled with a total volume of $100 \mu \mathrm{~L}$, containing 0.2 M acetate buffer pH 5 , inhibitor, substrate and enzyme. All kinetics were performed between $25^{\circ} \mathrm{C}$ and $27^{\circ} \mathrm{C}$ and started by enzyme addition. After $30-50 \mathrm{~min}$ of incubation, the reaction was quenched by addition of $100 \mu \mathrm{~L}$ of $1 \mathrm{M} \mathrm{Na}_{2} \mathrm{CO}_{3}$. The absorbance of the resulting solution was determined at $405 \mathrm{~nm} . K_{\mathrm{i}}$ values were determined in triplicate, using the Dixon and Lineweaver-Burk graphical methods within Microsoft Excel. Stock solutions of inhibitors were prepared with DMSO/buffer for final well DMSO content under 5\%. The stability of the enzyme in the presence of the same concentrations of DMSO was controlled and enzyme activity was unaffected.

## 4. Conclusions

Propargylated bambus[4,6]urils were fully functionalized by click chemistry with linear $N$-alkylDNJ ligands either having 6 or 9 carbon alkyl azido linkers or a trivalent DNJ derivative to generate multivalent clusters bearing up to 24 iminosugars. The novelty of this study lies in the unique combination of anion-transporting BU[6] scaffolds with iminosugar inhitopes that have already proven their efficiency towards the multivalent inhibition of glycosidases. For clusters grafted with DNJ ligands linked by short C6 arms, scaffold size showed a strong impact on $\alpha$-mannosidase inhibition, with the best results obtained for BU[4] clusters. With nonyl chains, the enzyme affinity per inhibitory head increases drastically whichever platform is used, the best affinity increases being obtained with trivalent dendrons providing higher local inhibitor concentration. Bromide and iodide sequestered in BU[6] grafted by DNJ inhibitors were also prepared and their activity was compared to their corresponding anion-free counterparts, showing that the presence of anions neither modified the inhibition potency of the clusters nor their inhibition mode. Our study thus shows a first proof of concept for glycosidase-directed ion caging agents based on unprecedented bambusuril-based iminosugar clusters. Altogether, these results open the way to unique water-soluble probes/therapeutic agents with both strong glycosidase inhibition potency and ion receptor properties.
