Ashley S. Roman<sup>1</sup>, Christina A. Penfield<sup>3</sup>

<sup>1</sup>NYU Langone Health, New York, NY, <sup>2</sup>North Shore University Hospital & Long Island Jewish Medical Center, New York, NY, <sup>3</sup>Olive View- UCLA, Sylmar, CA

**OBJECTIVE:** To characterize the progression of disease in women with hypertensive disorders of pregnancy (HDP) undergoing induction of labor (IOL) at term.

**STUDY DESIGN:** This is a retrospective cohort study of nulliparous women with a singleton pregnancy and diagnosis of HDP who underwent term IOL at an academic center from 2018-2019. Women were categorized by diagnosis of HDP at the start of IOL (gestational hypertension (GHTN), preeclampsia without severe features (PEC), preeclampsia with severe features (PEC-SF), HELLP syndrome, and eclampsia). Women who presented in labor (modified Bishop score >5) were excluded. Progression of disease (POD) was defined as new lab abnormalities, symptoms, or abnormal vital signs that developed after the start of IOL and conferred a more severe HDP diagnosis per ACOG criteria. Rates of POD were compared by initial HDP diagnosis and mode of delivery (vaginal versus cesarean delivery (CD)). Time course of POD – labor, immediately postpartum, or delayed postpartum (after delivery hospitalization discharge) was also compared between groups. Chi-square and Fisher's exact tests were used for analysis with significance of  $p < 0.05$ .

**RESULTS:** 576 women were included and 90 (15.6%) had POD. Women with an initial diagnosis of PEC were significantly more likely to have POD (21.6%) compared to GHTN (14%), and PEC-SF (7.7%) ( $p=0.04$ , Table 1). Those who underwent CD had highest risk of POD (20.1% vs 12.8% for vaginal delivery,  $p=0.03$ ). POD occurred at similar rates during labor, immediate postpartum, and delayed postpartum, and time course was not associated with initial HDP diagnosis or mode of delivery (Table 2).

**CONCLUSION:** Nulliparous women with HDP undergoing term IOL had an overall low risk of progression of HDP, and over half of these cases occurred during the postpartum period. Therefore, a diagnosis of HDP should not preclude women from IOL due to provider concerns for potential progression of disease. Further investigation into how decisions for IOL or CD at the time of diagnosis influence risk of perinatal complications will continue to inform patient and provider counseling.

Table 1 – Progression of disease by initial HDP diagnosis and mode of delivery

	Progression of disease N= 90	No progression of disease N=486	p-value
<b>Diagnosis</b>			
GHTN	49 (14%)	301 (86%)	
PEC	37 (21.6%)	134 (78.4%)

## 780 Acceptance of vaccines during pregnancy during the COVID-19 pandemic

Allison Perelman<sup>1</sup>, Megan E. Trostle<sup>1</sup>, Jillian Pecoriello<sup>1</sup>,  
Ashley S. Roman<sup>1</sup>, Christina A. Penfield<sup>2</sup>

<sup>1</sup>NYU Langone Health, New York, NY, <sup>2</sup>Olive View- UCLA, Sylmar, CA

**OBJECTIVE:** To evaluate patient acceptance of standard vaccines against infectious diseases in pregnancy - Tetanus, Diphtheria and Pertussis (Tdap) and influenza (flu) - during the COVID-19 pandemic compared to historical controls.

**STUDY DESIGN:** This was a retrospective cohort study comparing rates of Tdap and flu vaccine uptake in women who received prenatal care at an academic center from 9/1/2020 to 1/31/2021 ("COVID cohort") compared to the same period the prior year ("2019 cohort"). Patients with an allergy or contraindication to vaccination were excluded. Demographic information, trimester of initiation of prenatal care, insurance status, and medical comorbidities were evaluated. Outcomes were analyzed using Chi-squared and Fisher's exact test, as well as multivariable logistic regression, with  $p < 0.05$  considered significant.

**RESULTS:** 1713 women were included. The COVID cohort differed in age, race, timing of initiation of prenatal care, insurance status, and medical comorbidities. In unadjusted analysis, acceptance of Tdap decreased in the COVID cohort (92% vs 89%,  $p=0.03$ ), while the uptake of influenza was similar (83% vs 81%,  $p=0.35$ ). However, after adjusting for covariates, women were significantly more likely to accept influenza vaccine in the COVID cohort (aOR 1.7, 95% CI [1.27-2.29]), although this trend was not observed for the entire obstetric population. Non-white race, public insurance status and medical comorbidities were associated with lower rates of both flu and Tdap vaccine acceptance during the pandemic (Tables 1 and 2).

**CONCLUSION:** In a pandemic era, the overall population of pregnant women were more likely to accept vaccination with the influenza vaccine. However, this trend did not apply to other vaccines that protect against infectious disease such as Tdap and did not apply to high-risk groups with public insurance and medical comorbidities. This study highlights disparities in vaccination acceptance and supports increased efforts in vaccine counseling for these high-risk populations.

**781 Risk of adverse outcomes for small fetuses not meeting consensus criteria for fetal growth restriction**

Jennifer E. Powel, Emily W. Zantow, Matthew F. Bialko, Lauren G. Farley, Tracy M. Tomlinson

Saint Louis University School of Medicine, St. Louis, MO

**OBJECTIVE:** To assess whether an independent association exists between an estimated fetal weight (EFW) and/or abdominal circumference (AC) < 10<sup>th</sup> centile and adverse outcomes when Delphi consensus criteria [Gordijn S et al Ultrasound Obstet Gynecol 2016;48(3):333-9] for fetal growth restriction (FGR) are not met.

**STUDY DESIGN:** Data was derived from singleton non-anomalous gestations with an EFW and/or AC < 10<sup>th</sup> Hadlock centile at a tertiary care institution (2010-2020). An approximately equal number of fetuses with birthweight between the 20<sup>th</sup> and 80<sup>th</sup> centile were randomly selected from the same period as an appropriately grown ('AGA') comparator group. The cohort was retrospectively analyzed according to the occurrence of composite adverse perinatal outcome (APO): perinatal demise, 5-minute Apgar < 7, cord pH ≤ 7.1, or cord base excess ≥ 12.

**RESULTS:** 2653 consecutive pregnancies met inclusion criteria. 374 (14%) were complicated by APO. None of the 455 pregnancies with an EFW and/or AC < 10<sup>th</sup> centile that failed to meet consensus criteria based on Doppler waveforms (and growth velocity ≥ 32 weeks) for FGR ('SGA') resulted in perinatal demise. 42 (9%) were affected by APO based on 5-minute Apgar scores and/or cord gas results compared to 110 (8%) in the AGA group (RR 1.10, 95% CI 0.84-1.44). 222 of 860 (25.8%) that met consensus FGR criteria ('FGR') resulted in APO (RR 1.96, 95% CI 1.77-2.16), including 32 with perinatal demise. Factors independently associated with APO included: BMI (< 25 and ≥ 50), pregestational diabetes, male fetal sex, hypertensive disorders of pregnancy, and 'FGR'. The bias-corrected bootstrapped AUROC for the 7-factor model predicting APO was 0.71 (95% CI 0.68-0.74).

**CONCLUSION:** We found no evidence that fetuses with an EFW and/or AC between the 3<sup>rd</sup> and 9<sup>th</sup> centile that fail to meet consensus criteria for FGR are at increased risk of adverse outcomes. While growth of these fetuses should be monitored to rule out evolving FGR, the majority are healthy constitutionally small fetuses that do not warrant additional antenatal testing or iatrogenic preterm/early term delivery.

Table 1. Characteristics of pregnancies (N=2653) by severe adverse perinatal outcome.
