## Abstract

The efficacy of minoxidil (MXD) ethanolic solutions (1%-5% w/v) in the treatment of androgenetic alopecia is limited by adverse reactions. The toxicological effects of repeated topical applications of escalating dose (0.035%-3.5% w/v) and of single and twice daily doses (3.5% w/v) of a novel hydroxypropyl- $\beta$ -cyclodextrin MXD GEL formulation (MXD/HP- $\beta$ -CD) and a MXD solution were investigated in male rats. The cardiovascular effects were evaluated by telemetric monitoring of ECG and arterial pressure in free-moving rats. Ultrasonographic evaluation of cardiac morphology and function, and histopathological and biochemical analysis of the tissues, were performed. A pharmacovigilance investigation was undertaken using the EudraVigilance database for the evaluation of the potential cancer-related effects of topical MXD. Following the application of repeated escalating doses of MXD solution, cardiac hypertrophy, hypotension, enhanced serum natriuretic peptides and K<sup>+</sup>-ion levels, serum liver biomarkers, and histological lesions including renal cancer were observed. In addition, the administration of a twice daily dose of MXD solution, at SF rat vs human = 311, caused reductions in the systolic, diastolic, and mean blood pressure of the rats ( $-30.76 \pm 3\%$ ,  $-28.84 \pm 4\%$ , and  $-30.66 \pm 5\%$ , respectively, vs the baseline; *t* test *P* < .05). These effects were not reversible following washout of the MXD solution. Retrospective investigation showed 32 cases of cancer associated with the use of topical MXD in humans. The rats treated with MXD HP- $\beta$ -CD were less severely affected. MXD causes proliferative adverse effects. The MXD HP- $\beta$ -CD inclusion complex reduces these adverse effects.

**Abbreviations:** AGA, androgenetic alopecia; DHT, dihydrotestosterone; HR, heart rate; MXD, minoxidil.

androgenic alopecia, ATP-sensitive potassium channels, cell proliferation, minoxidil, toxicology

## 1 | INTRODUCTION

Androgenetic alopecia (AGA), characterized by a progressive miniaturization of terminal scalp hair with a pattern distribution, is the most common cause of hair loss in adults.<sup>1</sup> The etiology is considered to be multifactorial, involving a complex interplay among several genes, androgens, and environmental factors. Although the exact molecular mechanisms are not fully understood, an abnormal level of dihydrotestosterone (DHT), a potent androgen, appears to be an important causative factor.<sup>1,2</sup> Indeed, the upregulation of the 5 $\alpha$ -reductase enzyme is required to convert testosterone into DHT and is a drug target.<sup>3,4</sup>

Currently, only two treatments have been approved by the US Food and Drug Administration for the treatment of male AGA: finasteride, a 5 $\alpha$ -reductase inhibitor<sup>3,6,7</sup> administered at 1 mg daily, and topical minoxidil (MXD) formulations (2% solution, 5% solution, or 5% foam). The effectiveness of both drugs in improving the symptoms of the disease has been demonstrated in several well-designed studies.<sup>8,9</sup> However, many side effects of finasteride have been reported, including sexual dysfunction,<sup>9,10</sup> hypersensitivity reactions, and breast enlargement.<sup>10</sup>

MXD (2,4-diamino-6-piperidino-pyrimidine-3-oxide) is a potent oral antihypertensive drug developed at the end of the 1980s which is now most often prescribed for AGA.<sup>11</sup> The antihypertensive functions of MXD occur through its sulfate metabolite,<sup>12</sup> MXD sulfate, which exerts its effects by opening ATP-sensitive potassium channels (KATP channels) in several tissues, including vascular smooth muscle cells, thereby causing relaxation similar to other KATP-channel openers.<sup>13-18</sup> However, antihypertensive treatment with MXD causes severe hypotension, cardiac hypertrophy, and fluid retention.<sup>18</sup> One of these unwanted side effects, the hypertrichosis, has been exploited in the treatment of AGA.<sup>19-23</sup>

Although topical MXD is generally accepted (as shown in many studies), the literature indicates that its chronic use can cause hypotension and cardiovascular side effects, including tachycardia, minor left ventricular hypertrophy, palpitations, dizziness, and syncope.<sup>24-26</sup> This suggests that, even when topically applied, it may be systemically absorbed, reaching pharmacologically active concentrations. Novel drug treatments and formulations are therefore under development.<sup>27</sup> A web-based review on MXD use points out that 2816 people reported side effects caused by MXD, 51 of whom (1.8%) reported syncope.<sup>24-29</sup> Rare cases of association between the topical application of MXD to a mother's scalp and fetal toxicity and malformations have also been described.<sup>30-32</sup> When locally applied, MXD can be absorbed through the skin, causing multiple local and systemic pharmacological effects. Three children (aged 10-14) with alopecia areata, who were treated with 2% topical MXD solution twice a day for up to 1 month, developed palpitations after starting MXD treatment. This has also been observed in other cases.<sup>33,34</sup>

In addition, the MXD solution currently used is responsible of contact dermatitis, which is associated with itching or irritation of the

scalp.<sup>35</sup> This event can be related to the high percentage of propylene-glycol and ethanol used as vehicles in the solution. Moreover, MXD solution can cause bilaterally symmetrical growth of vellus hair in nontreated areas, such as on the cheek and sideburn areas, because of the handling of the liquid during treatment. These events may suggest that MXD has uncontrolled systemic effects. Several novel MXD formulations are under development from different laboratories.<sup>36-38</sup>

To improve the therapeutic efficacy and tolerability of the currently used MXD formulation, a new aqueous alginate/hydroxypropyl- $\beta$ -cyclodextrin (HP- $\beta$ -CD) MXD gel which does not contain ethanol or propylene-glycol was developed in our laboratories. The new aqueous alginate/HP- $\beta$ -CD MXD gel was developed for several technological characteristics.<sup>39</sup> In our previous studies,<sup>40,41</sup> the new aqueous alginate/HP- $\beta$ -CD GEL with 3.5% MXD showed greater improvements in hair counts and global imaging assessments than the currently used ethanol/propylene-glycol 3.5% MDX solution. "In vivo" pharmacological investigations showed that the MXD HP- $\beta$ -CD GEL enhanced hair growth, hair length, and bulb diameter, as well as showing improvements in the mRNA levels of pharmacodynamic markers, such as AKT2 and the SUR2 and Kir6.1 subunits of the KATP channels, and downregulation of the androgen receptor gene.<sup>41</sup> An "in vitro" study showed that both MXD ( $10^{-4}$  mol/L) formulations were equally effective in potentiating KATP currents. In summary, the new aqueous alginate/HP- $\beta$ -CD GEL with 3.5% MXD has shown a favorable efficacy profile following topical use vs the ethanol/propylene-glycol MXD solution.

In this study the tolerability and toxicology profile of the new aqueous alginate/MXD HP- $\beta$ -CD GEL were evaluated in male rats and compared with those of the ethanolic/propylene-glycol MXD solution. The dosing protocol of repeated escalating doses on the same rat was used to study the effects of increasing the MXD concentrations of both formulations, starting with 0.035% and 0.07%, corresponding to the therapeutic doses in humans, and increasing to 3.5% (w/v). The systemic cardiovascular effects associated with MXD topical application were evaluated by monitoring the heart rate (HR), QT intervals, T- and P-wave amplitudes, systemic arterial pressure, and body temperature in freely moving laboratory animals using a telemeter biosensory system inserted in the abdominal cavity of the animal. In addition, at the end of treatment, cardiac evaluations, included parasternal long-axis assessments (B-mode) and short-axis measurements (M-mode) of the left ventricular diastolic and systolic volumes, stroke volume, cardiac output, wall thickness, ejection fraction, and fractional shortening, were performed using echocardiography analyses on the rats treated with both formulations, as well as those in the control group. Histopathological analysis of the tissues isolated from the MXD-treated rats and serum biochemical evaluations for markers of toxicity were also performed. The effects of the treatments on cardiovascular ECG and arterial blood pressure were also investigated by topical application of single and twice daily doses of the two MXD formulations at 3.5% (w/v) concentrations, corresponding to rat vs human safety factors (SFs) of 155 and 311, respectively.

## 2 | MATERIALS AND METHODS

### 2.1 | Chemical and pharmaceutical tools

MXD (2,4-diamino-6-piperidino-pyrimidine-3-oxide, M. W. 209.25, 99% purity), HP-β-CD (MS 0.65, M. W. 1396), and sodium alginate (NaAlg, viscosity 1% at 25°C and 500-600 mPa s) were gifts of Farmalabor. The chemicals and salt reagents were purchased from Sigma-Aldrich (Milan). The biological reagents were provided by Promega (C. N. N2511). All drugs were prescribed by local veterinarians for experimental use and provided by Murgjivet, Gioia del Colle.

### 2.2 | Animal groups and treatments

The animal treatment was carried out according to Italian Legislative Decree No. 26 of 04 March 2014, and performed under the supervision of a local veterinary official. Using an operator-blinded design, the animals were randomly assigned to each experimental condition. The protocol was approved by the Organisation for Animal Health of the University of Bari on 15 April 2019 (Prot. 34091-x/10,

06 May 2019) and by the Minister of Health, Rome (No. 673/2019-PR Prot. DGSAF0025334-P-04/10/2019, prog. 7307D.11).

The temperature of the laboratory animals was maintained at  $22 \pm 1^\circ\text{C}$ , with a relative humidity of  $50 \pm 5\%$  and a 12:12 hour light-dark cycle; animals were maintained on a standard laboratory diet of 30 g per rat per day and water ad libitum. Moreover, during the study, the animals were observed for changes in body weight, ambulation, and behavior (brightness, alertness, and responsiveness), signs of lethargy, lack of grooming, guarding (abdominal and muscular), pale conjunctivae, and decreased food intake. The experiments were performed on male Wistar rats (Charles River S.p.A., Calco, Lecco) with an initial mean body weight of  $360 \pm 14$  g and a final body weight of  $450 \pm 19$  g at the end of topical treatment (total number of rats = 28). The humane endpoints for animal drop out and sacrifice were a change in body weight  $\geq 10\%$  and a change in rectal body temperature  $\geq 4^\circ\text{C}$ , persistent for more than 3 days. The primary endpoint of the study was a body weight change  $\geq 10\%$  following any treatment. Body weight was evaluated in 24-h-fasted animals using digital analytical balances (AV114C, 500 g and 100 g; OHAUS corp.) and the data stored for further analysis.

A repeated escalating dose of one of the two MXD formulations at concentrations of 0.035%, 0.07%, and 3.5% (w/v-w) was administered once daily (Figure 1A). There were five groups of animals:

**FIGURE 1** The first dosing protocol (A) was applied to evaluate the effects of escalating doses of minoxidil (MXD) on blood pressure in two rats per group, and on ultrasonographically evaluated cardiovascular functioning, and histopathological and biochemical parameters in five rats per group. The second dosing protocol (B) was applied to evaluate the effects of high doses of MXD on blood pressure and ECG parameters in two rats per group. Each 5-day treatment period with the MXD formulations was followed by a 2-day washout period to evaluate the reversibility of the observed blood pressure effects. Before starting treatment, each rat underwent an 8-day recording period as an internal control for the evaluation of baseline values of the measured parameters. At the end of treatment, the animals were monitored for a further 2 days to evaluate the reversibility of the effects. The animals were then sacrificed, and the organs collected

1A, rats receiving vehicle treatments with HP- $\beta$ -CD GEL (number of rats = 5); 2A, rats receiving vehicle treatments with ethanol/glycol propylene solution (number of rats = 5); 3A, rats treated with MXD HP- $\beta$ -CD GEL at 0.035% (0.777 mg/kg/day), 0.07% (1.554 mg/kg/day), and 3.5% (w/v-w) (77.7 mg/kg/day) concentrations (number of rats = 7); and 4A, rats treated with MXD ethanol/glycol propylene solution (number of rats = 7). Two rats per MXD-treated group (3A and 4A) were used for telemetric monitoring of mean blood pressure and HR using this protocol.

Additionally, we evaluated the effects of the repeated topical application of 3.5% (w/v) concentrations of the two MXD formulations applied once daily, and twice daily at 6 hour intervals, on ECG and blood pressure parameters (rats per group = 2) (Figure 1B). There were two groups of animals: 1B, rats treated with MXD HP- $\beta$ -CD GEL at 3.5% (w/v) (number of rats = 2) (77.7 mg/kg/day concentration); and 2B, rats treated with MXD ethanol/glycol propylene solution at 3.5% (w/v) (number of rats = 2).

The MXD 3.5% (w/v) solution (1 mL) was applied using a Pasteur pipette. The MXD 3.5% (w/w) GEL (1 g) was applied using a laboratory spatula. This corresponded to 35 mg (77.7 mg/kg/day) over 5 days of treatment and 70 mg (155.5 mg/kg/day) after an additional 5 days of treatment. Animal preparation was performed as described below; briefly, the dorsal area of the rats was shaved using an appropriate cream under moderate anaesthesia.<sup>41,42</sup> Starting 7 days after the surgical implantation of the telemeter in the rat abdominal cavity, BP and ECG measurements were collected continuously over a period of 8 days under baseline conditions (internal control conditions) in freely moving animals.

During the internal control, treatment, and washout periods, the rats were held in the SmartPad for intervals of 3-12 hour to record their ECG and blood pressure signals. A washout period was planned to avoid any carryover effects related to the rapid pharmacokinetics of the MXD, and so that each experimental phase was not influenced by the previous one.

After the surgical procedure, a reduction in rat body weight by about 10% was observed, together with impaired motility. Within 5 days of the surgical procedure, the rats fully recovered their initial condition in terms of body weight, locomotion, and general behavior. The experimental animals were sacrificed at the end of treatment, under a saturated CO<sub>2</sub> atmosphere, and following cervical dislocation; body weight data were collected and then the treated skin area, tissues, and organs were immediately extracted, washed in saline, and dried with filter paper. The tissues and organs were fixed in 10% formalin and thereafter used for histological analysis.

## 2.3 | General anesthesia and surgical preparation

The general anesthesia was induced by intramuscular injections of Zoletil 50/50 (Pfizer) ip using three refracted doses of 20 mg/kg for a cumulative dose of 60 mg/kg. This drug induced a rapid and general anesthetic effect and complete muscle relaxation with no arrhythmias, avoiding the risk of epilepsy, and did not cause hepatic and/

or renal toxicity in our experiments.<sup>42</sup> Moreover, awakening was rapid, without spastic movements, and therefore without the risk of wounding the animals.

The animals were fasted for 24 hour before and after the surgical procedure. After injection of the anesthetic cocktail, the rat was placed on a heated surgical pad in dorsal recumbency. The surgical site was shaved and the skin was aseptically prepared using Hibitane, UK (8 g/L chlorhexidine gluconate) and ethanol (70%). The analgesic buprenorphine (10-20  $\mu$ g/kg s.c.) and the antibiotic enrofloxacin (5 mg/kg im) were administered for prophylactic reasons before the start of surgery at the induction of anesthesia, then the rat was draped with sterile gauze. During surgery the rat was closely monitored for the depth of its anesthesia.

### 2.3.1 | Surgical procedure for BP catheter and ECG electrode implantation

The body of the implantable telemeter was positioned within the abdominal cavity and placed so that it would be parallel to the SmartPad when the rat was standing on all four legs. The telemeter was sutured to the abdominal muscle wall using both suture tabs (Figures S1 and S2). The ECG electrodes (constructed from a 1-mm-OD stainless steel spring and inserted into silicon tubing with a 5-mm tip exposed) were tunneled subcutaneously. Briefly, one electrode was placed on the xiphoid process and the other was placed subcutaneously facing the head and then pushed along the trachea into the mediastinum region.<sup>43</sup> In both cases, the end of the electrode was firmly sutured to the underlying tissue (<https://millar.com/node/413>).

### 2.3.2 | ECG and systemic arterial pressure acquisition and analysis

The ECG and blood systemic arterial pressure signal from the implanted telemetry unit were received via a dedicated receiver (Telemetry Research). This signal was band-pass filtered between 1 and 2000 Hz, and the reconstructed analogue signal was displayed using a PowerLab data acquisition system (sampling at 4000 Hz) with associated LabChart software (model ML870, ADInstruments). The signals were further analyzed using pre-established/fixed algorithms within the Lab Chart 6 Pro Software. The ECG data were analyzed using ECG Analysis module software to assess HR, QT interval, and T-wave amplitude and the BP data were analyzed using BP Analysis module software to assess the systolic, diastolic, and mean pressure. The data were expressed as the mean  $\pm$  standard error (SD) for 15 min intervals. Each point was collected in one 30 min block, giving 5-10 sampled points per observation period. To adjust for the rate, the corrected QT (QTc) was calculated by applying the Mitchell algorithm to the QT interval recordings:  $QTc = QT0/(RR/100)^{1/2}$ .<sup>22</sup> This algorithm is designed to correct for the higher HR and altered QRS-T-wave morphology of rodents. High-amplitude ECG spiking was defined as sharp electrographic events three times the baseline

voltage and counted using LabChart Spike Analysis within a 15 min bin. Movement artifacts were identified on the ECG and eliminated from the ECG analysis.

The ECG and BP data for each rat were grouped into three periods:

- The baseline period used to evaluate the quality of transmitted data and the progress of ECG and BP in the absence of treatment;
- The treatment period; and
- The washout period.

Each period consisted of a temporal sequence of the average values of both variables under study each day. The daily mean was the result of a data file generated by LabChart software and related to a sampling file which considered 15 min recording blocks every 30 min throughout the period, starting 30 min after the topical application of the formulations investigated in this study. In addition, the associated SDs were calculated for each sample throughout the recording period. For each rat, the average value of both variables was first calculated for each day and then this mean was used to calculate the mean for the whole period (Figure S3).

## 2.4 | Ultrasonographic evaluation

At the end of treatment, an ultrasonographic evaluation of cardiac structure and function was performed on control rats and rats treated with the formulations under investigation (rats per group = 5). At least 48 hour had elapse after the end of the previously described in vivo topical treatment to avoid any additional source of stress for the animals which could potentially influence the outcome of the ultrasound procedure. The ultrasonography experiments were conducted using the ultrahigh-frequency ultrasound biomicroscopy system Vevo<sup>®</sup> 2100 (VisualSonics), which allows multiple image acquisition modes.<sup>44-46</sup> The animals were properly prepared prior to each imaging session to allow optimal image acquisition. Each rat was anesthetized via inhalation (induced with ~3% isoflurane and 1 L/min 1.5% O<sub>2</sub> and then constantly maintained via a nose cone at ~2% isoflurane and 1.5% O<sub>2</sub>) and placed on a thermostatically controlled table (kept at 37°C). Body temperature was carefully maintained between 37.0°C and 37.5°C. The table was equipped with four copper leads for monitoring both the heart and respiratory rate of the rat to minimize any physiological variation. Also, body temperature was monitored throughout the imaging session using a rectal probe. A petroleum-based lubricant was used to cover the eyes to prevent drying. The thorax of the animal was properly shaved with depilatory cream to avoid any interference during image acquisition, and a small amount of pre-heated ultrasound gel was applied between the animal's skin and the probe to guarantee a proper image recording. At the end of the procedure the anesthetic influx was discontinued, and each animal was first cleaned with water, and then returned to its cage in the animal facility after briefly recovering from the anesthesia in an oxygenated box. Echocardiography was performed on the control

and treated rats in bidimensional (B-Mode) and monodimensional (M-Mode) modes using a high-resolution transducer at a frequency of 21 MHz (MS550). The images were acquired in a modified parasternal long-axis view with the animal placed in a supine position. Briefly, after M-mode image acquisitions, the LV M-Mode trace was used to measure the ejection fraction (%), shortening fraction (%), stroke volume (μL), and cardiac output (mL/min). The left ventricular diastolic and systolic chamber internal diameter, posterior wall thickness, and intraventricular septum were also measured. Sample images of the left ventricle acquired in B (up) and M (down) mode are shown in Figure S4. Cardiac output was normalized for the body surface area of each rat. The left ventricle diameter in systole and diastole was calculated.<sup>47,48</sup>

## 2.5 | Serum biochemistry and electrochemistry

At the end of treatment, the animals were treated with the anesthetic agent and a 0.8 mL sample of the ventricular intracardiac blood was collected using a sterile microsyringe (1 mL) and an EDTA Vacutainer. The cardiac natriuretic peptides NT-proANP and NT-proBNP were evaluated using electrochemiluminescent assays, including the Rat Muscle Injury Panel 1 Assay, Rat NT-proANP kit K153MBD, and Rat NT-proBNP kit K153JKD from Meso Scale Discovery (MSD, Gaithersburg, MD).<sup>49</sup> The serum samples were diluted 1:4 and 50 μL of diluted sample (for Rat NT-proANP and Rat NT-proBNP) was dispensed and tested in duplicate according to the manufacturer's protocol. After the completion of the procedure based on the MSD assay protocol, the plates were analyzed using an MSD Sector Imager, Model 2400. The average of the two values was used to report the final results. The serum biochemical assay was performed in a Chem Analyzer (Gesam) using appropriate operativity methodology such as turbidimetry and spectrophotometry. The reagents and kits for the veterinary biochemical assays were purchased from Gesam Production, Campobello di Mazara, TP, Italy.

## 2.6 | Histopathology analysis

At the end of treatment, the animals were sacrificed by overdose of the anesthetic agent, followed by cervical dislocation, and the tissue samples were immediately preserved in 10% buffered formalin. The EDTA blood and serum were processed and analyzed for biochemistry. The histological examination was performed for each animal sample a minimum of 48 hour after fixation. The tissues and organs were embedded in paraffin, sections were cut into 5-10 μm, and stained using standard techniques with hematoxylin and eosin. The histopathology and necropsy analysis included a gross/macrosopic and microscopic examination of the tissue samples, and organ assessment of the preserved heart, liver, kidneys, skin, and muscles. Finally, examination of the cellular morphology as well as intracellular structures was conducted. A histopathological scoring system, based on

the semiquantitative ordinal system, was used to evaluate the severity of the observed lesions. The pathologist was blind to the treatment of the analyzed samples. 50,51 Images from 10 random fields were acquired for the 10 stained sections of each specimen using a D 4000 Leica DMLS microscope equipped with a camera and image analyzer, NIS-elements BR (Nikon). The analysis of the sections was performed in Leica QWin software. Organ weigh was not evaluated to avoid possible damage to the tissues which were needed for the histological analysis.

### 2.6.1 | Proliferative activity

For the evaluation of Ki-67 proliferative activity in the kidney sections, a three-layer biotin-avidin-peroxidase system was adopted. Briefly, 5- $\mu$ m-thin serial sections were incubated with MIB-1, an M7240 ki-67 antigen (Dako). The bound antibodies were visualized using biotinylated secondary antibody, avidin-biotin peroxidase complex, and 3-amino-9-ethylcarbazole (Dako). Nuclear counterstaining was performed on each tissue sample, with Gill's hematoxylin (Polysciences). Data were expressed as the percentage of positive cells over the total number of cells in the section. The labeled Ki67-positive cell population was measured by counting more than 100 Ki67-positive cells per animal section, and was expressed as a percentage of proliferative activity in each tissue.

## 2.7 | Pharmacovigilance investigation

The investigation on MXD-associated cancer reactions was performed as previously described.<sup>52</sup> The reactions list contained cancer, tumor, and neoplasm associated with the use of topical MXD for the treatment of alopecia. The EudraVigilance database from 2014 to 2018 was searched.

## 2.8 | Statistical analysis

Data from each animal were collected in electronic datasheets (Excel Software, Microsoft Office 10) and expressed as mean  $\pm$  SE. Student *t* tests were used for statistical comparisons between means ( $P < .05$ ). One-way analysis of variance (ANOVA) followed by multiple comparisons tests were applied ( $P < .05$ ). The sample size for the rats undergoing the protocol reported in Figure 1A was calculated using a one-way ANOVA on the primary endpoint of a body weigh change  $\geq 10\%$  of the mean between groups by the end of treatment. Using G\*Power 3.1 software, we calculated a sample size of 20 rats, five per experimental group (four experimental groups), and a power of 0.98. In accordance with the 3R statement, this calculation did not include the animals used for the telemetry investigation, which were kept to a minimum (two rats per experimental group) considering that each animal was its own control.

## 3 | RESULTS

### 3.1 | Telemetric evaluation of blood pressure and HR, and ultrasonographic evaluation of cardiac function and morphology following the topical administration of repeated escalating doses of two MXD formulations at 0.035%, 0.07%, and 3.5% (w/v) once daily in male rats

The application of therapeutic doses of MXD 0.035% and 0.07% w/v to the dorsal area of the rats once daily did not significantly change the mean arterial blood pressure or HR vs the baseline (Figure 2), as observed in either of the treated rats (rats per group = 2) (Figure 1A). The application of repeated high doses of MXD ethanol/glycol propylene solution (3.5% w/v) at SF rat vs human = 155, however, significantly reduced the mean blood pressure vs baseline in both of the treated rats, as evaluated by a Student *t* test ( $P < .05$ , period of treatment 1 vs baseline). In contrast, no significant changes were observed following the treatment of the rats with the MXD HP- $\beta$ -CD GEL formulation, as observed in both treated rats (rats per group = 2) (Figure 2).

We therefore investigated the effects of repeated escalating doses of the MXD formulations and their relative vehicles on cardiac function and morphology. Heart structure and function were evaluated by echocardiography in rats treated with MXD ethanol/glycol propylene solution, MXD HP- $\beta$ -CD GEL formulation, and their relative vehicles (rats per group = 5). Significant enhancements of the systolic (30.23%) and

**FIGURE 2** Mean blood pressure (mmHg) following topical administration of the minoxidil (MXD) ethanol/glycol propylene solution (rats per group = 2) and the MXD hydroxypropyl- $\beta$ -cyclodextrin GEL formulation (rats per group = 2) in male rats. Each point represents the mean  $\pm$  SEM of *n* sampling time points ( $\geq 4000$ ) collected during the daily recording of individual rats during 5 days of treatment and monitoring. Statistically significant changes were detected in the mean blood pressure of the rats treated with the MXD ethanol/glycol propylene solution vs the baseline at 3.5% w/v dose, as evaluated by a Student paired *t* test ( $P < .05$ ). No significant changes to this parameter were observed in the rats following the application of the MXD hydroxypropyl- $\beta$ -cyclodextrin GEL formulation

diastolic (18.24%) left ventricle diameter, systolic (89.91%) and diastolic (45.8%) left ventricle volume, stroke volume (30.9%), left ventricle mass (33.71%), and systolic (36.32%) and diastolic (20.89%) left ventricle internal diameter were observed in the rats treated with the MXD ethanol/glycol propylene solution (Figure 3A-E). In the rats treated with the MXD HP-β-CD GEL formulation, we observed significant, but less pronounced, enhancements of the systolic (19.17%) and diastolic (14.93%) left ventricle diameter, diastolic (37.03%) left ventricle volume, stroke volume (31.4%), left ventricle mass (10.28%), and systolic (22.32%) and diastolic (19.25%) left ventricle internal diameter (Figure 3A-E). No significant variations were observed for the other ultrasonographic parameters under investigation (data not shown). The rats in neither vehicle group showed significant abnormality.

### 3.2 | Body weight changes, histopathology, and immunohistochemistry of organs following the topical administration of repeated escalating doses of two MXD formulations (0.035%-3.5% w/v) once daily in male rats

At the end of the treatment period (Figure 1A), we found that the animal groups treated with the MXD ethanol/glycol propylene solution and relative vehicle showed significantly reduced body weights of 400.2 ± 15 g and 420.4 ± 18 g, respectively (rats per group = 5; one-way ANOVA,  $F = 3.23$ ), vs the animal groups treated with the MXD HP-β-CD GEL and its relative vehicle which showed

body weights of 440.3 ± 19 g and 460.4 ± 19 g, respectively (rats per group = 5).

The histological analysis performed at the end of the treatment on the rats treated with escalating doses of either the MXD ethanol/glycol propylene solution or the MXD HP-β-CD GEL formulation, showed a notable inflammatory mononuclear presence in different organs vs the control condition (rats per group = 5). The histological analysis revealed that in both animal groups the treatment caused significant lesions in the following organs: the kidneys, liver, and skeletal and cardiac muscles, with no effects in dermal tissues. All five of the rats treated with the MXD ethanol/glycol propylene solution showed lesions in all the organs sampled (Figure 4). Three of the five rats treated with the MXD HP-β-CD GEL formulation showed lesions in all the organs sampled. Liver (Figure 4, panels: 6-7), kidney (Figure 4, panels: 1-5), heart (Figure 4, panels: 8-9), and skeletal muscle (Figure 4, panels: 10-11) lesions were observed in three rats treated with the ethanol/glycol propylene vehicle solution, while one rat showed only liver lesions. Liver, kidney, and skeletal muscle lesions were observed in two rats treated with the HP-β-CD GEL vehicle. Lesions in other tissues which were not sampled cannot be excluded. The degree of the lesions was more elevated in rats treated with the MXD ethanol/glycol propylene solution and in its relative vehicle than in those treated with the MXD HP-β-CD GEL formulation and its relative vehicle (Table 1).

Immune staining of the kidney section with Ki-67 was performed to evaluate the proliferative status of the cells. We found that 85.2 ± 1% and 38.3 ± 2% of the cells in the analyzed sections (five sections per organ) were positive for the antibody reaction following treatment with the MXD ethanol/glycol propylene solution (Figure 4, panel: 12) and the MXD HP-β-CD GEL formulation, respectively.

**FIGURE 3** Cardiac ultrasonographic parameters obtained from control rats and rats treated with repeated escalating doses of the minoxidil (MXD) ethanol/glycol propylene solution (MXD solution), the MXD hydroxypropyl-β-cyclodextrin GEL formulation (MXD GEL) (0.035%-3.5% w/v), and their relative vehicles, once daily. (A) left ventricle diameter in systole (D, s) and diastole (D, d); (B) left ventricle volume in systole (V, s) and diastole (V, d); (C) left ventricle internal diameter in systole (LVID, s) and diastole (LVID, d); (D) stroke volume; (E) left ventricle mass (LVmass). Each bar is the mean ± SE. \*Significantly different with respect to relative vehicle group (unpaired Student's *t* test,  $P < .05$ ; rats per group = 5)

### 3.3 | Serum biomarkers following topical application of repeated escalating doses of two MXD formulations (0.035%-3.5% w/v) once daily in male rats

The rats which were histopathologically positive also showed biochemical abnormalities. In the rats treated with the MXD ethanol/glycol propylene solution (rats per group = 5), a significant enhancement in the serum ALP, GPT, and GOT levels was observed, as evaluated by one-way ANOVA (Table 2) ( $P < .05$ ;  $F = 1.62$ ). Both formulations caused significant enhancement of the serum natriuretic peptide and  $K^+$  ions levels vs the affected rats in other groups ( $P < .05$ ;  $F = 1.31$ ). The ethanol/glycol propylene solution treatment significantly enhanced the serum ALP, GPT, GOT, CK, and NT-proANP levels in four rats ( $P < .05$ ;  $F = 1.32$ ). The unaffected rats treated with the MXD HP-β-CD GEL formulation and its relative vehicle showed biochemical parameters similar to control animals (data not shown).

In conclusion, the treatment of the rats with the MXD ethanol/glycol propylene solution and the HP-β-CD GEL formulation

**FIGURE 4** Histopathological samples of the tissue lesions induced by treatment with escalating doses of minoxidil (MXD) ethanol/glycol propylene solution in the rats (0.035%-3.5% w/v) once daily. The digitally captured images show histological sections of the kidney (image 1-5 and 12), liver (6-7), myocardium (8-9), and skeletal muscle (10-11) of rats treated with MXD ethanol/glycol propylene solution. The sections have been divided into quadrants of 1 cm<sup>2</sup> and the values for each quadrant were calculated based on a histopathological scoring system (see Methods). Images were captured at 40× magnification. *Kidney*: The rats treated with the MXD ethanol/glycol propylene solution show areas of mesangio-capillary glomerulonephritis characterized by hypercellularity due to endothelial and mesangial proliferation and light capsular thickening (image 1) or semi-moon formations between the capillary ball and bowman capsule (image 2). Interstitial-type deformities with interstitial and papillary mononuclear cell inflammation (image 3) and tubular necrosis (image 4) were also observed. In some cases, there is evidence of one tubular microcarcinoma with an acinar appearance, characterized by a clear increase in tumor cell volume, large nuclei (double arrows in image 5), and mitotic activity (single arrow in image 5). In these samples, immunostaining with Ki-67 also highlighted a positive result in the papillary duct (single arrow in image 12). *Liver*: The rats treated with the MXD ethanol/glycol propylene solution show liver cells with steatosis phenomena, enlarged due to the presence of optically empty macro- and microvesicles. Widespread areas of chronic hepatitis, with widespread lymphocytic infiltration of portal spaces (image 6) and lobules, which may surround necrotic areas were observed (image 7). *Myocardium*: Heart hypertrophy and severe myocarditis were observed in the rats treated with MXD ethanol/glycol propylene solution, and to a lesser degree, in the rats treated with the MXD GEL formulation. Myofibrils with sarcoplasmic vacuolations (image 8) and exudate characterized by inflammatory mononuclear cells causing tissue disorganization, were reported (image 9). *Skeletal muscle*: In the rats treated with the MXD ethanol/glycol propylene solution, the endomysium and perimysium were widely infiltrated by inflammatory cells like macrophages and lymphocytes, and serous exudate was observed (image 10). Hypertrophic myofibrils with eosinophilic cytoplasm and vacuoles were also reported (image 11)

significantly affected their ultrasonographic cardiovascular functioning and morphology, the histopathology of their tissues, and biochemistry markers. The MXD ethanol/glycol propylene solution-treated

rats were severely affected. The arterial blood pressure was reduced in the MXD ethanol/glycol propylene solution-treated rats at the highest dose tested (3.5% w/v) but not in the MXD HP- $\beta$ -CD GEL-treated rats. We therefore additionally investigated the effects of higher doses of the MXD formulations (Figure 1B) (rats per group = 2) on the ECG parameters and blood pressure of freely moving rats.

### 3.4 | Electrophysiological ECG parameters, blood pressure, and HR following topical application of repeated single and twice daily doses of two MXD formulations (3.5% w/v) in male rats

The topical administration of a single daily dose of MXD ethanol/glycol propylene solution at 3.5% (w/v) concentration (SF rat vs human = 155) caused significant reductions of  $-22.52 \pm 9\%$ ,  $-22.89 \pm 8\%$ , and  $-23.04 \pm 9\%$  of the systolic, diastolic, and mean blood pressure, respectively, vs the baseline, as evaluated by Student paired t tests ( $P < .05$ , period of treatment 1 vs baseline) (Figure 1B). The application of twice daily doses of this MXD formulation (SF rat vs human = 311) caused further significant reductions of  $-30.76 \pm 3\%$ ,  $-28.84 \pm 4\%$ , and  $-30.66 \pm 5\%$  of the systolic, diastolic, and mean blood pressure, respectively, vs the baseline ( $P < .05$  period of treatment 2 vs baseline) (Figure 5A). The washout period at the end of treatment 2 failed to restore the arterial blood pressure to the baseline value in the rats treated with the MXD ethanol/glycol propylene solution. Subsequently, the effects were not reversible at the end of treatment.

In contrast, the application of the MXD HP- $\beta$ -CD GEL formulation (Figure 5B) caused mild and insignificant reductions in the systolic, diastolic, and mean blood pressure vs baseline (t test,  $P > .05$ , periods of treatments 1 and 2 vs baseline).

No changes in the systolic, diastolic, or mean blood pressure were observed in any of the experimental animals during the baseline period of 8 days (t test,  $P > .05$ ). Hypotensive events appeared with a frequency of +28.57% following treatment with the MXD ethanol/glycol propylene solution and +14.28% after treatment with the MXD HP- $\beta$ -CD GEL formulation. The changes in blood pressure were observed starting from the third day of MXD ethanol/glycol propylene solution application and from the sixth day of MXD HP- $\beta$ -CD GEL formulation application. The rats treated with both MXD formulations showed mild and insignificant increases in HR frequency (Figure 6).

A significant decrease in the QTc interval and a depression of the ST segment were observed following treatment with once and twice daily doses of MXD 3.5% (w/v-w) in treatment periods 1 and 2 in the rats treated with either MXD formulation (Figure 7, Table 3) ( $P < .05$ , periods of treatments 1 and 2 vs baseline). In addition, treatment with the MXD ethanol/glycol propylene solution caused an enhancement of the T amplitude following treatment periods 1 and 2 vs baseline ( $P < .05$ , periods of treatments 1 and 2 vs baseline).

The topical application of single (SF rat vs human = 155) and twice daily doses (SF rat vs human = 311) showed that the novel MXD HP- $\beta$ -CD GEL formulation at a 3.5% concentration (w/v) had a better profile in terms of changes in arterial blood pressure, HR,

**FIGURE 5** Time course of changes in mean blood pressure (mmHg), systolic pressure (mm Hg), and diastolic pressure (mm Hg) of rats following topical administration of the minoxidil (MXD) ethanol/glycol propylene solution (A) (rats per group = 2) and the MXD hydroxypropyl-β-cyclodextrin GEL formulation (B) (rats per group = 2). Each point represents the mean ± SEM of n sampling time points (≥4000) collected during the daily recording of individual rats. Statistically significant changes in mean blood pressure were detected for the rat treated with MXD ethanol/glycol propylene solution vs the baseline, as evaluated by Student paired t test ( $P < .05$ ). No significant changes were observed following the application of the MXD hydroxypropyl-β-cyclodextrin GEL formulation

and electrophysiological action potential parameters, as evaluated by the telemetry monitoring of these parameters in free-moving rats.

### 3.5 | Pharmacovigilance investigation of cancer, tumor, and neoplasm associated with the use of topical MXD for the treatment of alopecia in the EudraVigilance database from 2014 to 2018

Renal cancer was one of the most serious and unexpected effects observed in rats. We also investigated the association between MXD treatment and cancer in humans. We found 32 spontaneous reports (individual case safety reports) in humans of whom 15 were cases of breast cancer, 7 of skin cancer, and 1 of each prostate, colon, and hepatic cancers, as well as 4 benign neoplasms and other unknown conditions. In 18 cases, the safety action of

the clinician was drug withdrawal. Of the 32 patients, 22 were female and 10 male, and 7 patients were >65 while the others were adults. In most of the individual case safety reports no concomitant drugs were reported. <http://www.adrreports.eu/it/index.html>

## 4 | DISCUSSION

In this work, we investigated the toxicological effects of two different MXD formulations: one mimicking the commonly used MXD ethanol/glycol propylene solution and a second which is a novel MXD HP-β-CD GEL formulation. In our previous experiments, these formulations appeared to be equally effective in improving hair growth in male rats with advantage, in terms of better hair quality, lower in vitro cytotoxicity, and fewer local dermal reactions, in favor of the MXD HP-β-CD GEL formulation.<sup>41</sup>

In the repeated escalating doses of MXD (0.035%-3.5% w/v-w) experiment, the rats treated once daily with either of the MXD formulations at concentrations of 0.035% (0.0777 g/kg/day), 0.07% (0.1555 g/kg/day), and 3.5% (w/v-w) (7.777 g/kg/day) experienced mild and insignificant reductions in their arterial blood pressure with no change in HR, shown by telemetry monitoring in free-moving rats. The cumulative dose of MXD which the experimental groups received using this protocol was 71.15 g/kg.

However, the echocardiographical, morphological, and functional analyses performed at the end of the treatment period showed a significant enhancement of systolic and diastolic left ventricle diameter, systolic and diastolic left ventricle volume, stroke volume, left ventricle mass, and systolic and diastolic left ventricle internal diameter in

**FIGURE 6** Time course of changes in the heart rate (HR) of rats treated with the MXD ethanol/glycol propylene solution (rats per group = 2) and MXD hydroxypropyl-β-cyclodextrin GEL formulation (rats per group = 2). Each point represents the mean ± SEM of n sampling time points (≥4000) collected during the daily recording of individual rats. No significant changes were observed following the application of the MXD hydroxypropyl-β-cyclodextrin GEL formulation vs the baseline, as evaluated by Student paired t test ( $P < .05$ )

the rats treated with either of the MXD formulations; the rats treated with the MXD ethanolic formulation were more severely affected.

The post mortem tissues of the MXD-treated animals showed abnormalities in several organs, as demonstrated by the histopathological and biochemical analyses, and the MXD ethanol/glycol propylene solution-treated rats were more severely affected. Additionally, we found cancerous cells positive for Ki-67 in the kidney tissue sections. A previous dermal study in mice showed an increased incidence of mammary adenomas and adenocarcinomas in females at all dose levels (8, 25, and 80 mg/kg/day), which was attributed to increased serum prolactin (Product monograph ROGAINE®, 2017). Similarly, in rats there were significant increases in the incidence of pheochromocytomas in both genders and of preputial gland adenomas in males, as well as an increase in prolactin secretion, following treatment with topical MXD for 90 days.

KATP channels are composed of an assembly of sulfonylureas receptor subunits (SUR1 and SUR2A/B) and inwardly rectifying potassium channels subunits in different tissues (Kir6.1 and Kir6.2), including skin cells.18,41,52,53 KATP channels and calcium-activated potassium channels couple the nucleotide and intracellular calcium transient levels with the electrical properties of the cells regulating cell cycling and proliferation.53,54 KATP-channel openers, including MXD, induce cell growth in the muscles and dermal tissues, while the downregulation or pharmacological blockage of these channels induces caspase-3-dependent atrophy.44-45,53-56

Hypertrophic signaling and cell proliferation are associated with the activation of KATP channels in different tissues. From a pathogenic point of view, the abnormal activation of KATP channels in human glioma cell lines has previously been reported.46 The upregulation of the Kir6.2 subunit, the pore-forming subunit of the KATP channels, has been associated with cervical cancer in human biopsies.57 Several features of Cantù Syndrome, including cardiac hypertrophy and hypotension, suggest that the effects of MXD in humans and animals are a pharmacological model of this disease.58

Note: These parameters were recorded from individual rats before treatment (baseline) and after treatment with a single daily dose (treatment period 1) and twice daily doses (treatment period 2) of 3.5% (w/v) minoxidil formulations. Data are expressed as mean ± SE (n ≥ 4000 time points, ECG recording). Data significantly different vs baseline \*(Student t test, P < .05) (rats per group = 2).

In our pharmacovigilance investigation using the EudraVigilance database, we detected 32 cases of cancer, neoplasm, and tumor in different organs, associated with the use of topical MXD. Pre-existing undiagnosed cancer in the patients using topical MXD cannot be excluded as a possible causative factor in the reports from the EudraVigilance database. Despite MXD not being mutagenic, the activation of KATP channels may induce cell proliferation, promoting tumor growth with drug-disease interactions. Two signaling pathways have been associated with MXD proliferative action: the AKT pathway, which is involved in hair growth and is oncogenic in cancers; and the ERK pathway, which is oncogenic in skin cancer and hypertrophic in cardiac ventricles.<sup>59</sup>

Additional experiments were performed to evaluate the effects of high doses of the two MXD formulations on ECG parameters and arterial blood pressure. The once and twice daily topical application of the MXD HP-β-CD GEL 3.5% w/v formulation showed a better profile in terms of arterial blood pressure, HR, and electrophysiological action potential parameters. Indeed, the once daily application of the MXD 3.5% formulations (w/v-w) induced a significant decrease in the QTc interval and depression of the ST segment for both formulations, without affecting the arterial blood pressure or HR. The MXD dose investigated corresponds to 7.777 g/kg/day in a rat of 450 g body weight, which is 155 times higher than the human therapeutic dose for the topical application of MXD solution (0.05 g/kg/day). As expected, the twice daily application of the MXD 3.5% (w/v-w) formulations, corresponding to 311 times the therapeutic human dose

with a cumulative dose of 116.655 g/kg of MXD at the end of treatment periods, caused marked cardiovascular effects. This treatment, other than inducing a significant decrease in the QTc interval and depression of the ST segment with both formulations, also significantly reduced the arterial blood pressure in the rats treated with the MXD ethanol/glycol propylene solution. The observed enhancement of the T amplitude following the once and twice daily doses of the MXD 3.5% (w/v) ethanol/glycol propylene solution can be related to vehicle effects, as they were not observed in the rats treated with the MXD HP-β-CD GEL formulation.

In conclusion, histopathological analysis of organs collected at the end of treatment confirmed the severe condition of the rats treated with the MXD ethanol/glycol propylene solution, showing severely affected kidney, liver, and cardiac muscle tissues. The HP-β-CD inclusion complex of the MXD gel reduces the adverse proliferative effects of this drug. HP-β-CD alone is reported to exert antiproliferative effects in vitro.<sup>40,41</sup> In male rats, the MXD HP-β-CD GEL formulation showed improved tolerability and toxicological profiles at a wide range of dosages vs the MXD ethanol/glycol propylene solution.

However, with over 30 years of usage in a large population worldwide, the MXD ethanol/glycol propylene solution demonstrates few adverse events. The adverse effects which have been reported in the literature concerning topical MXD formulations are mostly related to the tolerability of the formulation. We should point out that, in our experience, high doses of MXD ethanol/glycol propylene solution

are necessary to cause cardiovascular and renal adverse effects in rats. Despite no PK data being provided in previous in vitro experiments, the novel formulation released MXD more slowly than the MXD ethanol/glycol propylene solution and a significant release of  $70.80 \pm 6.0\%$  was obtained at 24 hour. In ex vivo experiments, the best accumulation in the ear skin of pigs was demonstrated for the MXD HP- $\beta$ -CD GEL formulation, with a value about two-fold greater than, and significantly different from, the MXD ethanol/glycol propylene solution.<sup>40</sup> In addition, in a multicenter trial on 307 subjects treated with topical MXD solution (2% or 5%), a MXD plasma level of 21.7 ng/mL was found, which should not be high enough to cause changes in the pulse rate; nevertheless, this effect was observed in patients, suggesting that the plasma concentration of MXD cannot be considered as an indicator of systemic adverse effects after use of the topical formulation.<sup>60</sup> The novel MXD HP- $\beta$ -CD GEL formulation could be appropriate for local treatment avoiding the systemic side effects of MXD.

## ACKNOWLEDGEMENTS

We acknowledge the University of Bari, Italy (founds ATENE0 2014), the Italian Ministero dell'Università e della Ricerca (MIUR, Italy), the Inter-University Consortium for Research on the Chemistry of Metal Ions in Biological Systems (CIRCMSB, Bari, Italy), and the Farmalabor srl. Centro Studi e Ricerche "Dr Sergio Fontana 1900-1982" (Canosa di Puglia, Italy) for support.

## CONFLICT OF INTEREST

The authors declare no conflicts of interest.

## AUTHOR CONTRIBUTIONS

DT conceived this study, designed the experiments, and wrote this manuscript. FM, NZ, AM, ND, RS, GP, AC, and VL conducted the experiments and analyzed the data. A.L, F.L, SV, MF, and DT contributed the essential reagents, tools, and technique. D.T, SF, and MF supervised this project.

## DECLARATION OF TRANSPARENCY AND SCIENTIFIC RIGOR

This declaration acknowledges that this study adheres to the principles for transparent reporting and scientific rigor of preclinical research as stated in the BJP guidelines for Design & Analysis, Immunoblotting and Immunochemistry, and Animal Experimentation and as recommended by funding agencies, publishers, and other organizations engaged with supporting research.
