

How does Corowa-kun work?

Corowa-kun is the mascot of an online chatbot. This chatbot in LINE is used to answer COVID-19 vaccine frequently asked questions (FAQs) via text messages. As of May 10th, 70 FAQs are available.

Results. A total of 59,676 persons used Corowa-kun during February to April 2021. The most commonly accessed message categories were: "I have (select comorbidity), can I get a COVID-19 vaccine?" (23%); followed by questions on adverse reactions (22%) and how the vaccine works (20%). 10,192 users (17%) participated in the survey. Median age was 55 years (range 16 to 97), and most were female (74%). Intention to receive a COVID-19 vaccine increased from 59% to 80% after using Corowa-kun ($p < 0.01$). Overall, 20% remained hesitant: 16% (1,675) were unsure, and 4% (364) did not intend to be vaccinated. Factors associated with vaccine hesitancy were: age 16 to 34 (odds ratio [OR] = 3.7, 95% confidential interval [CI]: 3.0–4.6, compared to age ≥ 65), female sex (OR = 2.4, CI: 2.1–2.8), and history of another vaccine side-effect (OR = 2.5, CI: 2.2–2.9). Being a physician (OR = 0.2, CI: 0.1–0.4) and having received a flu vaccine the prior season (OR = 0.4, CI: 0.3–0.4) were protective.

COVID-19 vaccine acceptance increased and hesitancy decreased after using Corowa-kun, Japan, 2021 (n=10,192)

*There was a statistically significant difference in responses between before and after using Corowa-kun ($p < 0.01$, Chi-square test).

Univariable logistic regression models of factors associated with COVID-19 vaccine hesitancy, Japan, 2021 (n=10,192)

	Vaccine hesitancy N=2,039		Vaccine acceptance N=8,153	Odds ratio	
Age					
16-34	229	11.2%	569	7.0%	3.7 (3.0-4.6)

Pregnant	31	1.5%	36	0.4%	3.3 (2.0-5.3)
Not pregnant	1072	52.57%	4087	50.1%	Ref
Desire to be pregnant	84	4.1%	144	1.8%	2.2 (1.7-2.9)
Not applicable	852	41.8%	3886	47.7%	0.8 (0.8-0.9)

Ref: reference NA: Logistic regression was not performed due to too small number ($n \leq 3$)

Conclusion. Corowa-kun reduced vaccine hesitancy by providing COVID-19 vaccine information in a messenger app. Mobile messenger apps could be leveraged to increase COVID-19 vaccine acceptance.

Session: P-21. COVID-19 Research

Background. A naïve Bayes classifier is a popular tool used in assigning variables an equal and independent contribution to a binary decision. With respect to COVID-19 severity, the naïve Bayes classifier can consider different variables, such as age, gender, race/ethnicity, comorbidities, and initial laboratory values to determine the probability a patient may need to be admitted or transferred to an intensive care unit (ICU). The aim of this study was to develop a screening tool to detect COVID-19 patients that may require escalation to ICU status.

Methods. Patients hospitalized with COVID-19 were gathered from the end of March 2020 to the end of May 2020 from four hospitals in our metropolitan area. We began searching for potential variables to include in the classification model using chi-square analysis or calculating the optimal cutpoint to separate ICU and non-ICU status. After identifying significant variables, we began using standard procedures to construct a classifier. The dataset was split 7:3 to create samples for training and testing. To appraise the model's performance, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), area under the curve (AUC), and the Matthew's correlation coefficient (MCC) were calculated.

Table 1. Univariate analysis of variables in the COVID-19 dataset dichotomized by ICU status

Variable	Non-ICU (n = 397)	ICU (n=177)	P value
Age ≥ 55 years	260 (65.5)	150 (84.7)	<0.001
Male	175 (44.1)	101 (57.1)	0.005
African American	143 (36.0)	63 (35.6)	0.997
Hypertension	276 (69.5)	132 (74.6)	0.257
Chronic kidney disease	67 (16.9)	60 (33.9)	<0.001
Chronic obstructive pulmonary disease	58 (14.6)	40 (22.6)	0.026
Obstructive sleep apnea	49 (12.3)	42 (23.7)	0.001
Diabetes mellitus type II	136 (34.3)	91 (51.4)	<0.001
Presenting with fever	252 (63.5)	122 (68.9)	0.242
Presenting with diarrhea	123 (31.0)	37 (20.9)	0.017
C-reactive protein ≥ 10 mg/L	39 (9.8)	35 (19.8)	0.002
Lactate dehydrogenase ≥ 400 U/L	145 (36.5)	95 (53.7)	<0.001
Ferritin ≥ 550 ng/mL	162 (40.8)	104 (58.8)	<0.001
Troponin-I ≥ 0.1 ng/mL	27 (6.8)	45 (25.4)	<0.001

Results. A total of 574 COVID-19 patients were included in the study. There were 402 patients in the training sample and 172 patients in the testing sample. The naïve Bayes classifier demonstrated an overall accuracy result of 75.6% (95% CI; 68.5% – 81.8%) using the 14 variables listed in Table 1. The model was able to correctly classify 84.9% of ICU status patients (sensitivity), but only 54.7% of non-ICU status patients (specificity). The PPV and the NPV were 80.1% and 61.7%, respectively. The AUC was 0.717 (95% CI; 0.629 – 0.805) and the MCC was 0.410.

Conclusion. Our naïve Bayes classifier operates by recognizing certain aspects of severe COVID-19 cases and looking for the probability of the variables in said patients. We present a classification model that potentially could be used alongside other tools to screen patients with COVID-19 early in their hospital course to identify those needing escalation to ICU level care.
