ABSTRACT Amylases catalyze the cleavage of α -D-1,4 and α -D-1,6-glycosidic bonds in starch and related carbohydrates. Amylases are widely distributed in nature and are important in carbohydrate metabolism. This is the release of four single and two double deletions in Salmonella enterica serovar Typhimurium LT2 that are important for glycan degradation during infection.

Amylases in Salmonella spp. are poorly characterized glycosyl hydrolases. The **Importance of amylases during Salmonella infection is understudied, especially as** new virulence factors. The genome of Salmonella enterica serovar Typhimurium LT2 contains four amylases that are classified under the glycoside hydrolase 13 (GH13) family: malS (periplasmic α-amylase), amyA (cytoplasmic α-amylase), glgX (glycogendebranching enzyme), and $glgB$ (1,4- α -glucan-branching enzyme). Although $glgX$ and glgB are not annotated as amylases, both have a conserved α -amylase domain and function as amylases. Investigating the genomic diversity of microbial amylases will aid in understanding their importance during pathogenesis. Inhibitors of amylases can be new drug targets.

Amylases play an important role by altering the host glycan profiles during infection to gain access of the host epithelial cells by binding to terminal mannose molecules to initiate glycan degradation, as was shown by Arabyan et al. [\(1\)](#page-1-0). That group also demonstrated that each of the four mutant amylase strains (ΔmalS, ΔamyA, ΔglgX, and ΔglgB mutants) had different invasion phenotypes during the in vitro infection of differentiated colonic epithelial cells (Caco-2) [\(1\)](#page-1-0); however, only the ΔmalS mutant significantly ($P < 0.05$) reduced adhesion and invasion during infection that were comparable to those seen with a nonpathogenic Salmonella strain [\(1\)](#page-1-0).

The 100K Pathogen Genome Project (http://www.100kgenomes.org) is a large-scale sequencing consortium that offers the use of new next-generation sequencing methods to provide cutting-edge methods for pathogen detection and control in the food supply. This project is focused on producing genomes of pathogenic isolates from the environment, plants, animals, and humans worldwide, providing new insights into the genetic diversity of Salmonella and other foodborne pathogens. These amylase mutant strains (four single-deletion and two double-deletion mutants) were constructed in the Weimer laboratory (UC Davis, Davis, CA) [\(1\)](#page-1-0), as described by Datsenko and Wanner [\(2\)](#page-1-1). Cultures were grown on 1.5% Luria-Bertani (LB) agar (Difco, Franklin Lakes, NJ) with 10 μ g/ml chloramphenicol at 37°C and lysed [\(3\)](#page-1-2); genomic DNA (gDNA) was extracted [\(4\)](#page-1-3), checked for quality [\(5\)](#page-1-4), and fragmented [\(6\)](#page-1-5). Libraries were 350 to 500 bp [\(7,](#page-1-6) [8\)](#page-1-7) and were indexed (96 genomes/lane) and sequenced (Illumina HiSeq 3000; PE150) [\(9](#page-1-8)[–](#page-1-9)[11\)](#page-1-10) at UC Davis DNA Technologies Core (Davis, CA). Paired-end reads were de novo assembled using CLC Workbench version 6 (Qiagen), with default parameters. Here, the 100K

TABLE 1 Salmonella enterica serovar Typhimurium LT2 amylase deletion mutants

aCDSs, coding sequences.

Pathogen Genome Project has assembled four genomes of single- and two doubleamylase-deletion strains of Salmonella enterica serovar Typhimurium LT2.

Accession number(s). All sequences are publicly available and can be found at the 100K Project BioProject (NCBI PRJNA186441) in the Sequence Read Archive [\(http://](http://www.ncbi.nlm.nih.gov/sra) [www.ncbi.nlm.nih.gov/sra\)](http://www.ncbi.nlm.nih.gov/sra) and genome assemblies can be found in NCBI GenBank [\(Table 1\)](#page-1-11).

ACKNOWLEDGMENTS

We gratefully acknowledge funding for this project from Mars, Inc., NIH (grants 1R01HD065122-01A1 and NIH-U24-DK097154) and an Agilent Technologies Thought Leader Award to B.C.W.
