From 16th International Conference on Human Retroviruses: HTLV and Related Viruses
Montreal, Canada. 26-30 June 2013

Human T-lymphotropic virus type 1 (HTLV-1) is the causative agent of adult T cell leukemia (ATL) and other HTLV-1 associated neurological disorders. Unlike most retroviruses, cell-free HTLV-1 virions are poorly infectious and do not stably infect its primary CD4+ T lymphocyte target. However, HTLV-1 efficiently infects cells of the myeloid lineage, leading to productive infection of myeloid cells. Here, we investigate the mechanisms underlying monocyte infection by HTLV-1 and demonstrate that HTLV-1 infection induced apoptosis of monocytes in a SAMHD1-dependent manner. SAMHD1, a deoxynucleoside triphosphate triphosphohydrolase, functions as a restriction factor that limits HIV-1 replication by reducing the availability of deoxy-nucleosidetriphosphates (dNTPs) required for reverse transcription. RNAi-mediated silencing of SAMHD1 inhibited monocyte apoptosis, while addition of exogenous dNTPs, or pre-treatment with azidothymidine (AZT) to block reverse transcription also inhibited apoptosis. To investigate a role for reverse transcription intermediates (RTI) in triggering apoptosis, a biotinylated 90 nucleotide RTI from the U5 region of HTLV-1 was introduced into monocytes; strikingly, the biotinylated RTI induced apoptosis and bound to the DNA sensor STING - which mediates the antiviral response via IRF3 activation. We further demonstrated that STING-mediated apoptosis in infected monocytes required the generation of a pro-apoptotic complex between IRF3 and the Bcl-2 protein Bax. These studies provide a mechanistic explanation for HTLV-1 abortive infection of monocytes and report a link between SAMHD1 restriction of reverse transcription, sensing of retroviral reverse transcription

intermediates by STING, and the initiation of IRF3-Bax driven apoptosis.
