Background: Primary open-angle glaucoma (POAG) is a progressive optic neuropathy with numerous risk factors. Its severity with associated risk factors remains a widely debated topic.

Aim: To evaluate the severity of POAG in patients with hypertension (HTN) and diabetes or both.

Patients and methods: This hospital-based, cross-sectional descriptive study was conducted for a period of 18 months from January 2016 to June 2017. Diagnosed cases of POAG were evaluated for severity with associated risk factors.

Results: A total of 221 patients were enrolled in the study. The mean age of the patients was 54.4 (SD \pm 15.9) years with a male to female ratio of 0.93:1. Of the 221 patients, 68 (31%) had a family history of POAG. Mean intraocular pressure was 15.8 \pm 4.87 mmHg, and mean central corneal thickness was 535.4 \pm 34.9 μ m. A total of 81 (36%) patients had HTN, 21 (9.50%) had diabetes mellitus (DM), and 15 (6.80%) had both HTN and DM. Analysis using SPSS version 20 was done. The severity of POAG was found to be significantly higher in patients with HTN, DM, or both when evaluated on the basis of anatomical and functional loss.

Conclusion: POAG patients with HTN, DM, or both were found to have more severe POAG. Patients with these risk factors could represent “high-risk patients” with POAG. Patients with HTN and DM, or both may require evaluations on a more frequent basis to access the progression/severity of POAG.

Keywords: glaucoma in Nepal, POAG in Nepal, severity of POAG, hypertension, diabetes, systemic disorders in POAG

Background

Glaucoma is the second most common cause of blindness worldwide.¹ It is a major global issue, causing significant ocular morbidity and disability due to its progressive nature resulting in an irreversible visual loss.² Due to its chronicity, it is often also dubbed as a “silent killer” of the eye. Patients are usually asymptomatic until very advanced stage, making visual loss irrecoverable by the time they present to an ophthalmologist.^{3,4}

One of its variant and the most common form – primary open-angle glaucoma (POAG) is a chronic, progressive, and anterior optic neuropathy that is associated with characteristic cupping and atrophy of the optic disc, visual field loss, open angles, and no obvious causative ocular or systemic conditions.⁵ POAG accounts for nearly three-quarters (74%) of all glaucoma cases.^{6,7} Various estimates and meta-analysis data show that estimated there could be 60,500,000 people with open-angle glaucoma (OAG) and angle-closure glaucoma (ACG) in 2010.^{6,8}

Risk factors

Hypertension (HTN) data on the relationship among HTN and intraocular pressure (IOP) are consistent across examination. This relation between POAG and blood pressure (BP) is unpredictable and inadequately understood. A few large-scale epidemiologic studies have investigated this relationship – depicting conflicting reports. A few investigations have concluded that there is a low risk of glaucoma in individuals with elevated BP,⁹ whereas others reported significant associations between high systemic BP and POAG using cross-sectional data.^{10–13}

Diabetes mellitus (DM)

DM and POAG are thought to have a direct relationship. Several theories on relation among DM and POAG have been proposed. The presence of long-standing hyperglycemia along with dyslipidemia may increase the danger of neuronal damage from oxidative stress.¹⁴ Various investigations have likewise demonstrated that diabetic eyes have a diminished ability to autoregulate blood flow and exhibit diminished retinal blood flow.¹⁵ Ciccone et al¹⁶ have described the effect of elevated sugar levels or insulin resistance in pre-diabetic patients with a strong history of DM in the family. Various biochemical pathways and cascades are thought to be activated causing endothelial dysfunction – ultimately leading to dysregulated vascular flow.

Patients and methods

This study is a prospective review of patients recruited from glaucoma clinic. Patients were eligible if they had a working diagnosis of POAG from their treating ophthalmologist with systemic illness such as HTN, DM – with or without medications, since they represent the major fraction of the study. Patients having a narrow angle in either eye or with PACG or any history of intraocular surgery (eg, vitreo-retinal procedures, glaucoma filtration surgeries), with secondary open-angle-closure glaucoma, inflammatory glaucoma, acute congestive glaucoma, and optic disc anomalies were excluded from the study.

Full threshold, Swedish Interactive Threshold Algorithm (SITA) standard, and SITA fast fields were accepted, with the majority of fields being SITA standard. Visual fields were manually screened by the author and any fields with an obvious neurological scotoma were also excluded. The data from both the subject’s right and left eye were used if they individually satisfied the inclusion and exclusion criteria.

For every eligible patient, clinical evaluation was conducted were recorded in a database. Information collected includes the subject’s age, sex, refraction, IOP (measured with Goldmann tonometry), and central corneal thickness. Furthermore, the medical, ocular, surgical, and medication histories of the subjects were obtained from patient files and recorded. Medical conditions were confirmed usually via correspondence from general practitioners, optometrist, or previous treating ophthalmologists.

The presumed risk factors include HTN, DM, or both. Severity on the basis of cup–disc ratio (CDR), disc hemorrhages, neuroretinal rim changes and Humphrey Visual Field Analysis Score (Parrish-Anderson [HPA])¹⁷ and Speath Field Damage likelihood score staging systems¹⁸ was done.

Data processing and analysis

Preformed proforma designed for this study was used to record the relevant history and clinical findings. Data were analyzed using SPSS 20 software (IBM Corporation, Armonk, NY, USA) after matching age, sex, and duration of the POAG/HTN/DM among the participants.

Ethical clearance

The research was approved by the ethics committee and the institutional review board of Institute of Medicine, Nepal, and has adhered to the tenets of the Declaration of Helsinki. Written informed consent was provided by the patients or their parents or legal guardian if the patients were under the age of 18 years.

Results

Detailed ophthalmic examination, including glaucoma workup was performed in 442 eyes of all 221 POAG patients.

Table 1 describes the demographic characteristics according to age and sex of all participants during the study period. In this study, a total of 221 cases of POAG were included.

Table 1 Age and sex distribution of POAG

Age, years	Sex		Total (%)
	Male	Female	
11–20	2	4	6 (2.7)
21–30	9	3	12 (5.4)
31–40	11	15	26 (11.7)

Figure 1 POAG patients with hypertension and diabetes.
Abbreviation: POAG, primary open-angle glaucoma.

In this study, there were 81 (36%) participants with HTN, 21 (9.5%) with DM, and 15 (6.8%) with both HTN and DM (Figure 1). We analyzed these groups differently as a single and combined risk factor for severity, comparing it with the patients with POAG without either of the conditions.

The mean IOP (Table 2) in 2 groups at CI of 95% was comparable while the mean visual field defect (VFD) (Table 2) of the participants with HTN had tendency of being categorized under moderate VFD, in contrast, to mean VFD among participants without HTN, which has tendency of categorizing them under mild VFD. The CDR (Table 2) of the patients with HTN was also comparatively larger than the participants without HTN at CI of 95%.

The comparison shows that the participants with HTN have higher chances of having severe VFD compared with the participants without HTN (odds ratio [OR] 2.75, 95% CI: 1.51 to 5.00, $p=0.001$; Table 3).

Severity of POAG in patients with DM

Similarly, for DM, there were 21 (9.5%) participants with DM and 15 (6.8%) with both HTN and DM.

Table 2 Ocular findings of patients of POAG with and without HTN

		Patients with HTN	Patients without HTN
IOP	Mean	15.0	15.7
	95% CI for mean, $p<0.05$	14.2 to 15.9	14.9 to 16.5
HVFA	Mean	-8.39	-4.85

Abbreviation: VFD, visual field defect.

tendency of being categorized under moderate VFD, in contrast, to mean VFD among participants without DM and HTN, which has tendency of categorizing them under mild VFD (Table 6).

The comparison shows that the participants with DM and HTN have higher chances of having severe VFD compared with the participants without DM (OR 19.9, 95% CI: 2.52 to 156.8, $p = 0.0046$; Table 7).

Discussion

Among vascular factors, it has been long postulated that systemic HTN may cause increases in IOP mainly via overproduction from ciliary body or impaired outflow of aqueous humor.¹⁹ However, this relationship remains inconclusive and under debate. While some studies highlight that systemic HTN is a risk factor for glaucoma,^{10,20} other studies indicate that low systemic BP is more dangerous and poses a serious risk for the development and progression of glaucoma. In this study, 81 (36%) participants had HTN. This was comparable with a study done by Garg et al²¹ where HTN was seen in 35.1% of their participants.

This study found that the mean IOP in patients with HTN was 15.04 (95% CI: 14.2 to 15.9, $p < 0.05$), mean VFD of -8.39 (95% CI: -11.1 to -5.64, $p < 0.05$), and mean CDR of

Table 6 Ocular findings of patients of POAG with HTN and DM and without HTN and DM

		Patients with HTN and DM	Patients without HTN and DM
IOP	Mean	16.0	15.7
	95% CI for mean $p < 0.05$	13.9 to 18.0	14.9 to 16.5
HVFA	Mean	-9.08	-4.85
	95% CI for mean $p < 0.05$	-16.9 to -1.27	-5.83 to -3.86

Abbreviations: DM, diabetes mellitus; HTN, hypertension; VFD, visual field defect.

0.71 (95% CI: 0.62 to 0.81, $p < 0.05$) in comparison with the patient without HTN who had mean IOP of 15.74 (95% CI: 14.9 to 16.5, $p < 0.05$), mean VFD of -4.85 (95% CI: -5.83 to -3.86), and mean CDR of 0.61 (95% CI: 0.58 to 0.64, $p < 0.05$). The mean IOP in 2 groups at 95% CI was comparable, while the mean VFD of the participants with HTN had a tendency of being categorized under moderate VFD, in contrast, to mean VFD among participants without HTN, which has a tendency of categorizing them under mild VFD. The CDR of the patients with HTN was also comparatively larger than the participants without HTN at CI of 95%.

This study compared the severity of VFD among the POAG participants with and without HTN. The results showed that participants with HTN had OR 2.75 (95% CI: 1.51 to 5.00, $p = 0.001$) of having severe visual field changes in comparison with the participant group without HTN.

The inclusion criteria for our participants were diagnosed case for HTN for at least 5 years and under medication. Earlier it was hypothesized that elevated BP might be protective against POAG, but He et al²² reported that it was only an acute BP elevation, which makes retinal function and blood flow less susceptible to IOP. The improved ocular

perfusion pressure to compensate for the acute rise in IOP is compromised after 4 weeks of HTN. Chan et al²³ also reported that patients with cardiovascular disease were 2.33 times more likely to develop rapidly progressive glaucoma disease despite significantly lower mean and baseline IOPs.

DM is a serious and increasingly prevalent health issue worldwide due to an aging population and lifestyle changes. The prevalence of DM worldwide was estimated to be 2.8% in 2000 and is forecasted to be 4.4% in 2030.²⁴ Some studies also found that DM has a strong link with POAG^{25,26} This relationship, however, still remains controversial.^{27,28}

We compared patients with DM with patients without DM in this study. There were 21 (9.5%) participants with DM. We found that the mean IOP in patients with DM was 16.3 (95% CI: 12.2 to 20.4, $p < 0.05$), mean VFD of -8.52 (95% CI: -13.4 to -3.64 , $p < 0.05$), and mean CDR of 0.74 (95% CI: 0.66 to -0.82 , $p < 0.05$). In comparison, the patient without DM had a mean IOP of 15.7 (95% CI: 14.9 to 16.5, $p < 0.05$), mean VFD of -4.85 (95% CI: -5.83 to -3.86 , $p < 0.05$), and mean CDR of 0.61 (95% CI: 0.58 to 0.65 $p < 0.05$), which were of significant statistical value to show that POAG was more severe among the diabetic group compared with that of the non-diabetic group.

This study also showed that DM had higher chances of having severe VFD compared with the participants without DM (OR 4.72, 95% CI: 1.69 to 13.2, $p = 0.0031$). Much research has been done to see if there is an association between POAG and DM. In one study done by Shakya-Viadya et al,²⁹ they reported overall risk of a diabetic patient developing POAG increasing by 3.50 fold when compared with patients without diabetes.

Blue Mountains Eye Study³⁰ provided crucial data of an entire population who underwent a detailed eye examination to establish a diagnosis of glaucoma or ocular HTN. The OR for glaucoma in diabetic patients compared with those without DM was 2.12 (95% CI: 1.18 to 3.79). This was one of the first studies to establish a relationship between glaucoma and DM. The Baltimore Eye Study,²⁸ which was conducted similar to the Blue Mountains Eye Study, also reported age-race adjusted OR of 1.03 (95% CI: 0.85 to 1.25). But neither study describes or correlates if the severity of POAG is more with DM.

However, Toda and Nakanishi-Toda³¹ reported about a direct relationship between DM and POAG, which could help support our result. A few theories on relation among DM and POAG have been proposed. There is a developing assortment of confirmation that long-standing hyperglycemia, alongside lipid abnormalities, may increase the danger of neuronal damage from oxidative stress.³² Data from various laboratories have provided strong evidence for such an association.³³

Another theory discusses that diabetic eyes have a dysfunctional autoregulation of blood flow hence causing decreased blood flow in the retina.³⁴ This creates an environment of relative hypoxia – causing overexpression of hypoxia-inducible factor-1 alpha (HIF-1 α).³⁵ It is now known that there is an increase in levels of HIF-1 α in ganglion cells of the retina and in the optic nerve head of human glaucomatous eyes.³⁶ Ciccone et al¹⁶ have further described regarding the endothelial dysfunction due to activation of various cascades, which may further catalyze this vicious cycle.

Another theory postulates that in diabetic eyes, there is remodeling of the connective tissue of the optic nerve head. This might reduce compliance at the trabecular meshwork and also in the lamina cribrosa, resulting in increased IOP and elevated mechanical stress on the optic nerve head.³⁷ Research has shown that DM can deregulate connective tissue remodeling and amplify these biomechanical changes.³⁸ A systematic review and meta-analysis by Zhou et al³⁹ have also concluded that although the exact mechanism of how the DM and POAG is still under debate, their meta-analysis results show a significant association between DM and the risk of POAG. Patients with DM had about 1.4-fold increased risk of developing POAG in cohort studies while the case-control studies had nearly 49% increased odds of developing POAG compared with individuals without DM.

In the final part of this study, we compared patients with DM and HTN with participants without DM and HTN. There were 15 (6.8%) participants in this group. This study found that the mean IOP in patients with both DM and HTN was 16.0 (95% CI: 13.9 to 18.0, $p < 0.05$), mean VFD of -9.08 (95% CI: -16.9 to -1.27 $p < 0.05$), and mean CDR of 0.68 (95% CI: 0.571 to 0.785, $p < 0.05$). In comparison, the patient without DM and HTN had a mean IOP of 15.7 (95% CI: 14.9 to 16.5, $p < 0.05$), mean VFD of -4.85 (95% CI: -5.83 to -3.86 , $p < 0.05$), and mean CDR of 0.61 (95% CI: 0.58 to 0.65, $p < 0.05$). The comparison shows that the participants with DM and HTN have higher chances of having severe VFD compared with the participants without DM (OR 19.9, 95% CI: 2.52 to 156.8, $p = 0.0046$).

In a study done by Shakya-Vaidya et al,²⁹ a strong association between POAG and DM (OR 3.15) was demonstrated. They concluded that their results suggest that POAG associates positively with HTN and DM in all ethnic groups. Newman-Casey et al⁴⁰ – reported in one their study with 2,182,315 enrollees who met the inclusion criteria, 55,090 (2.5%) had OAG. After adjustment for confounding factors, those with DM (hazard ratio [HR] = 1.35, [95% CI: 1.21 to 1.50]) or HTN (HR = 1.17, [95% CI 1.13 to 1.22]) alone or

in combination (HR=1.48, [95% CI 1.39 to 1.58]) had an increased hazard of developing OAG relative to persons with neither of these conditions. They also reported that people with DM alone had a 35% increased risk of developing OAG and those with HTN alone had a 17% increased risk. For people with both DM and HTN, there was a 48% increased risk of developing OAG.

This shows a strong link of development of POAG among the patients with the various vascular conditions. This study has evaluated for severity of POAG among patients in similar groups as theirs. Although they have not reported on severity, an assumption might be made based on their study that – the association of these vascular phenomena on increasing the risk of developing POAG in the first place might also have a vital role to play in progression and severity of the disease as found in this study.

Conclusion

We found that patients with HTN and DM or both had a more severe form of POAG when compared with the participants without these risk factors. Patients with these risk factors could represent “high-risk patients” and should be identified and be explained about the condition. A good documentation of the previous investigation is a must to analyze the rate of progression – and modification in the treatment may be required accordingly. The patients should be made aware of the various risk factors they may have, which may alter the course of the disease. They should be advised/recommended regarding the requirement of evaluations on a more frequent basis to access the progression/severity of POAG.

Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy

Dovepress

Publish your work in this journal

Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy is an international, peer-reviewed open-access journal committed to the rapid publication of the latest laboratory and clinical findings in the fields of diabetes, metabolic syndrome and obesity research. Original research, review, case reports, hypothesis formation, expert

opinion and commentaries are all considered for publication. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
