

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

## Letter to the Editors-in-Chief

## Major cardiovascular events in patients with Coronavirus Disease 2019: Experience of a cardiovascular department of Northern Italy<sup>\*</sup>

### 1. Introduction

Since the declaration of the Coronavirus Disease 2019 (COVID-19) pandemic, much of clinical attention has been focused on ARDS, treatment, and respiratory outcomes [1]. More recent studies have shed light on another worrisome complication, namely the association between COVID-19 infection and hypercoagulability [2]. Venous thromboembolism and myocardial injury have been described in preliminary reports, but so far few of the published studies have reported observations of arterial involvement triggered by COVID-19 infection [3–6]. What was strikingly unexpected during this outbreak period was the unexpectedly high occurrence of peripheral arterial thromboembolism across MACE (Fig. 1).

If the pandemic continues throughout 2020 which is predicted, we will observe a significantly higher number of patients suffering from PE and ALI compared to the same period of first three months of 2019 (Fig. 2).

Although hypercoagulable state, thrombophilias, and sepsis-induced coagulopathy have been preferentially associated with venous thromboembolism, in our early experience the COVID-19 related hypercoagulability involved the arterial system (cardiac and peripheral) in over 30% of cases. There are different reasonable aspects to support this observation. First, though the mean age of the ALI group in our series was significantly higher compared to patients with PE and ACS, the incidence of COVID-19 related pneumonia in ALI group was the same as the PE group [2,4,5]. Second, histological evaluation of the thrombi removed during ALI interventions is dense with inflammatory elements, similar to the description from the previous SARS-CoV-1 epidemic [7]. Third, we have seen a higher than expected rate of technical failure after percutaneous coronary interventions or lower limb surgical revascularization. As early failure rate of 23% is astonishingly high when compared to the operative results of such procedures in a non-COVID-19 time [6]. This is alarmingly high if we consider that, although special considerations were taken in terms of personnel reorganization during this pandemic, cardiovascular and surgical teams were the same comparing COVID-19 and non-COVID-19 periods. Fourth, the positive response to heparin treatment and the observation that, at least in the ALI group, the use of a more aggressive treatment protocol with intravenous heparin led to no thrombotic recurrence in treated vessels, may

serve as evidence of coagulopathy leading to the high failure rate [2]. Whether all these data can be ascribed to the acute hypercoagulability states or due to advanced preoperative condition is currently impossible to be ascertained, but may support the concept of endothelial aggressiveness of the virus in the arterial system [2,9]. Furthermore, the fact that, potentially, we are observing significantly fewer patients suffering from ACS is surprising and somewhat unexpected [3,4,8]. Currently, we are not able to find an unquestionable explanation for our finding, especially if we consider that in our series the ACS group showed a medical history characterized by a higher rate of cardiovascular risk factors if compared to what reported in larger cohort [4,8]. It is also possible, that people with cardiac symptoms are not utilizing the healthcare system due to inability to access or fear, and thus, are under-reported [9].

Overall mortality was 38% in our early experience, which is comparable to the 37–69.4% range reported in COVID-19 cohorts with cardiovascular complications, albeit we have not seen a higher mortality rate in COVID-19 patients with pre-existing cardiovascular risk factors [4,8,9]. There are three different findings from our initial experience. First, chest hrCT assisted in confirmation of a COVID-19-related pneumonia, with progressive parenchyma involvement also predicting an increase in mortality risk as recently published. Specifically, an involvement score >75% was associated with a 72% probability of death [1]. Second, while the SOFA score was born as intensive care unit risk score to predict mortality, and despite not all our patients needed intensive care unit stay, mortality was significantly higher for those patients presenting with a SOFA score  $\geq 3$  [10]. Third, in our cohort, heparin was used in a similar percentage with all MACE and we did find that the use of heparin was significantly associated with better survival independent of the types of drugs received as pharmacological treatment for COVID-19 [2]. In summary, the type of MACE did not affect mortality, and both cardiac and peripheral vascular events were characterized by a high rate of technical failure with recurrent thromboses providing additional evidence to the coagulopathy that is becoming increasingly recognized with this pandemic. While lung parenchyma derangement >75% induced by the COVID-19 pneumonia is inherently to this pandemic infection, the use of heparin in addition to COVID-19 pharmacological treatment improved survival compared to those who did not receive heparin.

**Abbreviations:** ARDS, acute respiratory distress syndrome; COVID-19, novel coronavirus disease 2019; MACE, major adverse cardiovascular event; PE, pulmonary embolism; ACS, acute coronary syndrome; ALI, acute limb ischemia; hrCT, high resolution computed tomography; SOFA, sequential organ failure assessment; SIC, sepsis-induced coagulopathy; SD, standard deviation; IQR, interquartile range; OR, odds ratio; AUROC, area under the receiving operator curve; CI, confidence interval.

<sup>\*</sup> These authors take responsibility for all aspects of the reliability and freedom from bias of the data presented and their discussed interpretation.
