Synthesis of calixresorcarenes using magnetic poly triazine-benzene sulfonamide-SO₃H†

 Alireza Gharekhani, Ramin Ghorbani-vaghei * and Sedigheh Alavinia

The purpose of this work is to develop a magnetically recyclable immobilized base catalyst for the green synthesis of calixresorcarenes. To achieve this, poly triazine-benzene sulfonamide (PTBSA) has been coated on magnetic Fe₃O₄ nanoparticles and subsequently chlorosulfonic acid has been supported to obtain Fe₃O₄@PTBSA-SO₃H. The structure of nano-Fe₃O₄@PTBSA-SO₃H was characterized by TEM, XRD, FT-IR, VSM, WDX, EDX, TGA/DSC and FE-SEM. The catalytic efficiency of this catalyst was also investigated in the synthesis of novel calixresorcarene derivatives. The advantages of heterogeneous nature, catalytic activity and the recyclability of the polymer support were also strengthened by advanced surface treatment. These key factors (basic sites, acidic sites and heterogeneity) play essential roles in the catalyst performance. This procedure has some advantages such as short reaction time, clean and fast work-up and easy separation of the catalyst by an external magnet.

1 Introduction

A calixarene/calixresorcinarene is one of the most important macrocyclic molecules in materials chemistry.¹ This compound is the key structural fragment of fluorescent and chromogenic sensors.² Calixarene and its derivatives demonstrate numerous biological activities such as, anti-infective, antibacterial, anti-tumour and antifungal.³ Moreover, many researchers have concentrated on the phase transfer catalyst activity,⁴ encapsulation,⁵ and supramolecular chemistry of calix[4]arene and its derivatives.⁶ The functionalization of calix[4]arene has attracted considerable interest,⁷ from characterization such as the ease of functionalization or modification, the flexibility and rigidity of the four different three dimensional conformations.³ For the synthesis of various calixarenes/calixresorcarenes, the reaction of resorcinol with benzaldehyde derivatives is a particularly important method.⁸ Despite the existence of this synthetic method, the synthesis of these structures by the above-mentioned routes has some drawbacks such as multi-step synthetic operation, low product yield, inaccessible starting materials, limited scope and using a homogeneous catalyst.

Homogeneous catalysts function in the same phase as reactants but heterogeneous or heterogenized ones react in a different phase. With respect to the reaction medium, the advantage of heterogeneous catalysts compared to homogeneous ones is that the former function in a different phase leading to cheap and easy separation.⁹ Magnetic nanoparticles

(MNPs) have recently been developed as a very useful type of supported catalyst because of their easy synthesis and functionalization, good stability, high surface area, low toxicity and low price as well as facile separation using magnetic forces.¹⁰ Also, to bridge the gap between heterogeneous and homogeneous catalysis, surface functionalization of magnetic particles can be considered to be a good method.¹¹

Surface modification of heterogeneous support with polymer have attracted much attention of researchers due to its remarkable catalytic efficiency in organic synthesis which addresses the sustainability concerns including ease of recyclability, high capacity chelating, excellent chemical and thermal stability.¹² Thus, the application of magnetic nanoparticles and polymers as attractive candidates is currently a subject of interest in chemical processes and organic reaction.¹³

Many of the organic reactions can be performed in the presence of acidic catalysts. These catalysts generally are classified into two groups: homogeneous and heterogeneous acidic catalysts. Homogeneous acids are hazardous in handling, damaging the plant and environment through their corrosiveness, add process difficulties using quenching and separation stages, which led to the large volume of toxic and corrosive wastes. Consequently, in recent years there has been developed a great interest in using heterogeneous acid catalysts instead of those homogeneous acid catalysts, because of the possibility for recovering and recycling solids, and therefore significantly reducing the environmental impact.¹⁴

There are numerous organic and inorganic materials which can be used as supporting reagents to produce heterogeneous catalysts such as polymers,¹⁵ carbons,^{16,17} zeolites,^{18,19} silica,²⁰ hydroxyapatite,^{21,22} zirconia,²³ magnetite nanoparticle,²⁴ alumina²⁵ and *etc.* Consequently, progress in heterogeneous

solid acid catalysts as a fundamental principle in green chemistry is expected to have a major impact on industrial applications as well as on scientific aspects.

In view of the green chemistry, we tried in this work to substitute harmful mineral acids by magnetic polysulfonamide nanocomposite which contains high surface density functional group (SO_3H groups). In continuation of our previous effort on the synthesis of heterogeneous polysulfonamide-based catalyst,²⁶ we have been encouraged to develop a unique nanocatalyst $\text{Fe}_3\text{O}_4@PTBSA-SO_3H$ by immobilization of chlorosulfonic acid over the PTBSA grafted magnetic Fe_3O_4 NP (Scheme 1) and employed it in the green synthesis of calixresorcarenes (Scheme 2). The presence of chlorosulfonic acid as a strongly basic material efficiently promotes the reaction.²⁷

In order to take advantage of the high surface area, high coordination group and easy magnetic reusability, Fe_3O_4 MNP grafted PBTSA was used as the base matrix. To the best of our knowledge, there is no report hitherto on the catalytic green synthesis of calixresorcarenes using magnetic-polysulfonamide based nanocomposite.

2 Experimental section

2.1. Material and methods

All reagents and materials used in this work were of analytical reagent grade. Iron(III) chloride hexahydrate [$\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$, $\geq 98\%$], iron(II) chloride tetrahydrate [$\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$, $\geq 98\%$], melamine [1,3,5-triazine-2,4,6-triamine, $\geq 98\%$], ammonia

Scheme 2 Synthesis of calixresorcarenes derivatives using $\text{Fe}_3\text{O}_4@PTBSA-SO_3H$.

solution, $\geq 25\%$], [chlorosulfonic acid, $\geq 99\%$], [resorcinol $\geq 99\%$], were purchased from Sigma-Aldrich (Germany). Melting points were measured with open capillary tubes in the device BUCHI 510. Infrared (IR) spectroscopy was conducted on a PerkinElmer GX FT-IR spectrometer. Nuclear magnetic resonance spectra have been reported in DMSO- d_6 with ppm chemical displacement. Mass spectrometer was recorded in a spectrometer Shimadzu QP 1100 BX. The thermal properties of the samples were conducted using a thermogravimetric analyzer (TGADSC/Mettler Toledo) ranging from room temperature to $600\text{ }^\circ\text{C}$ at a rate of $10\text{ }^\circ\text{C min}^{-1}$ under N_2 atmosphere.

2.2. Preparation of Fe_3O_4 MNPs

First, $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ (5.83 g) and $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ (2.147 g) were dissolved in 100 mL of deionized water and subjected to magnetic stirring at $80\text{ }^\circ\text{C}$ for 10 min. Then 10 mL of ammonia solution (25% aqueous) was added to the reaction mixture for 30 min. To prepare Fe_3O_4 nanoparticles, the reaction was refluxed for 10 h. Then, the suspended Fe_3O_4 nanoparticles were separated by an external magnet and washed with distilled water and ethanol, and dried in an oven at $80\text{ }^\circ\text{C}$ for 12 h.^{13a}

2.3. Synthesis of poly(triazine-benzene sulfonamide) (PTBSA)

A mixture of melamine (0.7 mmol) and benzene-1,3-disulfonyl chloride (1 mmol) monomers was refluxed in dry acetonitrile (40 mL) for 12 h. The resulting PTBSA precipitate was washed with acetonitrile and subsequently dried in a vacuum oven at $60\text{ }^\circ\text{C}$ (Scheme 1).

2.4. Synthesis of Fe_3O_4 @PTBSA nanocomposite

To 100 mL acetonitrile, a mixture of Fe_3O_4 NPs (1 g) and poly(triazine-benzene sulfonamide) (1 g) was added and refluxed for 24 h. Fe_3O_4 @PTBSA were separated by an external magnet, washed with acetonitrile and subsequently dried in a vacuum oven at $60\text{ }^\circ\text{C}$ (Scheme 1).

2.5. Synthesis of Fe_3O_4 @PTBSA- SO_3H

In order to sulfonation of Fe_3O_4 @PTBSA, 1.0 g of prepared nanocomposite was dispersed in 20 mL of dichloromethane and chlorosulfonic acid (10 mmol) was slowly added. The pre-synthesized Fe_3O_4 @PTBSA- SO_3H were then stirred for 24 h. The resulting catalyst (Fe_3O_4 @PTBSA- SO_3H) were separated by an external magnet, washed thoroughly with dichloromethane (20 mL) and dried.

2.6. Preparation of calixresorcurene derivatives using Fe_3O_4 @PTBSA- SO_3H

A mixture of resorcinol (5 mmol), benzaldehyde derivatives (5 mmol), and Fe_3O_4 @PTBSA- SO_3H catalyst (0.2 g) was added in a mortar and pestle and ground vigorously at room temperature. After reaction completion (monitored by TLC, *n*-hexane/ethyl acetate, 10 : 4), the catalyst was separated from the reaction mixture by an external magnet and washed with hot ethanol. After solvent evaporation, the crude product was crystallized in ethanol, and the product was obtained with good efficiency.

3 Results and discussion

3.1. Analysis of catalyst characterization data

Fig. 1 represents the FTIR spectra of the samples. According to the results of the spectrum pattern, Fe–O vibrations have been observed in the wavelength of 427–627 cm⁻¹. The signals at around 3239 cm⁻¹ are related to vibrations of O–H functional groups (Fig. 1a). After modification of Fe₃O₄ NPs with PTBSA, the presence of new bands appeared at around 1115 and 1181 cm⁻¹ are attributed to the stretching vibrations of C–S and C–N in the polymer, respectively. Also, the absorption vibrational bands at 1650 and 1693 cm⁻¹ related to the N–H and C=N bands of the polymer. In addition, the vibration of N–S, S=O bands was found at 1528 cm⁻¹ and the broad absorption band between 3339–33 590 cm⁻¹ is mainly due to the N–H and O–H bonds (Fig. 1b). These approved the successful

modification of Fe₃O₄ MNPs with PTBSA. In the case of Fe₃O₄@PTBSA-SO₃H, new adsorption bands related to chlorine and SO₃H as well as all the above characteristic absorption bands were observed in the nanocomposite structure (Fig. 1c).

The XRD pattern of Fe₃O₄@PTBSA-SO₃H is shown in Fig. 2. The XRD spectrum of Fe₃O₄@PTBSA-SO₃H sample contains all characteristic peaks of both Fe₃O₄ NPs, polymer and chlorosulfonic acid, which is indicative of the successful combination and simultaneous presence of both organic and inorganic phases in the nanocomposite texture. Three distinct peak values observed at 2θ angle are 38.9°, 44.4°, and 60°, which are also related to the Fe₃O₄ MNPs.^{13b} The diffraction peaks at 2θ angles of 25°, 26.7° and 28.4° confirmed the presence of SO₃H groups.³⁵ Additionally, the peak observed at 42.65°, 18.5°, 9.45° and 21.65° is attributed to the PTBSA.³⁶ Through the Scherrer formula, the average particle size is found to be 6.81 nm (Fig. 2).

The surface morphologies of the samples were observed by the FESEM technique and are shown in Fig. 3. The bulk polymer structure of the pure PTBSA is given in Fig. 3a; the soft, polymeric surface of the TBSA is well visible. Surface morphologies of the Fe₃O₄@PTBSA and Fe₃O₄@PTBSA-SO₃H are shown in Fig. 3b and c. The formation of sub-micrometer-sized poly TBSA and the presence of Fe₃O₄ NPs on the surface of the Fe₃O₄@PTBSA and Fe₃O₄@PTBSA-SO₃H can be observed, indicating the growth and formation of PTBSA after surface modification of Fe₃O₄ MNPs. The simultaneous presence of both Fe₃O₄ MNPs and polymer matrix can be observed in the FESEM images of Fe₃O₄@PTBSA and Fe₃O₄@PTBSA-SO₃H nanocomposite (Fig. 3b and c), indicating the successful combination of Fe₃O₄ core and PTBSA polymeric matrix for preparation of nanocomposite structure. According to the Fe₃O₄@PTBSA-SO₃H particle size distribution, most particles are 40 nm (Fig. 3d). Also, the images obtained from TEM image are shown, that the nanocatalyst Fe₃O₄@PTBSA-SO₃H has a core-shell structure and a uniform spherical morphology of 30 nm (Fig. 4).

Fe₃O₄@PTBSA-SO₃H was analysed using EDX as shown in Fig. 5. The presence of Fe, O, N, S and Fe signals in Fig. 5 indicates that the iron oxide particles are coated with PTBSA. The characteristic peak of Cl in Fig. 5 indicate that the Fe₃O₄@PTBSA have been immobilized with chlorosulfonic acid.

According to this analysis, we conclude that Fe₃O₄@PTBSA-SO₃H has been successfully synthesized. Elemental mapping images of nano-Fe₃O₄@PTBSA-SO₃H, shows the elements of Cl, C, N, Fe, S and O in the framework of catalyst with a uniform distribution (Fig. 6).

Fig. 7 shows the magnetic properties of the catalyst as determined using VSM. According to the figure, the amount of saturated magnetization (M_s), coercivity field (H_c), remanent magnetization (M_r) for Fe₃O₄@PTBSA-SO₃H are 3.26 emu g⁻¹, 30 Oe and 0.26 emu g⁻¹, respectively. Also, due to the s-shape of the curve and the H_c values, the synthesized materials are supermagnetic. The value is quite reduced from the bare unmodified ferrite NPs due to the surface functionalization by SO₃H groups and the polysulfonamide around it.^{13b}

Thermal properties of the nanocomposite were investigated by thermal gravimetric analysis (TGA) and differential scanning calorimetry (DSC). The TGA curve of Fe₃O₄@PTBSA-SO₃H shows the mass loss of the organic materials as they decompose upon heating (Fig. 8). TGA curve of Fe₃O₄@PTBSA-SO₃H can be divided into several regions corresponding to different mass loss ranges. The first region, situated below 200 °C, displays a mass loss that is attributed to loss of trapped water or adsorbed solvent from the catalyst. The weight loss at higher temperature can be mainly ascribed to the evaporation and

Scheme 3 The plausible mechanism for the synthesis of calixresorcarenes using $\text{Fe}_3\text{O}_4@PTBSA-SO_3H$.

subsequent decomposition organic groups. Thus, the catalyst is stable up to $600\text{ }^\circ\text{C}$, establishing that it could be safely used in organic reactions at temperatures in the region of $200\text{ }^\circ\text{C}$. According to Fig. 8, as mentioned, the material is decomposed in 4 steps. In the first stage at $60.87\text{ }^\circ\text{C}$, the second stage at $124.37\text{ }^\circ\text{C}$, the third stage at $390.21\text{ }^\circ\text{C}$ and finally at $473.11\text{ }^\circ\text{C}$, it loses 76.29% of its weight. The glass transition occurs at $173\text{ }^\circ\text{C}$. According to TG/DSC analysis, $\text{Fe}_3\text{O}_4@PTBSA-SO_3H$ nanocomposite is decomposed in 4 steps. In the first stage at $131.4\text{ }^\circ\text{C}$, the second stage at $251\text{ }^\circ\text{C}$, the third stage at $373.2\text{ }^\circ\text{C}$ and finally at $438.9\text{ }^\circ\text{C}$, it loses 40.3% of its weight (Fig. 9).

3.2. Titration for the determination of SO_3H group density

In order to compare the synthesized catalyst with the literature reported magnetic catalysts with SO_3H group, surface density of the SO_3H groups was determined using back titration method.

According to back titration method, surface high density functional group is 12 mmol per H^+ per g.

3.3. Catalytic studies

After the full characterization of prepared $\text{Fe}_3\text{O}_4@PTBSA-SO_3H$ nanocomposite, we evaluated its catalytic efficiency for the synthesis of 2,8,14,20-tetraphenyl-4,6,10,12,16,18,22,24-octahydroxycalix[4]-resorcarene (3a). The venture was started with the optimization of the reaction conditions and thereby the influence of an array of parameters like solvents, catalysts with their loads and temperature for the model reaction. Table 1 displays the corresponding results. The reaction was not successful without the catalyst (entry 1), thus signifying its

importance. To investigate the effect of the catalyst concentration, systematic studies were carried out in the presence of various amounts of the nanocatalyst (entries 2–6). Thus, the best yield is found in the presence of just 0.2 g of $\text{Fe}_3\text{O}_4@PTBSA-SO_3H$ (entry 5), and the use of higher amounts of catalyst up to 0.25 g does not improve the result (entry 6). Thereafter, we optimized the ideal solvent in the reaction by screening the probe in different solvents like EtOH, DMF, toluene and CH_3CN (entries 7–10). The results indicated that solvent-free condition play an important role in the reaction efficiency. Considering the model reaction at different temperature (entry 11), the room temperature is the best temperature that affects the progress of the model reaction process (entry 5).

Fig. 10 Recycling of the $\text{Fe}_3\text{O}_4@PTBSA-SO_3H$ for the reaction of benzaldehyde and resorcinol.

Fig. 11 Zeta potential of Fe₃O₄@PTBSA MNPs.

In order to study the effect of surface modification on the reaction progress, Fe₃O₄ MNPs, Fe₃O₄@PTBSA, PTBSA-SO₃H and PTBSA was used to carry out the same model reaction and none of them produced satisfactory results (Table 2). Therefore, Fe₃O₄@PTBSA-SO₃H has a larger surface area for catalytic reactions and higher efficiency.

With the optimized condition in hand, we then investigated the reactions scope, not only with unsubstituted substrates but

also with a wide range of substrates bearing electron withdrawing and electron-donating functional groups. The reactions proceeded smoothly, affording calixerane derivatives in moderate to good yields (Table 3).

A probable mechanistic sequence for the formation of calixresorcarenes catalyzed by Fe₃O₄@PTBSA-SO₃H is presented in Scheme 3. It is assumed that during the course of reaction, the nucleophilic addition of resorcinol to activated benzaldehyde

Fig. 12 Zeta potential of Fe₃O₄@PTBSA-SO₃H MNPs.

Table 4 Comparison of the present methodology with other reported catalyst for the synthesis of 2,8,14,20-tetraphenyl-4,6,10,12,16,18,22,24-octahydroxycalix[4]-resorcinarene (**3a**)

Entry	Conditions	Yield (%) [Ref]
1	Stage 1: recoreinol with hydrogenchloride in ethanol; water at 70 °C; for 1 h Stage 2: benzaldehyde in ethanol; water for 8 h; Reflux	94 (ref. 38)
2	Yttrium(III) nitrate hexahydrate in neat (no solvent) at 120 °C; for 0.25 h	92 (ref. 34)
3	Toluene-4-sulfonic acid in ethanol at 20 °C; for 1 h	85 (ref. 28)
4	Fe ₃ O ₄ @PTBSA-SO ₃ H (0.2 g), grinding condition in solvent-free, R.T., 5 min	92 [this work]

by Fe₃O₄@PTBSA-SO₃H leads to the formation of intermediate (**A**). By leaving the water, the intermediate **A** is converted to the intermediate (**B**), and then intermediate (**C**) is obtained. By performing the steps described above, the desired final product is synthesized (Scheme 3).

To explore the stability and recyclability of Fe₃O₄@PTBSA-SO₃H, the synthesized nanocatalyst was examined for six runs in the synthesis of C-phenilcalix[4]resorcinarene (**3a**) under the optimized reaction conditions. The observed slight decrease in the activity during the sixth runs of the recycling experiments was due to the absorption/adsorption of the reactants/products in the channels or on the surface of the Fe₃O₄@PTBSA-SO₃H (Fig. 10) (92, 92, 90, 89, 87, 85%).

Surface charge of the prepared magnetic Fe₃O₄@PTBSA and Fe₃O₄@PTBSA-SO₃H were estimated using zeta potential measurements. The zeta potentials of Fe₃O₄ MNPs is -10.63 mV.³⁷ As shown in Fig. 10 and 11, the zeta potentials of Fe₃O₄@PTBSA and Fe₃O₄@PTBSA-SO₃H are -23.0 and -13.3 mV, respectively. Zeta potential measurements indicate the successful coating of magnetite nanoparticles. The increase in the negative charge density of the Fe₃O₄@PTBSA is attributed to the presence of the triazine groups (Fig. 11) and the decrease in the negative charge density on the surface of Fe₃O₄@PTBSA is attributed to the presence of the chlorosulfonic acid groups (Fig. 12).

The efficiency of Fe₃O₄@PTBSA-SO₃H as a catalyst for the synthesis of the model compound **3a** was compared with that of other catalysts reported in the literature (Table 4). It is clear from this table that Fe₃O₄@PTBSA-SO₃H is a more efficient catalyst for the synthesis of calixresorcinarenes. Many SO₃H groups of the catalyst provide efficient acidic sites and good catalytic activity of Fe₃O₄@PTBSA-SO₃H. Compared to the other catalysts, Fe₃O₄@PTBSA-SO₃H provides short reaction times, simple isolation of products, high to excellent yields, stability of the catalyst and its easy magnetic separation and re-use with no significant loss of activity.

4 Conclusions

The main goal of the current study was to design and synthesis of a novel magnetic polysulfonamide based nanocatalyst (Fe₃-O₄@PTBSA-SO₃H). The synthesized sample was characterized with different instrumental techniques including FE-SEM, TEM, XRD, FT-IR, and VSM to gain an in-depth insight into the physicochemical features of the synthesized catalyst. To

evaluate the effectiveness of this material in practical use the catalytic performance of the Fe₃O₄@PTBSA-SO₃H nanocomposite toward synthesis of novel calixresorcinarenes was monitored. The results of this study revealed that Fe₃O₄@PTBSA-SO₃H nanocomposite can be utilized as a highly efficient catalyst for green synthesis of calixresorcinarenes.
