## Abstract

A new species of *Nicon* Kinberg, 1866 from the east Pacific coast of Ecuador is described. The new species is characterized by a long, thin dorsal ligule on median and posterior parapodia and infracircular sesquigomph falcigers in the neuropodia. A key to all species of *Nicon* is provided.

## Keywords

Annelida, polychaetes, Nereididae, intertidal, Ecuador, taxonomy, systematics

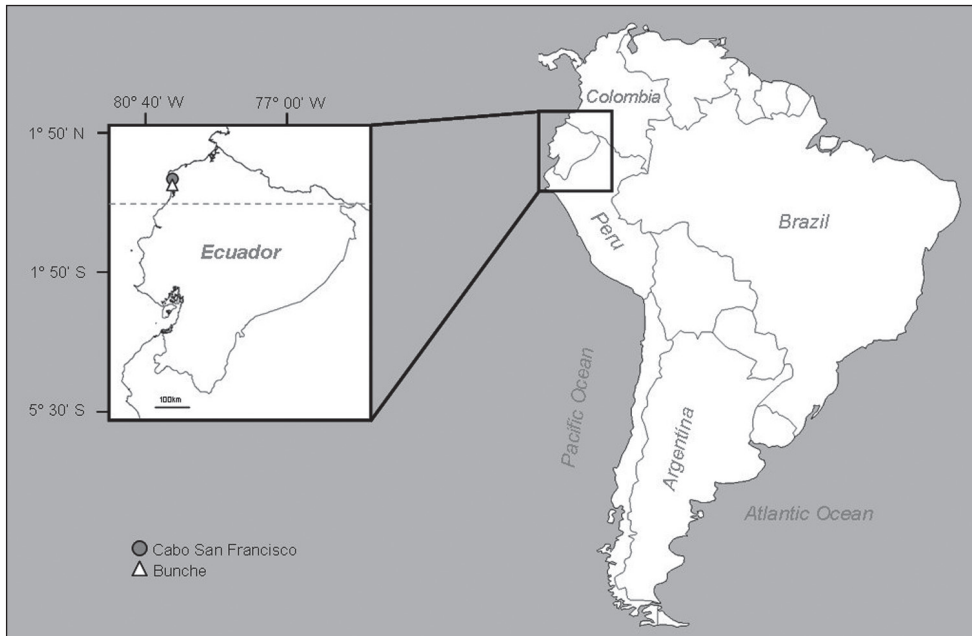

## Introduction

Ecuador possesses a great variety of coastal environments resulting in a high diversity of marine species; however, taxonomic studies on marine invertebrates are few, especially in the case of the polychaetes. In Ecuador (excluding the Galapagos), only 29 families, 53 genera and 75 species of polychaetes have been recorded. Hartman (1939) was the first to report on the polychaetes from Ecuador and described four new species and ten new records from Puna and Santa Clara Islands (Guayas Province). Later, Cruz et al. (1980) provided four new records from benthic samples collected on the Estero Salado, Guayaquil Gulf. In the same Gulf, 29 species of polychaetes were identified by Villamar (1983). Villamar (1989) later reported marine species at Canal del Morro and Jambeli in the Guayaquil Gulf. Villamar and Cruz (2007) reported three taxa for Ecuador from the intertidal zone of Monteverde (Guayas Province). A new species of *Australonuphis*, used as fishing bait, was described by de León-González et al. (2008) in Santa Elena Bay (Guayas Province). In northern Ecuador very little is known about the polychaete fauna and only one ecological study has been carried out by Villamar (2006) in the intertidal zones of Manabi and Esmeraldas Provinces. In that paper he reported 27 species, of which 14 constituted new records for Ecuador. More recently, Trovant et al. (2012) reported 12 new species records in the Bunche and Cabo San Francisco intertidal sandy beaches of northern Ecuador (Esmeraldas Province).

The importance of the family Nereididae is manifested by their high diversity and abundance in all marine substrates, occurring in all oceans from the supralittoral to the abyssal zone. This family includes 44 genera and approximately 460 valid species (de León-González, 2009). *Nicon* is one of the least species rich genera of Nereididae. The genus was first described by Kinberg, (1866) for six species, *N. pictus*, *N. tahitianus*, *N. maculata*, *N. eugeniae*, *N. loxechini* and *N. virgini*, none of which were figured. In this paper, a new species of *Nicon* is described. It is characterized by having an elongate notopodial dorsal ligule, resembling a long cirrus on median and posterior parapodia, as well by the presence of sesquigomph falcigers in the neuropodia.

## Material and methods

Samples were collected in March 2009 (dry season) in the intertidal zone of two sandy beaches located in the Esmeraldas Province, northern Ecuador (Fig. 1). Bunche beach (0°37'55"N, 80°02'14"W) is a protected area characterized as a low energy beach, with soft sloping banks and very fine particle sand, and Cabo San Francisco beach (0°39'11"N, 80°04'10"W) is characterized as a high energy environment, subjected to frequent and severe storms, with high slopes. Fresh-water discharges affect both beaches. Sediment samples were sieved through a 1mm mesh. Specimens were fixed in 10% formalin and later preserved in 70% ethanol. Terminology of parapodial structures was taken from Bakken and Wilson (2005). Type material has been deposited in the Natural History Museum of Los Angeles County, Allan Hancock Foundation Polychaete Collection (LACM-AHF), and the Polychaetological Collection of the Universidad Autónoma de Nuevo León (UANL).

## Results

### Systematics

**Class Polychaeta** Grube, 1850

**Order Phyllodocida** Örsted, 1843

**Family Nereididae** Lamarck, 1818

***Nicon* Kinberg, 1866; emended**

<http://species-id.net/wiki/Nicon>

**Type species.** *N. maculata* Kinberg, 1866.

**Diagnosis.** Prostomium pyriform to subpyriform, with two pairs of eyespots, paired frontal antennae and biarticulate palps. Four pairs of tentacular cirri with distinct cirrophores, smooth or articulated. Parapodia of first two chaetigers subbi-ramous, notopodium represented by a single ligule with dorsal cirri at its base. Subsequent notopodia with dorsal and ventral ligules with or without a small notopodial prechaetal lobe decreasing in far posterior parapodia. Neuropodia with superior and inferior prechaetal lobes, digitiform or conical postchaetal lobe present or absent along body, and a ventral ligule which can be reduced in posterior parapodia; ventral cirri short, tapered. All notochaetae homogomph spinigers; neurochaetae homogomph, heterogomph or sesquigomph falcigers, may be accompanied by homogomph and heterogomph spinigers, and simple chaetae. Pygidium with paired anal cirri. Pharynx with paired mandibles, without paragnaths or papillae.

**Remarks.** This generic diagnosis was modified from Pettibone (1971), Wu and Sun (1979) and Hutchings and Reid (1990). Some important characteristics were not included by Pettibone (1971) because at that time she recognized *N. maculata* as the only member of the genus. Later on, Wu and Sun (1979) and Hutchings and Reid (1990) expanded the genus diagnosis including characters of recently described species such as *N. japonicus* Imajima, 1972, *N. yaguinae* Fauchald, 1972, *N. sinica* Wu & Sun, 1979 and *N. rotunda* Hutchings & Reid, 1990. Some new characters included in the present diagnosis are the presence-absence of a notopodial prechaetal lobe, and the occurrence of neuropodial sesquigomph falcigers.

***Nicon orensanzi* sp. n.**

Figures 2, 3

**Material examined.** Holotype (LACM-AHF 4999), Paratype (LACM-AHF 5000) and Paratype (UANL 7840) collected at Bunche beach (0°39'01.98"N, 80°03'55.01"W), Esmeraldas Province, Ecuador, March 21 2009, coll. Berenice Trovant and Santiago Tineo. Additional material: seven anterior fragments, same data as holotype; two complete specimens and three anterior fragments, Cabo San Francisco beach (0°38'16.35"N, 80°3'14.07"W), Esmeraldas Province, Ecuador, March 20 2009, coll. Berenice Trovant and Santiago Tineo.

**Description.** Holotype incomplete posteriorly, with 85 chaetigers, 19mm long, 1.4mm wide. Prostomium pyriform, with frontal cleft extending to middle of prostomium. Two pairs of eyespots in trapezoidal arrangement, anterior pair slightly larger, with lenses. Pair of small cirriform antennae extending slightly beyond palps. Palps biarticulate, globose, with subspherical palpostyles. Peristomium longer than next segment, with four pairs of short tentacular cirri, longest reaching chaetiger two (Figs 2A, 3A). Pharynx lacking papillae or paragnaths, armed with pair of toothed mandibles (Fig. 3B). Anterior notopodia with short cirriform dorsal cirri, subtriangular dorsal ligule, and subulate notopodial ventral ligule. Small triangular prechaetal lobe, restricted to limited number of anterior chaetigers, reducing in size posteriorly, last present about chaetigers 28–30. Anterior neuropodia with superior and inferior lobe, subulate ventral ligule, ventral cirrus with inflated base (Fig. 2B, 3C), postchaetal neuropodial lobe subulate, present in first 18 chaetigers, not visible in anterior view. Median and posterior notopodia with dorsal ligule long cirrus-like; prechaetal lobe absent, notopodial ventral ligule triangular, decreasing in size in posterior chaetigers. Median and posterior neuropodia with superior and inferior lobes poorly defined, neuropodial postchaetal lobe absent, neuropodial ventral ligule subulate, decreasing in size in posterior chaetigers until disappearing completely, ventral cirri cirriform, shorter than dorsal one (Figs 2C–D, 3D–E). All notochaetae homogomph spinigers, with long, thin blades. Anterior supracircular neurochaetae 6 long-bladed homogomph spinigers superiorly; 6 short-bladed

**Figure 2.** *Nicon orensanzi* sp. n. Holotype. **A** Anterior end, dorsal view **B** Parapodium 10, anterior view **C** Parapodium 25, anterior view **D** Parapodium 60, anterior view **E–G**. Infracicular sesquigomph falcigers of parapodia 10, 25 and 50 respectively. Scale bars: **A**= 1 mm; **B–D**= 100  $\mu$ ; **E–G**= 30  $\mu$ .

heterogomph spinigers inferiorly. Anterior infracicular chaetae homogomph spinigers with long blade, and sesquigomph falcigers with anterior part ending in a blunt tooth (Fig. 2 E). Median and posterior supracicular neurochaetae with long-bladed homogomph spinigers. Infracicular neurochaetae with a few homogomph spinigers superiorly, and sesquigomph falcigers inferiorly, anterior end sharper (Figs 2F–G, 3F). Pygidium lacking in holotype, with terminal anus and two thin lateral cirri on others specimens.

**Type locality.** Bunche beach, Esmeraldas Province, Ecuador

**Distribution.** This species is only known from Bunche and Cabo San Francisco beaches, Esmeraldas Province, Ecuador.

**Discussion.** Of the six species originally included in the genus *Nicon* by Kinberg (1866) two have been transferred to other genera (*N. eugeniae*, currently *Nereis eugeniae* from Strait of Magellan and *N. loxochini*, currently *Platynereis magalhensis* from Strait of Magellan) and three species are considered indeterminable due to their incomplete descriptions and the poor condition of the available syntypes (*N.*

*maculata* from La Plata, Argentina, *N. pictus* from Brazil, *N. tahitianus* from Tahiti, and *N. virginii* from Strait of Magellan) (Pettibone, 1971). Of these species, only *N. maculata* is considered valid at the present time. No type species was designated by Kinberg. Hartman (1949) designated *N. pictus* as the type species, even though she did not provide a diagnosis or figures. Pettibone (1971) later revised the genus and designated *N. maculata* as the type species. Currently this genus consists of ten species: *N. maculata* Kinberg, 1866 from La Plata, Argentina, *N. moniloceras* (Hartman, 1940) from Catalina Island, USA, *N. aestuarensis* Knox, 1951 from New Zealand, *N. polaris* Hartman, 1967 from the Antarctic peninsula, *N. abyssalis* Hartman, 1967

from the Antarctic peninsula, *N. japonicus* Imajima, 1972 from Japan, *N. yaquinae* Fauchald, 1977 from off the Oregon coast, USA, *N. sinica* Wu & Sun, 1979 from the Yellow Sea, *N. rotunda* Hutchings & Reid, 1990 from Australia, and *N. pettibonae* de León-González & Salazar-Vallejo, 2003 from the Loyalty Islands, New Caledonia. Pettibone (1971) also considered that *N. abyssalis* and *N. polaris* had doubtful generic affinities with *Nicon*; however, we believe that *N. abyssalis* possesses the generic characters of *Nicon* and therefore should be included in the genus. *Nicon polaris* was described based on an epitoke; however, the possession of an expanded elytra-shaped dorsal cirrus in the chaetiger 7 makes it doubtful that it belongs to *Nicon*; a similar structure is found in *Kainonereis*, currently a genus in *inquirenda* described from an epitokous stage by Chamberlin (1919).

Species of *Nicon* may be separated into two groups based on the presence or absence of notopodial prechaetal lobes. Those species with a notopodial prechaetal lobe are: *N. aestuarensis*, *N. japonicus*, *N. polaris*, *N. rotunda*, and *N. sinica*; while *N. abyssalis*, *N. maculata*, *N. moniloceras*, *N. pettibonae* and *N. yaquinae* lack a superior notopodial lobe. Some important characteristics of *Nicon* species are listed in Table 1.

*Nicon orensanzi* sp. n. is a member of the first group but differs in its long, thin notopodial dorsal ligule in median and posterior parapodia. *N. orensanzi* sp. n. and *N. pettibonae* are the only species in the genus with neuropodial infracicular sesquigomph falcigers in all parapodia. These two species differ in the shape of their sesquigomph falcigers, the presence of heterogomph falcigers, and a reduced dorsal ligule in the posterior parapodia of *N. pettibonae*.

**Table 1.** Diagnostic features of the species of *Nicon* (modified from Hutchings and Reid 1990). Abbreviations: TC= chaetiger number reached by longest tentacular cirri, ho sp= homogomph spinigers, he sp= heterogomph spinigers, ho f= homogomph falcigers, he f= heterogomph falciger, sf= sesquigomph falciger, DL= dorsal ligule, PL= Prechaetal lobe, ST= Subtriangular, SU= Subulate; DI= Digitate, CI= Cirriform, CO= Conical, E= Elongated.

Species	Neuropodial chaetae												
	Supracicular						Infracicular					Notopodia	
	TC	ho sp	he sp	ho f	he f	sf	ho sp	he sp	ho f	he f	sf	DL	PL
<i>N. abyssalis</i>	2	X	X	-	-	-	X	X	-	X	-	CI	-
