## Abstract

**Background:** The use of antibody–drug conjugates for the treatment of advanced-stage human epidermal growth factor receptor 2 (HER2)-low expression in breast cancer (BC) has shown prominent curative effects, which has led to increased academic interest. However, the role of HER2-low expression in the prognosis of BC remains controversial.

**Methods:** We conducted a systematic search of the PubMed, Embase, and Cochrane library databases and several oncology conferences until 20 September 2022. We used fixed- and random-effects models to calculate odds ratio (OR) or hazard ratio (HR) with 95% confidence interval (CI) for overall survival (OS), disease-free survival (DFS), progression-free survival (PFS), and pathological complete response (pCR) rates.

**Results:** Overall, 26 studies encompassing 677,248 patients were included in the meta-analysis. Patients with HER2-low BC showed significantly better OS than those with HER2-zero BC in the overall population (HR=0.90; 95% CI: 0.85–0.97) and hormone receptor-positive population (HR=0.98; 95% CI: 0.96–0.99), whereas no significant difference was observed in the OS of the hormone receptor-negative population ( $p > 0.05$ ). In addition, there was no significant difference in the DFS of the overall and hormone receptor-negative population ( $p > 0.05$ ), but better DFS than those with HER2-zero BC in the hormone receptor-negative population (HR=0.96; 95% CI: 0.94–0.99). There was also no significant difference in the PFS of the overall population, hormone receptor-positive, and hormone receptor-negative population ( $p > 0.05$ ). Patients with HER2-low BC had a lower pCR rate after neoadjuvant treatment than those with HER2-zero BC.

**Conclusions:** Compared to patients with HER2-zero BC, those with HER2-low BC had better OS in the overall population and hormone receptor-positive population, DFS in hormone receptor-positive population and lower pCR in the overall population. The biological differences between HER2-low and HER2-zero BCs, particularly in hormone receptor-positive patients, and the relationship between HER2-low expression status and prognosis need to be explored further.

**Keywords:** antibody–drug conjugates, breast cancer, HER2-low, overall survival, prognosis

Received: 31 October 2022; revised manuscript accepted: 21 January 2023.

## Introduction

The prognosis of patients with human epidermal growth factor receptor 2 (HER2)-positive breast cancer (BC) is remarkably improved after anti-HER2 therapy. In clinical practice, as there are no targeted drugs, low expression of HER2 has been

classified as HER2-negative to guide treatment. However, the recent development of antibody–drug conjugates (ADCs) has significantly improved the prognosis of patients with HER2-low BC.<sup>1,2</sup> Thus, HER2-low status in BC has received increasing attention worldwide.

HER2 is a tyrosine kinase receptor that belongs to the human epidermal receptor family and is encoded by the ERBB2 gene.<sup>3</sup> Current HER2 status assessment relies on immunohistochemistry (IHC) and *in situ* hybridization (ISH). If the IHC result is 0 or 1+, the cancer is considered HER2-negative. In recent years, most of the published data and ongoing clinical trials have defined HER2-low BCs as those with an IHC score of 1+ or 2+ with ISH result.<sup>4</sup> Few studies have shown significant differences in clinical and pathological characteristics between patients with HER2-low and HER2-zero BC. For instance, patients with HER2-low BC have higher histological grading, are positive for hormone receptor, and have lower proliferation index-67 (Ki-67) expression than those with HER2-zero BC. Moreover, HER2-low tumors tend to have more mutations in PI3K-Akt signaling pathway-related genes than HER2-zero tumors.<sup>1,5</sup>

Patients with HER2-low BC account for approximately 45%–55% of all patients with BC.<sup>6</sup> Because the biological behavior and clinical characteristics differ between patients with HER2-low and HER2-zero BC, researchers speculate that their prognosis may also be different. Many clinical studies have investigated the difference in prognostic outcome between patients with HER2-low and HER2-zero BC but have shown inconsistent and contradictory results. Therefore, we conducted a meta-analysis to explore the relationship between prognosis and HER2 expression status.

## Materials and methods

### Study objectives

The primary endpoint was to compare the overall survival (OS) of patients with HER2-low and HER2-zero BC. In subgroup analysis, hormone receptor-positive and hormone receptor-negative patients were compared in the HER2-low and HER2-zero cohorts, respectively. The secondary endpoint was to compare the disease-free survival (DFS) and progression-free survival (PFS) of patients with HER2-low and HER2-zero BC and conduct hormone receptor-positive and hormone receptor-negative subgroup analysis similar to that performed for OS. We also compared the pathological complete response (pCR) rates of patients with HER2-low and HER2-zero BC following drug treatment.

### Literature search

A systematic search for the relationship between HER2-low expression status and survival was conducted using sources such as PubMed, Embase, the Cochrane library, American Society of Clinical Oncology (ASCO) Meeting, European Society for Medical Oncology Meeting, San Antonio Breast Cancer Symposium, and the American Association for Cancer Research Meeting. The search terms were ‘HER2-low’ or ‘ERBB2-low’ or ‘human epidermal growth factor receptor 2 low’ and ‘breast cancer’ or ‘breast neoplasm’ and ‘prognosis’ or ‘survival outcome’ and ‘overall survival’ or ‘disease-free survival’ or ‘progression-free survival’. Further details of the search strategy are shown in Supplemental eTable 1. Based on the latest definitions of HER2 from the 2018 ASCO and College of American Pathologists, HER2-low expression status was defined as an IHC score of 1+ or 2+ and an ISH result of non-amplified status (ISH–), whereas HER2-zero expression status was defined as an IHC score of 0.<sup>7</sup> The preliminary screening was performed by carefully reading the titles and abstracts of English manuscripts, before determining whether they could be included after reading the full text. Manuscripts were searched until 20 September 2022. The Preferred Reporting Items for Systematic Reviews and Meta-analyses guidelines were used to conduct this meta-analysis.<sup>8</sup>

### Inclusion and exclusion criteria

The inclusion criteria were as follows: (1) titles with HER2-low or HER2-zero in either early or advanced BC; (2) recorded odds ratios (OR) and hazard ratios (HR) with 95% confidence intervals (CI) of random survival data in the full text; and (3) either hormone receptor-positive or hormone receptor-negative data. The exclusion criteria were as follows: (1) meta-analyses, reviews, and duplicate studies and (2) only the comparative analysis of HER2 IHC score of 2+ *versus* 0/1+.

### Data extraction

The data extracted for each study included the name of the first author, journal name, publication year of journal, type of study, sample size, median follow-up time, OS, DFS/recurrence-free survival (RFS; the DFS and RFS were combined into one category owing to their similar meanings), PFS, and pCR rates. We also extracted data from hormone receptor-positive and hormone receptor-negative populations of OS, DFS,

PFS, and pCR rates. The HRs and 95% CIs of the original data were clearly written in the results section in most articles. For some articles, we extracted the HRs and 95% CIs from Kaplan–Meier curves using GetData Graph Digitizer software. To ensure that the data were not duplicated, we chose to cite the peer-reviewed full text when the same patient population appeared in both the conference and the full text. Available data were independently extracted from each study by two authors (YT and ZL) and any disagreements were resolved through negotiation.

### Statistical analysis

Review Manager 5.4 software was used to generate forest and funnel plots. The HRs and 95% CIs of the original data were used to analyze the OS, DFS, and PFS. The heterogeneity of the data was determined based on  $p$  values and  $I^2$  value statistics. When  $p$  was  $<0.1$  or  $I^2$  was  $>50\%$ , the random-effects model was used; otherwise, the fixed-effects model was used ( $I^2 < 50\%$ ,  $p > 0.1$ ). A  $p$  value of  $<0.05$  (two-side) was considered statistically significant, and  $I^2 < 25\%$ ,  $I^2 = 25\text{--}50\%$ , and  $I^2 > 50\%$  were considered to indicate low, moderate, and high heterogeneity, respectively.<sup>9</sup> Sensitivity analysis was used to assess the stability of the results.

### Quality assessment

We used the Cochrane quality assessment tool to estimate the quality of the included studies. The risk of bias from six fields was determined, with each category comprising three levels, including ‘low risk’, ‘unclear risk’, and ‘high risk’.

## Results

### Identification of relevant studies

Figure 1 showed the screening process of relevant studies. We screened 2107 articles and 12 meeting abstracts, of which 26 were eventually included in the meta-analysis. All of the 26 studies were retrospective cohort studies and no prospective studies were reported up until 20 September 2022.

A total of 677,248 patients were included in our meta-analysis. Among them, 446,398 patients had HER2-low BC and 230,850 patients had HER2-zero BC. The main characteristics of the included studies are summarized in Table 1.

**Table 1.** Characteristics of 26 studies included in this meta-analysis.

**Figure 1.** PRISMA flow chart summarizing the study selection process. PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-analyses.

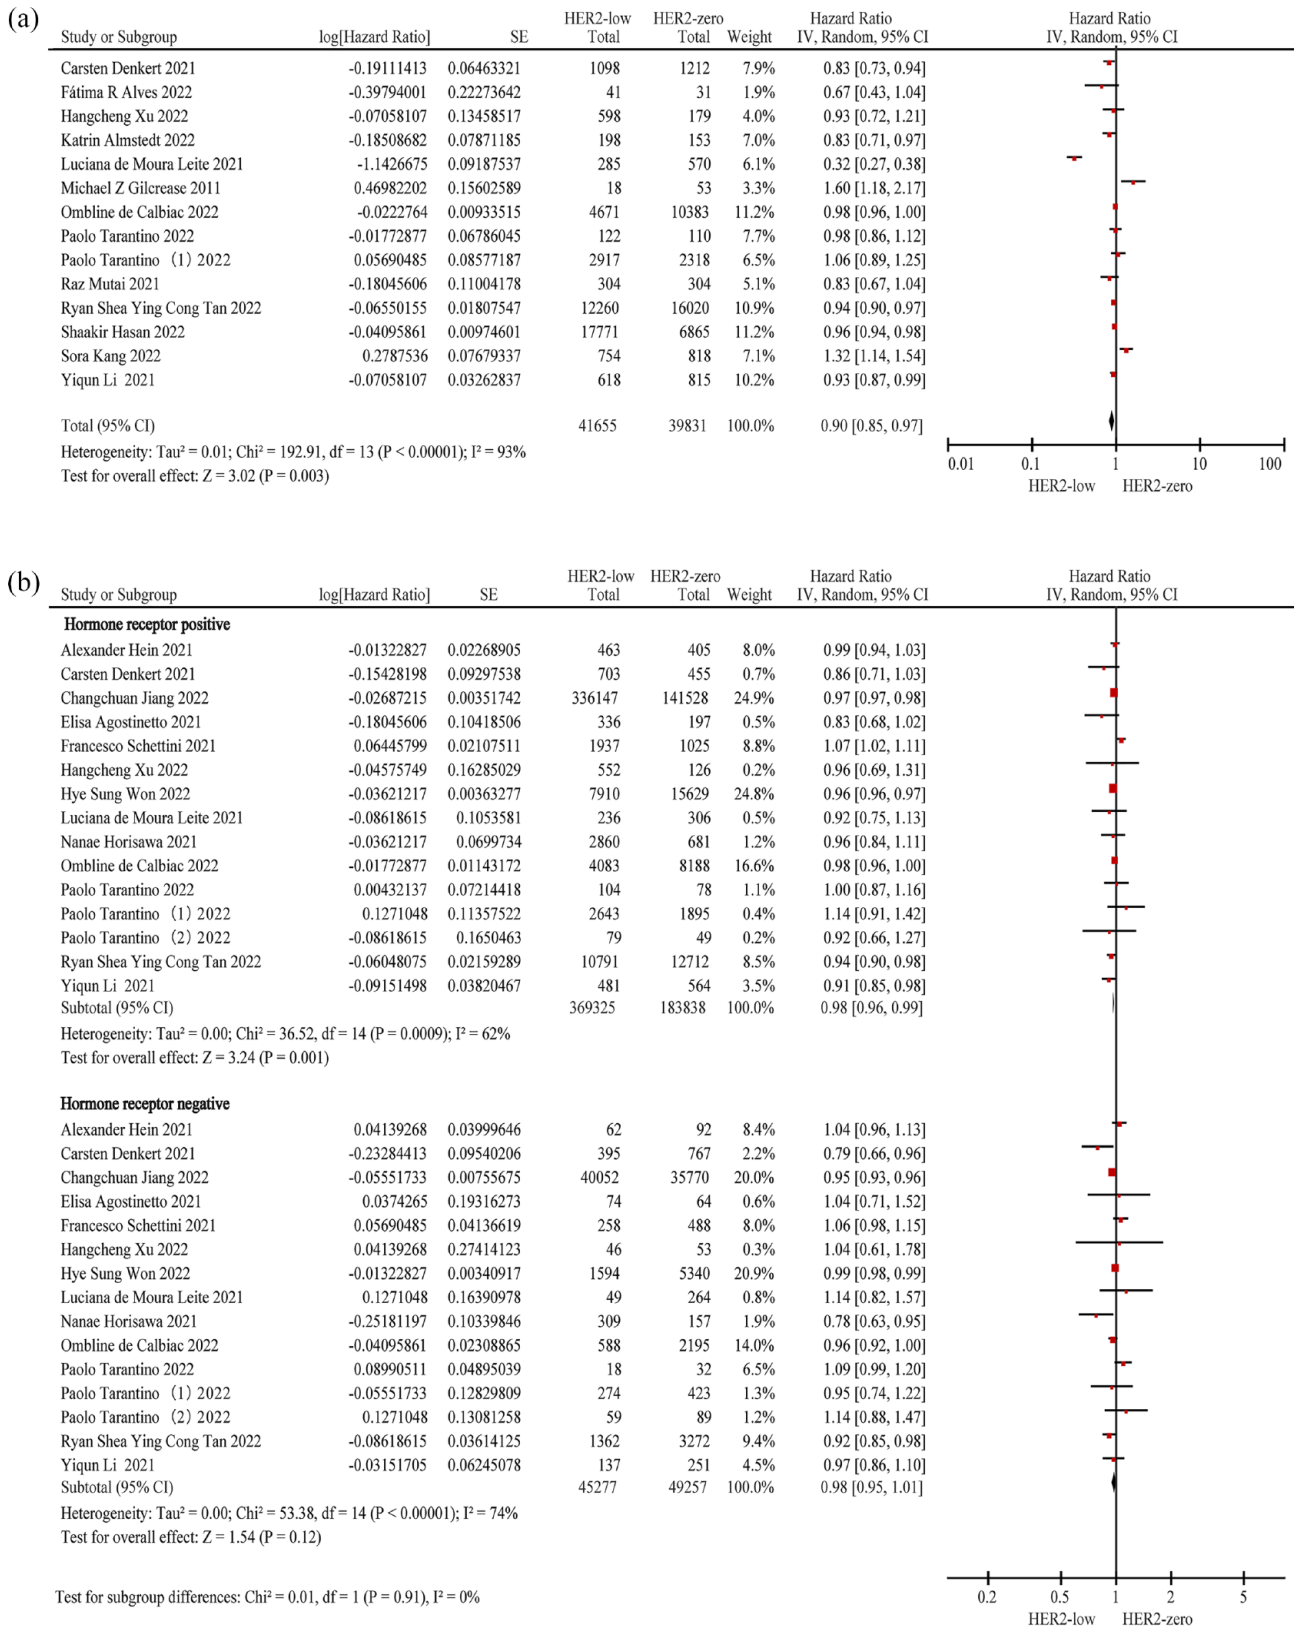

### *Comparison of OS between patients with HER2-low and HER2-zero BC*

*OS of the overall population.* In all, 14 studies<sup>3,4,12,15,18,20,22,23,25,26,28–30,32</sup> ( $n = 81,486$ ) were included to evaluate the OS of the overall population. The results demonstrated that patients with HER2-low BC had better OS than those with HER2-zero BC (HR = 0.90; 95% CI: 0.85–0.97;  $p = 0.003$ ), despite considerable heterogeneity between the studies ( $p < 0.01$ ;  $I^2 = 93\%$ ) (Figure 2(a); Table 2).

*OS of the hormone receptor-positive and hormone receptor-negative population.* We evaluated 15 studies<sup>4,10,12–14,16,18,19,22,24,25–28</sup>; 7 new studies<sup>10,13,14,16,19,24,27</sup> were included and 6 studies<sup>3,15,20,23,29,30</sup>

were excluded from evaluation of the OS of the overall population.

The OS results for the hormone receptor-positive ( $n = 553,163$ ) population were similar to those of the overall population; patients with HER2-low BC had better OS than those with HER2-zero BC (HR = 0.98; 95% CI: 0.96–0.99;  $p = 0.001$ ), with high heterogeneity observed in the hormone receptor-positive population ( $p < 0.01$ ;  $I^2 = 62\%$ ). In the hormone receptor-negative population ( $n = 94,534$ ), no significant difference in OS was observed between patients with HER2-low and HER2-zero BC (HR = 0.98; 95% CI: 0.95–1.01;  $p = 0.12$ ), and high heterogeneity was observed in

**Figure 2.** Forest plot of the OS of patients with HER2-low BC and HER2-zero BC in the overall population (a), hormone receptor-positive population and hormone receptor-negative (b) population. BC, breast cancer; HER2, human epidermal growth factor receptor 2; OS, overall survival.

**Table 2.** Pooled HRs and 95% CIs for OS, DFS, PFS about HER2-low versus HER2-zero in this meta-analysis.

Outcome	Population	No. of studies	HR (95% CI)	<i>p</i>	Heterogeneity		Effects model
					<i>I</i> <sup>2</sup> (%)	Ph	
OS	Overall	14	0.90 (0.85–0.97)	0.003	93	<0.01	Random
	Hormone receptor positive	15	0.98 (0.96–0.99)	0.001	62	<0.01	Random
	Hormone receptor negative	15	0.98 (0.95–1.01)	0.12	74	<0.01	Random
DFS	Overall	13	0.97 (0.92–1.02)	0.27	59	0.003	Random
	Hormone receptor positive	9	0.96 (0.94–0.99)	0.003	13	0.32	Fixed
	Hormone receptor negative	9	0.97 (0.94–1.00)	0.08	1	0.42	Fixed
PFS	Overall	3	1.06 (0.95–1.18)	0.34	63	0.07	Random
	Hormone receptor positive	3	1.00 (0.99–1.02)	0.79	0	0.63	Fixed
	Hormone receptor negative	3	0.98 (0.94–1.01)	0.15	49	0.14	Fixed

the hormone receptor-negative population ( $p < 0.01$ ;  $I^2 = 74\%$ ) (Figure 2(b); Table 2).

#### Comparison of DFS and PFS between patients with HER2-low and HER2-zero BC

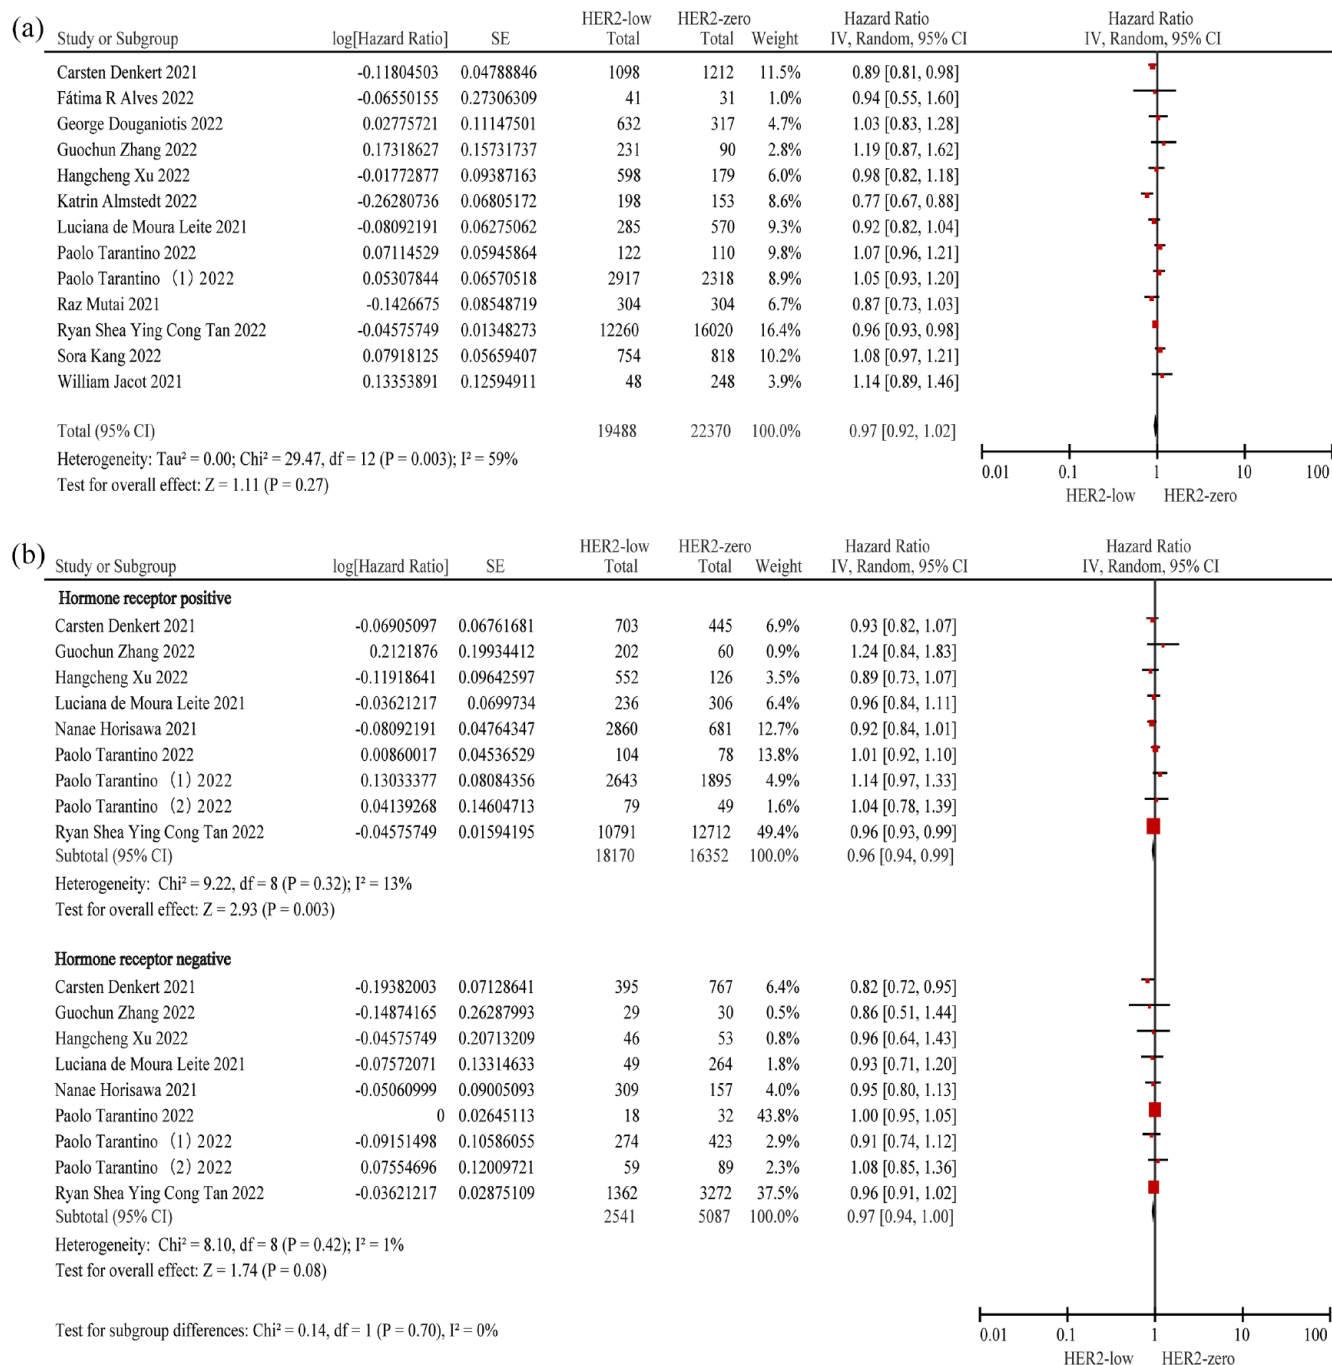

**DFS of the overall population.** A total of 13 studies<sup>3–5,12,15,17,18,20,22,26,28,31,30</sup> comprising 41,858 patients were included. No significant difference in DFS was observed between patients with HER2-low and HER2-zero BC (HR=0.97; 95% CI: 0.92–1.02;  $p=0.27$ ), and high heterogeneity was observed in the overall population ( $p=0.003$ ;  $I^2=59\%$ ) (Figure 3(a); Table 2).

**DFS of the hormone receptor-positive and hormone receptor-negative population.** In this subgroup analysis, we assessed nine studies<sup>4,5,12,18,22,24,26–28</sup> for the evaluation of DFS of the hormone receptor-positive ( $n=34,522$ ) and hormone receptor-negative ( $n=7628$ ) populations. To evaluate DFS, we included two new studies<sup>24,27</sup> and excluded six studies<sup>3,15,17,20,31,30</sup> from those considered for the evaluation of DFS of the overall population. Patients with HER2-low BC had better DFS than those with HER2-zero BC in the hormone receptor-positive populations (HR=0.96; 95% CI: 0.94–0.99;  $p=0.003$ ) as well as in the hormone receptor-negative population (HR=0.97; 95% CI: 0.94–1.00;  $p=0.08$ ). There was low heterogeneity

among studies included for the evaluation of DFS in the hormone receptor-positive and hormone receptor-negative populations (hormone receptor positive:  $p=0.32$ ;  $I^2=13\%$  and hormone receptor negative:  $p=0.42$ ;  $I^2=1\%$ ) (Figure 3(b); Table 2).

**PFS of the overall population.** Three studies<sup>4,21,25</sup> ( $n=15,392$ ) were included to evaluate the PFS of the overall population. No significant difference in PFS was observed between patients with HER2-low and HER2-zero BC (HR=1.06; 95% CI: 0.95–1.18;  $p=0.34$ ), with high heterogeneity observed among the studies ( $p=0.07$ ;  $I^2=63\%$ ) (Figure 4(a); Table 2).

**PFS of the hormone receptor-positive and hormone receptor-negative population.** Three studies<sup>4,10,25</sup> were included to determine the PFS of the hormone receptor-positive ( $n=13,321$ ) and hormone receptor-negative ( $n=2987$ ) population. We added one new study<sup>10</sup> and excluded one study<sup>21</sup> from those considered for the evaluation of PFS of the overall population. There was no significant difference in PFS between patients with HER2-low BC and HER2-zero BC in both the hormone receptor-positive and hormone receptor-negative populations (hormone receptor positive: HR=1.00; 95% CI: 0.99–1.02;  $p=0.79$ ; and hormone receptor negative: HR=0.98; 95% CI: 0.94–1.01;  $p=0.15$ ). Furthermore, there was

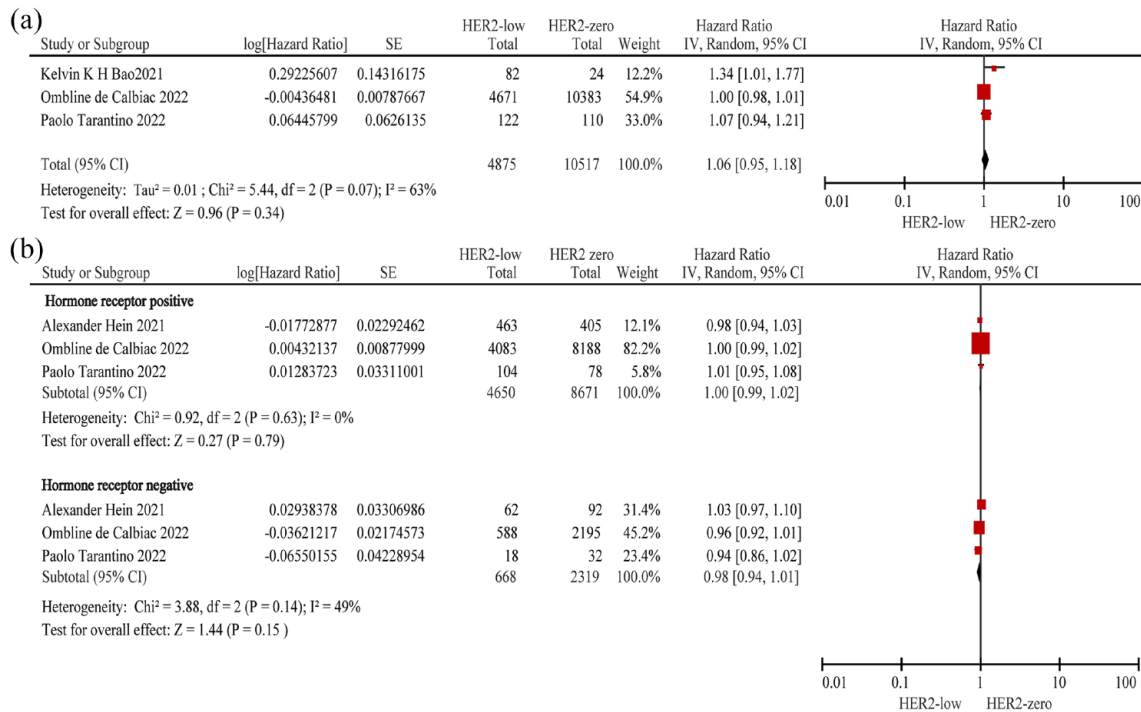

**Figure 3.** Forest plot of the DFS of patients with HER2-low BC and HER2-zero BC in the overall population (a), hormone receptor-positive population and hormone receptor-negative (b) population. BC, breast cancer; DFS, disease-free survival; HER2, human epidermal growth factor receptor 2.

no heterogeneity among the studies included for the evaluation of PFS in the hormone receptor-positive population ( $p = 0.63$ ;  $I^2 = 0\%$ ), but moderate heterogeneity was observed in the hormone receptor-negative population ( $p = 0.14$ ;  $I^2 = 49\%$ ) (Figure 4(b); Table 2).

*Comparison of pCR rates between patients with HER2-low and HER2-zero BC*  
PCR rate of the overall population. Eight studies<sup>5,11,12,15,17,26,27,30</sup> comprising 2757 patients with HER2-low BC and 2952 patients with HER2-zero BC were included to evaluate the difference

**Figure 4.** Forest plot of the PFS of patients with HER2-low BC and HER2-zero BC in the overall population (a), hormone receptor-positive population and hormone receptor-negative (b) population. BC, breast cancer; HER2, human epidermal growth factor receptor 2; PFS, progression-free survival.

in pCR rates. Patients with HER2-low BC had a lower pCR rate than those with HER2-zero BC (19.91% *versus* 30.18%; OR = 0.60; 95% CI: 0.53–0.68;  $p < 0.001$ ) (Figure 5).

#### Assessment of bias

The analysis of Cochrane risk assessment tools to estimate the risk of bias showed that the main problem we encountered in the evaluation was the high risk, as they had incomplete outcome data. Most of the studies were of moderate quality. The summary and funnel plot was used to estimate the publication bias were shown in Supplemental eFigure 2 and Supplemental eFigure 3.

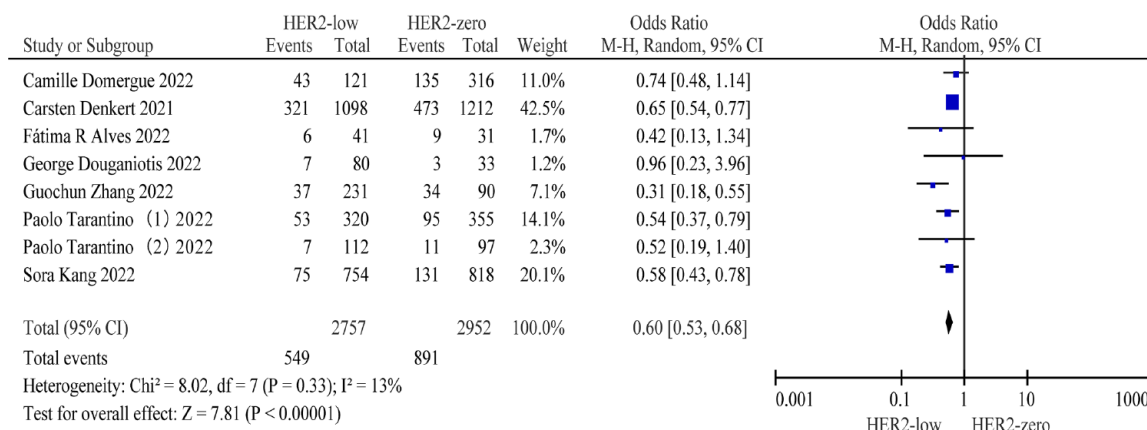

#### Discussion

To the best of our knowledge, this is the first meta-analysis to investigate the correlation between HER2-low and HER2-zero expression status and the prognosis of patients with BC. Our results demonstrated that patients with HER2-low BC had better OS in the overall and hormone receptor-positive populations, better DFS in the hormone receptor-positive populations and lower

pCR rates in the overall population than those with HER2-zero BC. Nevertheless, patients with HER2-low and HER2-zero BC had similar OS in the hormone receptor-negative population, similar DFS in the overall, and negative populations and similar PFS in the overall, hormone receptor-positive, and receptor-negative populations.

Previous prospective and retrospective studies have compared the outcomes between HER2 2+/ISH-negative patients and HER2 0/1+ patients.<sup>33–35</sup> Novel ADCs such as trastuzumab deruxtecan have exhibited high activity in HER2-low BCs, including IHC 1+ or IHC2+/ISH-negative BC, and most recent studies also use these criteria. This meta-analysis also defined HER2-low-positive status as IHC 1+ or IHC2+/ISH-negative and HER2-zero expression status as IHC 0 according to the ASCO/College of American Pathologists guidelines. As HER2-low BC accounts for approximately 50% of all BCs<sup>6</sup> and has significant heterogeneity,<sup>36</sup> it is necessary to clarify the association of HER2-low and HER2-zero expression status and with prognosis.

Considering that the included studies included both early- and metastatic-stage disease over a

**Figure 5.** Forest plot of the pCR of patients with HER2-low BC and HER2-zero BC in the overall population. BC, breast cancer; HER2, human epidermal growth factor receptor 2; pCR, pathological complete response.

long period (1985–2021), we used OS, DFS, and PFS as survival indices. The better OS observed for patients with HER2-low BC than for those with HER2-zero BC has several possible explanations. First, compared to patients with HER2-zero expression status, those with HER2-low expression status presented with more favorable clinical and pathological characteristics, such as a higher proportion of hormone receptor positivity rates,<sup>12,16,22,24</sup> lesser number of grade III tumors,<sup>37</sup> lower Ki-67 expression,<sup>37</sup> lesser recurrences of central nervous system and visceral complications,<sup>22</sup> and better performance status.<sup>32</sup> Second, hormone receptor-positive patients with HER2-low expression status were less likely to be older, have basal-like subtypes according to the PAM50 intrinsic subtypes, and more likely to be progesterone receptor-positive and have the luminal A subtype compared to hormone receptor-positive patients with HER2-zero expression status; in contrast, hormone receptor-negative patients showed no such differences but had a higher proportion of molecular apocrine-like profiles.<sup>18,19,31</sup> Third, HER2-low tumors harbor distinct clinical and molecular features, including reduced expression of TP53, increased expression of luminal-related genes,<sup>16</sup> reduced expression of androgen receptor,<sup>31</sup> reduced expression of proliferation-related genes and tyrosine kinase receptor genes,<sup>12,16</sup> and increase in mutations in the PI3K-Akt signaling pathway<sup>5</sup> compared with HER2-zero tumors. Lastly, patients with HER2-low expression status are more sensitive to some treatments, such as CDK4/6 inhibitors and PI3K-Akt signaling inhibitors, than patients with HER2-zero expression status, as they have a tendency to

have HER2-enriched intrinsic subtypes and PI3K-Akt signaling mutations but less basal-like subtypes.<sup>5,6,21,38,39</sup> Generally, these clinical, pathological, and molecular characteristics and the response to treatment are associated with hormone receptor-positive expression. This strongly suggests that hormone receptor status plays a crucial role in HER2-low BC and contributes to favorable clinical behavior and prognosis. In addition, the increased heterogeneity of PAM50 intrinsic subtypes between HER2-low and HER2-zero expression status in the hormone receptor-positive population compared with that in the hormone receptor-negative population partly accounts for the differences in prognosis of the two hormone receptor expression subgroups. Nevertheless, not all HER2-low BC characteristics are associated with better prognosis compared with HER2-zero BC. Indeed, several studies have shown that compared with HER2-zero expression status, HER2-low expression status is more common in patients who are overweight (body mass index  $\geq 25$  kg/m<sup>2</sup>) and is characterized by increased axillary lymph-node involvement, a higher proportion of stage IV disease,<sup>32</sup> and higher histological grade.<sup>16,19</sup> To date, the exact mechanisms underlying a favorable prognosis remain poorly understood.

Though the included studies are not identical in overall and subgroup analyses for DFS, patients with HER2-low and HER2-zero expression status showed similar DFS in the overall and hormone receptor-negative populations. No difference in PFS was observed between patients with HER2-low and HER2-zero expression status in

both the hormone receptor-positive and hormone receptor-negative populations. However, this result should be interpreted with caution because only three studies were included in this analysis. When combining these survival indicators, the better OS of patients with HER2-low expression status is likely because the early-stage hormone receptor-positive population comprised a large sample size, considering that this was the group of patients that showed different prognoses compared to those with HER2-zero expression status.

Moreover, patients with HER2-low expression status had a lower pCR to neoadjuvant treatment compared to those with HER2-zero expression status. This is likely related to the presence of more locally advanced tumors in patients with HER2-low expression status,<sup>16,39</sup> a low Ki-67 index, and lower proportion of grade III tumors<sup>28,40,41</sup> than in those with HER2-zero expression status as well as therapy resistance due to cross-talk between hormone receptor signaling and HER2 signaling.<sup>42</sup> Patients with both early and advanced stage BC were included in this meta-analysis, and advanced stage tumors were enriched for HER2-low expression compared to early stage tumors, which was shown to be due to the fact that there is an evolution of HER2 expression from early to advanced stage, with a small percentage of HER2 low transforming to HER2 zero, while the majority still transformed from HER2 zero to HER2 low. In addition, HER2 expression is also upregulated in patients with advanced disease after multiple lines of therapy.<sup>4</sup>

The strengths of the study include the fact that this is the first available meta-analysis to investigate the association of HER2-low and HER2-zero expression status with prognosis in BC, with a large sample of patients, the adoption of new HER2 definitions, and the inclusion of multiple survival endpoints. However, this study also has several limitations. First, all of the included studies were retrospective in nature or were retrospective analyses of prospective studies that may have bias. Second, as the subgroup analyses included only few studies, the results should be interpreted with caution. Third, the included studies showed some heterogeneity considering the lack of standardized criteria for the IHC evaluation of HER2 expression status, the difference in follow-up time, systemic treatment, and the extended study period.

## Conclusions

The results of this meta-analysis demonstrate that compared to patients with HER2-zero BC, those with HER2-low BC had better OS in the overall and hormone receptor-positive populations but similar OS in the hormone receptor-negative populations. HER2-low BC had better DFS in the hormone receptor-positive populations. In addition, patients with HER2-low expression status had similar DFS in the overall and hormone receptor-negative populations, similar PFS in the overall, hormone receptor-positive, and hormone receptor-negative populations, and a lower pCR rate in the overall population than patients with HER2-zero expression status. Further studies are needed to clarify the biological differences between HER2-low and HER2-zero BCs and the association between HER2-low expression status and prognosis.
