#### Abstract

Oxidation of zero-valent phosphine complexes $\left[M\left(P^{t} B u_{3}\right)_{2}\right] \quad(M=P d, P t)$ has been investigated in 1,2difluorobenzene solution using cyclic voltammetry and subsequently using the ferrocenium cation as a chemical redox agent. In the case of palladium, a mononuclear paramagnetic $P d^{I}$ derivative was readily isolated from solution and fully characterized (EPR, X-ray crystallography). While in situ electrochemical measurements are consistent with initial oneelectron oxidation, the heavier congener undergoes $C-H$ bond cyclometalation and ultimately affords the 14 valence-electron $P t^{I I}$ complex $\left[P t\left(\kappa_{P C}^{2}-P^{t} B u_{2} \mathrm{CMe}_{2} \mathrm{CH}_{2}\right)\left(P^{t} B u_{3}\right)\right]^{+}$with concomitant formation of $\left[\mathrm{Pt}\left(\mathrm{P}^{t} B u_{3}\right)_{2} \mathrm{H}\right]^{+}$.

0ver the past few decades a rich variety of chemistry has emerged based on the reactions of palladium and platinum complexes in the 0 and + II formal oxidation states, epitomized by the omnipresence of palladium catalyzed crosscoupling reactions in contemporary organic chemistry. ${ }^{[1,2]}$ In contrast, the organometallic chemistry of well-defined complexes of these elements bearing formal +I oxidation states is much less established and examples are largely limited to unstable or dinuclear species with distinct metal-metal bonds. ${ }^{[3,4]}$ Halogen bridged palladium complexes of the type $\left[\mathrm{Pd}(\mu-\mathrm{X})\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)\right]_{2}(\mathrm{X}=\mathrm{Br}, \mathrm{I})$ are notable examples and are believed to act as reservoirs for reactive $\left\{\mathrm{Pd}^{0}\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)\right\}$ fragments in catalytic transformations. ${ }^{[5]}$ In other systems, $\mathrm{Pd}^{\mathrm{I}}$ and $\mathrm{Pt}^{1}$ species have been postulated as intermediates, but with little supporting evidence. ${ }^{[6]}$ With a view to isolating welldefined mononuclear complexes in the +I oxidation state relevant to catalysis, we report herein our work involving one-

[^0]electron oxidation of widely used and commercially available palladium(0) and platinum(0) complexes of tri-tert-butylphosphine $\left[\mathrm{M}^{0}\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)_{2}\right](\mathrm{M}=\mathrm{Pd}, \mathbf{1} \mathbf{a} ; \mathrm{Pt}, \mathbf{1 b})$.

As a starting point we determined the redox potentials of 1a and 1b by cyclic voltammetry (CV) in the weakly coordinating solvent 1,2-difluorobenzene ( 0.2 M [ $\left.{ }^{\mathrm{B}} \mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{PF}_{6}\right]$ electrolyte, Figure 1). ${ }^{[7]}$ Reversible one-electron oxidation was observed at $E_{1 / 2}=-0.44 \mathrm{~V}(\mathbf{1 a})$ and $E_{1 / 2}=-0.10 \mathrm{~V}(\mathbf{1 b})$ relative to $\mathrm{Fc} /[\mathrm{Fc}]^{+}(\mathrm{Fc}=$ ferrocene $)$. The electrochemical characteristics of closely related cyclic alkyl(amino) carbene (CAAC) analogues have recently been studied by CV and the redox potentials of $\mathbf{1 a}$ and $\mathbf{1 b}$ are similar in magnitude to those found for $\left[\mathrm{M}^{0}(\mathrm{CAAC})_{2}\right](\mathrm{M}=\mathrm{Pd},-0.60 \mathrm{~V} ; \mathrm{Pt},-0.07 \mathrm{~V})$ in THF $\left(0.1 \mathrm{~m}\left[{ }^{\mathrm{B}} \mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{ClO}_{4}\right]\right) \cdot{ }^{[8]}$ Consistent with the generation of a stable $\mathrm{Pd}^{\mathrm{I}}$ species ( $\mathbf{2} \mathbf{a}$ ), the peak current ratios ( $i_{\mathrm{p}}^{\text {red }} / i_{\mathrm{p}}{ }^{\text {ox }}$ ) in the palladium voltammograms are essentially unity (ca. 0.99). Conspicuously lower ratios were observed for the platinum complex (ca. 0.90).

Figure 1. Cyclic voltammograms for the oxidation of $\mathbf{1 a}$ and $\mathbf{1} \mathbf{b}$ in 1,2 $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}_{2}$ (2 mm 1; $0.2 \mathrm{~m}\left[{ }^{\mathrm{n}} \mathrm{Bu}_{4} \mathrm{~N}\right]\left[\mathrm{PF}_{6}\right]$ electrolyte; glassy carbon working electrode, Pt counter electrode and Ag wire reference electrode; scan rates $=10,30,50,70$, and $100 \mathrm{mV} \mathrm{s}^{-1}$ ).

Encouraged by these data, $\mathbf{1}$ a was reacted with one equiv of $[\mathrm{Fc}]\left[\mathrm{PF}_{6}\right]$ in 1,2 -difluorobenzene at 293 K and dark blue $\left[\mathrm{Pd}^{\mathrm{I}}\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)_{2}\right]\left[\mathrm{PF}_{6}\right] \mathbf{2 a}$ was subsequently isolated in $92 \%$ yield following addition of $n$-pentane. The electrochemical characteristics of isolated 2a are equivalent to those measured in situ starting from 1a ( $E_{1 / 2}=-0.42 \mathrm{~V}$; see Supporting

Information). This new paramagnetic species was additionally characterized in solution using UV/Vis spectroscopy ( $\lambda_{\max }=$ 667 nm ), ESI-HRMS (positive ion mode, $510.2736 \mathrm{~m} / \mathrm{z}[\mathrm{M}]^{+}$; calculated $510.2740 \mathrm{~m} / \mathrm{z}$ ), and EPR spectroscopy. The EPR spectrum ( $1,2-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}_{2}$ glass at 200 K , Figure 2), shows a superposition of a single resonance at $g=2.316(5)$ with a lower intensity sextet arising from hyperfine coupling to ${ }^{105} \mathrm{Pd}$

Figure 2. The solid-state structure ${ }^{[22]}$ and EPR spectrum of $\mathbf{2 a}$ (1,2$\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}_{2}$ glass, 200 K , a.u. $=$ arbitrary units). ${ }^{[1]]}$ Ellipsoids are set at $50 \%$ probability; anion omitted for clarity. The starred atom is generated by the symmetry operation 1-x, 1-y, 1-z. Selected data: Pd1-P2 $2.3470(6) \AA$ A P2-Pd1-P2* 180 ${ }^{\circ}$, Pd1-P2-C3 $108.81(5)^{\circ}$.
( $I=5 / 2,22 \%$ abundance), corroborating formation of an $S=1 / 2 \mathrm{Pd}^{1}$ species. The unusually large ${ }^{105} \mathrm{Pd}$ hyperfine coupling of approximately 25 mT , and lack of resolved coupling to ${ }^{31} \mathrm{P}(I=1 / 2,100 \%$ abundance $)$ is consistent with strong localization of the unpaired electron spin on the Pd center. Complex 2a crystallizes in the high-symmetry cubic space group Pa $\overline{3}$ with the palladium atom on a center of inversion (Figure 2). In comparison to $\mathbf{1 a}$, the $\mathrm{Pd}-\mathrm{P}$ bond length is significantly elongated, from 2.285 (3) to $2.3469(6) \AA$ $(\Delta(\mathrm{Pd}-\mathrm{P})=+0.062(4) \AA)$; the P-Pd-P angles in both cases are symmetry enforced at $180^{\circ} \cdot{ }^{[9]}$ To the best of our knowledge, this is the first example of an unsupported twocoordinate $\mathrm{Pd}^{1}$ complex. A similar bond length elongation has been noted in closely related NHC complexes of $\mathrm{Ni}^{0} / \mathrm{Ni}^{1}$ $\left(\Delta\left(\mathrm{Ni}^{-}-\mathrm{C}\right)=+0.08(2) \AA\right) .{ }^{[10]}$ Isolated 2a is air-sensitive in solution, but shows good stability under an argon atmosphere. For instance, under argon the EPR spectrum intensity was essentially unchanged after 24 h at $293 \mathrm{~K}(15 \mathrm{~mm})$. However, slow degradation of $\mathbf{2 a}$ was observed by UV/Vis spectroscopy under high dilution conditions ( $t_{1 / 2} \approx 30 \mathrm{~h} ; 0.15 \mathrm{~mm}$ ), which we attribute to the presence of adventitious water as the rate of degradation increased significantly when water was added deliberately. Moreover, 2a can be stored in the solid-state in air ( 72 h ) with no evident change by UV/Vis spectroscopy.

When preparation of the analogous $\mathrm{Pt}^{1}$ complex $\mathbf{2 b}$ was attempted by reaction of $\mathbf{1 b}$ with one equiv of $\left[\mathrm{Fc}^{2}\right]\left[\mathrm{PF}_{6}\right]$, a 1:1 mixture of the new diamagnetic cyclometalated complex $\left[\mathrm{Pt}^{\mathrm{II}}\left(\kappa^{2}{ }_{\mathrm{PC}}-\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2} \mathrm{CMe}_{2} \mathrm{CH}_{2}\right)\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)\right]\left[\mathrm{PF}_{6}\right] \mathbf{3 b}$ and known $\mathrm{Pt}^{\mathrm{II}}$ hydride $\left[\mathrm{Pt}^{\mathrm{II}}\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)_{2} \mathrm{H}\right]\left[\mathrm{PF}_{6}\right] 4\left(\delta\left({ }^{1} \mathrm{H}\right)-36.30 \mathrm{ppm} ;{ }^{2} J_{\mathrm{PH}}=\right.$ $\left.8.6,{ }^{1} J_{\mathrm{PtH}}=2590 \mathrm{~Hz} ; \delta\left({ }^{31} \mathrm{P}\right) 86.3 \mathrm{ppm} ;{ }^{1} J_{\mathrm{PtP}}=2621 \mathrm{~Hz}\right)$ was formed within 15 min instead, as indicated by ${ }^{1} \mathrm{H}$ and

Scheme 1. Chemical oxidation of 1 b .
${ }^{31} \mathrm{P}$ NMR spectroscopy ( Fc observed; Scheme 1). ${ }^{[12]}$ This outcome suggests only transient stability of $\mathbf{2 b}$ in solution, with subsequent $\mathrm{C}-\mathrm{H}$ bond homolysis accounting for the divergence from fully reversible one-electron oxidation of $\mathbf{1 b}$ observed by CV. ${ }^{[13]}$ Reaction of $\mathbf{1 b}$ with two equiv of $[\mathrm{Fc}]\left[\mathrm{PF}_{6}\right]$ in the presence of excess hindered base 2,6-bis(decyl)pyridine (5 equiv), which is able to deprotonate $\mathbf{4}$, resulted in selective formation of 3b within 15 min . In this manner, $\mathbf{3 b}$ was isolated in $93 \%$ yield following successive crystallizations from $1,2-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}_{2}$ to remove ferrocene, excess base, and pyridinium salt. ${ }^{[13]}$ For comparison, no significant reaction was detected by ${ }^{1} \mathrm{H}$ or ${ }^{31} \mathrm{P}$ NMR spectroscopy on mixing of $\mathbf{1 b}$ and 2,6-bis(decyl)pyridine in 1,2-difluorobenzene at 293 K ( 24 h ) or heating 1b alone in 1,2-difluorobenzene at 353 K (24 h).

Two independent but structurally similar cations are observed in the solid-state structure of $\mathbf{3 b}$ (one is shown in Figure 3), both illustrating adoption of a T-shaped coordination geometry ${ }^{[14]}$ and cyclometalation of one of the tert-butyl substituents; these are identified by distinctly acute Pt1-P2-C3 angles $\left[90.0(3) / 89.5(3)^{\circ}\right]$ and $\mathrm{Pt} 1-\mathrm{C} 4$ bond lengths of $2.063(17) / 2.065(17) \AA$. The 3b cation is formally a 14 valence-electron (VE) complex, but is stabilized by adoption

Figure 3. Solid-state structures of $\mathbf{3 b}$ and 6. ${ }^{[22]}$ Ellipsoids are set at $50 \%$ and $30 \%$ probability, respectively; minor disordered components and anions omitted for clarity; only one of the two independent molecules is shown for $\mathbf{3 b}$. Starred atoms in $\mathbf{3 b}$ are generated by the symmetry operation $1-x, 2-y, 1-z$. Selected data 3 b : Pt1-P2 $2.297(2) \AA, \mathrm{Pt} 1-\mathrm{C} 42.063(17) \AA, \mathrm{Pt} 1 \cdots \mathrm{C} 4 \mathrm{~B}$ * 2.83 (2) Å; P2-Pt1-P2* $180^{\circ}$, Pt1-P2-C3/C3* 90.0(3) ${ }^{\circ}$. 6: Pt1-P2 2.235(2) Å, Pt1-C4 2.077(10) Å, Pt1-N15 2.080(7) Å, Pt1-N26 2.156(7) Å; P2-Pt1-N15 166.3(2) ${ }^{\circ}$, C4-Pt1-N26 175.4(3) ${ }^{\circ}$, Pt1-P2-C3 88.5(3) ${ }^{\circ}$.
of an agostic interaction between the non-cyclometalated phosphine ligand and Pt center ( $\mathrm{Pt} 1 \cdots \mathrm{C} 4 \mathrm{~B}$ $2.83(2) / 2.84(2) \AA)$. In solution, the structure of $\mathbf{3 b}$ was fully corroborated by NMR spectroscopy $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, 298 \mathrm{~K}\right)$. Formation of the metallacycle is apparent by distinctive ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ methylene resonances at $\delta\left({ }^{1} \mathrm{H}\right) 2.75 \mathrm{ppm}\left({ }^{2} J_{\mathrm{PtH}}=110 \mathrm{~Hz}\right)$ and $\delta\left({ }^{13} \mathrm{C}\right) 10.3 \mathrm{ppm}\left({ }^{1} J_{\mathrm{PtC}}=670 \mathrm{~Hz}\right)$ with platinum satellites, two doublet ${ }^{31} \mathrm{P}$ resonances with a large (trans) ${ }^{2} J_{\mathrm{PP}}$ coupling constant and platinum satellites ( $\delta\left({ }^{31} \mathrm{P}\right) 59.1 \mathrm{ppm}\left({ }^{1} J_{\mathrm{PtP}}=\right.$ $\left.2896 \mathrm{~Hz}, \quad{ }^{2} J_{\mathrm{PP}}=317 \mathrm{~Hz}, \quad \mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right), \quad \delta\left({ }^{31} \mathrm{P}\right) \quad 25.2 \mathrm{ppm} \quad\left({ }^{1} J_{\mathrm{PtP}}=\right.$ $\left.1916 \mathrm{~Hz},{ }^{2} J_{\mathrm{PP}}=317 \mathrm{~Hz}, \underline{\mathrm{P}}^{\mathrm{A}} \mathrm{Bu}_{2} \mathrm{CMe}_{2} \mathrm{CH}_{2}\right)$ ), and a platinum chemical shift of $\delta\left({ }^{195} \mathrm{Pt}\right)-3816 \mathrm{ppm}(225 \mathrm{~K})$. Although the signals associated with the non-cyclometalated phosphine ligand broadened on cooling to 185 K , the agostic interaction could not be definitively resolved by ${ }^{1} \mathrm{H}$ NMR spectroscopy.

Cyclometalation reactions of $\mathrm{Pt}^{\mathrm{II}}$ complexes have extensive precedent. ${ }^{[14 \mathrm{a}, 15]}$ For instance, T-shaped complexes $\left[\mathrm{Pt}^{\mathrm{II}}\left(\kappa^{2}{ }_{\mathrm{PC}}-\mathrm{PR}_{2} \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{MeCH}_{2}\right)\left(\mathrm{PR}_{2} \mathrm{Xyl}\right)\right]^{+} \quad(\mathrm{R}=\mathrm{Cy}, \mathrm{Ph} ; \mathrm{Xyl}=$ 2,6-dimethylphenyl) with similar structural and spectroscopic metrics compared to $\mathbf{3 b}$, were prepared by cyclometalation reactions involving halide abstraction from $\left[\mathrm{Pt}^{\mathrm{II}}\left(\mathrm{PR}_{2} \mathrm{Xyl}\right)_{2}(\mathrm{Me}) \mathrm{Cl}\right]$ and subsequent elimination of methane ${ }^{[16]}$ Intramolecular $\mathrm{C}-\mathrm{H}$ bond activation of $\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}$ in $\left[\mathrm{Pt}^{\mathrm{II}}\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)_{2} \mathrm{HX}\right]\left(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{OTf}, \mathrm{NO}_{2}\right)$ has also been described and results in coordinatively saturated products $\left[\mathrm{Pt}^{\mathrm{II}}\left(\kappa^{2}{ }_{\mathrm{PC}}-\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2} \mathrm{CMe}_{2} \mathrm{CH}_{2}\right)\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right) \mathrm{X}\right]$. ${ }^{[17]}$ In the case of 3b, the presence of a $\mathrm{Pt}^{\mathrm{II}}$ intermediate proceeding cyclometalation can be discounted on the basis of the electrochemical characteristics of $\mathbf{1 b}$. Instead the formation of $\mathbf{3 b}$ and $\mathbf{4}$ presumably occurs via concerted bimetallic (radical) oxidative addition, ${ }^{[18]}$ or proceeds through a common $\mathrm{Pt}^{\text {III }}$ alkyl hydride intermediate $\left[\mathrm{Pt}^{\mathrm{II}}\left(\kappa_{\mathrm{PC}}^{2}-\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2} \mathrm{CMe}_{2} \mathrm{CH}_{2}\right)\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right) \mathrm{H}\right]^{+}$ (5). In the latter case, subsequent comproportionation (5+ 2b), disproportion (via a $\mathrm{Pt}^{\mathrm{IV}}$ alkyl dihydride), or $\mathrm{Pt}-\mathrm{H}$ bond homolysis (i.e. $2 \times \mathbf{5} \rightarrow 2 \times \mathbf{3 b}+\mathrm{H}_{2} ; \mathbf{3 b}+\mathrm{H}_{2} \rightarrow \mathbf{4}$ ) would afford the observed 1:1 mixture of $\mathbf{3 b}$ and $\mathbf{4} .{ }^{[19]}$

Seeking to gain more insight into this mechanism, trapping of the postulated intermediate $\mathbf{5}$ was attempted by coordination of $2,2^{\prime}$-bipyridine (bipy). However, oxidation of $\mathbf{1 b}$ with either one or two equiv of $[\mathrm{Fc}]\left[\mathrm{PF}_{6}\right]$ in the presence of one equiv of bipy resulted in formation of a new cyclometalated complex $\left[\mathrm{Pt}^{\mathrm{II}}\left(\kappa^{2}{ }_{\mathrm{PC}}-\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2} \mathrm{CMe}_{2} \mathrm{CH}_{2}\right)(\right.$ bipy $\left.)\right]\left[\mathrm{PF}_{6}\right] 6$ instead, alongside protonated phosphine ( $\left.\delta\left({ }^{31} \mathrm{P}\right) 54.2 \mathrm{ppm}\right)$. The identity of this new complex was verified by independent synthesis from 3b and bipy in $1,2-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}_{2}(97 \%$ yield of isolated product). As with $\mathbf{3 b}$, the cyclometalated phosphine in $\mathbf{6}$ is characterized by an acute Pt1-P2-C3 angle (88.5(3) ${ }^{\circ}$ ) and bears a similar Pt1-C4 bond length of $2.077(10) \AA$ (Figure 3). Moreover, both solution and solid-state data are fully consistent with a coordinatively saturated metal complex. Notably, the substantially higher trans-influence of the methylene ligand is reflected in different $\mathrm{Pt}-\mathrm{N}$ bond lengths (Pt1-N15, 2.156(7) versus Pt1-N26, 2.080(7) $\AA$ ); the associated ${ }^{13} \mathrm{C}$ resonance shows a reduced ${ }^{1} J_{\mathrm{PtC}}$ coupling in comparison to $\mathbf{3 b}$ ( 580 versus 670 Hz ). Stronger $\mathrm{Pt}-\mathrm{P}$ bonding is apparent in $\mathbf{6}$ relative to $\mathbf{3 b}$, on the basis of a shorter $\mathrm{Pt}-\mathrm{P}$ bond (2.235(2) versus 2.297(2)/2.299(3) A), and a larger ${ }^{1} J_{\mathrm{PtP}}$ coupling constant determined by ${ }^{31} \mathrm{P}$ NMR spectroscopy (3105 versus 1916 Hz ). A platinum chemical shift of $\delta\left({ }^{195} \mathrm{Pt}\right)$
$-3788 \mathrm{ppm}(225 \mathrm{~K})$ was also measured for 6 and is very similar to that of $\mathbf{3 b}\left(\delta\left({ }^{195} \mathrm{Pt}\right)-3816 \mathrm{ppm}\right)$.

Reaction of isolated $\mathbf{3 b}$ with $\mathrm{H}_{2}(1 \mathrm{~atm})$ results directly in the formation of 4 , which is reconcilable with $\mathrm{Pt}^{-} \mathrm{H}$ bond homolysis or disproportion (via an unstable $\mathrm{Pt}^{\mathrm{IV}}$ alkyl dihydride intermediate) during the formation of $\mathbf{3} \mathbf{b} / \mathbf{4}$. However, the underlying mechanism is still not completely clear at this time. For instance, we cannot discount the formation of $\mathbf{3 b}$ through a pathway involving deprotonation of 5 (mediated by $\mathbf{1} \mathbf{b}^{[20]}$ or 2,6 -bis(decyl)pyridine) and a second one-electron oxidation. The redox potential of the associated $\mathrm{Pt}^{1} / \mathrm{Pt}^{\mathrm{II}}$ couple, assessed by CV experiments using both isolated 3b ( $E_{1 / 2}=-1.90 \mathrm{~V}$, irreversible) and $6\left(E_{1 / 2}=-1.68 \mathrm{~V}, i_{\mathrm{p}}{ }^{\mathrm{ox}} / i_{\mathrm{p}}\right.$ red $\approx 0.96$ ), indicates that such a one-electron oxidation is at least conceptually feasible using $[\mathrm{Fc}]\left[\mathrm{PF}_{6}\right]$ (see Supporting Information for CVs).

Motivated by the cyclometalation observed on oxidation of $\mathbf{1 b}$, we have also preliminarily investigated whether similar reactivity can be induced in the palladium analogue. Our studies are on-going, but we do note that reaction of $\mathbf{1 a}$ with two equiv of $[\mathrm{Fc}]\left[\mathrm{PF}_{6}\right]$ in the presence of excess 2,6-bis(decyl)pyridine (5 equiv) resulted in the gradual appearance of a diamagnetic complex with spectroscopic characteristics consistent with cyclometalation ( $\mathbf{3 a}$; $\delta\left({ }^{31} \mathrm{P}\right) 57.0,-1.3 \mathrm{ppm}$; $\left.{ }^{2} J_{\mathrm{PP}}=316 \mathrm{~Hz}\right) .{ }^{[21]}$ However, this species was only formed in situ in about $30 \%$ yield after 72 h at 293 K , as measured by NMR spectroscopy (using an internal standard), and the resulting reaction mixture has proved intractable so far to further characterization.

In summary, we have described a simple method for accessing the reaction chemistry of mononuclear palladium and platinum complexes bearing a +I formal oxidation state, as demonstrated by one-electron oxidation of [ $\mathrm{M}^{0}\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)_{2}$ ] ( $\mathrm{M}=\mathrm{Pd}, \mathrm{Pt}$ ) using $[\mathrm{Fc}]\left[\mathrm{PF}_{6}\right]$. While the $\mathrm{Pd}^{1}$ derivative was readily isolated from solution and fully characterized, the heavier congener undergoes $\mathrm{C}-\mathrm{H}$ bond cyclometalation to afford the 14 VE $\mathrm{Pt}^{\mathrm{II}}$ complex $\left[\mathrm{Pt}^{\mathrm{II}}\left(\kappa^{2}{ }_{\mathrm{PC}}-\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2} \mathrm{CMe}_{2} \mathrm{CH}_{2}\right)\left(\mathrm{P}^{\mathrm{A}} \mathrm{Bu}_{3}\right)\right]^{+}$with concomitant formation of $\left[\mathrm{Pt}^{\mathrm{II}}\left(\mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{3}\right)_{2} \mathrm{H}\right]^{+}$. Future work is focused on charting the reactivity and catalytic activity of these novel Group 10 species, and will be published in due course.

[11] EPR data were obtained using, 50 mW microwave power in a $\mathrm{TM}_{110}$ cavity at 9.51 GHz , with 0.5 mT field modulation at 100 kHz . The simulation was performed using EasySpin: S. Stoll, A. Schweiger, J. Magn. Reson. 2006, 178, 42-55. A minimal parameter set from esfit was used; $g_{\text {iso }}=2.3165, A_{\text {iso }}=24.976 \mathrm{mT}$, and phenomenological line broadenings of 9.8 mT (Gaussian) and 5.25 mT (Lorentzian). No attempt was made to extract the anisotropy of the magnetic interactions.
[12] R. G. Goel, R. C. Srivastava, Can. J. Chem. 1983, 61, 1352-1359.
[13] Following these reactions in situ ( 293 K ) by periodic analysis with EPR spectroscopy ( 200 K ) was uninformative when using $[\mathrm{Fc}]\left[\mathrm{BAr}^{\mathrm{F}}{ }_{4}\right]$ as a fully soluble ferrocenium salt. For context, $[\mathrm{Fc}]\left[\mathrm{BAr}^{\mathrm{F}}{ }_{4}\right]$ was EPR silent at 200 K as a component in reaction mixtures or in $1,2-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}_{2}$ alone.
