Purpose: Abnormal levels of lipid accumulation product (LAP) have been associated with risk of cardiovascular disease and diabetes. However, it is not clear whether LAP index is associated with diabetic retinopathy (DR). We investigated the association between LAP index and DR in Chinese adults with diabetes.

Patients and methods: We included 427 Chinese patients with type 2 diabetes aged 18-year over who participated in a community-based cross-sectional study in Shenyang. DR was addressed on retinal photographs graded using the modified Airlie House classification. LAP was defined as (waist circumference [cm]–65) × (triglycerides [mmol/L]) in men, and (waist circumference [cm]–58) × (triglycerides [mmol/L]) in women and analyzed continuously (per SD change) and categorically (quartile 1, <30; quartile 2, 30–50; and quartile 3, >50).

Results: Prevalence of DR among the study population was 17.8%. The mean level of LAP was 52.96±44.01. Compared to quartile 1 level, both quartile 2 and 3 levels were associated with DR with multivariable odds ratio (95% CI) of 0.23 (0.12–0.46) and 0.27 (0.14–0.54), respectively. These associations persisted when LAP was analyzed continuously (0.57 [0.35–0.92]).

Conclusion: Higher central lipid accumulation in Chinese diabetics is related to the lower risk of DR, suggesting that LAP may be useful for identifying type 2 diabetes mellitus patients who are at risk for DR.

Keywords: diabetic retinopathy, lipid accumulation product, diabetes

Introduction

China has become the largest country with diabetic population. Diabetic retinopathy (DR) is a common complication of diabetes and affects approximately a quarter of patients in China.¹ Moreover, DR triggers preventable blindness in working-age adults in world.² According to the increasing prevalence of diabetes, the prevention of DR is becoming a serious health problem for public. Hence, it is important to identify potential factors regarding DR.

The lipid accumulation product (LAP) level, a newly developed biomarker of central lipid accumulation, is estimated based on a combination of waist circumference (WC) and triglyceride (TG) levels. According to recent reports, growing evidence from both clinical-based and epidemiological studies, LAP index has been identified as an independent indicator of the risk of insulin resistance and type 2

diabetes.^{3,4} DR is a complication of diabetes; thus, it is reasonable to infer that LAP index may also have associated with DR. However, no data exist to show the relationship of LAP index with DR. To address this gap, we investigated the association between LAP index and DR in Chinese adults with diabetes who attended the Shenyang Diabetes Eye Study.⁵

Patients and methods

Study population

Shenyang Diabetes Eye Study is a community-based study that investigates the clinical, behavioral, genetic and environmental factors associating with DR among participants with diabetes in China. The methodology of the Shenyang Diabetes Eye Study has been described previously.⁵ Moreover, we conducted a cross-sectional study in 2014. We used the same sampling methods, questionnaire form, eye checking and blood testing items as Shenyang Diabetes Eye Study. Briefly, a total of 595 Chinese adults with type 2 diabetes aged ≥ 18 years were recruited from the Fengyutan District, Shenyang, China, from August to October 2014 according to their health files in health center of Fengyutan. Our study consists of data collected from a subset of participants available LAP were included in our study (both WC and TG levels; $n=434$). Then, we excluded 7 participants for lack of historical medical treatment information (eg, use of medication), leaving 427 participants available for analysis.

Standardized interviews were done that covered demographic measures, medication use (use of insulin), lifestyle (eg, smoking and drinking) as well as behavioral factors (eg, physical excises) for diabetes management.

Anthropometric tests and laboratory examinations

Body height and weight of the participants were measured and body mass index (BMI) was calculated as weight in kilograms divided by height in meters squared. WC was measured at the umbilicus level. Blood pressure was measured using mercury sphygmomanometer according to standardized methods.⁶ Fasting (≥ 8 hr) venous blood samples were obtained to measure for fasting plasma glucose (FPG), hemoglobin A_{1c} (HbA_{1c}), TG, and total cholesterol (TC) levels. All laboratory examinations were performed at the Endocrinology Laboratory, China Medical

University, using commercially available assays. LAP was defined as $[WC (cm)-65] \times [TG (mmol/L)]$ in men, and $[WC (cm)-58] \times [TG (mmol/L)]$ in women.⁷

Definition

Diabetes mellitus (DM) was defined as FPG ≥ 126 mg/dL (7.0 mmol/L), HbA_{1c} $\geq 6.5\%$, self-reported use of antidiabetic medication or physician-diagnosed diabetes.⁸ Presence of type 2 diabetes was defined as physician-diagnosed diabetes, with the information retrieved from participants' case notes.

In the current study, DR was assessed from the retinal photographs according to a standardized protocol.⁹ After pupillary dilation (1.0% tropicamide), two-field (one centred on the optic disc; and the other centred on the fovea) coloured fundus photographs were taken, according to the Early Treatment for Diabetic Retinopathy Study (ETDRS) standards using a digital retinal camera (Canon CR-DGi with a 10-D SLR back; Canon, Tokyo, Japan). Fundus photographs were read in a masked manner. DR was determined to be present if any characteristic lesion was present: microaneurysms, hemorrhages, cotton wool spots, intraretinal microvascular abnormalities, hard exudates, venous bleeding, and new vessels.⁹

Hypertensive patients were defined as those with systolic BP ≥ 140 mmHg, or diastolic BP ≥ 90 mmHg, or those previously diagnosed with hypertension. Smokers were defined as those currently smoking any number of cigarettes. Drinking was defined as those who reported currently drinking five or more drinks (four or more for females) at least once. Physical exercise was defined as performing physical activity in sports or exercises at least three times per week and lasting for at least 30 mins each time in our study.

This study was approved by the Ethics Committee of the First Affiliated Hospital of China Medical University. All the participants signed an informed consent form. Our research followed the tenets of the Declaration of Helsinki.

Statistical analysis

Statistical analysis was performed by using SPSS (Version 20.0, IBM). The Chi-square test (for categorical variables) and two-independent sample *t*-test (for continuous variables) were oriented to compare the demographic and clinical characteristics of subjects between the two groups divided by the presence or absence of retinopathy. LAP index was analyzed as both categorical and continuous variables. LAP index was treated as a categorical variable

which form tertiles and where moderate and high were referenced against normal levels of LAP index (quartile 1, <30; quartile 2, 30–50; and quartile 3, >50). Logistic regression models (Model 1: adjusted with age and gender; Model 2: adjusted with age, gender, smoking status, family history of DM, use of insulin, duration of DM, high blood pressure (HBP), BMI and HbA_{1c} levels) were used to assess the associations of LAP index with DR. For all the tests, a *P*-value less than 0.05 was considered to be significant.

Results

There were 427 participants with type 2 diabetes involved in the current population-based study, of which 76 (17.8%) participants had DR. Among those 76 participants with DR, 68 (89.5%) had nonproliferative diabetic retinopathy (NPDR) and eight (10.5%) had proliferative diabetic retinopathy (PDR). As shown in Table 1, participants with DR were more likely to be male, on insulin, and had longer diabetes duration, higher diastolic BP and HbA_{1c} levels, lower waist and LAP levels, compared to those without DR. There were no significant differences between participants with and without DR in age, lifestyle (smoking, drinking, physical exercise and without anti-diabetes treatment), family history of diabetes, HBP, systolic BP, BMI, FPG, TG and TC levels.

In age- and gender-adjusted models (Table 2, Model 1), higher LAP index was associated with reduced risk for DR (OR: 0.53; 95% CI: 0.33–0.83; *P*<0.001). After adjusting for additional confounding factors (smoking status, family history of DM, use of insulin, duration of DM, HBP, BMI and HbA_{1c} levels) in Model 2, higher LAP index was still associated with reduced risk for DR (OR: 0.57; 95% CI: 0.35–0.92; *P*<0.001). A consistent, significant association was found between LAP index and DR when LAP index was treated as a categorical variable in both Model 1 and Model 2 (*P* for trend <0.001). Moreover, when the participants with PDR were excluded, higher LAP level was associated with a lower risk of DR (OR: 0.68; 95% CI: 0.42–0.89; *P*<0.001).

Discussion

To the best of our knowledge, this is the first study for investigating the association on LAP levels with presence of DR. In this community-based sample of Chinese participants with type 2 diabetes, we found that higher levels of LAP were continuously associated with a decreased presence of DR. When LAP index was analyzed categorically, the increased LAP index was still associated with decreased presence of DR.

Interestingly, our findings revealed the inverse association between LAP index and DR in Chinese adults with diabetes. The exact mechanisms underlying this inverse association are unclear. However, a similar counterintuitive association has

Table 1 Basic characteristic of the study participants

Variables	Overall (n=427)	DR (n=76)	NDR (n=351)	P-value
Age (years)	61.69±9.90	60.13±9.59	62.03±9.95	0.131

been reported in other disease states, including chronic kidney disease, congestive cardiac failure, peripheral arterial disease, stroke risk and thromboembolism.^{10–13} This inverse association has been labeled as the “obesity paradox”.¹⁴ On the other hand, it may not be true that higher LAP protects people by diabetes against DR, but that subjects with a lower LAP are more likely to be more severe DM (causing weight loss) and thus have an increased risk of DR. In addition, long-term duration of diabetes is associated with DR.¹⁵ Moreover, due to a lesser capacity for insulin secretion, people with long-term duration of diabetes tend to have a lower LAP as compared to those with shorter diabetes duration. This could be a key factor in explaining the inverse association of LAP index and DR.

In the current study, a higher LAP index was associated with lower risk of DR, but our finding should be interpreted with caution. It must not be made to summarize that a higher LAP index is preferable. It should be noted that many health problems including diabetes and overall increased mortality are associated with obesity.¹⁶

The LAP is an index used for evaluating lipid overaccumulation and metabolic disorder. In addition, BMI is also another biomarker of obesity, and in assessment related to DR in adults with diabetes. However, it is not clear whether BMI could affect DR. In our univariate analysis exploring the risk factors of early stage of DR, BMI index was not associated with DR. Additionally, in the multivariate regression adjusting for potential confounders (Table 3), BMI was not association with DR. This is consistent with other cohorts^{17,18} that showed no association between BMI and DR. However, another Singapore Malay and Indian eye study showed that higher BMI was associated with a lower incidence of DR.¹⁹ Furthermore, in another population-based cohort study, increased DR incidence was found in individuals with higher BMI.²⁰ Hence, the actual relationship between BMI and DR warrants further studies. In order to address this gap, we investigate the association between LAP index and DR. Compared with BMI, LAP index might be better for identifying US adults at cardiovascular risks.⁷ Moreover, a recent cross-sectional study on 2,524 nondiabetic Chinese subjects

Table 3 Associations of LAP index with DR adjusted potential confounders with full models

Variable	Model 1 ^a		Model 2 ^b	
	OR (95%CI)	P-value	OR (95%CI)	P-value
Age (years)	0.984 (0.959–1.010)	0.223	0.966 (0.937–0.996)	0.025
Gender (male)	0.660 (0.397–1.099)	0.66	0.527 (0.279–0.996)	0.048
LAP (cm mmol/L)	0.987 (0.977–0.997)	0.013	0.987 (0.976–0.998)	0.02
Smoke (yes)			0.571 (0.258–1.268)	0.169
Family history of DM (yes)			0.927 (0.497–1.729)	0.811
Duration of DM (year)			1.115 (1.060–1.173)	<0.001
High blood pressure (mmHg)			1.745 (0.963–3.161)	0.066
BMI (kg/m ²)			0.935 (0.839–1.055)	0.275
Use of Insulin (yes)			1.288 (0.635–2.613)	0.483
HbA1c (%)			1.228 (1.041–1.448)	0.48

Notes: ^aAdjusted age and gender. ^bAdjusted for age, gender, smoking status, family history of DM, use of insulin, duration of DM, HBP, BMI, and HbA1c levels.

Abbreviations: LAP, lipid accumulation product; DR, diabetic retinopathy; HbA1c, hemoglobin A1c; DM, diabetes mellitus; BMI, body mass index.

showed that, compared to BMI, LAP had a greater impact on the homeostasis model assessment insulin resistance index (HOMA-IR).²¹ Further cohort study is still needed to identify the relevance of LAP and BMI in the causation of DR and determine which one may then be used as an effective biomarker of DR.

The strengths of the current study include a community-based survey to minimize the selection bias and a standardized and comprehensive protocol for identifying factors. However, there were some limitations to our study. First, it was a cross-sectional study with a small sample size and the lack of healthy control subjects. Second, among patients with DR, majority had NPDR (89.5%) stage; thus, the association between LAP index and severity of DR had not been explored extensively. Third, two-field retinal photographs were used to evaluate and monitor the presence of DR. This may have led to an underestimation of the true prevalence of DR. Finally, we were not able to adjust other potential confounders such as education and income levels as such data were not collected.

In conclusion, we showed in this population-based study that higher LAP index was associated with a lower risk of DR. As obesity and DR are complex and multifactorial traits influenced by multiple environmental and genetic factors, further studies may be warranted to investigate the multifactorial effects of LAP index on the presence of DR.
