ABSTRACT

Introduction Nutritional challenges are common consequences of cancer, and they do not only occur in the hospital setting. They are also frequent after completion of treatment, and nutritional interventions in community-based post-treatment rehabilitation services are important. The first step towards initiating any nutritional intervention is to identify the individual in need hereof, but evidence is limited on the applicability of different nutrition screening and assessment tools in the post-treatment rehabilitation services. The aim is to systematically review and identify nutrition screening and assessment tools appropriate for use in patients with cancer and survivors of cancer in hospital or community-based healthcare settings.

Methods and analysis In this systematic review, the electronic databases PubMed, CINAHL Complete and Embase were searched systematically using comprehensive search strategies. Primary searches were carried out in August 2018 with updated searches performed in November 2019. Clinicaltrials.gov and PROSPERO International Prospective Register of Systematic Reviews will be searched for additional relevant studies. Studies will be included if they validate a nutrition screening or assessment tool in adult patients with cancer or survivors of cancer. No restriction on publication date will be applied, and full-text articles in English, Danish, Norwegian and Swedish are eligible for inclusion. Two reviewers will independently conduct screening of search results, study selection, data extraction and quality assessment. Data will be synthesised narratively.

Ethics and dissemination No ethical approval is required. Results will be reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses statement and published in an international peer-reviewed journal. Furthermore, results will be presented in relevant research and clinical fora to facilitate transfer of results to clinical practice in benefit of patients. **PROSPERO registration number** CRD42018096678.

INTRODUCTION

Nutritional challenges are common consequences of cancer, and their occurrence is not restricted to the hospital setting.^{1,2} Cancer and cancer treatment may affect nutritional

Strengths and limitations of this study

- The systematic review protocol has been developed in accordance with the Preferred Reporting Items for Systematic review and Meta-Analysis Protocols guidelines.
- A comprehensive literature search strategy has been developed to retrieve a broad spectrum of relevant studies.
- Excluding other publication types than full text articles may impose a risk of relevant grey literature being excluded.

intake and requirements,^{1,3} and the high risk of cancer-related malnutrition has been documented in several groups of patients with cancer^{4–9} and survivors of cancer.¹⁰ Nutrition impact symptoms affecting dietary intake, nutritional status and quality of life are frequent,^{10–13} and may occur or persist years after completion of treatment.^{10,14} Hence, nutritional challenges are not only topics of concern in the hospital setting during cancer treatment but also in the community-based post-treatment rehabilitation services. The nature of the nutritional challenges may vary across settings. In the hospital setting where patients with cancer are in the acute phase of their trajectory, tumour-related metabolic derangements and systemic inflammation contribute greatly to cancer-related malnutrition.³ In the post-treatment phase, nutritional challenges are often caused by nutrition impact symptoms and other late effects¹⁵ rather than by a metabolic stress response.

For several cancer types, increasing incidence rates combined with increased survival¹⁶ have led to an increase in the population of survivors of cancer and thereby an increased demand for appropriate community-based

post-treatment rehabilitation services including management of nutritional challenges.

Nutritional interventions can improve nutritional status and quality of life in some patients with cancer^{17 18} and survivors of cancer,¹⁹ but initiation of any nutritional intervention requires a systematic identification of the individual patient who requires and will benefit from the intervention. The European Society for Clinical Nutrition and Metabolism recommends that nutrition screening is performed at cancer diagnosis and repeated regularly depending on the clinical situation,¹ and that any nutritional intervention is initiated with a nutritional assessment of among others dietary intake and nutrition impact symptoms.¹ Yet, there is no consensus on which tools to use in this nutrition screening or assessment in the different healthcare settings. Several tools have been developed to screen for and assess nutritional risk, nutritional status and nutrition impact symptoms,^{1 20 21} but many of these tools have primarily been validated in patients with cancer during treatment. Less is known on their ability to assess post-treatment nutritional challenges and to identify survivors of cancer who will benefit from post-treatment nutritional interventions. Since the nature of nutritional challenges may vary across settings, so may the applicability of different nutrition screening and assessment tools. Furthermore, nutrition screening and assessment tools may have been designed for different purposes, for example, identify nutritional status, identify need for nutritional interventions or predict effect of nutritional interventions.²² An overview of the different nutrition screening and assessment tools for patients with cancer and survivors of cancer and the tools' applicability in the different healthcare settings could inform healthcare professionals in the selection of tools for their clinical practice. Hence, this systematic review seeks to answer the following research question: 'Which nutrition screening and assessment tools are appropriate for systematic nutrition screening and assessment in patients with cancer and survivors of cancer in hospital or community-based healthcare settings?'

Study objectives

The objectives of the study are:

- ▶ To identify nutrition screening and assessment tools validated in patients with cancer and/or survivors of cancer.
- ▶ To evaluate the following for each identified tool:
 - Purpose of the tool: is the tool validated for assessment of nutritional status as defined by the authors of the given study, nutritional risk, nutrition impact symptoms, to identify patients who will benefit from nutritional intervention and so on or other purposes? Benefit from nutritional interventions can be defined as a clinically relevant improvement in clinical outcome following nutritional interventions in patients with cancer/survivors of cancer who have been categorised as being malnourished/at nutritional risk according to the tested tool.

- Patient group: which patient groups according to cancer diagnoses and treatment modality has the tool been validated in?
 - Setting: is the tool validated in patients with cancer during treatment or survivors of cancer after completion of treatment?
 - Administration: is the tool supposed to be administered or filled out by health professionals or patients?
 - Validation: how was the tool validated? (content validity or other domains recommended by COnsensus-based Standards for the selection of health Measurement INSTRUMENTS (COSMIN),²³ predictive values compared with a gold standard or a given clinically relevant outcome, etc).
- ▶ To discuss whether the identified tools can be recommended for use in systematic nutrition screening and assessment in patients with cancer and survivors of cancer, and at which time point of the cancer trajectory the tool will be relevant to use.

METHODS AND ANALYSIS

This systematic review protocol has been developed in accordance with the Preferred Reporting Items for Systematic review and Meta-Analysis Protocols statement.²⁴

Eligibility criteria

Inclusion and exclusion criteria based on population, exposure, comparators and outcome are summarised in table 1.

Population

The population of interest includes adult patients with cancer and survivors of cancer (18+ years).

No restriction on cancer type is applied, and studies are included regardless of whether they focus on one specific group of patients with cancer/survivors of cancer or on a heterogeneous group of patients with cancer/survivors of cancer. Studies including patients with cancer/survivors of cancer as a part of a heterogeneous patient population will only be included, if data for the subgroup of patients with cancer/survivors of cancer are presented separately. In that case, only data regarding the cancer subgroup will be extracted.

Exposure

Studies will be included if they test the validity of a given nutrition screening or assessment tools. To assess the eligibility of the studies, the following definition of nutrition screening and assessment tools will be used: tools (including patient reported outcome measures) that combine more than one variable related to nutritional intake, nutritional risk, nutritional status²⁵ and nutrition impact symptoms (as described under the Search strategies section) to yield an overall result. Hence, studies assessing single variables, for example, body weight, will not be included, while a study that uses a combination of, for example, body weight and dietary intake to categorise participants according to nutritional status or risk

Table 1 Inclusion and exclusion criteria

| | Inclusion criteria | Exclusion criteria |
|-------------------------|--|--|
| Population | Adult patients with cancer and survivors of cancer (18+ years) | |
| Exposure | Nutrition screening or assessment with a tool that assesses nutritional status, nutritional risk, nutrition impact symptoms or identifies individuals who needs or will benefit from nutritional interventions using more than one variable to yield an overall result | Nutrition screening or assessment with tools that includes invasive measures (eg, blood samples) |
| Comparators | Gold standard (defined by the authors of the given study) or none | |
| Outcomes | Studies testing the validity of a tool Validity, predictive value, sensitivity, specificity, accuracy, internal consistency, reliability, measurement error, content validity, structural validity, hypotheses testing, cross-cultural validity, criterion validity, responsiveness, prognostic value | Studies merely performing linguistic validation of a given tool |
| Types of studies | | |
| <i>Study design</i> | Clinical studies (controlled and uncontrolled clinical trials, observational studies), systematic reviews | Case studies, non-systematic reviews |
| <i>Publication type</i> | Full text articles | |
| <i>Publication date</i> | No restriction | |
| <i>Language</i> | English, Danish, Swedish, Norwegian | |

can be eligible. The definition of nutritional status or risk may vary across included studies, and studies who fulfil remaining eligibility criteria will not be excluded based on their definition of nutritional status. Since blood samples and other biochemical tests are not readily available in all healthcare settings, the tools must comprise non-invasive measurements. Hence, tools including blood samples and other biochemical tests will be excluded.

Comparators

Comparators can be a gold standard defined by the authors of the given study or none. The gold standard may vary between studies depending on the type of tool being assessed, and an example of a gold standard could be another validated assessment tool or a clinical test. Studies with no comparator may include studies assessing internal consistency, cross-cultural validity and other domains where a comparator is not needed.

Outcomes

Studies will be included if they test the validity of a tool using any of the following outcomes: validity, predictive value, sensitivity, specificity, accuracy, internal consistency, reliability, measurement error, content validity, structural validity, hypotheses testing, cross-cultural validity, criterion validity, responsiveness, prognostic value.

The validity can be tested against a gold standard or a given clinically relevant outcome related to a nutritional intervention, for example, body weight, benefit

from nutritional intervention, etc. Benefit from nutritional interventions is defined as clinically relevant improvements in clinical outcome following nutritional interventions in patients with cancer/survivors of cancer categorised as being malnourished/at nutritional risk with the given tool. Studies merely performing linguistic validation of translated tools will not be included. However, a note will be added to these studies, and they may be included in the discussion of the worldwide availability of a given tool.

Types of studies to be included

Clinical studies (controlled and uncontrolled clinical trials, observational studies) and systematic reviews will be considered for inclusion, while case studies and non-systematic reviews will be excluded. No restriction on publication date will be applied, and full-text articles in English, Danish, Swedish, Norwegian will be considered for inclusion. The decision to only include full text articles may impose a risk of grey literature identified in Clinicaltrials.gov and PROSPERO International Prospective Register of Systematic Reviews²⁶ being excluded. Yet, we find that full text access is necessary to make a comprehensive evaluation of whether a study meets the other inclusion criteria.

Search strategies

The primary searches were performed in the following electronic databases: PubMed, CINAHL Complete and

Table 2 Search terms included in the search strategies for the electronic databases PubMed, CINAHL Complete and Embase

| Population | Cancer survivor(s), cancer patient(s), neoplasms |
|------------|--|
| Exposure | nutrition(al) assessment, nutrition(al) screening OR needs assessment, self-reported outcome(s), patient reported outcome(s), patient reported outcome measures, screening, assessment, tool(s), instrument(s), questionnaire(s), surveys and questionnaires AND nutrition(al), nutritional status, malnutrition, nutrition therapy, nutrition impact symptom(s), feeding and eating disorders, eating difficulty/difficulties, eating problem(s), appetite, anorexia, xerostomia, dry mouth, mouth dryness, hyposalivation, dysgeusia, altered taste, taste alteration(s), distorted taste, taste distortion(s), taste change(s), abdominal pain, dyspepsia, mouth pain, oral pain, sore mouth, mouth soreness, mucositis, stomatitis, dysphagia, swallowing difficulty/difficulties, swallowing disorder(s), deglutition disorder(s), oesophageal motility disorders, chewing difficulty/difficulties, dental problem(s), poor dentition, digestive problem(s), digestive symptom(s), gastrointestinal symptom(s), nausea, vomit(ing), vomitus, constipation, constipated, diarrhoea, flatulence, meteorism, bloating, bloatedness, bloated, weight, body weight, body weight changes, public eating |
| Outcome | validity, validation, valid, validated, predictive value(s), predictive value of tests, sensitivity, specificity, accuracy, reproducibility of results, internal consistency, reliability, measurement error, hypotheses testing, responsiveness, prognostic value |

Embase. The searches were not date restricted and they were based on combinations of the search terms showed in [table 2](#). The exact search strategy for one of the databases is provided in online supplemental file 1. Furthermore, Clinicaltrials.gov, PROSPERO International Prospective Register of Systematic Reviews,²⁶ Cochrane Library and reference lists of included articles will be searched to identify additional relevant studies published as full-text articles.

The search strategies for the electronic databases were developed with support from an information specialist. Search terms related to the exposure were selected with inspiration from The European Organization for Research and Treatment of Cancer's (EORTC) quality of life questionnaire, QLQ-C30²⁷ and relevant diagnosis specific modules for different types of cancer.^{28–38} The search terms are based on items related to nutritional intake, nutritional status and nutrition impact symptoms. These nutrition impact symptoms include eating difficulties, anorexia, xerostomia, dysgeusia, abdominal pain, dyspepsia, oral pain, mucositis, stomatitis, dysphagia, dental problems, nausea, vomiting, constipation, diarrhoea, flatulence, meteorism and body weight changes.

Search terms related to outcomes were selected to identify studies that either test validity as accuracy, sensitivity, specificity or predictive values compared with a gold standard or a given clinically relevant outcome or assesses the domains recommended by COSMIN²³ for assessment of methodological quality of studies on measurement properties (internal consistency, reliability, measurement error, content validity, structural validity, hypotheses testing, cross-cultural validity, criterion validity and responsiveness).

The protocol was registered at PROSPERO International Prospective Register of Systematic Reviews²⁶ before the primary searches were carried out in August 2018. Updated searches using the same search strategy were performed in November 2019.

Study selection

The Covidence³⁹ software tool for systematic reviews will be used in the selection and management of articles. Duplicates will be removed after transferring searches to Covidence. Removal of duplicates will be documented in a flow chart of the selection process.

The titles and abstracts of all identified articles will be screened for relevance by two authors (MBK+either AMB, IW or KSU) independently. All articles with irrelevant titles and/or abstracts will be excluded. Two authors (MBK+either AMB, IW or KSU) will independently inspect the full text of the remaining articles and decide on their eligibility for inclusion using the inclusion and exclusion criteria. Reasons for exclusion of articles in the full text screening will be documented, and a flow chart of the selection process will be developed. A list of references excluded in the full text screening will be available on request.

Possible disagreement between the two authors in the selection process will be solved through discussion or by involving a third independent author. As a pilot test of the study selection process, all four authors who will be involved in the selection of studies (MBK, AMB, IW, KSU) initially screened the same 25 references and potential conflicts were solved by discussion.

Data extraction

Data extraction will be performed by two authors independently. The following data will be extracted using a customised data extraction form:

- ▶ Study information: authors, publication year, source of publication.
- ▶ Methods and study design.
- ▶ Population: description of study population, setting of recruitment, inclusion criteria, exclusion criteria.
- ▶ Exposure: the studied screening or assessment tool(s)
- ▶ Outcome: how the validity of the studied screening or assessment tool(s) is assessed.
- ▶ Study results.

- ▶ Review of authors conclusions.
- ▶ Evaluation of potential bias.
- ▶ Funding of the study and reported conflict of interests of the authors.

Risk of bias assessment

The methodological quality of included papers will be assessed using appropriate checklists according to study type.

Randomised clinical trials are assessed using the Cochrane Risk of Bias Tool.⁴⁰ Observational studies (cohort studies and case–control studies) are assessed using Risk Of Bias In Non-randomized Studies - of Interventions (ROBINS-I),⁴¹ and diagnostic primary studies will be assessed using the checklist developed by the Quality assessment of Diagnostic Accuracy Studies (QUADAS) Initiative.⁴² Systematic reviews are assessed using the A MeaSurement Tool to Assess systematic Reviews (AMSTAR) 2 checklist.⁴³

Studies will not be excluded based on quality issues. However, issues related to the methodological quality will be documented and considered in the analysis and the conclusions of the review. These considerations will be stated explicitly in the presentation of the results.

Strategy for data synthesis

A summary of extracted data will be presented in tables in the presentation and dissemination of the results. Analysis of data will include comparisons of the different screening and assessment tools with regards to how they are validated, target group and type of tool (patient reported or performed by health professionals). No meta-analyses will be made, and comparisons will be described narratively.

All included articles will be presented in a table with information on authors, publication year, study type, methods and results. Furthermore, identified tools will be presented in tables with information on their purpose, patient group (cancer diagnoses and treatment modality), setting (hospital/during treatment or post-treatment), administration and validation (method, outcome and result). In these tables, tools will be grouped according to their purpose (eg, to assess anorexia) to allow for comparison and to make results targeted and clinically meaningful for clinicians. Discussions on whether identified tools can be recommended for systematic nutrition screening and assessment in patients with cancer and survivors of cancer and on which time point each tool will be relevant to use will be based on results summarised in the tables. Within the given setting, patient group and group of tools according to their purpose, highest recommendations will be given to the tool that have been validated most thoroughly and hence, have been validated across the largest number of domains and in studies with the highest methodological quality.

Analysis of subgroups or subsets

In addition to the full overview of tools, data will be analysed and presented separately for tools validated in

patients with cancer during treatment and survivors of cancer post-treatment, respectively. In these tables, results will be presented according to which cancer diagnoses the given tools have been validated in (eg, heterogenous groups of patients with cancer, patients with head and neck cancer, etc).

Study status

The protocol was registered within PROSPERO International Prospective Register of Systematic Reviews²⁶ in June 2018. Primary searches were carried out in August 2018 and updated searches using the same search strategies were performed in November 2019. Study selection and data extraction is expected to be completed in October 2020.

ETHICS AND DISSEMINATION

No ethical approval is required for this systematic review, as it is based on published articles, and does not directly include patients. Results will be reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Statement⁴⁴ and published in an international peer reviewed journal. Results will furthermore be presented at national and international conferences.

PATIENT AND PUBLIC INVOLVEMENT

No patients or public stakeholders were involved in the development of this systematic review protocol. The results of the systematic review will inform and form the basis of future clinical studies where patients and public stakeholders will be invited to participate in development of study designs and protocols. In this process, patients' perceptions of user-friendliness and relevance of the tools identified in this review will be taken into consideration when selecting nutrition screening and assessment tools to use for inclusion criteria and/or outcome measures.

DISCUSSION

This systematic review will identify nutrition screening and assessment tools appropriate for use in systematic nutrition screening and assessment in patients with cancer and survivors of cancer. The review will provide health professionals in hospitals and community-based healthcare services with a useful overview that can inform them in their selection of tools.

The scope of the systematic review is broad as it includes different types of tools, tools for all cancer diagnoses and tools validated in both patients with cancer during treatment and survivors of cancer after treatment. It could be argued, that a narrower scope focusing on one setting or one group of patients with cancer would have increased the applicability of review results. However, while cancer-related health services at hospitals are often highly specialised and diagnosis specific, community-based healthcare services are often aimed at heterogenous groups of cancer

survivors.⁴⁵ So, for many clinicians in community-based healthcare services, this broad group may represent the target group they see every day in their clinical practice. For these clinicians, a broad overview can be very useful since it will provide a better understanding of generic and cancer diagnosis specific tools, and of how the different tools might supplement each other. Despite the broad scope of the review, results will be presented separately for specific groups of patients with cancer/survivors of cancer allowing health professionals to select between diagnosis-specific and generic tools to improve their clinical practice depending on the target population.

Excluding tools that include blood samples and other invasive measures may lead to exclusion of relevant tools, since blood samples can be good indicators of inflammation and hence, of metabolic derangements during the acute phase of the trajectory.³ This exclusion criteria was applied since blood samples are not readily available in all healthcare settings and to ensure that the identified screening tools are brief and inexpensive as the recommendation from The European Society for Clinical Nutrition and Metabolism prescribes.¹

A strengthening of the evidence on nutrition screening and assessment in patients with cancer and survivors of cancer may contribute to strengthen the implementation of systematic nutrition screening and assessment, and to ensure that patients with cancer with documented needs of nutritional interventions are referred to appropriate services during and after cancer treatment.
