**Abstract:** Leaf-stripe smuts on grasses are a highly polyphyletic group within *Ustilaginomycotina*, occurring in three genera, *Tilletia*, *Urocystis*, and *Ustilago*. Currently more than 12 *Ustilago* species inciting stripe smuts are recognised. The majority belong to the *Ustilago striiformis*-complex, with about 30 different taxa described from 165 different plant species. This study aims to assess whether host distinct-lineages can be observed amongst the *Ustilago* leaf-stripe smuts using nine different loci on a representative set. Phylogenetic reconstructions supported the monophyly of the *Ustilago striiformis*-complex that causes leaf-stripe and the polyphyly of other leaf-stripe smuts within *Ustilago*. Furthermore, smut specimens from the same host genus generally clustered together in well-supported clades that often had available species names for these lineages. In addition to already-named lineages, three new lineages were observed, and described as new species on the basis of host specificity and molecular differences: namely *Ustilago jagei* sp. nov. on *Agrostis stolonifera*, *U. kummeri* sp. nov. on *Bromus inermis*, and *U. neocopinata* sp. nov. on *Dactylis glomerata*.

## INTRODUCTION

The term “stripe smut” is commonly used to refer to *Ustilaginomycotina* species that cause dark brown to black linear sori of varying length in the leaves of grasses (*Poaceae*). Black spore masses are released after the spores have matured beneath the epidermis in the mesophyll of the host leaves (Fischer 1953, Vánky 2012). The spore release process of sori is unknown, but may be facilitated either by the withering of dead epidermal cells or by enzymatic action, as in the white blister rusts (Heller & 2009). Of the smut genera that infect grasses, *Ustilago* is the most prevalent (Stoll *et al.* 2003, 2005, Vánky 2012).

The term stripe smut does not reflect phylogenetic relatedness, as at least two other genera, *Tilletia* and *Urocystis*, contain species that manifest similar symptoms. The vast majority of leaf-stripe smuts belong to *Ustilago*, including *U. agropyri*, *U. bahuichivoensis*, *U. bethelii*, *U. calamagrostidis*, *U. calcarea*, *U. davisii*, *U. deyeuxiicola*, *U. echinata*, *U. filiformis*, *U. phlei*, *U. scrobiculata*, *U. serpens* s. lat., *U. sporoboli-indici*, *U. striiformis* s. lat., *U. trebouxii*, *U. trichoneurana*, and *U. ulei* (Vánky 2012). Of these species, *U. striiformis* s. lat., with the type species described on *Holcus lanatus*, is a complex occurring on 164 species of *Poaceae* representing 44 different genera

(*Achnatherum*, *Agropyron*, *Agrostis*, *Alopecurus*, *Armmophila*, *Anthoxanthum*, *Arctagrostis*, *Arrhenatherum*, *Avena*, *Beckmannia*, *Brachypodium*, *Briza*, *Bromus*, *Calamagrostis*, *Cleistogenes*, *Cynosurus*, *Dactylis*, *Danthonia*, *Deschampsia*, *Deyeuxia*, *Elymus*, *Festuca*, *Helictotrichon*, *Hierochloë*, *Holcus*, *Hordeum*, *Hystrix*, *Koeleria*, *Leymus*, *Lolium*, *Melica*, *Milium*, *Pennisetum*, *Phalaris*, *Phleum*, *Piptatherum*, *Poa*, *Polypogon*, *Puccinellia*, *Sesleria*, *Setaria*, *Sitanion*, *Trisetaria*, and *Trisetum*). Based on host specificity and minor differences in spore size and surface ornamentation, approximately 30 different taxa have been described in the *U. striiformis* species complex on various host plants (Vánky 2012, Savchenko *et al.* 2014a). *Ustilago serpens* probably represents an overlooked species complex, occurring on five host genera: *Agropyron*, *Brachypodium*, *Bromus*, *Elymus*, and *Leymus*. Whether other species with large warts on their spores also belong to this complex, such as *U. echinata* and *U. scrobiculata*, is currently unclear.

*Ustilago striiformis* s. lat. on *Alopecurus pratensis* has often been the sole representative of this group in phylogenetic analyses (Stoll *et al.* 2005, Begerow *et al.* 2006, McTaggart *et al.* 2012a). Stoll *et al.* (2005) supported the recognition of *U. calamagrostidis*, a parasite of several species of *Calamagrostis*, as separate from *U. striiformis*.

The morphological difference was mainly in spore size and ornamentation. Savchenko *et al.* (2014a) provided a more detailed analysis of the *U. striiformis* species complex using several host-fungus combinations and phylogenetic reconstructions based on the nrITS and partial LSU regions. However, while two additional species were proposed as distinct in the *U. striiformis*-complex, the phylogenetic resolution was too low to draw further conclusions regarding host specificity and potential species boundaries. To resolve undescribed lineages within this species complex, Savchenko *et al.* (2014a) suggested that several additional gene loci and host-fungus combinations should be included. However, in line with Vánky (2012), Savchenko *et al.* (2014a) suggested that it would be difficult to distinguish between these lineages based on morphological characters. DNA-based characteristics, such as diagnostic SNPs, along with host specificity might be a solution towards characterizing and describing previously-named and new species (Denchev *et al.* 2009, Piątek *et al.* 2013). The aim of this study was to use a multigene phylogeny to infer the phylogenetic differentiation in the leaf stripe smuts in the genus *Ustilago*, particularly those in the *U. striiformis* species complex.

## MATERIAL AND METHODS

### Plant and fungal material

Specimens used in the study are listed in Table 1. The names of the hosts and fungi was derived from the latest version of The International Plant Names Index ([www.ipni.org](http://www.ipni.org)), Index Fungorum ([www.indexfungorum.org/](http://www.indexfungorum.org/)) and Vánky (2012), and partly following a broad generic concept for *Ustilago* (Thines 2016). A majority of the samples were collected in Germany (about 76) and most collections were not older than 20 years. Samples are deposited in Herbarium Senckenbergianum Görlitz (GLM). All host identifications were confirmed by ITS sequences.

### DNA extraction and PCR

About 2–20 mg of infected plant tissue was taken from fungarium samples, placed in 2 mL plastic reaction tubes and homogenized in a mixer mill (MM2, Retsch) using a combination of three to five 1 mm and two 3 mm metal beads at 25 Hz for 5–10 min. Genomic DNA was extracted using the BioSprint 96 DNA Plant Kit (Qiagen, Hilden) loaded to a KingFisher Flex robot (Thermo Scientific, Dreieich).

The complete nrITS of all DNA extracts were amplified using PCR following the procedure of White *et al.* (1990). The primer pairs M-ITS1 (Stoll *et al.* 2003) / ITS4 (White *et al.* 1990) or M-ITS1 / smITS-R1 (Kruse *et al.* 2017a) were used as the reverse and forward primers, respectively. For DNA samples from historic specimens, including type specimens, the *Ustilaginaceae*-optimised reverse primer ITS-US3R (5'-TATCAAAACCCGGCAGGGAAAG3'), located at the ITS2 region, was used.

The NL1 and NL4 primer pair (O'Donnell 1993) were used to amplify the Large Subunit (LSU) of the nrDNA with an annealing temperature of 53 °C. For other loci, the following regions were amplified with their respective primer pairs and annealing temperatures in brackets: *myosin* R0.5/F3 (55 °C),

*map* R6/F2 (56 °C), *rpl3* R1/F1 (53 °C), *tif2* R3/F3 (53 °C), *ssc1* R1/F2 (53 °C), *sdh1* R3/F2 (53 °C), *rpl4A* R1/F4 (53 °C), and *atp2* R4/F6 (53 °C) (Kruse *et al.* 2017b).

The plant ITS was amplified using the primer pair ITS1P and ITS4 (Ridgway *et al.* 2003) at 53 °C annealing temperature. The cycling reaction was performed in a thermocycler (Eppendorf Mastercycler 96 vapo protect; Eppendorf, Hamburg) with an initial denaturation at 95 °C for 4 min, 36 PCR cycles of denaturation at 95 °C for 40 s, annealing between 53–56 °C (depending on the specific primer pair) for 40 s and elongation at 72 °C for 60 s, followed by a final elongation at 72 °C for 4 min. For DNA samples older than 50 years, PCR cycles were increased to 46 cycles and a larger amount of DNA (1.5 µL of extracted DNA in a reaction volume of 11 µL) was used. The resulting amplicons were sequenced at the Biodiversity and Climate Research Centre (BiK-F) laboratory using the abovementioned PCR primers. However, amplicons from M-ITS1/smITS-R1 were sequenced using the ITS4 reverse primer. The resulting sequences were deposited in GenBank (<https://www.ncbi.nlm.nih.gov/genbank/>, Table 1).

### Alignments and phylogenetic tree reconstruction

We used 93 samples (including 62 of the *Ustilago striiformis*-complex) for the phylogenetic analysis; 93 had sequences from nrITS, *atp2* (ATP synthase subunit 2) and *ssc1* (member of the heat shock proteins), and 70 had additional sequences from *myosin* (myosin group I), *map* (methionine aminopeptidase), *rpl3* (ribosomal protein L3), *tif2* (initial translation factor of eIF4A), *sdh1* (succinate dehydrogenase ubiquinone flavoprotein), and *rpl4A* (ribosomal protein L4-A) (Table 1). About two thirds of the samples (62) belonged to the *U. striiformis* species complex. *Sporisorium inopinatum* (syn. *Langdonia inopinata*) was chosen as outgroup, according to the findings of McTaggart *et al.* (2012a).

Alignments were made on individual loci using mafft v. 7 (Katoh & Standley 2013) using the G-INS-i algorithm. Both leading and trailing gaps of the alignments were removed manually. Two different sets of concatenated alignments for the phylogenetic constructions were generated. The first multigene-alignment includes three loci (ITS, *atp2*, and *ssc1*) from 93 smut samples. The resulting total alignment was 1502 bp (ITS: 643 bp, *atp2*: 595 bp, *ssc1*: 264 bp). The second multigene-alignment included nine genes with a final alignment of 3156 bp (ITS: 643 bp, *atp2*: 595 bp, *ssc1*: 264 bp, *map*: 251 bp, *myosin*: 257 bp, *rpl4A*: 415 bp, *rpl3*: 218 bp, *sdh1*: 269 bp, *tif2*: 244 bp).

The diagnostic bases for the *U. striiformis* species complex for all gene markers were determined using the above mentioned alignments. One further ITS alignment was created (443 bp), with the sequence of the type specimen of *U. bromina* (Table 1), the *U. bromina* sequences from GenBank (KF381006-8) and sequences from the same host-fungus-combination from this study, to check if all specimens were sequence-identical with the type collection of *U. bromina* on *Bromus inermis* (data not shown).

For phylogenetic tree constructions, Minimum Evolution (ME) analysis was done using Mega 6.06 (Tamura *et al.* 2013) with the Tamura-Nei substitution model and assuming

Type specimens are printed in bold face.

complete deletion at 80 % cut-off with 1000 bootstrap replicates. All other parameters were set to default values. Maximum Likelihood (ML) analysis was done using RAxML (Stamatakis 2014) with parameters set to default values and Bayesian analysis was done using MrBayes 3.2 (Ronquist & Huelsenbeck 2003) running five times with model 6 (GTR) using four incrementally heated chains for 10 million generations, sampling every 1000<sup>th</sup> tree discarding the first 30 % of the obtained trees, all other parameters were set to default on the TrEase webserver (<http://www.thines-lab.senckenberg.de/trease>).

To account for potentially deviating evolutionary properties, the analysis in ME was done also on a partitioned concatenated dataset. As no supported differences within the topology of the trees were observed in comparison with the un-partitioned dataset, the other analyses were carried out without partitioning.

### Morphological examination

For light microscopy, fungarium specimens (GLM-F107417, GLM-F105836, GLM-F107435, GLM-F107413, GLM-F047379, GLM-F105827) were transferred to 60 % lactic acid on a slide. Morphological examination was carried out using a Zeiss Imager M2 AX10 microscope (Carl Zeiss, Göttingen). Measurements of the spores were performed at x400. The measurements are reported as maxima and minima in parentheses, and the mean plus and minus the standard deviation of a number of measurements is given in parenthesis. The means are placed in italics.

## RESULTS

### Phylogenetic inference

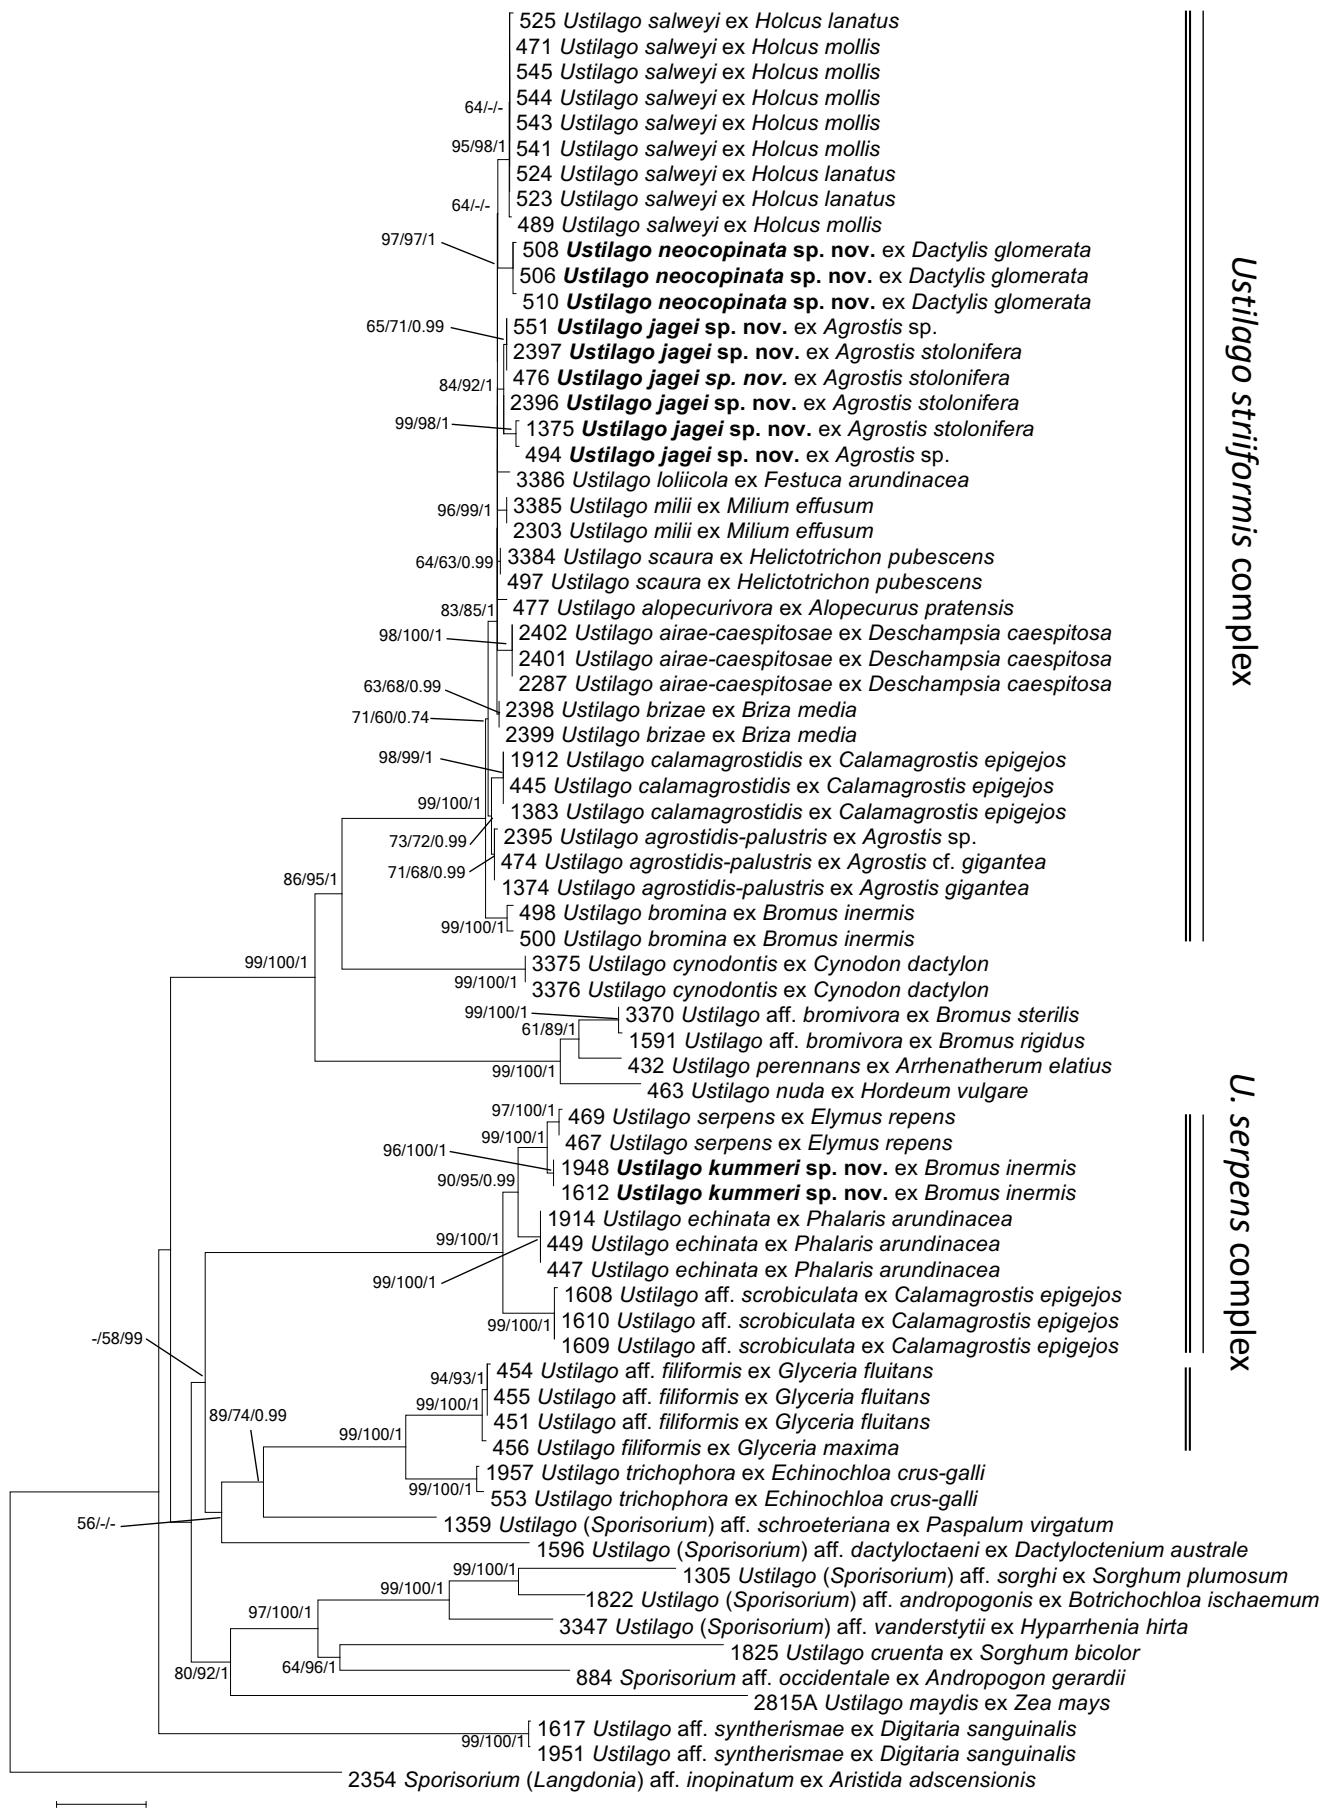

The LSU sequence data were excluded from further analysis since sequences were identical for all members of the *Ustilago striiformis* species complex (data not shown). All other loci showed SNPs within the *U. striiformis* cluster. The diagnostic bases (SNPs) with their specific positions are given in Fig. 6.

There were no supported conflicts in the topology of the trees of the single loci and the concatenated trees. Thus, the datasets were combined and used as concatenated for further analysis. The multigene tree based on nine different loci (Fig. 1) showed strong to maximum support for a monophly of the *U. striiformis* species complex. If multiple specimens from one host species were included, these grouped together with strong to maximum support, except for the clades corresponding to *U. scaura* s. lat. (ME 64, ML 63, BA 0.99), *U. brizae* (ME 63, ML 68, BA 0.99), and *U. agrostidis-palustris* (ME 71, ML 68, BA 0.99), which received weak to strong support (Fig. 1).

A phylogenetic reconstruction (Fig. 2) with an additional 21 specimens but based on only half of the characters per specimen (ITS, atp2, and ssc1) revealed the same groups as the double-sized alignment, but expectedly with weaker statistical support. For example, the three weak to strongly supported lineages shown in Fig. 1 still grouped together, but with no or weak support (*U. brizae* – ME 64, ML -, BA 0.79; *U. scaura* s. lat. – ME -, ML -, BA 0.79; *U. agrostidis-palustris* – no support), highlighting the importance of gene selection.

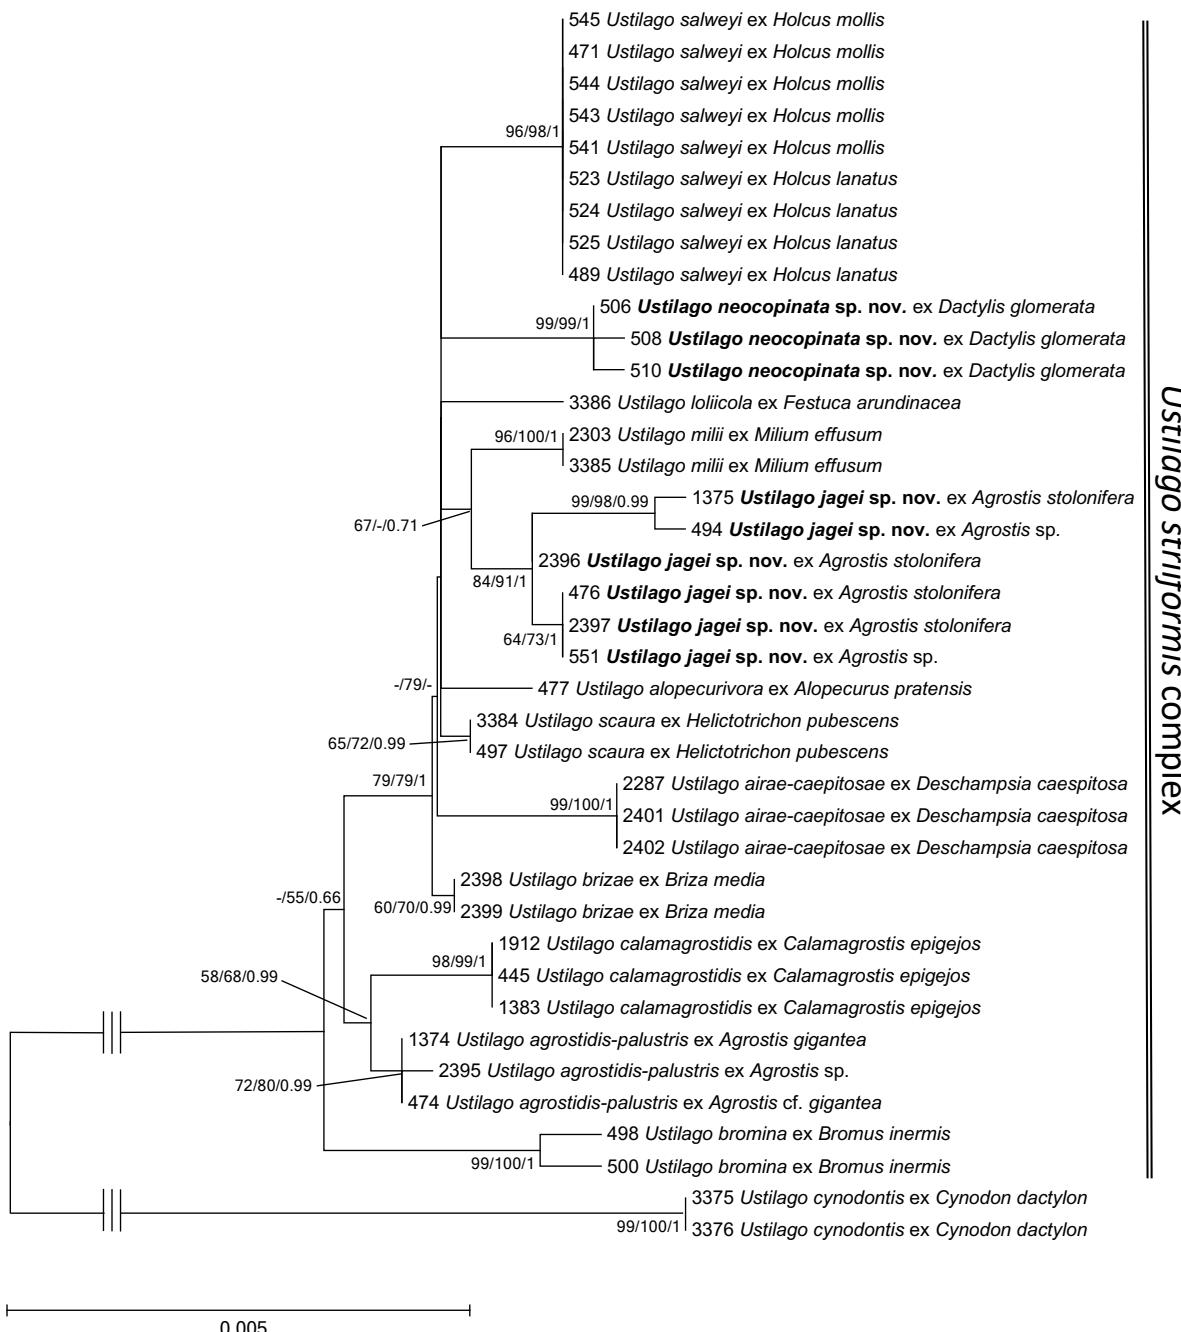

In the phylogenetic reconstruction based on fewer genes (Fig. 2) additional specimens were included, which further supported the high degree of genetic differentiation in conjunction with the host species infected. Specimens from *Festuca* and *Lolium* grouped together with strong support, while the monophly of the clade containing samples from *Alopecurus* species was unsupported to weakly supported (ME 64, ML -, BA -). Two monophyletic groups were absent from the tree with more loci (Fig. 1): one on *Calamagrostis villosa* and another on *Arrhenatherum elatius*. Both of these groups were highly supported (*Calamagrostis*: ME 76, ML 94, BA 0.99; *Arrhenatherum*: ME 92, ML 99, BA 1) in the tree based on fewer loci (Fig. 2).

In both phylogenetic trees (Figs 1–2), *U. cynodontis* was inferred as the sister species to the whole *U. striiformis* species complex. To illustrate the relationships within this species complex further, two additional phylogenetic

*Ustilago striiformis* complex*U. serpens* complex

**Fig. 1.** Phylogenetic tree based on Minimum Evolution analysis of nine loci (ITS, myosin, map, rpl3, tif2, ssc1, sdh1, rpl4A, atp2). Numbers on branches denote support in Minimum Evolution, Maximum Likelihood and Bayesian Analyses, in the respective order. Values below 55 % are denoted by '-'. The bar indicates the number of substitutions per site.

*Ustilago striiformis* complex*U. serpens* complex

**Fig. 3.** Phylogenetic tree based on Minimum Evolution analysis of nine loci (ITS, *myosin*, *map*, *rpl3*, *tif2*, *ssc1*, *sdh1*, *rpl4A*, *atp2*) detailed showing the *Ustilago striiformis*-complex with the outgroup *U. cynodontis*. Numbers on branches denote support in Minimum Evolution, Maximum Likelihood and Bayesian Analyses, in the respective order. Values below 55 % are denoted by '-'. The bar indicates the number of substitutions per site.

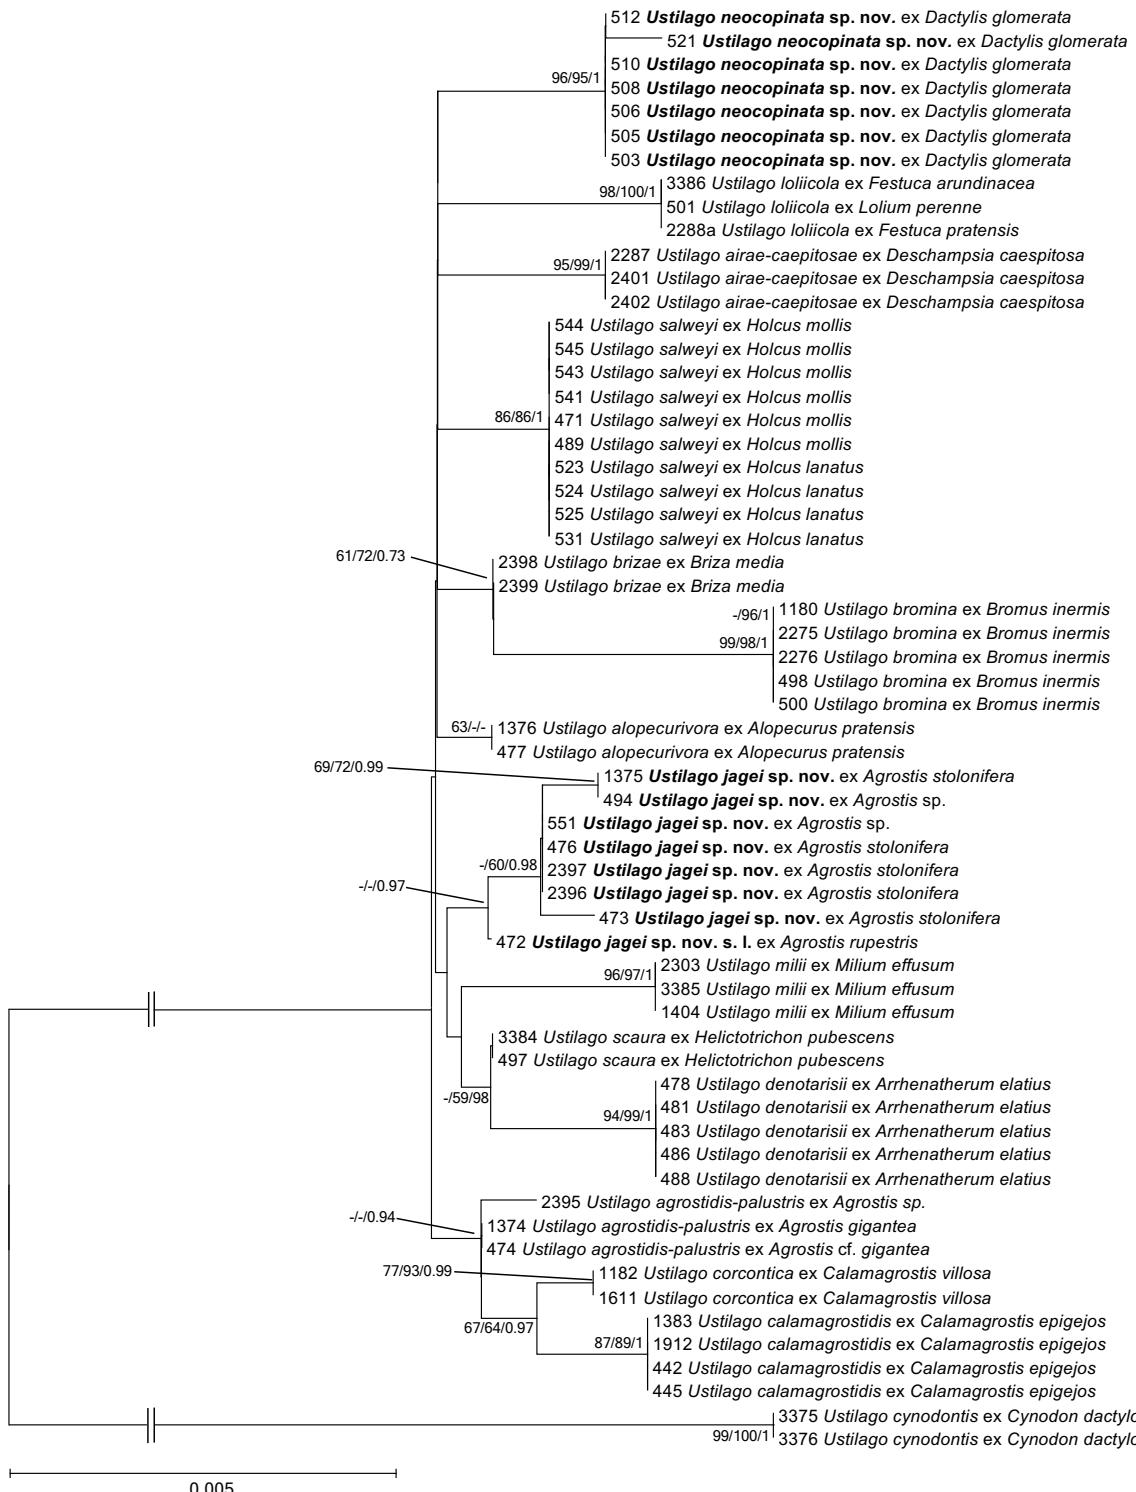

trees with a reduced sampling and *U. cynodontis* as outgroup are shown in Figs 3 (9 loci) and 4 (3 loci). The support values and the topology were comparable to the phylogenetic reconstructions in Figs 1–2. In both phylogenetic trees, *U. serpens* on *Elymus repens* and on *Bromus inermis* grouped together with high to maximum support. This group clustered with two further lineages with larger echinulate spores compared to the *U. striiformis* species complex, which is considered a synapomorphy of this lineage.

The resolution on the backbone was rather low, as highlighted also by the ambiguous placement of *U. maydis*, which was resolved as a sister group to the pathogens on the

majority of panicoid hosts in the tree based on 9 loci (Fig. 1) with moderate to maximum support, while being inferred as a sister to the clade containing the *U. species* complex as well as the *U. nuda* species group with lacking to maximum support in the tree based on three loci (Fig. 2).

### Morphology

The degree of overlap in morphological characteristics was too high in both species complexes to provide easily accessible characteristics for species delimitation (Fig. 5). The individual measurements are included in the species descriptions below and summarized in Table 3.

*Ustilago striiformis* complex

**Fig. 4.** Phylogenetic tree based on Minimum Evolution analysis of three loci (ITS, ssc1, atp2) detailed showing the *Ustilago striiformis*-complex with the outgroup *U. cynodontis*. Numbers on branches denote support in Minimum Evolution, Maximum Likelihood and Bayesian Analyses, in the respective order. Values below 55 % are denoted by '-'. The bar indicates the number of substitutions per site.

## TAXONOMY

Based on our phylogenetic analyses, the following nomenclature and taxonomic changes are proposed for leaf stripe smuts caused by species of *Ustilago*. The positions given for the diagnostic bases refer to specific positions in the alignments as highlighted in the alignment consensus sequences in Fig. 4. Only selected synonyms are given

here. For a complete synonymy reference should be made to Vánky (2012) and references therein.

***Ustilago agrostidis-palustris*** W. H. Davis ex Ciferri, *Ann. Mycol.* **29**: 54 (1931).

**Type:** USA: Wisconsin: Madison, on cultivated 'reddtop' (i.e. *Agrostis* "palustris Huds.", now *Agrostis gigantea*),

8 July 1921, W. H. & J. J. Davis (BPI 166994 – **lectotype designated here**, MBT 380628).

**Confirmed host:** *Agrostis gigantea*.

**Confirmed distribution:** Germany and USA.

**Notes:** *Ustilago agrostidis-palustris* can be distinguished from other leaf stripe smuts of the *U. striiformis* species complex based on its host specific occurrence on *Agrostis gigantea* s. lat. Furthermore, it differs in one diagnostic base from all other species of the *U. striiformis*-complex included in this study – in the *sdh1* gene there is a C instead of a T at position 138 (Table 2, Fig. 6).

***Ustilago airae-caespitosae* (Lindr.) Liro, Ann. Acad. Sci. Fenn., ser. A 17 (1): 71 (1924).**

**Basionym:** *Tilletia airae-caespitosae* Lindr., Acta Soc. Fauna Flora Fenn. 26:15 (1904).

**Type:** **Finland:** Nyland: Helsingfors, Hagasund, on *Aira caespitosa* (i.e. *Deschampsia caespitosa*), 10 Aug. 1902, J. I. Lindroth [Vestergren, Micr. Rar. Sel. no. 806; Sydow, Ustl. no. 316] (M-0236198 – **lectotype designated here**, MBT 380628; from one of the several duplicate collections treated as “lectotype” by Lindeberg, *Symb. Bot. Upsal.* 16 (2): 135, 1959).

**Confirmed host:** *Deschampsia caespitosa*.

**Confirmed distribution:** Austria and Finland.

**Notes:** Within the *Ustilago striiformis* species complex, *U. airae-caespitosae* can be distinguished from other species based on the host-specific occurrence on *Deschampsia caespitosa*. Furthermore, it differs in six diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *atp2* gene it has an A instead of a G at position 22 and 94, in the *map* gene there is a T instead of a C at position 227, in the *myosin* gene there is an A instead of a G at position 133, in the *rpl3* gene a T instead of a C at position 199, and an A instead of a G at position 576 in the ITS region (Table 2, Fig. 6).

***Ustilago alopecurivora* (Ule) Liro, Ann. Acad. Sci. fenn., ser. A 17 (1): 72 (1924).**

**Basionym:** *Tilletia alopecurivora* Ule, *Hedwigia* 25: 113 (1886).

**Synonyms:** *Uredo longissima* var. *megalospora* Riess, in Rabenhorst, *Herb. Viv. Myc.* no. 1897 (1854).

***Ustilago megalospora* (Riess) Cif., *Nuovo Giorn. Bot. Ital.* 40: 261 (1933).**

**Type:** **Germany:** Bavaria: Coburg, Hofgarten, on *Alopecurus pratensis*, June 1879, E. Ule (B – holotype lost); Berlin: Charlottenburg-Nord, Kolonie Königsdamm, slope of ditch, 9 Aug. 1988, H. Scholz (B 70 0014985 – **neotype designated here**, MBT 380629).

**Confirmed host:** *Alopecurus pratensis*.

**Confirmed distribution:** Germany.

**Notes:** Within the *U. striiformis* species complex, *U. alopecurivora* can be distinguished from other species based on the host-specific occurrence on *Alopecurus pratensis*. Furthermore, *U. alopecurivora* differs in three diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *atp2* gene, there is an A instead of a G at position 358, in the *map* gene there is a G instead of a T at position 192, and in the *myosin* gene there is a T instead of a C at position 83 (Table 2, Fig. 6).

***Ustilago brizae* (Ule) Liro, Ann. Acad. Sci. Fenn., Ser. A 17 (1): 74 (1924).**

**Basionym:** *Tilletia brizae* Ule, *Verh. Bot. Ver. Prov. Brandenb.* 25: 214 (1884).

**Type:** **Germany:** Bavaria: Coburg, Rögener Berg, on *Briza media*, July 1879, E. Ule [Rabenhorst, *Fungi Eur.* no. 3604] (M-0147750 – **lectotype designated here**, MBT 380630; from one of the several duplicate collections treated as “lectotype” by Lindeberg, *Symb. Bot. Upsal.* 16(2): 135, 1959).

**Confirmed hosts:** *Briza media*.

**Confirmed distribution:** Austria and Germany.

**Notes:** Within the *U. striiformis* species complex, *U. brizae* can be distinguished from other species based on the host-specific occurrence on *Briza media*. Furthermore, *U. brizae* differs in one diagnostic base from all other species within the *U. striiformis* species complex included in this study, except *U. bromina* on *Bromus inermis*, in having a C instead of a T at position 621 in the ITS region, and differs from *U. bromina* by having an A instead of a G at position 223 in the ITS region (Table 2, Fig. 6).

***Ustilago corcontica* (Bubák) Liro, Ann. Acad. Sci. Fenn., ser. A 17 (1): 383 (1924).**

**Basionym:** *Tilletia corcontica* Bubák, *Houby Ceské Hemibasidii* 2: 47 (1912).

**Type:** **Czech Republic:** on the crest of Riesengebirge Mts, on *Calamagrostis halleriana* (i.e. *C. villosa*), 20 July 1872, J. Gerhardt (BPI 172761 – **lectotype designated here**, MBT 380631; one of the “isolectotypes” of Lindeberg, *Symb. Bot. Upsal.* 16(2): 114, 1959).

**Confirmed host:** *Calamagrostis villosa*.

**Confirmed distribution:** Czech Republic and Germany.

**Notes:** Within the *U. striiformis* species complex, *U. corcontica* can be distinguished from other species based on the host-specific occurrence on *Calamagrostis villosa*. Furthermore, *U. corcontica* differs in one diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *atp2* gene there is an T instead of a C at position 535 (Table 2, Fig. 6).

***Ustilago denotarisii*** A. A. Fischer v. Waldheim, *Aperçu Syst. Ustil.*: 22 (1877); as “de Notarisii”.

**Type:** Italy: on *Arrhenatherum* spp. (not located but could also not be confirmed as lost; a neotype may need to be designated for this species in the future).

**Confirmed hosts:** *Arrhenatherum* species.

**Confirmed distribution:** Germany and Italy.

**Notes:** Spores globose to ovoid, standard range (9.0–)10.5–(av. 11.2)–12.0 (–13.5) × (8.0–)9.0–(av. 9.7)–10.5(–12.0) µm, length/breadth ratio of 1.10–(av. 1.20)–1.38, olive-brown, and finely echinulate. Within the *U. striiformis* species complex, *U. denotarisii* can be distinguished from other species based on the host-specific occurrence on *Arrhenatherum* species. Furthermore, *U. denotarisii* differs in two diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *atp2* gene there is an A instead of a G at position 346, and in the gene *ssc1* there is an A instead of a C at position 182 (Table 2, Fig. 6).

***Ustilago echinata*** J. Schröt., *Abh. Schles. Ges. Vaterl. Kult., Abth. Naturwiss.*: 48: 4 (1870 [“1869”]).

**Type:** Poland: Silesia: ‘Schwarzwasserbruch’, near Legnica, on *Phalaris arundinacea*, June 1869, W. G. Schneider [Rabenhorst, Fungi Eur. no. 1497] (FR – **lectotype designated here**, MBT 380632; one of the several duplicate collections previously treated as “lectotype” in Rabenhorst, Fungi Eur. No. 1497).

**Reported hosts:** *Glyceria grandis*, *Phalaris arundinacea*, and *Scolochloa festucacea*.

**Confirmed host:** *Phalaris arundinacea*.

**Known distribution:** Asia, North America, and Europe.

**Notes:** This species shares one sequence motif (AACCCAAAC) at positions 20–27 in the ITS region with other coarsely ornamented stripe smuts (*U. serpens* clade in Fig. 1), and many SNPs which distinguish *U. echinata* from species of the *U. striiformis*-complex. Within the *U. serpens*-complex, *U. echinata* can be distinguished from other species based on its host-specific occurrence on *Phalaris arundinacea* (type host). Whether the other hosts of a similar ecotype are infected by the same species could not be clarified in the current study, but the high degree of host specificity observed in *Ustilago* renders it possible that specimens from other host genera will have to be described as new species. Furthermore, *U. echinata* differs

in eight diagnostic bases from all other species within the *U. serpens* species complex included in this study – in the *atp2* gene there is a G instead of an A at position 85, in the *map* gene there is an A instead of a G at position 208, in the *myosin* gene there is a C instead of an A at position 141 and a T instead of a C at position 156, in the *rpl3* gene there is a T instead of a C at position 91 and an A instead of a G at position 146, in the *sdh1* gene there is an A instead of a G and at positions 58 and 256, and in the ITS locus there is a C instead of an A at position 19, a C instead of a T at position 38, an A instead of a gap at position 186 and 596 and a G instead of an A at positions 188 and 604 (Tab. 2, Fig. 6).

Due to the generally narrow host specificity of smut fungi, it is conceivable that *U. echinata* will be revealed to be a species group.

***Ustilago jagei*** J. Kruse & Thines, sp. nov.

MycoBank MB819627

(Fig. 5A–B)

**Etymology:** Named after mycologist Horst Jage from Kemberg (Germany), who has made significant contributions to the knowledge of phytopathogenic fungi and has enabled well-sampled phylogenetic investigations in various plant pathogens by his outstanding collections.

**Diagnosis:** Within the *U. striiformis* species complex, *U. jagei* can be distinguished from other species based on its host-specific occurrence on *Agrostis stolonifera* s. lat. Furthermore, *U. jagei* differs in two diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *atp2* gene there is an A instead of a G at position 466 and in the gene *rpl3* there is an A instead of a G at position 92 (Table 2, Fig. 6).

**Type:** Germany: Saxony-Anhalt: Dessau, Kühnauer Sea, southern shore east-southeast of Großkuhnau, wayside, on *Agrostis stolonifera*, 16 Sept. 2001, H. Jage (GLM-F047379 – holotype).

**Description:** Sori as long narrow streaks parallel to vascular bundles, mostly in the leaves, rarely ascending into the inflorescence, initially covered by the epidermis of the plants, which soon frays. Spore mass dark brown to almost black, powdery. Infection systemic, infected plants usually sterile. Spores globose to ovoid, (9.5–)10.0–(av. 10.9)–11.5(–13.5) × (7.5–)8.5–(av. 9.3)–10.0(–11.5) µm, length/breadth ratio 1.04–(av. 1.24)–1.5, olive-brown, finely echinulate (Table 3, Figs 3–4).

**Confirmed hosts:** *Agrostis rupestris* and *A. stolonifera*.

**Fig. 5.** Sori and spores of *Ustilago jagei* (A–B), *U. denotarisii* (C–D), *U. neocopinata* (E–F), *U. salweyi* (G–H), *U. kummeri* (I–J), and *U. serpens* s. str. (K–L). **A.** Sori of *U. jagei* on *Agrostis stolonifera* (GLM-F047379); **B.** Teliospores seen by LM; **C.** Sori of *U. denotarisii* on *Arrhenatherum elatius* (GLM-F105836); **D.** Teliospores seen by LM; **E.** Sori of *U. neocopinata* on *Dactylis glomerata* (GLM-F107413); **F.** Teliospores seen by LM; **G.** Sori of *U. salweyi* on *Holcus lanatus* (GLM-F107417); **H.** Teliospores seen by LM; **I.** Sori of *U. kummeri* on *Bromus inermis* (GLM-F107435); **J.** Teliospores seen by LM; **K.** Sori of *U. serpens* s. str. on *Elymus repens* (GLM-F105827); and **L.** Teliospores seen by LM.

**Table 2.** Diagnostic bases within the *Ustilago striformis* and the *Ustilago serpens* complexes.

Slash () = instead of. X = no diagnostic bases.

**Fig. 6.** Alignment consensus sequences for the alignments used in this study with positions of diagnostic bases highlighted in bold face.

*Confirmed distribution:* Germany and Switzerland.

*Notes:* It seems possible that *U. jagei* on *Agrostis stolonifera* s. lat. represents a species complex, and further investigations with more specimens and additional gene loci are needed to clarify this situation.

### ***Ustilago kummeri* J. Kruse & Thines, sp. nov.**

MycoBank MB819628

(Fig. 5I–J)

*Etymology:* Named after the mycologist Volker Kummer from Potsdam (Germany), who has made significant contributions to the knowledge of phytopathogenic fungi and has enabled well-sampled phylogenetic investigations in various plant pathogens by his outstanding ability to recognise easily overlooked plant pathogens.

*Diagnosis:* Differs from species of the *U. striiformis* species complex in the larger spores and taller warts. Furthermore, *U. kummeri* shares one sequence motif at positions 20-27 (AACCCAAAC) with other coarsely ornamented stripe smuts, and many SNPs distinguishing it from species of the *U. striiformis* species complex. Within the *U. serpens*-complex, *U. kummeri* can be distinguished from other species based on the host-specific occurrence on *Bromus inermis*. Furthermore, *U. kummeri* differs in two diagnostic bases from *U. serpens* on *Elymus repens* – in the ITS region there is an C instead of a G at position 260 and G instead of an A at position 629 (Table 2, Fig. 6).

*Type: Germany:* Brandenburg: Middlemark, Uetz: Hinterer Werder, southwest corner between Sacrow-Paretzer-Channel und Havel-Channel, on *Bromus inermis*, 19 June 2010, V. Kummer (GLM-F107435 – holotype; VK 2577/17 – isotype).

*Description:* Sori as long, narrow streaks parallel to vascular bundles, mostly in the leaves, rarely ascending to the inflorescence, initially covered by the epidermis of the plants, which soon frays. Spore mass dark brown, powdery. Infection systemic, infected plants mostly sterile. Spores ovoid to globose, (11.0-) 12.0- (av. 13.0) -14.0 (-15.5) × (9.0-) 10.5- (av. 11.5) -12.0 (-13.5), length/breadth ratio 1.04- (av. 1.15) -1.41, olive-brown, coarsely verrucose to echinulate (Table 3, Figs 5–6).

*Confirmed host:* *Bromus inermis*.

*Confirmed distribution:* Germany.

*Notes:* It seems likely that additional species will be discovered in the *U. serpens* clade once more stripe-smuts with coarse spore ornamentation will be scrutinised.

### ***Ustilago lollicola* Ciferri, *Fl. Ital. Crypt., Par. I. Fungi, Fasc.* 17: 345 (1938).**

*Type: Germany:* Berlin: Berlin-Weissensee, on *Lolium perenne*, Sept. 1877, E. Ule [Rabenhorst, Fungi Eur. no.

2491] (FR – **lectotype designated here**, MBT 380633; from one of the several duplicate collections treated as “lectotype” by Lindeberg, *Symb. Bot. Upsal.* 16 (2): 136, 1959).

*Confirmed hosts:* *Festuca arundinacea* s. lat. and *Lolium perenne*.

*Confirmed distribution:* Germany.

*Notes:* Within the *U. striiformis* species complex, *U. lollicola* can be distinguished from other species based on the specific occurrence on the closely related hosts *Festuca arundinacea* s. lat. and *Lolium perenne*. Furthermore, *U. lollicola* differs in four diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *ssc1* locus there is an A instead of a G at positions 210, 214 and 231, and a T instead of a C at position 243 (Table 2, Fig. 6).

### ***Ustilago milii* (Fuckel) Liro, *Ann. Acad. Sci. Fenn., ser. A* 17 (1): 78 (1924).**

*Basionym:* *Tilletia milii* Fuckel, *Jb. nassau. Ver. Naturk.* 23-24: 40 (1870).

*Type: Germany:* Hesse: Rabenkopf Mt., near Oestrich, on *Milium effusum*, L. Fuckel [Fungi Rhenani no. 2410] (FR – **lectotype designated here**, MBT 380634, from one of the several duplicate collections treated as “lectotype” in Fuckel, Fungi Rhenani no. 2410).

*Confirmed host:* *Milium effusum*.

*Confirmed distribution:* Germany.

*Notes:* Within the *U. striiformis* species complex, *U. milii* can be distinguished from other species based on the host-specific occurrence on *Milium effusum*. Furthermore, *U. milii* differs in two diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *atp2* gene there is an A instead of a G at position 301, and in the ITS there is a T instead of a C at position 206 (Table 2, Fig. 6).

### ***Ustilago neocopinata* J. Kruse & Thines, sp. nov.**

MycoBank MB819630

(Fig. 5E–F)

*Etymology:* Highlights the unexpected finding that there are several distinct and host-specific species within the *U. striiformis* species complex.

*Diagnosis:* Within the *U. striiformis* species complex, *U. neocopinata* can be distinguished from other species based on the host-specific occurrence on *Dactylis glomerata*. Furthermore, *U. neocopinata* differs in five diagnostic bases from all other species within the *U. striiformis* species complex included in this study – in the *ssc1* gene there is an A instead of a G at positions 69 and 198, in the *rpl4A* gene there is a T instead of a C at position 120, in the *rpl3* gene there is an A instead of a G at position 40, and in the ITS region there is an A instead of a G at position 617 (Table 2, Figs 5–6).

**Table 3.** Measurements from 100 teliospores for four different species of the *Ustilago striiformis*-complex on *Agrostis stolonifera*, *Dactylis glomerata*, *Arrhenatherum elatius*, and *Holcus lanatus*, as well as two species of the *Ustilago serpens*-complex on *Elymus repens* and *Bromus inermis*.

**Type:** **Germany:** Bavaria: Upper Franconia, Kronach county, Wallenfels, in the direction of the sewage treatment plant downstream of Stumpfenschneidmühle, on *Dactylis glomerata*, 15 July 2012, J. Kruse (GLM-F107413 – holotype).

**Description:** Sori as long small streaks parallel to vascular bundles, mostly in the leaves, very rarely ascending to the inflorescence, initially covered by the epidermis of the plants, which soon frays. Spore mass dark brown to almost black, powdery. Infection systemic, infected plants mostly sterile. Spores mostly globose, rarely ovoid, (9.0–) 10.0– (av. 10.5)–11.0 (–13.0) × (7.5–) 9.0– (av. 9.8)–10.5 (–11) µm, length/breadth ratio 1.00– (av. 1.07)–1.18, olive-brown, finely echinulate (Table 3, Figs 5–6).

**Notes:** As the host is widespread throughout the Holarctic region, it is conceivable that the species will prove to have a much wider distribution range than currently known.

***Ustilago salweyi* Berk. & Broome, Ann. Mag. Nat. Hist. 5: 463 (1850).**  
(Fig. 5G–H)

**Type:** **UK: Channel Islands:** Guernsey, St Martin's, on *Holcus lanatus* [originally misidentified as *Dactylis glomerata* fide Hubbard, in Stevenson, Plant Dis. Rep. 30: 57, 1946], 1847, T. Salwey (K-M – holotype; K-M00022071 – isotype).

**Synonyms:** *Uredo striiformis* Westend., Bull. Acad. R. Sci. Belg., cl. sci. 18: 406 (1852); as “*striaeformis*”.

*Uredo salveii* (Berk. & Broome) Oudem., Prodromus Florae Bataviae, 2<sup>nd</sup> edn, 4: 180 (1866).

*Tilletia debaryana* A.A. Fisch. Waldh., in Rabenhorst, Fungi eur. no. 1097 (1867).

*Tilletia striiformis* (Westend.) Magnus, Malpighia 1: 8 (1875).

*Ustilago striiformis* (Westend.) Niessl, Hedwigia 15: 1 (1876).

*Tilletia salveii* (Berk. & Broome) P. Karst., Bidrag. Känndom. Finlands Naurt. Folk. 6: 102 (1884).

**Confirmed hosts:** *Holcus lanatus* and *H. mollis*.

**Confirmed distribution:** Belgium, Germany, and UK.

**Notes:** Spores globose to ovoid, standard range (9.5–)10.0– (av. 10.6)–11.0 (–12.5) × (7.5–) 9.0– (av. 9.4)–10.0 (–10.5) µm, finely echinulate, length/breadth ratio 1.00– (av. 1.15)–1.39. Within the *U. striiformis* species complex, *U. salweyi* can be distinguished from other species based on the host-specific occurrence on *Holcus lanatus* and *H. mollis*. Furthermore, *U. salweyi* differs in three diagnostic bases from all other species within the *striiformis* species complex included in this study – in the *rp4A* gene there is a T instead of a C at position 85, in *rp3* there is a T instead of a C at position 133, and in the ITS region there is an A instead of a G at positions 103 (Table 2, Fig. 6).

The original host was misidentified as *Dactylis glomerata*, but this was found to be incorrect and actually *Holcus lanatus* by the leading grass specialist C.E. Hubbard (in Stevenson 1946). David Hawksworth also studied the type materials in K-M and concurs. Hosts in their vegetative stage can be

misidentified, as some characteristics, such as leaf shape, ligula, and general habit can be modified as a consequence of infection.

***Ustilago scaura* Liro s. lat.**, Ann. Acad. Sci. Fenn., ser. A, 17(1): 73 (1924).

**Replaced name:** *Tilletia avenae* Ule, Verh. Bot. Vereins Prov. Brandenburg 25: 214 (1884).

**Type:** **Germany:** Bavaria: Coburg, Fortress, on *Avena pratensis* (i.e. *Helictotrichon pratense*), June 1879, E. Ule (s. n. – lost); Hesse: county Tann/Rhön, at Galgenmount, on *Avena pubescens* [now, *Helictotrichon pubescens*], 16 Sept. 1990, H. Scholz (B 70 0014830 – **neotype designated here**, MBT 380637).

Non *Ustilago avenae* (Pers.) Rostrup, Overs. K. danske Vidensk. Selsk. Forh. Medlemmers Arbeider: 13 (1890).

**Confirmed host:** *Helictotrichon pubescens*, *H. pratense*?

**Confirmed distribution:** Germany.

**Notes:** Within the *U. striiformis* species complex, *U. scaura* s. lat. can be distinguished from other species based on the host-specific occurrence on *Helictotrichon pratense* and *H. pubescens*. Furthermore, *U. scaura* s. lat. differs in one diagnostic base from all other species within the *U. salweyi* species complex included in this study, except *U. denotarisi* on *Arrhenatherum* spp., in having a T instead of a C at position 628 in the ITS region, and from *U. denotarisi* on *Arrhenatherum elatius* in having a 13 nucleotide deletion at positions 222–241 in the ITS alignment (Table 2, Fig. 6).

Since the type has been lost, we designate a neotype for *Ustilago scaura* with material on the closely related *H. pubescens*.

***Ustilago scrobiculata* Liro**, Ann. Acad. Sci. Fenn., ser. A 17(1): 68 (1924).

**Type:** **Finland:** Nyland: Pornainen, Kirveskoski, on *Calamagrostis arundinacea*, 9 Aug. 1916, T. Putkonen & J. I. Liro (H – lectotype, designated by Lindeberg, Symb. Bot. Upsal. 16 (2): 130 (1959)).

**Synonym:** ? *Ustilago deyeuxiae* L. Guo, Mycosistema 6: 51 (1993).

**Reported hosts:** *Calamagrostis* spp. (see Vánky 2012: 1265).

**Reported distribution:** Asia and Europe.

**Notes:** This species shares one sequence motif with other coarsely ornamented stripe smuts (AACCCAAAC at positions 20–27), which distinguishes it from species of the *Ustilago striiformis* species complex, and many additional single SNPs. Within the *U. serpens* species complex, *U. scrobiculata* differs in 21 diagnostic bases from other species (Table 2, Fig. 6). It seems possible that *U. deyeuxiae* has not been sampled

on *Calamagrostis arundinacea*, as the host of *U. deyeuxiae* is given as “*Deyeuxia arundinacea*” by Guo (1993), which is often seen as a synonym of *D. pyramidalis* in Asian literature (e.g. Shenglian et al. 2006). Thus, it seems possible that the species needs to be reconsidered as independent from *U. scrobiculata* once sequence data from the type specimen become available.

***Ustilago serpens* (P. Karst.) B. Lindeb., *Symb. Bot. Upsal.* **16**(2): 133 (1959).**

*Basionym:* *Tilletia serpens* P. Karst., *Fungi Fenn. Exs., fasc. 6* : no. 599 (1866).

**Type:** **Finland:** Merimasku, on “*Dactylis glomerata*” [re-determined as *Elymus repens* by Lindeberg, *Symb. Bot. Upsal.* **16**(2): 133, 1959], July 1862, P. Karsten [Fungi Fenn. Exs no. 599] (HUV 10432 – **lectotype designated here**; MBT 380638 from one of the several duplicate collections treated as “lectotype” by Lindeberg, *Symb. Bot. Upsal.* **16**(2): 133, 1959).

*Confirmed host:* *Elymus repens*.

*Confirmed distribution:* Finland and Germany.

**Notes:** The spores are small to medium sized, (11.5–) 13.0–(av. 13.5)–14.5 (–15.5) × (10.5–) 11.5 (av. 12.5)–13.0 (–14.0) µm, with a length/breadth ratio of 1.00–(av. 1.09)–1.23 and with coarsely verrucose ornamentation. This species shares one sequence motif with other coarsely ornamented stripe smuts (AACCCAAC at position 20–27), which distinguishes it from species of the *U. striiformis* species complex and many additional SNPs. Within the *U. serpens*-complex, *U. serpens* can be distinguished from other species based on four diagnostic bases: in the *myosin* gene there is an A instead of G at position 93, in *rpl4A* gene there is a T instead of a C at position 232 and in the ITS locus there is a C instead of a T at position 260, and a G instead of an A at position 629 (Table 2, Fig. 6).

Vánky (2012) lists several additional hosts for *U. serpens*. Due to the narrow specialization of stripe-smut revealed in this study, however, it seems likely that these harbour several distinct species. Until sequence data become available for these host-pathogen combinations, *Ustilago* on these other hosts is probably best referred to as *U. serpens s. lat.*

## DISCUSSION

In this study, the closely related species of the *Ustilago striiformis*-complex and some other leaf stripe *Ustilago* smuts were investigated using multigene phylogenetic reconstructions to clarify their relationships. In total, 62 specimens of the *U. striiformis* species complex (incl. *U. calamagrostidis*) and four other leaf stripe smuts (*U. echinata*, *U. filiformis*, *U. scrobiculata*, and *U. serpens s. lat.*) were studied.

Phylogenetic analyses provided strong support for the polyphyly of the leaf-stripe smuts within *Ustilago*. However, the multilocus-based phylogenetic trees support the monophyly of the *U. striiformis* species complex, in contrast to the analysis

by Savchenko et al. (2014a), where it was concluded that the *U. striiformis* group was polyphyletic and the segregation of two species was necessary to render it monophyletic. That interpretation was mainly based on a combined LSU-ITS tree of *U. striiformis* species, where *U. bromina* and *U. nunavutica* were located outside the *U. striiformis s. lat.* clade. Because of this conflicting result, the ITS region of the type specimen of *U. bromina* was sequenced (Table 1) and compared with the deposited GenBank sequences of Savchenko et al. (2014a). The type specimen of *U. bromina* on *Bromus inermis* had an ITS sequence nearly identical (except for a base exchange in a poly A/T region) with the other specimens identified as this species in the current study. It differed in nine bases compared to the three sequences labelled as *U. bromina* in Savchenko et al. (2014a). It is conceivable that these specimens belong to another undescribed smut species (the three sequences were obtained from material from Israel and USA, while the type collection was from Germany), or the quality of the sequences was not optimal; almost all differences in the sequences from Savchenko et al. (2014a) in comparison to the sequences from this study were located behind a poly A/T site, which necessitated re-sequencing for several of the specimens used in this study. Furthermore, misidentification of the host plant seems also possible, as no records were found for the occurrence of *Bromus inermis* in the floras of Israel (<http://flora.org.il/en/plants/>) or Palestine (Feinbrun-Dothan 1986).

*Ustilago nunavutica* was the second species that led Savchenko et al. (2014a) to assume that the *U. striiformis* species complex was polyphyletic. Comparing the ITS and LSU sequences of *U. nunavutica* with sequences from the current study, the LSU sequence used by Savchenko et al. (2014a) showed several SNPs (data not shown), while all other *U. striiformis* samples investigated in this study were identical in the LSU region. In contrast, the ITS sequence of *U. nunavutica* has only few SNPs in comparison to other members of the *U. striiformis* species complex and is identical with *U. neocopinata*. It seems possible that the LSU sequence of *U. nunavutica* either was of bad quality or shows the amplification of a contaminant smut fungus. However, as the genera *Puccinellia* and *Dactylis* are not closely related (Schneider et al. 2009) and very high host specificity has been revealed for the closely related species of the *U. striiformis* species complex in this study, it is unlikely that *U. neocopinata* and *U. nunavutica* are conspecific.

In agreement with Stoll et al. (2005) and Spooner & Legon (2006), we found that *U. calamagrostidis* and *U. corcontica* belonged to the *U. striiformis* species complex. However, further resolution within the *U. striiformis* species complex was only achieved when the protein-coding loci introduced by Kruse et al. (2017b) were employed. The trees revealed a host genus or host species specific occurrence for almost all lineages within the *U. striiformis* species complex, thus they should be treated as distinct species, supported by the observations of Liro (1924). All specimens from a single host species formed a clade according to the host species (or the host genus, in case of *Holcus*), with the exception of the rather closely related species *Lolium perenne* and *Festuca arundinacea* (Malik & Thomas 1966, Catalán et al. 2004, Hand et al. 2010). As most of these clades received high to

maximum support, they should be considered to represent distinct species, which can be distinguished based on the host and diagnostic SNPs (Fig. 6). For most of the 14 lineages of the *U. striiformis* species complex validly published names are available, necessitating the description of only two new species in this complex, *U. neocopinata* on *Dactylis glomerata* and *U. jagei* on *Agrostis stolonifera s. lat.* Vánky (2012) and Savchenko *et al.* (2014a) mentioned that different species on different hosts within this complex vary remarkably in spore shape, size, and ornamentation. However, morphological variation was observed to be high even within the same host species in the current study and also by Vánky (2012). Thus it is difficult to distinguish these closely related species based on morphology, necessitating the consideration of hosts and SNPs for diagnosis. The host range of at least two species of *Ustilago* parasitic to *Agrostis* could not be inferred with certainty, as both ITS and chloroplast loci did not resolve closely related species in the *A. stolonifera* and *A. gigantea* clusters (Amundsen & Warnke 2012).

While investigating synonymies of the *U. striiformis* species complex, it was found that the name *U. salweyi* is the correct name for the stripe smut on *Holcus lanatus*. Stevenson (1946) flagged *U. salweyi* as a “*nomen ambiguum*”, although no action was taken to formally reject the name. Following the ICN (McNeill *et al.* 2012), the name *U. salweyi* has priority over *Uredo striiformis* as it was published two years earlier (Berkeley & Broome 1850: 463). Although the group generally referred to as the *U. striiformis*-group does not contain a species with that as the correct name, as it is still included as a synonym we feel that it is best to continue to use “*U. striiformis*-group” or “species complex” for these fungi as it is so well established and recalls the symptoms all species of the complex exhibit, although this feature is shared by some leaf-stripe smuts not belonging to this complex.

The species within the *U. striiformis* species complex have sometimes been recognised as special forms based on infection trials (Liro 1924, Davis 1930, 1935, Fischer 1940). However, it has been shown for various biotrophic pathogens that the special form concept, in which there is a population continuum with somewhat specialised forms, cannot be upheld (Göker *et al.* 2004, Lutz *et al.* 2005, Kemler *et al.* 2009, Thines *et al.* 2009, Ploch *et al.* 2011, Savchenko *et al.* 2014b, Choi & Thines 2015).

Similar to the situation in the *U. striiformis* species complex, *Ustilago serpens s. lat.* on different hosts clustered in phylogenetically distinct subgroups. As the type host for *U. serpens* is *Elymus repens*, the collections from *Bromus inermis* warrants recognition as a new species. *Ustilago serpens* is another example illustrating the narrow host specialization among smut fungi. As for both the coarsely ornamented stripe-smuts (*U. serpens* clade) and the finely ornamented stripe smuts (*U. striiformis* clade) only a subset of the known hosts could be included in the current study. It is therefore conceivable that some older names published for specific host-pathogen combinations in these groups warrant recognition and several new species await discovery.

With respect to the global phylogeny of *Ustilago* it is noteworthy that even based on nine loci the backbone of the phylogenetic tree was only poorly resolved. Conflicting supported topologies were inferred with respect to the

phylogenetic position of *U. maydis* in the reconstructions based on three (sister to a clade comprising, among others, the *U. nuda* and the *U. salweyi* clade) and nine loci (sister to a clade comprising the majority of smuts on panicoid grasses).

This highlights the high degree of uncertainty that there still is with respect to the global phylogeny of *Ustilago s. lat.* (Thines 2016). Considering the diversity of anatomical characteristics and disease syndromes caused, many of which have arisen several times independently (such as the stripe-smut habit; McTaggart *et al.* 2012a, b, c), any splitting of *Ustilago s. lat.* into smaller genera as suggested by McTaggart *et al.* (2012a, 2016) is probably premature and might become obsolete due to the high degree of parallel evolution and associated homoplasy.

## ACKNOWLEDGEMENTS

This study was funded by the LOEWE research funding programme in the framework of the Cluster for Integrative Fungal Research (IPF). We are grateful to the curators of B (Berlin), GLM (Görlitz), M (Munich), and TUB (Tübingen) for allowing the investigation of specimens in their keeping, and David Hawksworth for important information on *Ustilago salweyi* types in K-M (Kew fungarium) and nomenclatural corrections. We furthermore want to thank the curators of B (Berlin), HBG (Hamburg) and L (Leiden) for searching for the type collection of *Ustilago scaura*. We thank the private collectors Horst Jäge and Volker Kummer for allowing us to include some of their collections in this study. We want to thank Bagdevi Mishra for the opportunity to use TrEase (thines-lab@senckenberg.de/trease) for phylogenetic analysis. Furthermore, we are grateful to Y.-J. Choi for help with the primer design for an internal ITS primer and to Reuel Bennett for proof-reading an initial draft of the manuscript. MT and JK conceived the study; JK made collection trips; FK, HJ, HR, HZ, UR, WD, and VK provided material; JK performed laboratory experiments and microscopy, and also analysed the data; JK and MT interpreted the data and prepared the manuscript with contributions from the other authors.
