#### Abstract

Four tetranuclear heterobimetallic triangle complexes $\left[\mathrm{L}_{3} \mathrm{Co}_{3} \mathrm{Dy}_{2}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{MeOH}_{5}\right)_{5}\left[\left(\mathrm{NO}_{3}\right) \quad(\mathrm{C} 1)\right.\right.$, $\left[\mathrm{L}_{3} \mathrm{Co}_{3} \mathrm{Gd}^{\left(\mathrm{NO}_{3}\right)_{3}\left(\mathrm{MeOH}_{4}\right]}\right](\mathrm{C} 2)$, $\left[\mathrm{L}_{3} \mathrm{Co}_{3} \mathrm{La}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\left(\mathrm{NO}_{3}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{C} 3)\right.$, and $\left[\mathrm{L}_{3} \mathrm{CO}_{3} \mathrm{TbCl}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{0.5}\left(\mathrm{MeOH}_{3.5}\right]\right.$ (C4), where $\mathrm{H}_{2} \mathrm{~L}=1,4$-bisformylnaphthalene-2,3-diol, have been synthesised and structurally characterised. Each complex crystallises with a complete molecule in the asymmetric unit $\left(Z^{\prime}=1\right)$ and displays near perfect octahedrality in two out of three $\mathrm{Co}^{\prime \prime}$ centres. The third Co " ion assumes a different coordination geometry in each complex: six-coordinate octahedral in C1, six-coordinate with a distortion towards trigonal prismatic in C2, five-coordinate trigonal bipyramidal in C3, and fivecoordinate square pyramidal in C4; which has been attributed to increasing lanthanide cation size, coupled with a non-macrocyclic coordination environment. Continuous Shape Measurement (CShM) calculations and octahedral distortion parameter calculations were performed, using the SHAPE and OctaDist software packages, respectively, in order to aid in the assessment of each metal centre's local coordination geometry. The preliminary magnetic investigation of C 3 found $\chi_{\mathrm{m}} T=9.4 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ at 300 K and $M=7.1 \mu_{\mathrm{B}}$ at 1.8 K , which are approximately two thirds the maximum theoretical values for three Co" ions and indicates the presence of a relatively large zero-field splitting parameter $\left(\mathrm{D} / \mathrm{K}_{\mathrm{B}}=65\right.$ к) operative in each $\mathrm{Co}^{\prime \prime}$ ion rather than exchange coupling between the $\mathrm{Co}^{\prime \prime}$ centres.

## Introduction

Metal ions have a rich history in aiding otherwise untenable chemical transformations and play a pertinent role in the selfassembly process of many molecular clusters. Of particular importance, is the use of metals to template the formation of macrocycles and interlocked molecules in a controlled and predictable manner. ${ }^{1-8}$ While mononuclear and homometallic polynuclear complexes are among the most common, there is a great interest in heterometallic complexes with predictable nuclearities and topologies. Heterometallic polynuclear complexes have been explored in many fields of science from antibacterial agents ${ }^{9-11}$ and molecular machines, ${ }^{12-15}$ to heterogenous cata-lysts,,$^{16-19}$ molecular magnets, ${ }^{20-25}$ and spintronic devices. ${ }^{26-30}$

A hexa-phenolate macrocycle, templated with an all-in-plane tetranuclear $\mathrm{Zn}_{3} \mathrm{LaO}_{6} 3 \mathrm{~d} / 4 \mathrm{f}$ core, was first reported by Nabeshima. ${ }^{31}$ This metal cation templated route provided a vast

[^0]improvement in yield over their previous metal-free attempts to perform $3+3$ Schiff base condensations of 1,4-diformylbenzene-2,3-diol with various diamine linkers. ${ }^{32}$ This same method involving templated macrocyclisation was later extended to include various combinations of trivalent lanthanide ions with $\mathrm{Zn}^{\mathrm{II}},{ }^{33-40} \mathrm{Cu}^{\mathrm{II}},{ }^{41-46} \mathrm{Ni}^{\mathrm{II}},{ }^{47}$ or $\mathrm{Co}^{\text {II }}$ centres. ${ }^{48}$ Families of triangular macrocyclic complexes containing $\mathrm{Zn}^{\mathrm{II}}, \mathrm{Cu}^{\mathrm{II}}$, and $\mathrm{Ni}^{\text {II }}$ with a variety of $\mathrm{Ln}^{\text {III }}$ have been investigated by Brooker et al. for their magnetic properties. ${ }^{33,34,41-47}$ More recently, Mashima and Nozaki et al. have prepared macrocyclic complexes with a $\mathrm{Co}^{\mathrm{II}}{ }_{3} \mathrm{Ln}^{\mathrm{III}} \mathrm{O}_{6}$ core for the catalysis of copolymerisation of $\mathrm{CO}_{2}$ and cyclohexene oxide.

While some of the complexes discussed in these reports have been structurally characterised, many have not. In particular, the aldehyde containing intermediate complexes which selfassemble prior to condensation/macrocyclisation have only been successfully isolated, with full structural characterisation reported, for three older examples (Refcodes: HICLIP ${ }^{31}$ and XUVVIV/XUVVOB ${ }^{47}$ ) and four recently reported $\mathrm{Ni}_{3} \mathrm{Ln}$ examples (WARKIN, WARKEJ, WARKOT, and WARKUZ). ${ }^{49}$

MacLachlan et al. ${ }^{50}$ established a method to obtain heptanuclear $\mathrm{Zn}^{\text {II }}$ clusters from the reaction of a pre-formed macrocyclic hexa-phenolate ligand with seven equivalents of $\mathrm{Zn}(\mathrm{OAc})_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, which was later shown to be capable of forming the $\mathrm{Zn}_{3} \mathrm{LaO}_{6}$ type complex by Nabeshima et al. ${ }^{51}$ Nabeshima further showed that the $3+3$ condensation reaction can be
carried out in the presence of two equivalents of zinc per equivalent dialdehyde, yielding a hexanuclear complex contained within the expected macrocycle. ${ }^{31}$

While following our interest in exploring the magneto-structural correlations of non-macrocyclic dialdehyde ligated $\mathrm{TM}_{3} \mathrm{Ln}$ type complexes, four $\mathrm{Co}^{\mathrm{II}}{ }_{3} \mathrm{Ln}$ complexes have been synthesised with notably different $\mathrm{Co}^{\text {II }}$ coordination geometries. We now report the self-assembly and structural characterisation of four non-macrocyclic triangle complexes containing $\mathrm{Co}^{\mathrm{II}}{ }_{3} \mathrm{Ln}^{\mathrm{III}} \mathrm{O}_{6}$ cores, each of which features two octahedrally coordinated $\mathrm{Co}^{\text {II }}$ centres and a third $\mathrm{Co}^{\mathrm{II}}$ featuring a variation in geometry. Preliminary magnetic measurements have been carried out on the La ${ }^{\text {III }}$ containing complex, $\mathbf{C}$, and are briefly discussed.

## Results and discussion

The four $\mathbf{L}_{3} \mathrm{Co}_{3} \mathrm{Ln}$ complexes reported here were prepared from a 3:1:3 mixture of methanolic solution of cobaltous nitrate,

Fig. 1 Schematic showing the general metal-ligand connectivity of the complexes reported in this work. $\mathrm{C}=$ grey, $\mathrm{O}=$ red, $\mathrm{Co}^{\prime \prime}=$ purple, and $L n^{\prime \prime \prime}=$ green.
a lanthanide salt, and the relatively simple ligand, 1,4-bisformylnaphthalene-2,3-diol $\left(\mathrm{H}_{2} \mathbf{L}\right)$. Addition of the cobalt solution caused rapid dissolution of the ligand suspension regardless of order, the same effect was not observed when the lanthanide solution was added prior to the cobalt solution. The reaction mixture required stirring overnight as the reaction proceeded through a (non-product) precipitation stage which redissolved upon further stirring. The lanthanide salts utilised were $\mathrm{Dy}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(\mathbf{C 1}), \mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(\mathbf{C} 2), \mathrm{La}(\mathrm{OAc})_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (C3), and $\mathrm{TbCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (C4). While these complexes initially appeared to be stable in air, the crystallinity of some samples was observed to be fragile to desolvation.

Each lanthanide is bound equatorially in an $\mathrm{O}_{6}$ environment by three catecholate (equivalent to six phenolate) groups in an approximately planar arrangement, selected distances and angles can be found in Table 1. The prearrangement of the three ligand molecules around the lanthanide centre brings the aldehyde groups into proximity akin to the imine nitrogens of a salen moiety (Fig. 1). The two adjacent aldehyde and phenolate groups form an O 4 environment to bind to the equatorial sites of the cobalt centres while the remaining axial coordination sites of each metal are bound by a mixture of solvent molecules or anions. Complexes C1-C3 all crystallised in the triclinic space group $P \overline{1}$, while complex $\mathbf{C 4}$ crystallised in the monoclinic space group $C 2 / c$. Only $\mathbf{C 1}$ and $\mathbf{C} 2$ contain three 6coordinate $\mathrm{Co}^{\text {II }}$ centres, with $\mathbf{C} 3$ and $\mathbf{C 4}$ each containing one heavily distorted 5 -coordinate $\mathrm{Co}^{\mathrm{II}}$ centre. Of the four structurally characterised $\mathrm{Co}^{\mathrm{II}}{ }_{3} \mathrm{Ln}$ type complexes reported by Mashima and Nozaki et al. ${ }^{48}$ all but one $\mathrm{Co}^{\mathrm{II}}$ centre has near perfect octahedral geometry. A single $\mathrm{Co}^{\mathrm{II}}$ ion in the $\mathrm{Co}_{3} \mathrm{Ce}$ complex features a near square-pyramidal geometry. In order to assess the local coordination geometry of each $\mathrm{Co}^{\text {II }}$ centre, Continuous Shape Measurement (CShM) calculations ${ }^{52,53}$ were employed alongside octahedral distortion calculations $(\langle D\rangle, \Delta, \zeta$, and $\Sigma)$

using the OctaDist software package, ${ }^{54}$ the values of these parameters can be found in Table 2.

## Molecular structures

Crystal structure and refinement details for C1-C4 can be found in Table S1 of the ESI. $\dagger$

The crystal structure of $\mathbf{C 1}$ (Fig. 2) shows the complex takes a non-planar arrangement and is the only complex reported here to contain three near perfect six-coordinate octahedral $\mathrm{Co}^{\text {II }}$ centres with $\operatorname{CShM}(\mathrm{OC}-6) / \Sigma$ values of 1.586/66.70 (Co2), 1.634/ 68.80 (Co3), and 0.733/38.29 (Co4).

The Dy ${ }^{\text {III }}$ centre of $\mathbf{C 1}$ occupies a nine-coordinate environment where the three non-equatorial donors are an axially coordinated methanol and an axially coordinated $\mu_{2}-\mathrm{NO}_{3}$ group, binding opposite sides of the $\mathrm{Co}_{3}$ plane. The Co 2 and Co 3 cobalt centres of C1 are axially capped with solvent type molecules, whereas Co4

${ }^{a}$ Values near or below one indicate minimal distortion from the ideal geometry. ${ }^{b} \mathbf{C} 2-\mathrm{Co} 4$ is distorted towards $D_{3 \mathrm{~h}}$ trigonal prismatic. ${ }^{c}$ The octahedral distortion parameters calculated by OctaDist are defined as: $\langle D\rangle$, the average $\mathrm{M}-\mathrm{L}$ bond length; $\Delta$, the average of the deviations of $\mathrm{M}-\mathrm{L}$ bond lengths from $\langle D\rangle$; $\zeta$, the sum of the deviation of bond lengths from $\langle D\rangle$; and $\Sigma$, the sum of deviations of the 12 cis angles from $90^{\circ}$.
features an axially coordinated $\mu_{1}-\mathrm{NO}_{3}$ group as well as a methanol cap. In order to achieve charge neutrality, the total metal charge of $+9\left(\mathrm{Dy}^{3+}\right.$ and $\left.3 \times \mathrm{Co}^{2+}\right)$ is partially balanced by $3 \times \mathbf{L}^{2-}$ and the two coordinated $\mathrm{NO}_{3}{ }^{-}$groups, with the final negative charge originating from a non-coordinated $\mathrm{NO}_{3}{ }^{-}$anion, giving an overall formula of $\left[\mathbf{L}_{3} \mathrm{Co}_{3} \mathrm{Dy}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{MeOH})_{5}\right]\left(\mathrm{NO}_{3}\right) . \mathbf{C 1}$ features extensive intermolecular and intra-complex hydrogen bonding (Fig. 3). The non-coordinated nitrate group forms strong hydrogen bonds from its O26 oxygen to a methanol cap of Co2 $(\mathrm{O} 26 \cdots \mathrm{H} 13=1.989(10) \mathrm{A})$ and the water cap of $\mathrm{Co} 3(\mathrm{O} 26 \cdots \mathrm{H} 15 \mathrm{~A}$ $=1.904(10) \AA$ ). A symmetry generated complex provides two further hydrogen bonds, stemming from the H14* proton of a methanol cap of $\mathrm{Co}_{2}^{*}\left(\mathrm{O} 27 \cdots \mathrm{H} 14^{*}=2.496(9) \AA\right.$, and $\mathrm{O} 28 \cdots$ $\mathrm{H} 14^{*}=2.100(8) \AA$ ). There are also two strong hydrogen bonds formed between the two units complex by the methanol cap of Co4* with the water cap of $\mathrm{Co} 3\left(\mathrm{O} 15 \cdots \mathrm{H} 17^{*}=2.008(7) \AA \AA^{\circ}\right)$, and the proton of the Co3 water cap acting as a hydrogen bond donor

Fig. 4 X-ray crystal structure of C2. Thermal ellipsoids of metal atoms shown at $70 \%$ probability. H atoms have been omitted for clarity. $\mathrm{C}=$ grey, $\mathrm{O}=$ red, $\mathrm{N}=$ blue.
to the aldehyde binding $\operatorname{Co4}$ * in the symmetry generated molecule ( $\mathrm{O} 9^{*} \cdots \mathrm{H} 15 \mathrm{~B}=2.078(8) \AA$ ).

Complex $\mathbf{C} 2$ crystallised in the triclinic space group $P \overline{1}$ with the formula $\left[\mathbf{L}_{3} \mathrm{Co}_{3} \mathrm{Gd}(\mathrm{MeOH})_{4}\left(\mathrm{NO}_{3}\right)_{3}\right]$ (Fig. 4). C2 is significantly more planar than $\mathbf{C 1}$ and features two near perfectly octahedral cobalt centres ( Co 2 and Co 3 ) each axially coordinated by two methanol molecules with CShM(OC-6)/ $\Sigma$ values of 1.263/59.27 (Co2) and 0.301/29.48 (Co3). The remaining cobalt centre, Co4, is also six-coordinate but is capped by a $\mu_{2}-\mathrm{NO}_{3}$ group leading to a heavily distorted octahedral geometry tending towards $D_{3 \mathrm{~h}}$ trigonal prismatic with $\operatorname{CShM}($ OC- 6, TPR-6)/ $\Sigma$ values of $4.914,9.173 / 115.79$. At the heart of $\mathbf{C} 2$ is a tencoordinate $\mathrm{Gd}^{\mathrm{III}}$ ion, capped either side of the $\mathrm{Co}_{3}$ plane by a $\mu_{2}-\mathrm{NO}_{3}$ group, with a pseudo-hexagonal bipyramidal coordination geometry.

Similar to $\mathbf{C 1}$ and $\mathbf{C 2}$, complex $\mathbf{C} 3$ (Fig. 5) also crystallised in $P \overline{1}$, with the formula $\left[\mathbf{L}_{3} \mathrm{Co}_{3} \mathrm{La}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{NO}_{3}\right)\left(\mathrm{H}_{2} \mathrm{O}\right) \cdot[1.5$ $\mathrm{Et}_{2} \mathrm{O}$ ], but only has two six-coordinate cobalt centres ( Co 2 and Co3). Both Co 2 and Co 3 are axially coordinated by water molecules forming near perfect octahedral coordination geometries with CShM(OC-6)/ $\Sigma$ values of $0.355 / 28.61$ (Co2) and $0.605 / 43.62$ (Co3). In contrast, Co4 has only a single axially coordinated water molecule resulting in a five-coordinate distorted $D_{3 \mathrm{~h}}$ trigonal bipyramidal coordination geometry with a CShM(TBPY-5) value of 1.678 .

The $\mathrm{La}^{\text {III }}$ ion in the centre of $\mathbf{C} 3$ is coordinated by two $\mu_{2}-\mathrm{NO}_{3}$ groups and a water molecule, resulting in an 11-coordinate centre with the approximate $C_{5 \mathrm{v}}$ symmetry of a capped pentagonal antiprism with a CShM(JCPAPR-11) value of 4.655 . The final negative charge required to balance the +9 charge of the metal centres, as in $\mathbf{C 1}$, is present as a non-coordinated nitrate. This non-coordinated nitrate species is crystallographically disordered over two spatially similar sites with freely refined occupancies of $0.47(2)$ (site A) and $0.53(2)$ (site B) (Fig. 6, inset). A water cap of Co3 forms strong hydrogen bonds to three of the four possible oxygen atoms belonging to the disordered nitrate (setting the cut-off distance to 2.50 A). The inset of Fig. 6 shows

Fig. 5 X-ray crystal structure of C3. Thermal ellipsoids of metal atoms shown at $70 \%$ probability. H atoms and disordered species have been omitted for clarity. $\mathrm{C}=$ grey, $\mathrm{O}=$ red, $\mathrm{N}=$ blue.

Fig. 6 X-ray crystal structure of C3 showing the intermolecular hydrogen bonding between two units complex and the non-coordinated nitrate. Inset showing the two partial occupancy nitrate sites. Thermal ellipsoids of metal atoms shown at 70\% probability. Nonacidic $H$ atoms have been omitted for clarity. $H$ bonds shown as segmented yellow/pink bonds. $\mathrm{C}=$ grey, $\mathrm{O}=$ red, $\mathrm{N}=$ blue.
both non-coordinated nitrate sites and the hydrogen bonds they form with H15A: O31B $\cdots \mathrm{H} 15 \mathrm{~A}=1.848(9) \mathrm{A}, \mathrm{O} 33 \mathrm{~B} \cdots \mathrm{H} 15 \mathrm{~A}=$ $2.281(9) \AA$, and O33A $\cdots \mathrm{H} 15 \mathrm{~A}=2.154(9) \AA$, with an O31A $\cdots \mathrm{H} 15 \mathrm{~A}$ distance of $2.905(8) \AA$.

A second unit complex is generated by inversion symmetry (Fig. 6) which forms a symmetric set of hydrogen bonds between the N1 nitrate cap of La1 and O13 water cap of Co2 in each unit complex, resulting in an intramolecular hydrogen bond (O19... $\mathrm{H} 13 \mathrm{~A}=1.936 \AA$ ) and an intermolecular hydrogen bond $(\mathrm{O} 21 * \ldots$ H13B $=1.951 \AA$ ). The crystal structure of C3 was also found to contain diethyl ether molecules across at least 4 sites in the asymmetric unit. These lattice solvents were heavily disordered and unstable even to isotropic refinement, thus have been modelled within a solvent mask using the Olex2 implementation of BYPASS, containing 64 electrons in $192 \AA^{3}$ per asymmetric unit which fits well with 1.5 diethyl ether molecules ( 63 electrons). These solvate species were not observed in the

Fig. 7 X-ray crystal structure of C4. Thermal ellipsoids of metal atoms shown at $70 \%$ probability. H atoms and disordered species have been omitted for clarity. $\mathrm{C}=$ grey, $\mathrm{O}=$ red, $\mathrm{N}=$ blue, $\mathrm{Cl}=$ green.
microanalytical data, but are consistent with the observation of the crystalline sample rapidly crumbling upon sitting in air.

The crystal structure of $\mathbf{C 4}$ (Fig. 7) revealed a relatively nonplanar system featuring one five-coordinate and two sixcoordinate cobalt centres. Although the preparation of C3 reported here also utilised a non-nitrate lanthanide salt $\left(\mathrm{La}(\mathrm{OAc})_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}\right), \mathrm{C} 4$ exclusively features a mixture of nitrate and non-nitrate (chloride) anions. Both Co 2 and Co 3 are octahedral, with CShM(OC-6)/ $\Sigma$ values of 0.738/43.66 (Co2) and 0.947/56.12 (Co4), with Co4 being axially coordinated by two methanol molecules. Co2 has an axially coordinated methanol on one side of the plane, however the other cap is present as a crystallographically disordered 1:1 methanol/water species. Co3 is unambiguously capped by a single chloride anion originating from the $\mathrm{TbCl}_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ salt with an overall formula of $\left[\mathbf{L}_{3}{ }^{-}\right.$ $\left.\mathrm{Co}_{3} \mathrm{TbCl}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{0.5}(\mathrm{MeOH})_{3.5}\right] \cdot\left[2.5 \mathrm{H}_{2} \mathrm{O}\right]$. This fivecoordinate cobalt centre sits in an approximately $C_{4 \mathrm{v}}$ square pyramidal coordination geometry with a CShM(SPY-5) value of 1.734.

The crystal lattice was found to contain two solvent accessible voids equivalent to 14 electrons in $68 \AA^{3}$ and 8 electrons in $24 \AA^{3}$ when modelled within a solvent mask using Olex2, which corresponds to approximately 1.5 water molecules and 1 water molecule, respectively, per asymmetric unit and is consistent with the microanalytical data for $\mathbf{C 4}$ - see experimental details.

Based on the general formulation $\mathbf{L}_{3} \operatorname{Co}_{3} \operatorname{Ln}(\text { anion })_{3}+$ solvents, cobalt is expected to be in the +2 oxidation state $(+3$ from $\operatorname{Ln}^{\text {III }},-2$ from $\mathbf{L}$, and -1 from each anion, giving an overall charge of -6 to be balanced by three cobalt centres). The same result is evidenced by further examining the average equatorial Co-O bond lengths in Table 1, which are consistent with the longer bonds expected for $\mathrm{Co}^{\text {II }}$. Further, the bond valency ${ }^{55,56}$ of each cobalt centre has been assessed in PLATON ${ }^{57,58}$ and all sit in the range of $2.18-2.36$.

The structural differences between the four complexes are quite striking and in the first instance may be attributed to the differing sizes of the central lanthanide cation. For instance, the structure of $\mathbf{C 1}$, with a small $\mathrm{Dy}^{\text {III }}$ ion at its centre, is dictated by the cobalt centres, each one adopting an ideal octahedral geometry. The differences between the larger lanthanide cations in complexes C2-C4 is more subtle, with no clear or obvious reason for the different cobalt geometries, other than they are now unable to form idealised octahedral geometries.
$\pi-\pi$ stacking interactions were analysed in Olex2 (ref. 59) with aromatic centroid-centroid distances listed in Table 3 as well as the cross-sectional molecular area, calculated in the $\mathrm{Co}_{3}-\mathbf{L}_{3}$ plane using the inbuilt ChemCraft utility.

Table 3 Calculated $\pi-\pi$ stacking distances and cross-sectional area

| Complex | $\pi-\pi$ stacking $(\AA)$ | Molecular area <br> $\left(\AA^{3}\right)$ |
| :--- | :--- | :--- |
| C1 | $3.763-3.824$ | 206.5 |
| C2 | $3.731-3.740$ | 208.9 |
| C3 | $3.586-3.955$ | 213.1 |
| C4 | $3.551-3.791$ | 212.1 |

Fig. 8 Simplified X-ray crystal structure packing diagrams of C1 and C2 viewed along the crystallographic a-axis.

Complex C3, containing the largest trivalent lanthanide ion ( $\mathrm{La}^{\mathrm{III}}$ ), has the largest calculated molecular area as well as the longest range $\pi-\pi$ stacking interaction (as determined by Olex2). It also features the longest average $\mathrm{Co}^{\mathrm{II}}-\mathrm{Ln}^{\mathrm{III}}$ and $\mathrm{Co}^{\mathrm{II}}-$ $\mathrm{Co}^{\mathrm{II}}$ distances, however it interestingly also has the shortest $\mathrm{Ln}^{\mathrm{III}}-\mathrm{Ln}^{\mathrm{III}}$ distance (Table 3). The same trend in ionic radii $v s$. cross-sectional molecular area is not followed for the other three complexes. Complex C4 contains $\mathrm{Tb}^{\mathrm{III}}$ which is smaller than $\mathrm{Gd}^{\text {III }}(\mathbf{C} 2)$ but larger than Dy ${ }^{\text {III }}(\mathbf{C} 1)$, however $\mathbf{C 4}$ has the second largest calculated molecular area which may be attributed to the way in which the chloride cap of $\mathrm{Co3}$ in $\mathbf{C 4}$ influences the planarity and shape of the complex and hence the crystal packing.

The crystal packing diagrams of $\mathbf{C} \mathbf{1}$ and $\mathbf{C} 2$ viewed along the crystallographic $a$-axis (Fig. 8) show that these complexes pack similar to a two-dimensional layered system along the $a b$-plane with clear inter-layer separations along the $c$-axis. Although C3 has the same metric symmetry and space group as $\mathbf{C 1}$ and $\mathbf{C 2}$, the geometry of the unit cell is considerably different. Where $\mathbf{C 1}$ and $\mathbf{C} 2$ have similar lengths in $a$ and $b$ and both $\alpha$ and $\beta$ angles are near $90^{\circ}, \mathbf{C} 3$ has similar lengths in $b$ and $c$ with the corresponding $\alpha$ and $\gamma$ angles being near $90^{\circ}$. The shorter length of $c$ in C3 relative to the other two triclinic structures results in a greater proportion of a third molecule, whose centre of mass sits outside of the unit cell, occupying the space to ensure $Z=2$.

## Magnetic measurement

The DC magnetic susceptibility and magnetisation measurements have been performed to examine the potential Co-Co interactions and/or zero-field splitting effects present within this complex. As complexes C1-C4 each feature a $\mathrm{Co}^{\text {II }}$ centre

Fig. 9 Plot of $\chi_{\mathrm{m}} T$ vs. $T$ for C 3 measured at 0.5 T (A) and the $M$ vs. $H$ plot for C3 measured at $1.8 \mathrm{~K}(\mathrm{~B})$, including fits and parameters. Measurements were performed on a polycrystalline sample fixed in a small amount of eicosane.
with different coordination geometries, this initial study of C3 is not necessarily representative of the other three complexes.

Fig. 9A shows the $\chi_{\mathrm{m}} T$ product reaching $9.4 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ at 300 K , which clarified the presence of three $S_{\mathrm{Co}^{\mathrm{I}}}=3 / 2$ spins with $g=2.59$. The experimental magnetisation (Fig. 9B) at 7 T was 7.1 $\mu_{\mathrm{B}}$, which corresponds to $c a .60 \%$ of the theoretical limit (11.7 $\mu_{\mathrm{B}}$ ). If antiferromagnetic interactions were dominant, the experimentally measured magnetisation would be approximately one third of the theoretical value and the $\chi_{\mathrm{m}} T$ product at 1.8 K would approach one third of the value at 300 K . Hence the measured value of $7.1 \mu_{\mathrm{B}}$ indicates antiferromagnetic interactions are relatively small for this system. Part of the gradual decrease in the $\chi_{\mathrm{m}} T(T)$ profile is likely to originate from the single-ion nature of the spatially separated $\mathrm{Co}^{\text {II }}$ centres. To evaluate the zero-field splitting (ZFS) of the $\mathrm{Co}^{\mathrm{II}}$ ions, simulations were performed using MAGPACK ${ }^{60,61}$ to better comprehend the magnetic properties of C3.

An approximation based on a three-fold symmetry is applied to the magnetic analysis, to avoid overparameterization. Optimization of the ZFS $D$ value for each cobalt(II) ion with
neglecting any $E$ value gave $D / k_{\mathrm{B}}=65 \mathrm{~K}$ with $g_{\text {avg }}=2.55$. Calculated $\chi_{\mathrm{m}} T(T)$ and $M(H)$ profiles reproduced the experimental results well (the solid lines superposed in Fig. 9). This $D$ value is relatively large, but possible in comparison with the literature values. ${ }^{62-65}$ The large $D$ value seems to be related to the five-coordinate cobalt(II) ion (Co4, Fig. 5). On the other hand, the exchange coupling model using a spin-Hamiltonian based on an antiferromagnetic triangle, $H=-2 J\left(S_{1} S_{2}+S_{2} S_{3}+S_{3} S_{1}\right)$, cannot reproduce the experimental $M-H$ data (Fig. S2b, ESI $\dagger$ ).

## Conclusions

Four new non-macrocyclic heterometallic triangular $\mathrm{Co}^{\mathrm{II}}{ }_{3} \mathrm{Ln}^{\mathrm{III}}$ clusters have been prepared by the 1:3:3 reaction of $\mathrm{Dy}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Gd}\left(\mathrm{NO}_{3}\right)_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{La}(\mathrm{OAc})_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, or $\mathrm{TbCl}_{3}-$ $\cdot 6 \mathrm{H}_{2} \mathrm{O}$ with $\mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{2} \mathrm{~L}$ in methanol. Single-crystal X-ray diffraction quality crystals were obtained by the vapour diffusion of diethyl ether into concentrated methanolic solutions of C1-C4, allowing complete and unambiguous structural characterisation. The coordination geometry of each metal centre was examined by continuous shape measurements (CShM) using the SHAPE software package as well as OctaDist to calculate a series of octahedral distortion parameters. While C1 was found to contain three near-perfectly octahedral $\mathrm{Co}^{\mathrm{II}}$ centres, the remaining three complexes each contained one non-octahedral $\mathrm{Co}^{\mathrm{II}}$ ion. This non-octahedral site was found to be strongly distorted towards trigonal prismatic in $\mathbf{C} 2$, with five coordinate centres observed for C3, trigonal bipyramidal, and C4, square pyramidal. The magnetic study of C3 clarified a ground-state spin projection of $S_{\text {Tot }}=3 / 2$ where antiferromagnetic contributions to the Co-Co interactions are weak. Throughout the literature, magnetic characterisation for the macrocyclic analogues of this type of complexes have been limited to $\mathrm{Ni}^{\text {II }}, \mathrm{Cu}^{\mathrm{II}}$, and $\mathrm{Zn}^{\text {II }}$ with $\mathrm{d}^{8}, \mathrm{~d}^{9}$, and $\mathrm{d}^{10}$ electron configurations, respectively. While the $\mathrm{Co}^{\text {II }}$ based systems reported here do not crystallise with the same regularity (in terms of local coordination geometries) as previously published families of macrocyclic analogues, their potentially unique magnetic properties make for an interesting avenue of research, particularly with the inclusion of high spin $\mathrm{d}^{7}$ metal centres.
